Methods: A systematic literature search of Embase, MEDLINE, and PubMed was conducted in August 2025. Of the 947 articles, 14 studies (2 prospective, 8 retrospective, 4 randomized controlled trials) fulfilled the inclusion criteria.

Results: Nine studies evaluated simultaneous immunosuppression (3 on methotrexate [MTX], 2 on azathioprine [AZA], 4 on mycophenolate mofetil/mycophenolate sodium), and 5 studied sequential immunosuppression (3 on MTX, 2 on sirolimus). Efficacy in terms of disease activity reduction depends on the specific immunosuppressant. Sequential sirolimus and MTX significantly improved clinical activity and proptosis. Simultaneous mycophenolate was highly effective, improving disease activity, proptosis, visual acuity, diplopia, and reversing dysthyroid optic neuropathy. Simultaneous MTX provided early improvement in clinical activity and vision. Simultaneous AZA showed no benefit over steroids alone and had a significantly higher withdrawal rate due to adverse events. The sequential approach was better tolerated with a lower discontinuation rate.

Conclusions: The choice of immunosuppressants is more critical than timing alone. Simultaneous mycophenolate is effective for severe inflammation. Simultaneous MTX may offer early efficacy benefit but may not prevent disease progression. Sequential sirolimus or MTX is effective in consolidating response after IVMP. Simultaneous AZA is not recommended due to poor efficacy and tolerability. The sequential approach had fewer side effects. Further drug-specific RCTs are needed to establish optimal timing of adjuvant immunosuppressants.

Small Flap Saving Technique for Repeat Dacryocystorhinostomy (DCR)

First Author: Ravi RANJAN

Co-Author(s): Rohan RAJ

Purpose: To report the success rate of failed DCR by the small flap saving technique.

Methods: It is a prospective study of patients undergoing management of failed DCR at my centre. A single surgeon did all the surgery and used the same method to avoid bias. Skin incision was made through the previous scar. Roughly 1-2 mm of lacrimal sac mucosa around the common canaliculi opening in the sac was saved. Osteum in the nasal bone and nasal mucosa was made using Arruga's bone trephine. The upper part of the lacrimal sac remains was sutured with subcutaneous tissue or periosteum of the medial side to avoid sagging. Sac syringing with 1 ml of 0.4mg/ml Mitomycin c was done on the 5th postoperative day. Surgical outcome was assessed.

Results: Objective success is 133 (99.2 %; 95% confidence interval: 95.9-99.9%). Subjective success is 131 (97.7%; 95% Confidence interval: 93.6-99.5%).

Conclusions: External DCR with a small flap-saving technique is easier to perform with improved success rate.

Spontaneous Bilateral Retrobulbar Hemorrhage: A Rare Complication of Carotid-Cavernous Fistula

First Author: Lorenzo Miguel TRANQUILINO

Co-Author(s): Felice Katrina RANCHE

Purpose: To present a rare complication of carotid-cavernous fistula

Methods: Case report, review of literature

Results: A 70-year-old hypertensive female developed gradually progressive bilateral eye redness and eyelid swelling. Right proptosis and bilateral corkscrewing conjunctival vessels were seen on initial examination. She was diagnosed with carotid-cavernous fistula (CCF).

During this outpatient consultation, she had sudden headache and vomiting. Blood pressure was markedly elevated. She developed bilateral tight eyelids, bloody chemosis and elevated intraocular pressure. The left eye deteriorated to counting fingers with a relative afferent pupillary defect. Bilateral lateral canthotomy and cantholysis was performed immediately, followed by transfer to emergency medicine for management of the hypertensive crisis. Blood pressure and intraocular pressure were stabilized, but vision on the left eye remained poor. Angiography later confirmed a direct-type CCF from a right cavernous internal carotid artery aneurysm with intercavernous cross-drainage. She was first advised manual carotid compression as a non-invasive treatment. On the six-month follow-up, there was no light perception on the left eye, but the rest of the eye findings were normal.

Conclusions: Bilateral spontaneous retrobulbar hemorrhage is a rare, vision-threatening complication of carotid-cavernous fistula, precipitated in this case by severely elevated blood pressure. Prompt recognition and urgent canthotomy with cantholysis are critical when signs of orbital compartment syndrome are present to improve visual outcomes. Risk factor control and definitive CCF treatment are essential to prevent recurrence. This case underscores the importance of timely, interdisciplinary management involving Ophthalmology, Emergency Medicine, and Radiology departments.

Successful Management of Odontogenic Origin Orbital Abscess

*First Author: Diannisa Paramitha **SUSANTONO**
Co-Author(s): Neni **ANGGRAINI**, Rina La Distia **NORA**,
Adinda Mulya **PERTIWI***

Purpose: Orbital abscess is a rare disease with high morbidity and vision-threatening complications. Management remains challenging due to the complex anatomy of the orbit. This study aims to report a difficult case of orbital abscess management, originating from dental infection.

Methods: A type II diabetic 53-year-old woman came with progressive left eye proptosis and pain for 3 months, worsening within 4 days before admission. She had a history of pulp gangrene extraction and sinusitis surgery, revealing an orbital subperiosteal abscess. The left eye shows nonaxial proptosis with downward displacement, with 3/60 visual acuity, ophthalmoplegia, and an undulated palpable mass at the superolateral orbit. Broad-spectrum aero and non-aero antibiotics were initially given; however, later her blood culture revealed Methicillin-resistant *Staphylococcus aureus* (MRSE) positive. Orbital abscess drainage was conducted through anterior orbitotomy with lateral canthotomy due to no improvement with

conservative treatment. Two months post-surgery, visual acuity improved to 6/7.5 with minimal eye movement restriction.

Results: First-line therapy for orbital abscess is third-generation cephalosporins and metronidazole. Surgical drainage was done as no adequate response to antibiotics was seen, which is consistent with the Garcia-Harris criteria. Endoscopic sinus surgery promises excellent results; however, this case showed persistent orbital infection, possibly due to the nature of MRSE. Thus, external surgical drainage was necessary.

Conclusions: Orbital abscess is a complex disease with a risk of vision loss. Intense monitoring of clinical manifestations is necessary to evaluate response to therapy and progression to surgical management.

Surgical Correction of Upper Eyelid Entropion With Cutaneous Orbicularis Oculi Excision and Eyelid Margin Fixation in Pierre Robin Sequence: A Case Report

*First Author: Yungang **DING**
Co-Author(s): Jianhua **CHEN**, Wei **CHEN**, Chenyang **CONG**, Baoyi **DING**, Yan **ZHANG***

Purpose: Pierre Robin sequence (PRS) is a rare congenital condition that is characterized by a combination of mandibular hypoplasia, cleft palate, and glossoptosis, and it presents with various ocular and systemic anomalies. This report describes the successful surgical correction of upper eyelid entropion in a boy with PRS, using cutaneous orbicularis oculi excision with eyelid margin fixation.

Methods: A 6-year-old boy with a diagnosis of PRS presented with persistent left eye blinking and tearing. Ophthalmic examination revealed bilateral upper eyelid entropion and trichiasis, with the eyelashes in direct contact with the cornea, more pronounced in the left eye. The surgical procedure involved partial excision of the orbicularis oculi muscle from the upper eyelid, followed by fixation of the orbicularis muscle at the eyelid margin to the tarsus, which facilitated the gentle retraction of the eyelashes away from the cornea.

Results: The surgery was performed successfully without any postoperative complications or recurrence of entropion. The patient experienced significant improvement in ocular comfort, with complete resolution of symptoms and relief from eyelash contact with the corneal surface.

Conclusions: Cutaneous orbicularis oculi excision with eyelid margin fixation is a surgical option for correcting upper eyelid entropion in pediatric patients with Pierre Robin sequence. This approach yields both anatomical and functional improvements, enhancing the patient's quality of life.

Abstract No.: 206846**Panel No.: OOP-0801**

Systematic Review of Upper Lid Retraction Management in Thyroid Eye Disease Using Injectables

*First Author: Rachel LAI**Co-Author(s): Kelvin Kam Lung CHONG, Kenneth Ka Hei LAI, Venice Sze Wai LI, Precious UNTALAN, Hunter Kwok Lai YUEN*

Purpose: Upper lid retraction (ULR) in Thyroid Eye Disease (TED) can lead to exposure keratopathy and impact patients' quality of life. While surgical options are available, non-surgical approaches using injectables like botulinum toxin A (BA), triamcinolone acetate (TA), and hyaluronic acid fillers (HA), offer promising alternatives. This systematic review discusses efficacy and safety aspects of these injectables in managing ULR in both active and inactive phases of TED.

Methods: A systematic literature search of Embase, MEDLINE, and PubMed was conducted in July 2025. Of 889 articles, 21 studies fulfilled the inclusion criteria.

Results: Twenty-one studies (9 on BA, 3 on HA, 8 on TA, and 1 on BA and TA) were evaluated. Studies using triamcinolone showed improvement in ULR in terms of marginal reflex distance (MRD), palpebral fissure height, and marginal limbal distance, both in active and inactive TED. The majority of them showed rapid improvement in the first month of therapy, despite side effects of elevated intraocular pressure, ptosis, and menstrual cycle disturbances. BA was effective in decreasing MRD in the inflammatory and fibrotic stages of TED. Side effects of BA included ptosis and diplopia. HA showed sustained improvement in MRD and upper scleral show, and its effectiveness was greatest immediately after injection with minimal side effects.

Conclusions: Nonsurgical injectables like HA, BA, and TA are effective as a primary treatment or adjunct to other therapy for ULR in TED, both in active and inactive states. Further drug-specific RCTs and comparative studies are needed to compare the efficacy and safety profile of the various injectables directly.

Abstract No.: 207374**Panel No.: OOP-0805**

Teprotumumab Treatment in Patients With Dysthyroid Optic Neuropathy: A Case Series

First Author: Jing SUN

Purpose: The aim of this study was to evaluate the efficacy of teprotumumab in treating TED patients with DON in China.

Methods: This is a retrospective observational study. The case series included 5 patients (8 eyes) with confirmed DON. Some of them were resistant to steroids. The treatment protocol was 8 intravenous

infusions of teprotumumab administered every 3 weeks. Definition of DON recovery was based on changes in best-corrected visual acuity (BCVA) and visual field mean deviation (VF-MD).

Results: At the end of teprotumumab treatment, DON recovered in 7/8 (87.5%) of affected eyes, with BCVA improvement in all patients. In all 5 patients, DON improved after two infusions. All patients showed improvements in clinical activity score and proptosis. Inflammatory relapse has been observed in two patients. Due to adverse events, one patient did not complete all infusions.

Conclusions: Teprotumumab is a promising treatment for DON patients with rapid BCVA improvement.

Abstract No.: 202214**Panel No.: OOP-0764**

The 5-Fluorouracil Advantage: Enhanced Success in External Dacryocystorhinostomy

*First Author: Anya Dewi NASTITI**Co-Author(s): Yunia IRAWATI, Diannisa Paramitha SUSANTONO, Cynthia VIRYAWAN*

Purpose: This study aims to highlight the benefit of using 5-fluorouracil (5-FU) in external dacryocystorhinostomy (EX-DCR) in patients with trauma, including improved success rates and reduced complications.

Methods: The case illustrates a 16-year-old male with nasolacrimal duct obstruction following a traumatic injury.

Results: A patient presented with complaints of tearing and discharge from the left eye (LE). The symptoms began 1 year after a motorcycle accident. Visual acuity was 6/6 in both eyes, but the LE showed limited ocular motility. Orbital CT scan revealed fracture of the left orbital floor with associated deformity and narrowing of the lacrimal canal, leading to a dacryocystocele. The irrigation test was negative in the LE, indicating nasolacrimal duct obstruction. The patient underwent EX-DCR surgery. During the intraoperative examination, it was observed that the lacrimal sac wall and nasal mucosa were friable due to the impact of fracture fragments. The formation of anterior and posterior flaps was challenging. To prevent fibroblast proliferation and scar formation, we applied a small pledget soaked with 2 mg/mL (0.2%) 5-FU to the osteotomy site and surrounding tissues for about 3 minutes, then removed and irrigated. Post-operative follow-up showed a positive irrigation test, indicating restored tear drainage. The patient experienced significant improvement in symptoms, and the surgical outcome was deemed successful.

Conclusions: The use of 0.2% 5-FU in EX-DCR resulted in a successful outcome. The application of adjuvant 5-FU helped to minimize scarring and promote optimal tear drainage.

Three-Dimensional Culture of Orbital Fibroblasts From Thyroid Eye Disease Induces In Vivo-Like Tissue Remodeling and Fibrosis

First Author: Bao XIAOLI

Purpose: This study aimed to investigate the characteristics and molecular mechanisms of orbital fibroblasts under three-dimensional(3D)-culture conditions.

Methods: Orbital connective tissue was collected from patients with Thyroid Eye Disease (TED) and normal controls. Primary fibroblasts were cultured and used to generate 3D microspheres via the hanging drop. These spheroids were cultured for 9 days, followed by biomechanical testing, transmission electron microscopy (TEM), and RNA sequencing for transcriptomic analysis. Multiplex immunofluorescence staining was used to assess fibrosis markers, and quantitative PCR validated gene expression changes. TED and NC tissues, as well as primary cultured fibroblasts, were also subjected to transcriptomic sequencing.

Results: TED-3D microspheres exhibited enhanced contractility, denser fiber deposition, and a characteristic fibrous ring at the periphery. TEM revealed more ECM deposition and stronger tissue remodeling in TED-3D. Fibrosis markers (α -SMA, COL1A1, FN1) increased significantly in TED-3D. Biomechanical testing showed higher stiffness in TED-3D compared to NC-3D. Transcriptomic analysis revealed significant differences, with genes involved in ECM remodeling and fibrosis pathways enriched in TED-3D. Transcriptomic comparison of TED-tissue, TED-2D, and TED-3D revealed that TED-3D is closer to tissue than TED-2D.

Conclusions: The 3D culture of orbital fibroblasts from TED induces vivo-like tissue remodeling and fibrosis features. Compared to traditional 2D culture, the expression pattern of TED-3D is closer to tissue, making it a more effective model for studying the mechanisms of TED-related fibrosis.

Thyroid Eye Disease in Bahrain: Demographics, Clinical Features, and Treatment Patterns in a Prospective Cohort Study

First Author: Fatema ALJUFAIRI

Co-Author(s): Kelvin, Kam Lung CHONG, Kenneth LAI, Ebrahim MATAR, Chi PANG

Purpose: To report the demographics, clinical features, and treatment patterns of Arab patients with Thyroid Eye Disease managed at government hospitals in Bahrain.

Methods: A prospective cohort study was conducted from September 2023 to September 2025. Medical records and orbital imaging were reviewed in a masked manner. All patients were examined by a single investigator to assess the presence and characteristics of Thyroid Eye Disease.

Results: A total of 114 patients were included, of whom 82 (71.9%) were female. Eighteen patients (15.8%) were smokers, and 70 (61.8%) reported a family history of thyroid disease. Graves' disease was present in 89 patients (78.1%), while dysthyroid optic neuropathy was documented in 1 patient (0.9%). Regarding treatment, 12 patients (10.5%) received intravenous methylprednisolone, 17 (19.9%) received oral prednisolone, 5 (4.4%) underwent orbital radiotherapy, and 4 (3.5%) were treated with other immunosuppressants. The most common presenting symptoms were eyelid swelling (57 patients, 50.0%), tearing (39, 31.6%), blurry vision (24, 21.1%), and diplopia (12, 10.5%). On examination, chemosis was observed in 6 patients (5.3%), caruncular edema in 3 (2.6%), eyelid edema in 4 (3.5%), conjunctival injection in 10 (8.7%), and eye redness in 3 (2.6%). The mean clinical activity score was 0.27 ± 0.77 .

Conclusions: Thyroid eye disease in Bahrain predominantly affects women and is frequently associated with Graves' disease and a positive family history. Most patients presented with mild symptoms and low clinical activity scores.

To Quantitatively Assess and Compare the Degrees of Surgical Freedom in Lacrimal Keyhole-Assisted Lateral Orbitotomy Versus the Traditional Approach (Without Marginotomy)

First Author: Andre MA

Co-Author(s): Hunter Kwok Lai YUEN

Purpose: To quantitatively assess and compare the degrees of surgical freedom in lacrimal keyhole-assisted lateral orbitotomy versus the traditional approach (without marginotomy).

Methods: Preoperative orbital CT scans from consecutive patients, acquired between January 2023 and April 2025, were analysed. Surgical freedom – measured in terms of the attack angles and volume – was compared between traditional orbitotomy and the lacrimal keyhole-assisted technique using Brainlab software. Statistical analysis included paired t-tests and linear regression.

Results: This study evaluated 12 patients (mean age: 57.3 years; 67% female). The complete keyhole-assisted approach significantly increased the volume of surgical freedom by 21% ($6.2 \pm 2.2 \text{ mm}^3$ vs. $5.1 \pm 2.0 \text{ mm}^3$; $p = 0.005$) while partial keyhole techniques

(theoretical 75%, 50%, 25% of bone removal on CT) also demonstrated significant improvements ($p < 0.05$). Horizontal and vertical attack angles increased by 62% ($20.4 \pm 7.2^\circ$ vs. $12.6 \pm 4.2^\circ$; $p < 0.001$) and 38% ($36.4 \pm 9.5^\circ$ vs. $26.4 \pm 8.4^\circ$; $p < 0.001$), respectively, with progressive gains at incremental bone removal. Each 25% bone removal increment ($\approx 1\text{mm}$) improved surgical freedom by 16% (horizontal angle), 10% (vertical angle), and 6% (volume). Keyhole size correlated strongly with surgical freedom as measured by the attack angle and working volume ($r = 0.74$, $p = 0.02$). No postoperative cosmetic or functional deficits were observed.

Conclusions: The lacrimal keyhole-assisted lateral orbitotomy is a minimally invasive alternative to standard marginotomy to enhance surgical freedom and improve access to deeper orbital lesions. Importantly, bone removal can be tailored to individual lesion while minimising globe retraction.

Abstract No.: 206594

Panel No.: OOP-0794

Transconjunctival Intra-Levator Triamcinolone for Upperlid Retraction in Thyroid Eye Disease

First Author: Shaifali CHAHAR

Co-Author(s): Santosh HONAVAR

Purpose: To evaluate the role of transconjunctival intra-levator injection of triamcinolone acetate (TA) in upper eyelid retraction in thyroid eye disease (TED).

Methods: Retrospective interventional case series of 37 eyes of 22 patients who underwent transconjunctival TA injection (40 mg/mL) into the levator palpebrae superioris (LPS) muscle for TED-related upper eyelid retraction between 2019 to 2022.

Results: The mean age was 46.2 years. Pre-treatment margin-reflex distance (MRD) 1 was 6.0 ± 1.9 mm. The mean number of TA injections was 1.77 ± 0.97 . Time to maximal response was 37.6 weeks. At a mean follow-up of 16.3 months, MRD1 was 4.5 ± 1.5 mm, showing improvement in all cases. Mean reduction in MRD1 was 1.5 ± 1.6 mm ($p=0.000$), and there was no regression from maximal response. None of the patients showed any complications associated with TA.

Conclusions: TED is a complex, challenging disease. TA injection is an effective alternative to surgical procedures for upper lid retraction but due to the heterogenous nature of TED the case selection should be proper and the treatment must be tailor made for a given patient for best outcome. The subconjunctival administration of TA has shown promising results in our study group for tackling retraction in both active and inactive stages of the disease and is an established method of treatment of lid retraction in our armamentarium for management of TED.

Panel No.: OOP-0767

Use of APTOS Threads Lift Method in Facial Nerve Palsy: Two Case Reports

First Author: Pricila Tien Yan WANG

Co-Author(s): Hunter Kwok-lai YUEN

Purpose: Chronic facial nerve paralysis can lead to facial muscle degeneration and soft tissue changes on the affected side. It not only causes functional problems, such as exposure keratopathy, but also significantly contributes to the patient's aesthetic concerns. Brow ptosis often develops in patients with facial nerve palsy and may impair the patient's superior visual field by causing pseudo-ptosis. Traditional surgical approaches include direct brow lift, which may result in a visible scar, or endoscopic brow lift, which requires a high level of technical expertise. Minimally invasive thread-lifting techniques have been reported to correct facial asymmetry in facial nerve palsy. Here, we present two cases of chronic idiopathic facial nerve palsy (i.e., Bell's palsy) with brow ptosis and facial drooping, successfully treated using the APTOS thread lift method.

Methods: Case reports.

Results: N/A

Conclusions: N/A

Panel No.: POS-0853

A Case of Axenfeld-Rieger Syndrome With Bitot's Spot and Normal Vitamin A Levels

First Author: Mary Claudette ARCELLANA

Co-Author(s): Patricia CABRERA

Purpose: Axenfeld-Rieger Syndrome (ARS) is an autosomal dominant form of anterior segment dysgenesis that is associated with systemic abnormalities. Its ocular clinical features include corectopia, polycoria, ectropion uveae, posterior embryotoxon, and increased intraocular pressure. Systemic abnormalities may include dental issues, facial bone changes like maxillary hypoplasia, umbilical abnormalities, hypospadias, and pituitary abnormalities.

Methods: In this case report, we present a 14-year-old Filipino male diagnosed with Axenfeld-Rieger Syndrome presented with classic clinical ocular findings of posterior embryotoxon, corectopia, iris strands, and corneal opacity with associated systemic findings of developmental delay and telecanthus.

Results: The patient had not been in any medications at the time of consultation. Notably, Bitot's spot is observed in the patient's eye bilaterally in the presence of normal Vitamin A levels. Bitot's spot was also observed in the patient's mother, however Vitamin A levels were not measured. Disc photo findings also revealed tilted disc and tigroid retina. Plans include examination of family members, determination of the Vitamin A levels, and genetic testing to test the theory that Bitot spot is a feature of anterior segment dysgenesis.

Conclusions: Previous studies have reported an association between Bitot's spot among patients with normal Vitamin A levels. PAX6 and FOXC1 gene mutations found in ARS could present with Bitot's spot. Other conditions associated with Bitot's spot include aniridia, WAGR syndrome, and blepharokeratoconjunctivitis.

A Case of Consecutive Cyclic Esotropia After Surgical Correction of Intermittent Exotropia

First Author: Moustafa **ABDELHAFEZ**

Co-Author(s): Mahmoud **ABDELHAFEZ**

Purpose: To record a case of cyclic esotropia developed after surgical correction of exotropia.

Methods: A six-year-old girl had intermittent exotropia X(T) 35 prism diopter PD for distance and 30 for near with full ocular motility. She had no refractive error. We did bilateral lateral rectus recession 5.5 + 4.5. After surgery, the patient showed orthophoria in all 9 diagnostic positions of gaze, for distance and near. After 6 months, she started to develop consecutive esotropia that appeared in a rhythmic manner every 24 hours. Parents recorded the appearance of esotropia every other day. Twenty-four hours, the patient showed orthophoria, and 24 hours, she showed esotropia. On the day of esotropia, she had esotropia 25PD for distance and 30 for near. While the other day she was orthophoric. After 3 months, esotropia had increased to 40 PD for distance and 50 for near. She had a V-pattern with esotropia 35 on up gaze and 55 on down gaze. She had bilateral inferior oblique overaction with fundus extorsion. After 6 months from the development of cyclic esotropia, it became constant.

Results: The patient had constant, consecutive esotropia.

Conclusions: Cyclic esotropia may develop after surgical correction of intermittent exotropia.

A Rare Case Report of Crocodile Tears Syndrome Following Bell's Palsy in a Pediatric Patient

First Author: Al Farizi **SUNJAYA**

Co-Author(s): Primawita **AMIRUDDIN**, Sesy **CAESARYA**, Irawati **IRFANI**, Feti **KARFIATI**, Mayasari **KUNTORINI**

Purpose: To present a case with Crocodile tears syndrome following Bell's palsy in a pediatric patient.

Methods: This report discusses the anamnesis and physical examination of eye complications following Bell's palsy, suspected to be crocodile tears syndrome.

Results: An 11-year-old boy presented with complaints of crying every time he ate for the previous two months. The patient had a history of Bell's palsy on the left side of the face six months ago. Other complaints were denied. The results of the eyelid examination of both eyes showed that there was no orbicularis muscle weakness or eyelid laxity, and supporting lacrimation due to abnormalities in lacrimal gland secretion. The examination of the anterior and posterior segments of both eyes was within normal limits. We diagnosed the patient with Crocodile Tears Syndrome.

Conclusions: Crocodile tears syndrome is a rare case. Clinicians often overlook the symptoms, leading to their infrequent reporting. Further research on this syndrome is needed in a larger number of cases to enhance clinician knowledge, aid in diagnosis, and provide appropriate management.

A Rare Case of Mobius Syndrome Presenting with Esotropia and Cranial Nerve Palsies in a Child

First Author: Subarna **BARUA**

Co-Author(s): Md.Anwarul **AZIM**, Shahnaz **MARIYEM**

Purpose: To describe a rare case of Mobius syndrome presenting with esotropia, multiple cranial nerve palsies, eyebrow elevation, adenoid hypertrophy, and refractive error in a school-aged child.

Methods: A 12-year-old boy presented with a two-year history of progressive difficulty in distant vision and inward deviation of both eyes, noted since birth, gradually worsening. Parents reported a preference for near tasks. No history of trauma, ocular surgery, or consanguinity was present.

Results: Examination revealed abnormal head posture with left head tilt, chin depression, persistent mouth opening, and compensatory eyebrow elevation. Ocular evaluation demonstrated bilateral esotropia (~15°), refractive error, lagophthalmos with preserved Bell's phenomenon, and markedly restricted ocular motility. Seventh cranial nerve dysfunction included bilateral

facial palsy with absent forehead wrinkling, incomplete eye closure, loss of nasolabial folds, and deviation of the mouth. Twelfth cranial nerve involvement was evident with right-sided tongue wasting, fasciculations, weakness, and dysarthria. Oropharyngeal findings showed unilateral tonsillar/adenoid hypertrophy. MRI brain excluded intracranial pathology. The patient was managed conservatively with spectacles, lubricants, eyelid taping at night, and was scheduled for bilateral medial rectus resection under general anesthesia.

Conclusions: Mobius syndrome is a rare congenital cranial nerve disorder with variable ophthalmic and systemic manifestations. This case emphasizes the importance of early recognition, refractive correction, and multidisciplinary management to preserve vision and improve quality of life.

A Study on Cycloplegic Autorefractometry and Cycloplegic Retinoscopy in Pediatric Patients: A Prospective Study

First Author: Sreylin SIM

Co-Author(s): Guechlaing CHEA, Seiha DO, Amarin MAR, Povpronet NY, Saly SAINT

Purpose: To assess the accuracy and clinical utility of cycloplegic autorefractometry relative to standard cycloplegic retinoscopy in children.

Methods: A prospective analysis was performed on eligible children aged 3 to 16 years. Cycloplegia was induced using 1% cyclopentolate followed by a fixed-dose combination of 0.8% tropicamide and 5% phenylephrine hydrochloride. Autorefractometry was performed first, followed by cycloplegic retinoscopy. Data were analyzed using STATA version 18, with statistical significance set at P value < 0.05. Clinically significant differences were defined as >0.5 diopters (D) in sphere or cylinder, or >20 degrees in axis.

Results: Spherical power and spherical equivalent measurements did not differ significantly between the two methods. However, differences were observed in cylindrical power and axis. Cycloplegic autorefractometry produced slightly higher mean cylinder values (−1.62 D) and a different mean axis orientation (101.80°). These differences, although statistically significant, were within a clinically acceptable range for older children.

Conclusions: Cycloplegic retinoscopy remains the reference standard for pediatric refractive assessment, particularly in children younger than six years. However, cycloplegic autorefractometry provides comparable results for spherical power and spherical equivalent, making it a practical alternative in clinical settings where time and expertise are limited. These findings support its potential role in expanding access to pediatric vision screening in resource-constrained environments.

A Tailored Approach for Managing Thyroid-Related Strabismus

First Author: Bhavika BANSAL

Co-Author(s): Jaspreet SUKHIJA

Purpose: This case series presents a patient-based approach for the management of thyroid eye disease using a combination of conservative and invasive approaches.

Methods: Our study included 4 patients who were known cases of thyroid and were complaining of diplopia and strabismus. Treatment included inferior rectus recession alone or combined with botulinum toxin injection, inferior rectus disinsertion, and superior rectus plication. Prisms glasses were also advised to the patient with an acute onset of diplopia with small deviation.

Results: All four patients showed relief in diplopia and ocular misalignment. Inferior rectus recession was the preferred procedure for patients presenting with hypotropia in the primary position with tight inferior rectus on the force duction test, and it was combined with botulinum toxin injection to have an add-on effect. Superior rectus muscle plication was done in recalcitrant cases. Prism glasses were used in the case of small-angle deviation with diplopia in the primary position.

Conclusions: This case series highlights that the plication procedure can be done as a staged procedure in large-angle deviations. Patient-specific approach worked well in every case of thyroid eye disease, as surgical outcomes can be unpredictable due to variation in fibrous changes in extraocular muscles.

A Targeted Approach to Diplopia: Segmental Occlusion in Paralytic Strabismus

First Author: Anusha CHAWLA

Co-Author(s): Siddharth AGRAWAL, Tapan RAMAWAT, Latika TANDON

Purpose: To highlight the effectiveness of segmental occlusion as a simple, adaptable and non-invasive method to manage diplopia in patients with paralytic strabismus while preserving the functional, unaffected visual fields.

Methods: In this case series, three patients with paralytic strabismus were managed using customized segmental occlusion. Areas of diplopia were identified by assessing ocular motility, Hess charts, and patient feedback. Partial occlusion was applied to the spectacle lens corresponding to the diplopic field, sparing the diplopia-free binocular and unocular zones.

The occlusion was titrated periodically with clinical improvement.

Results: In all three cases, segmental occlusion successfully eliminated diplopia in the affected gaze while preserving diplopia-free binocular and unocular visual fields. Case 1 (sixth-nerve palsy) demonstrated stable binocular vision with progressive reduction in occlusion as recovery occurred. Case 2 (partially recovered sixth-nerve palsy) illustrated diplopia free unocular visual fields after segmental occlusion of the binocular field. Case 3 (right inferior oblique palsy) showed relief from vertical diplopia in the superonasal field with good comfort and adaptation. None reported visual discomfort.

Conclusions: Segmental occlusion provides a low-cost, patient-friendly, and effective strategy for managing diplopia in paralytic strabismus. By selectively targeting the diplopic field, segmental occlusion preserves unocular and binocular visual function, improving the quality of life and supporting recovery.

An Atypical Presentation of Retinoblastoma With Unilateral Total Hyphema and Periorbital Cellulitis

First Author: Yik To HO

Co-Author(s): Cheuk Ling YIM

Purpose: To report an atypical presentation of retinoblastoma with unilateral total hyphema and periorbital cellulitis.

Methods: This is a case report.

Results: A 1-year-old boy, with no family history of retinoblastoma, presented with a sudden onset of left upper lid swelling and complete ptosis. On examination, there was left eye total hyphema, chemosis, with raised intraocular pressure of 45mmHg. Left periorbital cellulitic changes were evident. Urgent magnetic resonance imaging showed a mixture of old and new blood products filling the intraocular cavity, with no definite intraocular mass seen. Imaging features initially favored trauma as the top differential diagnosis, though there was no trauma history. 4 days after the initial presentation, examination revealed a new white, well-circumscribed tumor in the right eye. The final diagnosis was group A retinoblastoma in the right eye and presumed group E retinoblastoma in the left eye. He was treated with 6 cycles of chemotherapy, and later underwent enucleation for the left eye and focal laser therapy for the right eye tumor. Histopathology of the enucleated eyeball subsequently confirmed retinoblastoma with clear resection margins. He remained stable and has been treatment-free for more than 1.5 years thereafter.

Conclusions: Retinoblastoma typically presents with leukocoria, but on rare occasions, it can present

atypically, as in this case, with total hyphema and periorbital cellulitis, which may pose a diagnostic challenge. This case report serves as a reminder that retinoblastoma can mimic any ocular or orbital pathology and should be considered as one of the differential diagnoses in atypical presentations that do not respond to standard treatments.

Analysis of Eye Axial Changes in Children With Different Refractive States

First Author: Tang YAN

Co-Author(s): Hao JINGJING, Wang YIHUI

Purpose: Analyze eye axial changes and refractive distribution in 3–12-year-olds with different refractive states to guide clinical interventions.

Methods: Retrospective cohort study of 332 children (164 males, 168 females) from Beijing Aier Yingzhi Eye Hospital (2020.09–2021.03) with ≥ 1 -year follow-up. Divided into 3 age groups: 3–5 years ($n=115$: hyperopia 23, emmetropia 16, myopia 76); 6–9 years ($n=148$: hyperopia 37, emmetropia 53, myopia 58); 10–12 years ($n=69$: hyperopia 7, emmetropia 7, myopia 56). Recorded 6-month/1-year refractive and eye axial changes; used ANOVA (AL/CR ratio) and rank-sum test (change rates).

Results: Refractive error showed negative progression (myopia deepened, hyperopia decreased, $p<0.05$); eye axis grew positively ($p<0.05$). 1-year eye axial growth rate (mm/year): 3–5 years (hyperopia 1.33, emmetropia 1.08, myopia 1.30, $p=0.164$); 6–9 years (hyperopia 1.20, emmetropia 1.78, myopia 1.40, $p=0.082$); 10–12 years (hyperopia 0.92, emmetropia 1.14, myopia 0.67, $p=0.172$). Hyperopes had no inter-age difference ($p>0.05$); emmetropes ($p=0.04$) and myopes ($p<0.01$) did, with emmetropes growing faster at 6–9 years, myopes slower at 10–12 years.

Conclusions: No inter-refractive-state difference in eye axial growth rate. Hyperopes had stable growth; myopes progressed fast at 3–5/6–9 years, slowing at 10–12 years.

Analysis on the Basic Principle and Effective Exploration of Telescopic Lens for Myopia Prevention and Control

First Author: Yang LINTAO

Purpose: Exploring the effectiveness and feasibility of using a telescope for myopia prevention and control based on its basic principles.

Methods: Through research and physical analysis, it has been found that the basic principle of myopia prevention and control with a telescope is usually

to use optical elements such as concave mirrors or concave convex composite lenses to reflect or refract the image of objects at close range. This allows the eyes to simulate a distant state when looking at close objects, thereby reducing the need for excessive adjustment (ciliary muscle relaxation) and minimizing the risk of axial elongation caused by close-range use.

Results: There is controversy over the effectiveness of clinical research statistics, and there is a lack of large-scale, authoritative verification. Some studies have shown positive effects, while more studies believe that the effects are limited or unclear. Cannot replace natural prevention and control methods, such as remote outdoor activities.

Conclusions: The effectiveness of using a telescope for myopia prevention and control is theoretically reasonable, but there is currently a lack of sufficient clinical evidence to support it as a mainstream prevention and control method. For the prevention and control of myopia in adolescent students, it can be attempted as an auxiliary tool under the guidance of a doctor, but more attention should be paid to outdoor activities and bathing in sunlight. The combination of traditional Chinese and Western medicine prevention and control requires reasonable basic prevention and control measures to avoid blindly relying on equipment and neglecting core factors.

Application and Outcomes of the Modified Nishida's Procedure for Various Etiologies of Incomitant Strabismus

First Author: Akila RAMKUMAR

Co-Author(s): Hennav DHILLION

Purpose: To highlight the various applications of Modified Nishida's technique and analyze its outcomes in various incomitant strabismus.

Methods: It was a retrospective analytical study. The patient with a minimum follow-up of 6 weeks post-operatively was included in the study. All clinical, demographic, pre- and postoperative strabismus deviation of the patients who underwent Modified Nishida's procedure for incomitant strabismus were studied.

Results: Eighteen eyes of 18 patients with various incomitant strabismus, like abducent palsy, monocular elevation deficit, Inferior rectus aplasia, and muscle avulsion, were included. The time from surgery to the last follow up ranged from 45-750 days. The mean $\pm$ SD preoperative horizontal deviations were 48 ± 34.46 PD, which reduced statistically significantly to 14.83 ± 15.37 PD at the first postoperative day and was 13.94 ± 14.76 PD at the last follow-up (P value 0.01 and 0.00). The mean $\pm$ SD preoperative vertical deviations were 13.33 ± 16.09 PD, which statistically significantly reduced to

4.61 ± 7.16 PD at the first postoperative day and was 3.56 ± 5.79 PD at the last follow-up (P value 0.00 and 0.00). There was statistically significant improvement in the adduction (-0.50 ± 1.20), elevation (-0.89 ± 1.32), and depression (-0.06 ± 0.99) with p value 0.00, 0.00, 0.02, respectively. There was improvement in abduction (-1.65 ± 1.96), which was not statistically significant.

Conclusions: Modified Nishida's procedure is a useful tool in the management of large-angle incomitant strabismus and provides good postoperative alignment as well as improvement in ocular motility.

Association Between Hemoglobin Levels and Severity of ROP in Premature Infants: Insights From a Tertiary Care Hospital

First Author: Muhammad MOIN

Co-Author(s): Mehreen AKRAM, Nida KHALID, Lubna SIDDIQUE, Zaib UN NISA

Purpose: To evaluate the correlation between hemoglobin (Hb) levels and the severity of retinopathy of prematurity (ROP) in low-birth-weight premature infants, with emphasis on vision-threatening ROP requiring treatment.

Methods: This retrospective cross-sectional study was conducted at the ROP screening facility of Mayo Hospital, Lahore, from July 2024 to June 2025. A total of 107 preterm infants meeting ROP screening criteria and with complete blood count (CBC) reports were included; those with major anomalies or incomplete data were excluded. Infants were stratified by mean Hb levels: ≤ 12 g/dL (moderate/severe anemia) and > 12 g/dL (mild/no anemia). Primary outcomes were incidence of vision-threatening ROP (stage 2 with plus disease, stage 3, or aggressive ROP) requiring treatment. Secondary outcomes included associations with ROP zone, stage, birth weight, and gestational age.

Results: Vision-threatening ROP occurred in 50% of infants with Hb ≤ 12 g/dL versus 28.5% in the Hb > 12 g/dL group ($p=0.003$). Zone 1 ROP was significantly more frequent among anemic infants (27.6% vs. 8%, $p=0.008$). Aggressive ROP was also more common in anemic infants (80% vs. 20%, $p=0.07$). Lower Hb levels correlated with lower birth weight and gestational age.

Conclusions: Low Hb levels (≤ 12 g/dL) were significantly associated with a higher risk of vision-threatening ROP, Zone 1 disease, and aggressive ROP. Monitoring and addressing anemia in preterm infants may help reduce ROP severity. Larger studies are warranted to confirm causality and guide interventions.

Panel No.: POS-0893

Association Between Short-Term Visual Plasticity and Refractive Change in Anisometropia

First Author: Wei SUN

Co-Author(s): Jin ZENG

Purpose: Visual plasticity varies among children with anisometropia, and its relationship with refractive development is not well defined. This study investigated whether short-term contrast sensitivity improvement after augmented reality (AR) dichoptic training is associated with spherical equivalent (SE) changes over six months.

Methods: Ninety anisometropic children were enrolled. All completed a 20-minute AR dichoptic training session at baseline, followed by cycloplegic refraction. Participants were classified into a plasticity group (n=20) or a non-plasticity group (n=70) based on post-training binocular contrast sensitivity improvement. All then underwent a 6-month home-based AR training program (10 minutes, twice daily). SE changes were compared between groups.

Results: Baseline characteristics were comparable between groups (mean age: 8.0 vs. 8.5 years; female: 45% vs. 50%; binocular SE: -2.14D vs. -1.78D; all $p > 0.05$). After 6 months, the non-plasticity group showed significant SE progression ($p = 0.038$), while the plasticity group maintained stable SE ($p = 0.23$). SE changes were $+0.08 \pm 0.36$ D (better eye) and -0.04 ± 0.40 D (worse eye) in the plasticity group, versus -0.37 ± 0.75 D and -0.21 ± 0.45 D in the non-plasticity group. Inter-group differences in SE change were significant for both eyes ($P < 0.05$).

Conclusions: Short-term AR training-induced contrast sensitivity improvement is associated with better refractive stability over six months in anisometropic children. Initial training response may help predict long-term refractive control outcomes.

Beyond Sutures: Intraoperative Botulinum Toxin as an Adjunct in Large-Angle Strabismus Surgery

First Author: Ching Hsi WU

Co-Author(s): Wei Wei HSIA

Purpose: To evaluate the role of intraoperative botulinum toxin injection as an adjunct to conventional surgery for large-angle strabismus.

Methods: Two patients with large-angle exotropia (≥ 75 prism diopters) underwent standard strabismus surgery combined with intraoperative botulinum toxin injection (2–3 units per lateral rectus). Postoperative

alignment, ocular motility, and complications were assessed during follow-up.

Results: Both patients achieved satisfactory postoperative alignment with fewer muscle interventions (three instead of four muscles). Early recovery showed reduced residual deviation and improved motility. No major complications (ptosis, vertical deviation, globe perforation) were observed. In one case, a transient residual exophoria < 10 PD at 1 week resolved after the botulinum toxin effect onset, leading to orthophoria in both eyes.

Conclusions: Intraoperative botulinum toxin injection appears to be a safe and effective adjunct for large-angle strabismus surgery, reducing the number of muscles operated while enhancing alignment stability. This approach may minimize undercorrection and improve outcomes in deviations ≥ 75 PD.

Cataract Surgery With Intraocular Lens Implantation in Pediatric Posterior Lenticonus: Visual Outcomes and Prognostic Factors

First Author: Shahrina MAHFOOZ

Co-Author(s): Quazi Sazzad IFTEKHAR

Purpose: To evaluate the clinical profile and visual outcomes of children with posterior lenticonus undergoing cataract surgery with intraocular lens (IOL) implantation in a tertiary center of Bangladesh.

Methods: This prospective interventional study included children diagnosed with posterior lenticonus and cataract who underwent lens aspiration with IOL implantation between 2020–2025. Patients with other ocular comorbidities or systemic conditions affecting vision were excluded. Preoperative evaluation included best-corrected visual acuity (BCVA), slit-lamp biomicroscopy, fundus examination, ultrasonography (when required), and assessment for strabismus and amblyopia. Intraoperative details such as surgical technique, site of IOL implantation, and posterior capsule status were recorded. Patients were followed up for a minimum of 6 months. Postoperative assessments included BCVA, binocular vision, anterior and posterior segment evaluation, and intraocular pressure. The primary outcome was postoperative visual acuity; secondary outcomes included factors influencing visual prognosis.

Results: A total of 48 children (67 eyes) aged 2–16 years were enrolled in the study. Preoperative posterior capsule dehiscence was noted in 87% of eyes. Mean preoperative BCVA was 1.03 ± 0.56 logMAR, which improved significantly to 0.57 ± 0.5 logMAR at final follow-up ($P < 0.001$). Over 80% of eyes achieved BCVA better than 0.3 logMAR. Visual outcomes were poorer in children presenting with strabismus ($P = 0.049$),

while age at surgery ($P = 0.533$) and PC dehiscence ($P = 0.735$) had no significant impact. Binocular vision improved postoperatively. No glaucoma was observed, though one patient required reoperation for IOL dislocation.

Conclusions: Cataract surgery with IOL implantation provides significant visual and functional improvement in children with posterior lenticonus.

Clinical Characteristics of Juvenile Xanthogranuloma Associated with Hyphema and Secondary Glaucoma

First Author: Di CAO

Co-Author(s): Man HU, Li LI, Tianwei LIANG

Purpose: To characterize the clinical and pathological features of juvenile xanthogranuloma (JXG) manifesting with hyphema and secondary glaucoma in infants, focusing on iris morphology documented by ultrasound biomicroscopy (UBM), and to evaluate therapeutic responses and clinical outcomes.

Methods: A retrospective analysis was conducted on the clinical records of 3 pediatric patients diagnosed with JXG accompanied by hyphema and secondary glaucoma.

Results: The cohort included patients aged 6 months, 6 months, and 1 year, exhibiting a mean initial intraocular pressure (IOP) of 37 mmHg. Two cases were unilateral, while one was bilateral. All affected eyes exhibited significant buphthalmos and enlarged cup-to-disc ratios. Anterior segment examination revealed fibrinous strands and residual hyphema. The iris showed diffuse disruption of normal architecture, including loss of crypts and stromal hypopigmentation. UBM demonstrated a characteristically irregular, bumpy iris surface. Systemic manifestations included cutaneous lesions in all patients, with one case having additional pulmonary infiltration. Management comprised topical corticosteroids for all patients, supplemented by systemic chemotherapy in the patient with pulmonary involvement. IOP normalized within 1–2 months in all eyes. At final follow-up intervals of 1, 6, and 24 months, all patients maintained normal IOP and showed no signs of recurrence.

Conclusions: JXG presenting with hyphema and secondary glaucoma typically occurs in an presents at an early age and can cause significant ocular damage. UBM reveals distinctive iris morphological alterations. Management with topical corticosteroids is effective in controlling intraocular pressure and preventing recurrence demonstrates characteristic morphological changes of the iris. Topical steroid therapy is effective in managing this condition.

Clinical Outcome of Inferior Rectus Transposition in Lateral Rectus Palsy

First Author: Piyush ADCHITRE

Co-Author(s): Rebika DHIMAN, Swati PHULJHELE, Rohit SAXENA

Purpose: To prospectively report clinical outcomes of Inferior Rectus Transposition (IRT) for lateral rectus palsy.

Methods: A prospective interventional study was conducted in 10 eyes of 10 patients with lateral rectus palsy aged >8 years, without any prior ocular surgeries. All underwent IRT with posterior augmentation suture with adjustable medial rectus recession (MRC). The primary outcome was correction of esotropia in primary gaze; the secondary outcome was improvement in abduction at 6 months postoperatively.

Results: One month postoperatively, esotropia significantly improved from $46.5 \pm 13.1^\circ$ to $6.8 \pm 4.0^\circ$ ($p < 0.01$), and abduction limitation improved from -3.7 ± 0.5 to -2.4 ± 0.8 ($p < 0.01$). Additionally, an improvement in head posture from $21.9 \pm 7.0^\circ$ to $2.0 \pm 2.3^\circ$ ($p < 0.01$) was noted. Vertical palpebral aperture width was relatively unchanged from 9.6 ± 1.2 mm to 9.8 ± 1.2 mm ($p = 0.39$). A pre-existing V pattern was noted in 5 patients, which reduced postoperatively in 2 patients & an induced A pattern was seen in 3 of these patients. None had induced cyclovertical deviations or fundus torsion.

Conclusions: Inferior rectus transposition is an effective treatment option for the correction of deviation and abduction limitation in lateral rectus palsy. It may have a tendency to induce an A pattern. Therefore, it may be more suitable in cases with a pre-existing V pattern.

Abstract No.: 206570

Clinical Spectrum, Systemic Associations, and Management of Congenital Cataract: A Retrospective Observational Study From a Tertiary Eye Hospital in Indonesia

First Author: Ivany RIZKY RAHMADANI

Co-Author(s): Sesy CAESARYA, Irawati IRFANI, Feti Karfiati MEMED, Primawita OKTARIMA, Mayasari WAHYU

Purpose: This study aims to elucidate the clinical spectrum, systemic associations, and management of congenital cataract in a tertiary eye hospital.

Methods: This is a retrospective observational study conducted at the Tertiary Eye Hospital in Indonesia. This study included children aged ≤ 12 months who were diagnosed with congenital cataract between 2021 and 2023. Data were collected from electronic medical records, including age at diagnosis, gender, cataract

laterality, morphology, systemic conditions, and type of surgery. The data were further processed using the software Microsoft® Excel 2016.

Results: A total of 130 patients (238 eyes) were included. Most patients were male (56.15%) and were diagnosed between 3 and 6 months after the onset of symptoms (58.46%). Bilateral cataracts were found in 83.07% of cases, and 76.92% had nystagmus. Common associated conditions included congenital rubella syndrome (7.69%) and Down syndrome (8.46%). Ocular abnormalities such as microcornea (10.50%) and microphthalmia (7.56%) were also common. Total cataract was the most common type (37.39%). Aspiration, primary posterior capsulotomy, and anterior vitrectomy without intraocular lens implantation was the most commonly used technique in the operation (60.08%).

Conclusions: Congenital cataract can be associated with a systemic condition or idiopathic. TORCH infection must be screened to detect other manifestations besides the ocular. Surgical methods were decided by the patient's condition and the type of cataract. The timing and surgical techniques used played a crucial role in determining the prognosis of visual acuity.

Abstract No.: 202766

Comparative Evaluation of 'Combined Lateral Rectus Suture Hang-Back Recession With Medial Rectus Plication' Versus 'Medial Rectus Muscle Resection With Lateral Rectus Recession' in Extra-Large Angle Exotropia

First Author: Amar PUJARI

Co-Author(s): Devashree MOKTAN

Purpose: To compare the clinical efficacy of «Combined Lateral Rectus Suture Hang-Back Recession with Medial Rectus Plication» versus «Medial Rectus Muscle Resection with Transplant-aided or Suture-aided Lateral Rectus Recession» in extra-large angle exotropia.

Methods: A prospective comparative study was undertaken. Group one underwent medial rectus resection with transplant-aided lateral rectus muscle recession. Group two underwent medial rectus resection with lateral rectus suture hang-back recession. The third group underwent lateral rectus suture hang-back recession with medial rectus plication. The pre-operative and post-operative outcomes were compared on follow-ups at 3 months, 6 months, and 1 year.

Results: The median preoperative deviation in group 3 was 90 prism dioptre (PD) (80-110), and the net correction achieved in group 3 was 84 PD (80-90); these two results are comparable to the two previously published groups (overall p value 0.677 and 0.625). The median medial rectus plication length was 6 mm (5.5-6), which is comparable to the amount of resection

of the earlier two groups (overall p value 0.347). The median hang-back suture length in group 3 was 6 mm (5-6), which is a larger spacer as compared to resection groups 1 vs 2 (p=0.007) and 1 vs 3 (p=0.032).

Conclusions: «Combined Medial Rectus Plication with Lateral Rectus Suture Hang-Back Recession» works on par with the other two procedures in extra-large angle exotropia. This provides additional advantages of negating the need for resection, leading to notable intraoperative ease.

Abstract No.: 206176

Comparison of Surgical Outcomes Between Bilateral and Unilateral Medial Rectus Recession in Acquired Esotropia

First Author: Ayaka NOGUCHI

Co-Author(s): Toshiaki GOSEKI, Erika MITSUI, Mayuka MIYAZAKI, Hiromi ONOUCHI, Satoru YAMAGAMI

Purpose: In pediatric esotropia, a few individual reports on bilateral vs. unilateral MR recession show conflicting outcomes; however, no such reports exist for adults. Therefore, we aimed to compare the effect per millimeter of bilateral versus unilateral MR recession in adults with acquired esotropia overall and further evaluate differences within subgroups of acute acquired comitant esotropia (AACE) and sagging eye syndrome (SES).

Methods: We retrospectively analyzed 76 adult patients (mean age: 52.1 ± 18.7 ; range, 21–86 years) who underwent MR recession between April 2020 and December 2024. Fifty-five underwent bilateral MR recession (21 with AACE and 7 with SES, all without high myopia), while 21 underwent unilateral MR recession (9 with AACE and 6 with SES, all without high myopia). The effect per 1 millimeter (Δ /mm) was calculated at the first and final postoperative visits and compared between groups.

Results: Among 76 patients with acquired esotropia, the effect per millimeter at the first postoperative visit (8 ± 3.6 days) was $1.98 \pm 0.72 \Delta$ /mm for bilateral and $1.79 \pm 0.53 \Delta$ /mm for unilateral recession ($P = 0.409$); at the final visit (173 ± 90 days), it was $2.11 \pm 0.72 \Delta$ /mm and $1.68 \pm 0.85 \Delta$ /mm, respectively ($P = 0.377$), with no significant differences. In AACE, no significant differences were observed (first visit: 2.14 ± 0.76 vs. $1.92 \pm 0.40 \Delta$ /mm; final: 2.11 ± 0.72 vs. $1.68 \pm 0.85 \Delta$ /mm). In SES, no significant differences were observed (first visit: 1.41 ± 0.23 vs. $1.54 \pm 0.25 \Delta$ /mm; final: 1.40 ± 0.52 vs. $1.80 \pm 0.32 \Delta$ /mm).

Conclusions: No significant difference in effect per millimeter was observed between bilateral and unilateral MR recession in adults with acquired esotropia, including both AACE and SES subtypes.

Abstract No.: 206896**Panel No.: POS-0901**

Congenital Ectopia Lentis: Clinical Profile and Surgical Outcomes in Posterior Iris Fixated Intraocular Lens in Pediatric Age Group

*First Author: Jigna **MOTWANI****Co-Author(s): Manjushree **BHATE***

Purpose: To study the clinical profile and surgical outcomes of posterior fixated iris claw intraocular lens (IOL) implantation in congenital ectopia lentis patients.

Methods: Twenty-one eyes of 11 patients who underwent lensectomy with secondary posterior iris claw intraocular lens implant were included. The clinical profile included etiological diagnosis, nature of subluxation, pre-operative visual acuity, and refraction. Intraoperative and postoperative details of IOL centration, intraocular pressure (IOP), and the status of cornea and pupil shape were documented. All surgeries were performed by a single surgeon.

Results: Mean age was 8 ± 1.41 , male: female ratio was 1.7:1. Etiology included Ectopia lentis ($n=17$; 56.6%), microspherophakia ($n=4$; 13.3%). Follow-up period ranged from 3 months-4 years (mean 1 year). Pre-operative best corrected visual acuity (BCVA) was 1.89 ± 0.12 logMAR. Post-operatively, mean BCVA at 6 months was 0.15 ± 0.2 ($n=8$), at 2 years was 0.3 logMAR, and at 4 years was 0.3 logMAR. The mean refraction was 1.25 ± 1.76 SE. Four eyes had IOP control with anti-glaucoma medications. The pupil was circular in all except 2 eyes (D shaped). IOL was well centered and well enclaved in 18 eyes and $n=3$ had a subluxation due to slippage of one enclave needing re-positioning.

Conclusions: Our cohort demonstrated good intermediate term outcomes with regards to IOL position and post-operative visual acuity with minimal to no complications.

Abstract No.: 201142**Panel No.: POS-0822**

Corneal Biomechanical Characteristics and Correlation Analysis in Children With Different Refractive States

*First Author: Yanhua **WANG***

Purpose: To investigate the correlation between corneal biomechanical characteristics and refractive status in children.

Methods: The study involved 339 children aged 5~13 with a spherical equivalent (SE) range from -6.00D to +2.00D. Axial A cross-sectional study involved 339 children aged 5 to 13 with spherical equivalent ranging from -6.00D to +2.00D. Axial length was measured by IOL Master; corneal biomechanical parameters by Corvis ST and Pentacam. According to SE, the subjects were divided into moderate myopia, mild myopia, and

emmetropia groups. The correlation between AL, SE, and corneal biomechanical parameters was analyzed.

Results: A2V in the moderate myopia group was lower than that in both the mild and emmetropia groups ($P<0.001$). PD in the emmetropia group was lower than that in the mild ($P<0.05$) and moderate groups ($P<0.01$). SSI in the emmetropia group was higher than that in the other two groups ($P<0.001$). A2V in 11-13 years was lower than that in 5-7 and 8-10 years old group ($P<0.01$). PD in the 11-13-year-old group was higher than that in the 8-10 and 5-7-year-old groups ($P<0.01$). SSI in 5-7 years old group was higher than that in 8-10 and 11-13 years old group ($P<0.01$). AL was positively correlated with PD, negatively correlated with SSI, and A2V. SE was positively correlated with A2V and SSI, and negatively correlated with PD.

Conclusions: Corneal stiffness decreases with an increase in SE. The changes of SSI, PD, and A2V can be predictors of myopia progression in children aged 5~13 years.

Abstract No.: 201394**Panel No.: POS-0826**

Demographic Profile, Epidemiology, Management and Outcome of Pediatric Glaucoma in a Tertiary Eye Hospital in Bangladesh

*First Author: Sidratul Muntaha **NAZNIN****Co-Author(s): Mohammad Mostafa **HOSSAIN***

Purpose: To describe the characteristics, Epidemiology, management and outcome of pediatric glaucoma in a tertiary eye care center in Bangladesh.

Methods: It was a retrospective study which was conducted in a tertiary level hospital since 2021 to 2023. Study included child whose age from four months to sixteen years. The patients whose age up to sixteen years with retinal pathology and developmental delay were excluded from study. After selection age, sex, intraocular pressure combined with glaucomatous history, visual acuity (VA), abnormal signs under a slit lamp, fundus findings, syndromic association, medications, surgical options were recorded and outcomes were analyzed.

Results: Total study population was 239 cases (278 eye). Affected boy were 152(65%) where's girls' number were 80(34.5%). Mean age was 6.6 ± 4.46 . Positive family history for glaucoma was 7.5%. Primary glaucoma was 64.7% where's secondary glaucoma was 35.3%. Primary congenital glaucoma (PCG), traumatic glaucoma, juvenile glaucoma was most common glaucoma type. The most common signs and symptoms were elevated intraocular pressure (38.07%) and eye pain (28.45%). Trabeculotomy (Trab) combined with trabeculectomy were the most commonly performed surgeries. Seventy-three percent child were treated by oral medication and 26.6% patients were undergoing

surgical intervention. From urban area 66.52% patients, rural area 33.47% patients were recorded. Sixteen percent pediatric glaucoma were associated with systemic syndrome.

Conclusions: Pediatric amblyopia might require full attention during the entire treatment, especially after glaucoma surgery. Government concern, economic development, more public education on glaucoma prevention and the importance of early diagnosis and treatment is time demanding.

Dichoptic Perceptual Training Based on Augmented Reality in Anisometropic Amblyopia

First Author: Yongchuan LIAO

Purpose: The study aimed to explore the effect of dichoptic perceptual training based on the augmented reality (AR) platform in anisometropic amblyopic children.

Methods: Seventy-two subjects were randomized to the occlusion group (AR0 group), the dichoptic perceptual AR training group (AR1 group), and the combined therapy in the former two groups (AR2 group).

Results: For the three groups, the best-corrected visual acuity (BCVA) was all improved after treatment ($P < 0.001$). There was no statistically significant difference in the change of visual acuity in the amblyopic eye among the three groups at the 2-month visit ($P = 0.621$) and at any best achieved acuity visit ($P = 0.745$). The stereoacuity was improved at the best achieved acuity visit for the AR1 and AR2 groups ($P < 0.01$), but not improved in the AR0 group ($P = 0.075$). At the best achieved acuity visit, the mean log contrast sensitivity function (CSF) of each spatial frequency didn't improve significantly after treatment, both in AR0 and AR1 groups ($P > 0.05$). However, in the AR2 group, the CSF value of all spatial frequencies had a significant improvement ($P < 0.05$).

Conclusions: In conclusion, this randomized controlled trial demonstrated that dichoptic perceptual training based on VR technology in anisometropic amblyopia could improve visual function such as BCVA, stereopsis and CSF. Although dichoptic AR training could not replace the traditional occlusion method to improve the visual acuity of amblyopia, it could be an alternative therapy for amblyopia, due to its effectiveness, high immersion, and interestingness, especially for amblyopes who could not accept patching. Moreover, the AR training seems to be more efficient in stereopsis and in CSF when combined with occlusion therapy.

Digital Therapeutics Approach for Young Children With Myopia Using SAT-001 Study Protocol for a Randomized Controlled Trial

First Author: Hae Jung PAIK

Purpose: To evaluate the efficacy and safety of the software as a medical device, SAT-001, for the inhibition of myopia progression and treatment in pediatric patients with myopia.

Methods: This clinical trial is a two-arm, prospective, randomized, open-label study with a duration of approximately 25 months. We will enroll 110 pediatric patients with myopia aged 5 to 9 years with $-0.75D$ to $-5.75D$ SE in each eye. Eligible participants will be randomly assigned in a 1:1 ratio to either the study group using SAT001 with single vision spectacles or the control group using single vision spectacles alone. The change in the SER (spherical equivalent refractive error) at 48 weeks from baseline serves as the primary endpoint. The change in SER at 24 weeks and axial length at every 12 weeks from baseline will be the secondary endpoints. Each change will be assessed depending on the myopic severity. Treatment-emergent adverse events will be evaluated for the safety analysis.

Results: Progression of myopia might slow down via maintaining scleral integrity and biosynthesis of ECM components via adjustments of NHFs such as insulin-like growth factor (IGF), cortisol, or dopamine. To adjust NHFs, SAT-001, translated into digital tasks, has been implemented within the investigational medical device, comprising three modules. SAT-001 is a software designed to non-invasively suppress the progression of myopia in children by employing eye activity in a well-lit environment through a game format. It also provides modules that promote appropriate relaxation effects.

Conclusions: This study to confirm the efficacy and safety of SAT-001 in slowing pediatric myopia progression.

Abstract No.: 205227

Early Intravitreal Bevacizumab Monotherapy for Aggressive Retinopathy of Prematurity: A Case Series

First Author: Md.Mominul ISLAM

Co-Author(s): Md.Anwarul AZIM, Quazi Sazzad IFTEKHAR, Omar JAFARULLAH, Tanzima SIDDIKA

Purpose: To evaluate the outcomes of early intravitreal Bevacizumab as a single therapy in infants with aggressive retinopathy of prematurity (AROP), with particular emphasis on disease regression without the need for laser indirect ophthalmoscopy (LIO) and the absence of reactivation at 6 months.

Methods: This retrospective case series included 5 infants (5 eyes) with AROP who presented within the first month after delivery. All eyes received a single intravitreal Bevacizumab injection (0.625 mg/0.025 ml) under aseptic conditions. Patients were followed regularly for at least 6 months with serial fundus examinations to assess regression, recurrence, and complications.

Results: • Number of cases: 5 infants. • Mean gestational age at birth: 33.2 weeks (range 30–38). • Mean birth weight: 1,780 g (range 1,350–2,500 g). • Age at presentation: 24–30 days postnatal. • Regression: Complete regression of AROP occurred in all eyes within 12–18 weeks (mean 14.4 weeks). • Recurrence at 6 months: None of the treated eyes showed reactivation. • Final outcome: At 6 months, all eyes achieved stable anatomical outcomes with complete vascularization. No ocular or systemic complications were recorded.

Conclusions: Early single-dose intravitreal Bevacizumab monotherapy can achieve complete and sustained regression of AROP without the need for adjunctive LIO, with no recurrence observed at 6 months. Early intervention may play a key role in favorable outcomes for high-risk infants.

Early Outcomes of a Paediatric Ophthalmic Collaborative Clinic: Australian College of Optometry (ACO) and the Royal Children's Hospital (RCH) Melbourne

First Author: Zeinab **FAKIH**

Co-Author(s): Nellie **DEEN**, Rumeysa **DOGER**

Purpose: This study reports early outcomes from a collaborative paediatric eye clinic established between the Australian College of Optometry (ACO) and the Royal Children's Hospital (RCH) Melbourne. The clinic aims to improve paediatric eye care pathways and reduce wait times within the public healthcare system. Children referred to or on the RCH waitlist were triaged by the RCH orthoptic team, and where appropriate, seen at the ACO Children's Clinic.

Methods: A retrospective review was conducted for the first 12 months of the clinic. Data collected included referral sources, diagnoses, time from referral to consultation, and clinical outcomes. Patient satisfaction surveys and clinical audits were also performed.

Results: The average wait time from external referral to consultation at the ACO was four weeks (range: 1–12 weeks). Most referrals came from community optometrists (28%) and general practitioners (12%). Notably, 24% of children required no active management under established protocols. Common diagnoses included refractive error (26%), pseudoesotropia (18%), esotropia (10%), and dry eye

(7%). Children needing refractive correction were prescribed glasses using subsidy schemes to reduce access barriers. Only 11% required referral to RCH ophthalmology for conditions like congenital cataract or ptosis, and were escalated directly to the paediatric registrar or triage team as needed.

Conclusions: This collaboration shows a joint optometry-ophthalmology model can safely and effectively reduce paediatric wait times while managing common eye conditions in a community setting. It enables timely identification and referral of children needing specialist care. Ongoing evaluation will assess its long-term impact on paediatric eye health services.

Effect of Patient Position on the Magnitude of Horizontal Strabismus Angle Measurements: Agreement Between Supine and Upright Positions

First Author: Napat **CHAIYAKHAM**

Co-Author(s): Somkiat **ASAWAPHUREEKORN**, Raveewan **CHOONTHANOM**, Phawasutthi **KEOKAJEE**, Worapot **SRIMANAN**

Purpose: To evaluate the reliability and agreement of horizontal strabismus angle measurements between upright and supine position.

Methods: We enrolled 102 patients with horizontal strabismus. Two masked ophthalmologists independently performed, in the same patient, alternate prism cover test (APCT) twice in both upright and supine positions at both distance (2 m) and near (33 cm). Intraobserver repeatability, interobserver reproducibility, and agreement between supine and upright positions were assessed using Bland–Altman analysis (mean difference and 95% limits of agreement (LoA)) and intraclass correlation coefficient (ICC).

Results: Both Intraobserver repeatability and interobserver reproducibility were excellent for both upright and supine position at both distant and near. The agreement of measurement between upright and supine position by examiner A at distant (at near) was 0.28 (0.49) PD, 95% LoA were -6.45 to 7.02 (-6.70 to 7.68) PD, and ICC was 0.96 (0.96); and by examiner B at distant (at near) was -0.03 (0.01) PD, 95% LoA were -5.81 to 5.75 (-5.31 to 5.33) PD, and ICC was 0.97 (0.98).

Conclusions: The reliability and agreement of horizontal strabismus angle measurements in the supine position are comparable to the upright position, with marginal and no clinically significant differences. It is recommended that APCT can be done in both upright and supine positions with excellent reliability and comparability.

Abstract No.: 201880

Elevated Ocular and Visual Disorder Risk in Developmental Disabilities

First Author: Xiaoxi LIU

Co-Author(s): Xiaotong LI, Wei ZHANG

Purpose: This study aims to clarify the associations between developmental disabilities (DDs) and ocular disorders, exploring correlations and potential causal relationships, to emphasize the importance of providing focused ocular attention for these children.

Methods: A.Cross-Sectional Association Study:13,889 students from Tianjin, China, were included, of which 309 had diagnosed developmental disabilities. The prevalence of refractive errors was compared to analyze associations. B.Mendelian Randomization Analysis: A two-sample Mendelian randomization analysis was conducted to infer genetic causal relationships between DDs and ocular parameters. The data is sourced from a publicly available genome-wide association study. C.Potential Causal Relationships: we conducted brain MRIs from the database, aiming to identify shared regions implicated in both disorders.

Results: A.Cross-Sectional Findings: Children with DDs had a significantly higher prevalence of astigmatism than their typically developing peers, especially in females. B.Mendelian Randomization Findings: DDs cause increased ocular disease risk and significantly affect refraction, e.g., autism linked to astigmatism, attention-deficit hyperactivity disorder to hyperopia. C.Shared Neuroanatomical Regions: The analysis of brain MRI data identified that the genetic variants were associated with both DDs and ocular diseases.

Conclusions: The cross-sectional analysis unequivocally affirms that developmental disabilities lead to an increased risk of astigmatism, while the Mendelian randomization analysis provides evidence for a close link between both disorders. Then we leveraged the brain MRI scans to elucidate potential intrinsic mechanisms of association. The findings of this study underscore the critical importance of implementing regular vision screenings for children with developmental disabilities.

Abstract No.: 205264

Panel No.: POS-0877

Evaluation of Surgical Outcomes in Comitant Horizontal Strabismus

First Author: Surabhi SAHAY

Co-Author(s): Amar PUJARI

Purpose: To prospectively investigate the rate of re-surgery in patients of comitant horizontal strabismus by following a homogenous surgical protocol.

Methods: The authors performed a single-centre prospective interventional study on 241 patients

with comitant horizontal strabismus who underwent strabismus surgery by a single surgeon with a predefined surgical dosage formula and intervention. The patients were followed up on Day 1, 1 Week, 1 month, 3 months, and 6 months postoperatively. Surgical success was defined as final deviation within 15 PD (Prism Diopters) with corresponding patient satisfaction. An assessment of factors responsible for re-surgery was performed.

Results: The rate of re-surgery was 7.05% (n=17). The rate was higher in exotropic patients (8.44%) as compared to esotropic patients (4.59%); however, this difference was not statistically significant. (p=0.263). Exotropes with extra-large angle deviation (47.05%) and Intermittent Divergent Squint (IDS) (17.6%) had higher rates of re-surgery. Similarly, in esotropes, exaggerated plication effect (11.7%), and overshoot of planned under-correction (11.7%) had a noticeable effect on the rate of re-surgery. Post-op manifestation of oblique muscle overaction and variable sensory exotropia for distance and near were other factors found responsible for isolated cases needing resurgery.

Conclusions: The rate of re-surgery in our cohort by following a single surgeon protocol was around 7%. Further, to mitigate the need for re-surgery, we recommend thorough pre-operative counselling, stratification of patients based on their deviation, and consideration of unpredictable factors.

From Tear to Repair: Surgical Management of Extraocular Muscle Injury Following Trauma: A Case Series

First Author: Akshat ARYA

Co-Author(s): Savleen KAUR, Prakriti SAINI, Jaspreet SUKHJIA

Purpose: Extraocular muscle injuries can significantly impair ocular alignment and function. While prompt diagnosis and intervention are critical for optimal recovery, standardized surgical strategies for strabismus secondary to trauma remain poorly defined.

Methods: We report a series of three patients presenting with diplopia and marked motility deficits following orbital trauma. Clinical evaluation and imaging suggested injury to one or more extraocular muscles. Detailed assessment was performed using anterior segment optical coherence tomography (AS-OCT) and dynamic magnetic resonance imaging (MRI).

Results: Imaging confirmed flap tears of the extraocular muscle in two patients. All three underwent exploratory strabismus surgery, during which the affected muscles were identified and repaired. Notably, trauma to the inferior rectus muscle was the most common finding. At six-month follow-up, all patients were free of diplopia and demonstrated significant

improvement in ocular motility, without requiring muscle transposition procedures.

Conclusions: Inferior rectus is the most frequently affected muscle in traumatic strabismus. This series highlights a distinctive pattern of post-traumatic muscle flap tears that can be effectively managed with timely surgical exploration and direct muscle repair. Advanced imaging modalities such as AS-OCT and dynamic MRI are valuable tools for diagnosis and surgical planning, contributing to improved functional outcomes.

Abstract No.: 205290

Panel No.: POS-0879

Genetic Landscape of Ectopia Lentis Over Three Years in a Single Tertiary Eye Care Centre

First Author: Bhargavi **PIDUGU**

Co-Author(s): Goura **CHATTANAVAR**, Rachana **MARAGANI**, Vyshnavika **MUPPARAPU**

Purpose: Ectopia lentis involves partial or complete lens dislocation and shows both autosomal dominant and recessive inheritance. Due to its genetic heterogeneity, genetic testing offers high diagnostic value and aids management. In this study, we describe the genetic characteristics of patients with ectopia lentis referred to a tertiary ocular genetics clinic in South India, with a focus on variant distribution.

Methods: All patients with ectopia lentis referred to the Ocular Genetics clinic in South India from January 2023 to August 2025 were included. Detailed phenotyping followed a standardized protocol, and whole-exome sequencing was recommended for all.

Results: Ectopia lentis was identified in 100 patients (59 males, 59%). Genetic testing was performed in 70 (70%) patients. FBN1 (41%) followed by LTBP2 (8%) were the commonest genes identified in our cohort. Among them, pedigree analysis showed 43 (61.5%) had autosomal dominant (AD) inheritance and 27 (38.5%) had probable autosomal recessive (AR) inheritance. In the AD group, FBN1 was the most common gene (41 patients, 95%), followed by FBN2 (1 patient, 2.3%), COL2A1 (1 patient, 2.3%), while three patients (11%) had no identifiable pathogenic variant. Among the 24 autosomal recessive cases, implicated genes included LTBP2 (8, 33.3%), ADAMTSL4 (6, 25%), ADAMTS17 (3, 12.5%), ADAMTS10 (2, 8.3%), ASPH (2, 8.3%), and 1 patient (4.1%) each of ADAMTS10, CBS, ZNF469, and GHR deletion.

Conclusions: These findings highlight the predominance of FBN1 variants in autosomal dominant ectopia lentis, even within a genetically constrained population, and the marked genetic heterogeneity among autosomal recessive cases.

Incidence and Risk Factors for Retinal Detachment After Anti-VEGF Therapy for Retinopathy of Prematurity: A Systematic Review and Meta-Analysis

First Author: Guina **LIU**

Co-Author(s): Jiazhi **LI**, Hongtao **LIU**, Wei **XU**

Purpose: To investigate the incidence of retinal detachment (RD) after anti-vascular endothelial growth factor (anti-VEGF) therapy in retinopathy of prematurity (ROP) to identify associated risk factors.

Methods: We searched PubMed, Ovid_embase/Medline, and Web of Science databases until September 2025 in accordance with PRISMA guidelines. Data were synthesized using a random-effects model, and subgroup analyses were performed to identify significant risk factors.

Results: Eleven retrospective studies, involving 3,013 eyes, were included. The pooled incidence of RD in ROP patients after receiving anti-VEGF therapy was 3% (95% CI -0.01-0.06), with negligible heterogeneity ($I^2=0.0\%$, $p=0.999$). Subgroup analysis revealed that a higher incidence of RD was significantly associated with greater disease severity (Zone I/AROP), lower gestational age (GA <27 weeks: 3% vs. >27 weeks: 2%), lower birth weight (BW <1000g: 3% vs. >1000g: 2%), and lower postmenstrual age at treatment (PMA <35.5 weeks: 6% vs. >35.5 weeks: 3%). Furthermore, the incidence was higher in single-center studies (3% vs. 2%) and was geographically highest in Europe (8%), followed by Asia (3%), then in North America (2%).

Conclusions: The 3% incidence of RD after anti-VEGF therapy, while low overall, is significantly stratified by patient-intrinsic and systemic factors. This finding mandates vigilant clinical oversight for high-risk infants, requiring close collaboration between neonatologists and pediatric ophthalmologists.

Incidence of Microbial Keratitis in Aphakic Children Using Elastofilcon a Extended Wear Versus Rigid Gas Permeable Lenses: A Retrospective Study

First Author: Helen **KEARNS**

Co-Author(s): Cheefoong **CHONG**, Shaun **DAI**, Leanie **LEESON**

Purpose: To compare the incidence of microbial keratitis in aphakic children fitted with elastofilcon A (EA) extended wear versus rigid gas permeable (RGP) contact lenses after lensectomy.

Methods: A retrospective multicentre study of 154 aphakic children (235 eyes), aged 3 weeks to 13.9 years, treated at two tertiary ophthalmology centres

in Australia and New Zealand. Records were reviewed for age at lensectomy, lens type (EA or RGP), visual outcomes, and incidence and treatment of contact lens associated microbial keratitis.

Results: Microbial keratitis occurred in 5 eyes (3.3%) in the EA group (n=121 eyes) and 6 eyes (5.2%) in the RGP group (n=114 eyes). Clinical diagnosis was based on corneal infiltrates with or without epithelial defects. No hypopyon, corneal oedema, or neovascularisation was observed. Age at onset ranged from 1.3 to 7.8 years. Average duration was 25.2 days (EA) and 11.4 days (RGP). No cases resulted in visually significant sequelae. Visual outcomes between the two groups were not statistically different ($p=0.11$).

Conclusions: There is ongoing debate on the optimal contact lens choice in paediatric aphakia. Our study found no significant difference in the incidence or visual impact of microbial keratitis between aphakic children fitted with EA or RGP contact lenses. These findings suggest that both lens types may offer similar safety profiles in this population.

Abstract No.: 204704

Panel No.: POS-0869

Incidence, Risk Factors, and Screening Sensitivity of Retinopathy of Prematurity in a Semiurban District in South India Using a Telemedicine Approach

First Author: Hema DURAICHAMY

Co-Author(s): Sreeramya PALANISAMY

Purpose: To determine the incidence of Retinopathy of Prematurity (ROP) and to investigate the associated risk factors for its development in a cohort of preterm infants who were assisted in two neonatal care units in a semi-urban district in South India, and to analyse the sensitivity and specificity of screening.

Methods: A prospective, observational, cohort study was conducted at two neonatal care units for a period of 6 months. According to the National screening guidelines, eligible babies were screened and stratified into subgroups of infants who developed ROP and those who did not. Informed consent taken from the parents and fundus images was taken with 3 Nethra-Neo camera, images graded and report obtained through Telemedicine.

Results: A total of 369 infants were screened, and the sensitivity and specificity of screening were found to be 98.64%, 100 % respectively. ROP was identified in 65 infants with an incidence of 17.62%. Log binomial regression analysis was done to find the relative risk of different risk factors on incidence. Thirty-three (50.77%) infants who were born with lower gestational age developed ROP ($P < 0.0001$). Of the total ROP, 38 (58.46%) infants with lower birth weight developed ROP ($P < 0.0001$), and 39 (60%) infants who received oxygen developed ROP ($P < 0.046$). Univariate and

multivariate regression analysis identified low birth weight, preterm births, and oxygen usage as significant risk factors for developing ROP with a statistical significance ($P < 0.05$).

Conclusions: The ROP trend is towards a rise in developing countries like India. In our study, the incidence of ROP was 17.62%, with screening demonstrating a high sensitivity (98.64%) and specificity (100%), underscoring the reliability of the national screening guidelines. Low gestational age, low birth weight, and oxygen supplementation emerged as significant risk factors for the development of ROP. Early detection through effective screening and timely intervention can substantially reduce the complications of ROP and the risk of irreversible vision loss.

Abstract No.: 201947

Panel No.: POS-0830

Initial Strabismus Surgery in Patients With Thyroid Eye Disease: Outcomes and Dose-Response in Various Types of Procedure

First Author: Shiyu TANG

Co-Author(s): Minghao CHEN, Mengya HAN, Jianhua YAN, Wen YUN

Purpose: This study aimed to assess outcomes and dose-response in initial strabismus surgeries using a large TED sample.

Methods: A retrospective review of TED patients undergoing initial strabismus surgery (2013–2023) at Zhongshan Ophthalmic Center included data on demographics, ocular deviation, motility, surgical techniques, and outcomes. Surgeries involved rectus recession and tenotomy, with traction sutures (TS) applied for deviations >35 prism diopters (PD). Success was defined as no diplopia and deviation ≤ 10 PD horizontally, ≤ 5 PD vertically. Dose-response (deviation change per mm rectus recession, DPR) and influencing factors were analyzed.

Results: Among 104 patients, rectus recession had a 70.65% success rate, while tenotomy achieved 12.5%. Success was highest for superior rectus (SR) recession (88.00%), followed by inferior rectus (IR) (70.00%) and medial rectus (MR) (38.46%). Two-muscle recessions succeeded in 55.56%. In single rectus recession with TS, DPR for IR, SR, and MR was 6.96 ± 2.18 , 5.92 ± 1.14 , and 9.78 ± 5.80 PD/mm, respectively, versus 4.26 ± 0.78 , 3.95 ± 0.83 , and 3.86 ± 0.29 PD/mm without TS. Preoperative deviation significantly affected DPR, especially in IR/SR surgeries ($P < 0.001$). Simultaneous MR recession did not alter IR/SR DPR in TS ($P = 0.266$) or non-TS ($P = 0.138$) groups. However, in non-TS cases, IR/SR recession impacted MR DPR ($P = 0.034$), but this effect was absent with TS ($P = 0.741$).

Conclusions: Single rectus recession achieves high success for TED vertical strabismus, with TS enhancing correction. Preoperative deviation is key to dose-

response, while vertical recession influences horizontal dose-response when deviation is <35PD.

Abstract No.: 203050

Panel No.: POS-0848

Insertional Anatomy of Horizontal Rectus Extraocular Muscles in Patients With Esotropia and Exotropia

First Author: Yun **WEN**

Co-Author(s): Tao **SHEN**, Jianhua **YAN**

Purpose: Strabismus, including esotropia and exotropia, significantly affects binocular vision and presents challenges in clinical management and surgical correction. Although previous studies have explored the anatomical characteristics of horizontal rectus extraocular muscles (EOMs) in strabismus, large-scale analyses of insertional anatomy remain limited. This study investigates anatomical variations in the insertions of horizontal rectus EOMs in patients with esotropia and exotropia, aiming to understand their impact on strabismus management.

Methods: A retrospective case-control study was conducted using clinical records from 4,781 patients diagnosed with strabismus who underwent surgery at the Zhongshan Ophthalmic Center, Sun Yat-sen University, from June 2014 to August 2020. Anatomical measurements of horizontal rectus EOM insertions were taken using a Castroviejo caliper. Statistical analyses, including regression analysis, were performed to examine the relationship between EOM characteristics and clinical outcomes.

Results: Significant anatomical differences were observed among the esotropia, exotropia, and control groups. Esotropia patients exhibited shorter medial rectus (MR) insertion distances (mean: 4.81 mm) than both exotropia (5.09 mm) and controls (5.08 mm, $p < 0.001$), with moderate effect sizes. Exotropia subtypes showed wider MR and lateral rectus (LR) insertions, particularly in constant and pattern types (MR width $p = 0.001$, LR width $p = 0.002$). Regression analysis indicated that shorter MR insertion distance was significantly associated with greater esodeviation at both near ($\beta = -13.60$, $p < 0.001$) and distance ($\beta = -12.76$, $p < 0.001$), though with small effect sizes. Refractive error (SE) and age were also significant predictors of deviation magnitude and AC/A ratio.

Conclusions: Anatomical variations in the horizontal rectus EOMs are significantly associated with esotropia and exotropia. These findings enhance our understanding of strabismus pathophysiology and may help guide surgical strategies for severe cases, though further research is needed to refine clinical applications.

Panel No.: POS-0824

Interobserver Variability in Retinopathy of Prematurity Grading: Implications for Rural Equity in Teleophthalmology

First Author: Emmanuel **RAMLI**

Co-Author(s): Brenda **BREIDENSTEIN**, Chee Foong **CHONG**, Steve **DAKIN**, Jack **JIAO**, Andrew **THOMPSON**, Anne-marie **YARDLEY**

Purpose: Retinopathy of prematurity (ROP) grading is fundamental to determining treatment, yet variability in clinician interpretation threatens consistency of care. For rural New Zealand communities, where geographical isolation and workforce shortages necessitate reliance on teleophthalmology, grading inconsistency risks compounding existing health inequities. This study aims to assess the degree of interobserver variability in ROP image grading and explore whether such variability influences treatment recommendations.

Methods: This cross-sectional observational study analysed 40 anonymised image sets of both eyes from infants screened for ROP using the 3nethra Neo camera. Four consultant ophthalmologists independently graded each set via a standardised pro forma, recording stage, zone, plus disease, image quality, and treatment recommendation. Graders were masked to each other's assessments. Data were collated by a non-grading investigator and analysed using Fleiss' kappa for multi-rater agreement, with interpretation guided by Landis and Koch criteria.

Results: Preliminary analyses indicate substantial interobserver variability in grading plus and pre-plus disease, moderate variability in zone classification, and higher agreement in staging. Image quality assessment demonstrated minimal variability, suggesting limited influence from technological factors such as resolution and file rendering. Variability in grading translated into differences in treatment recommendations in selected cases.

Conclusions: This study underscores the pressing need for improved standardisation of ROP grading in teleophthalmology. Without addressing interobserver variability, telemedicine risks perpetuating inequities in access and outcomes for rural communities most reliant on it. Findings highlight an opportunity to refine guidelines and strengthen reproducibility in remote ROP care.

Abstract No.: 208561

Investigation of the Novel Variants and Genotype-Phenotype Correlations in a Cohort of Chinese Patients With Infantile Nystagmus Syndrome

First Author: Mo WANG

Co-Author(s): Cong DUAN, Shiheng LU, Lei WANG

Purpose: Genotype-phenotype correlations in a cohort of Chinese patients with Infantile Nystagmus Syndrome (INS).

Methods: Ten unrelated INS families and three sporadic cases were included. All participants underwent comprehensive ophthalmic examinations. Demographic and clinical data were collected, and variants were identified via next-generation sequencing (NGS). Genotypic and phenotypic differences were further characterized.

Results: We identified 17 mutations across five genes: FRMD7 (n=5), GPR143 (n=4), HPS3 (n=2), HPS6 (n=2), TYR (n=2), and AIPL1 (n=2). Eleven of these variants were novel. FRMD7 (5/13, 38%) was the most frequently mutated gene, followed by GPR143 (4/13, 31%). Patients with GPR143 mutations exhibited significantly worse visual acuity compared to those with FRMD7 mutations ($p = 0.0261$). Higher grades of foveal hypoplasia, often accompanied by macular atrophy, were associated with visual impairment in patients carrying GPR143 variants. No significant differences were observed in other clinical manifestations across mutation types.

Conclusions: Our findings broaden the mutational spectrum of INS and confirm that FRMD7 and GPR143 are the two predominant mutational hotspots in both familial and sporadic INS cases. GPR143 mutations are associated with more severe ocular phenotypes. Early molecular diagnosis in infants with INS is recommended to facilitate accurate genetic counseling and improve clinical management.

Late-Onset Retinoblastoma in a 13-Year-Old Male: A Diagnostic Challenge

First Author: Nguyen Quynh Huong DAO

Co-Author(s): Dung PHAM

Purpose: To describe a rare case of late-onset retinoblastoma (RB) in a 13-year-old male presenting with atypical features mimicking uveitis.

Methods: We retrospectively reviewed the clinical history, imaging, and histopathology of the patient. He presented with one week of painless blurred vision and ocular redness in the left eye. Initial treatment for presumed uveitis with topical antibiotics and corticosteroids was ineffective. Ophthalmic

examination, multimodal imaging (B-scan, OCT, MRI), and laboratory tests were performed.

Results: At admission, left eye visual acuity was 3/10 with intraocular pressure of 48 mmHg. Slit-lamp examination showed corneal edema, anterior chamber cells (3+), and iris nodules. B-scan revealed a peripheral subretinal mass without calcification, while MRI suggested Coats disease. Blood tests were positive for Toxocara IgG. Despite anti-inflammatory and anti-parasitic therapy, there was minimal improvement. Examination under anesthesia demonstrated a creamy-white peripheral retinal mass with surface vessels and anterior chamber seeding. Enucleation was performed, and histopathology confirmed Group E RB.

Conclusions: This case highlights the diagnostic challenge of RB in older children, where clinical signs may mimic uveitis. Failure to respond to standard therapy should prompt consideration of intraocular malignancy. Early use of multimodal imaging and prompt referral are crucial to avoid delays and optimize outcomes.

Abstract No.: 206762
Panel No.: POS-0900

Late-Recognized CFEOM With Severe Restrictive Esotropia: Case Report and Surgical Considerations

First Author: Ronik H. KAMAL

Co-Author(s): Rozalina LOEBIS

Purpose: Congenital Fibrosis of the Extraocular Muscles (CFEOM) is a rare, non-progressive cranial dysinnervation disorder that poses diagnostic and therapeutic challenges, particularly in atypical adult-onset cases without ptosis or family history. This report describes the clinical course, imaging findings, surgical management, and outcomes of an adult patient with atypical CFEOM.

Methods: A 38-year-old woman presented with a ten-year history of right-eye esotropia and bilateral abduction difficulty. Examination revealed 50 prism diopter esotropia deviation, compensatory chin elevation, and severe symmetric motility restriction, most marked in vertical gaze. Orbital MRI showed bilateral superior rectus atrophy, right superior oblique atrophy, and bilateral inferior oblique atrophy. Diagnosis was based on clinical features, imaging, and intraoperative forced-duction testing.

Results: Bilateral medial rectus recession (6 mm) was performed, yielding significant improvement in ocular alignment. At four months, residual esotropia (30 prism diopters) and persistent motility limitations remained. Postoperative MRI excluded thyroid eye disease and intracranial pathology but reaffirmed extraocular muscle atrophy. Despite incomplete motility recovery, cosmetic alignment improved, and symptoms were alleviated.

Conclusions: This atypical adult-onset case emphasizes the importance of considering CFEOM in adults with restrictive esotropia even without ptosis. Diagnosis requires integration of clinical, imaging, and intraoperative data. Surgery enhances alignment and quality of life but is limited by irreversible fibrosis, underscoring the need for individualized surgical planning, multidisciplinary management, and realistic expectations.

Long-Term Efficacy of BTXA Injection With Reduced Volume for Acute Acquired Comitant Esotropia With Small- to Moderate-Angle

First Author: Bingbin MA

Co-Author(s): Jingchang CHEN

Purpose: To evaluate the long-term efficacy of Botulinum Toxin A (BTXA) injection with reduced volume for acute acquired comitant esotropia (AACE) with small- to moderate-angle.

Methods: We reviewed the medical records of 57 patients with AACE who received BTXA injection and completed a follow-up period of more than 6 months. All patients were injected with 3.75 to 6.25 U BTXA in 0.04 ml saline into the bilateral medial rectus muscles under topical anesthesia. Success was defined as the deviations $\leq 10 \Delta$ assessed with the prism and alternate cover test (PACT) at both distance and near fixations and with resolution of diplopia. Sensory success was defined as stereopsis $\leq 63''$.

Results: The mean age at treatment was 35.05 ± 13.09 years, the median disease duration was 18 (6.50, 40.50) months, and the mean follow-up time was 9.13 ± 4.76 months. Before treatment, the mean distance deviation was 15.32 ± 7.48 PD. At the last visit, the overall success rate of a single injection of BTXA was 52.6% (30/57); the sensory success rate was 49.1% (28/57). The mean distance deviation at the last visit was 7.23 ± 6.90 PD. 14.0% (8/57) of patients had a deviation $\leq 10 \Delta$, but had distance diplopia. Of the patients who did not achieve success, 66.7% (18/27) opted for re-injection, 11.1% (3/27) for surgery, and the remaining patients for observation or Fresnel glasses. 0.88% of the injected eyes (1/114) developed complicated ptosis.

Conclusions: BTXA injection with reduced volume is a simple, safe, and effective treatment for AACE patients with small- to moderate-angle, but the recurrence is the main potential disadvantage.

Long-Term Efficacy of a Perceptual Learning Technique to Improve and Maintain Vision: A Five-Year Study

First Author: Damaris MAGDALENE

Co-Author(s): Phinrikerbha BLAH

Purpose: To evaluate the long-term efficacy of RevitalVision's perceptual learning vision training software program in improving best corrected visual acuity in occlusion therapy-resistant adult amblyopic subjects.

Methods: This prospective observational study was conducted at a tertiary eye care centre in northeast India with 89 subjects who previously showed no visual improvement after six months of occlusion therapy. The main outcome assessed was the improvement in best corrected visual acuity (BCVA) and its maintenance over a 5-year follow-up.

Results: A total of 109 eyes of 89 subjects were assessed at presentation and reviewed at 1 year, 2 years, 3 years, and 5 years. Due to the loss of follow-up, the number of eyes decreased to 49 at the end of 2 years, and to 26 and 24 eyes at the end of 3 years and more than 3 years, respectively. The mean LogMAR acuity at presentation was 0.56 ± 0.27 . At 1 year, 0.42 ± 0.26 , 1-2 year visit 0.36 ± 0.26 , 2-3 years 0.32 ± 0.24 , and more than 3 years being 0.30 ± 0.24 . An improvement in the Mean LogMAR acuity was seen in each follow-up visit. The statistical analysis of bilateral and unilateral amblyopia shows significant improvement in acuity between the five follow-up visits, with a very low probability of a type I error.

Conclusions: Revital vision's perceptual learning improve vision and maintain it long-term by activating neural plasticity.

Abstract No.: 202916

Long-Term Visual, Refractive, and Safety Outcomes After Pediatric Cataract Surgery: A Retrospective Study

First Author: Phatchisa MEKHAAMNUAYCHAI

Co-Author(s): Narisa RATTANALERT, Penny SINGHA, Supaporn TENGTRISORN

Purpose: To evaluate long-term visual acuity (VA), refractive changes, and complications after pediatric cataract surgery.

Methods: Retrospective cohort at a tertiary center of children <16 years with congenital or developmental cataract who underwent cataract extraction with or without intraocular lens (2007–2023), with ≥ 2 years of follow-up. Best-corrected VA (BCVA) was recorded at 5 years and at the last visit. Refractive outcomes were analyzed by age at surgery: <2 , 2–5, and >5 years.

Results: A total of 345 eyes from 211 patients (268 bilateral, 77 unilateral) were included. Median age at surgery was 5.4 years, and median follow-up was 6.4 years. At 5 years (160 eyes) and final visit, mean logMAR BCVA was 1.31 ± 0.78 and 1.16 ± 0.88 in unilateral pseudophakia, 0.61 ± 0.48 and 0.65 ± 0.57 in bilateral pseudophakia, and 1.09 ± 0.78 and 1.07 ± 0.52 in bilateral aphakia. Overall spherical equivalent (SE) change in pseudophakia and aphakia was -10.94 diopters (D) and -5.78 D (<2 years), -6.46 D and -2.87 D (2–5 years), and -8.51 D and -0.37 D (>5 years). Annual SE change (D/year) in the first 5 years post-surgery was -1.38 D and -0.86 D (<2 years), -0.75 D and -0.34 D (2–5 years), and -0.38 D and -0.09 D (>5 years). Common complications were visual axis opacification in pseudophakia (16%) and glaucoma in aphakia (16%).

Conclusions: Bilateral pseudophakia achieved better BCVA than unilateral. Aphakia showed less myopic shift compared with pseudophakia.

Panel No.: POS-0845

Medial Rectus Insertion Site in Surgical Candidate Children With Esotropia

First Author: Moustafa ABDELHAFEZ

Co-Author(s): Mahmoud ABDELHAFEZ

Purpose: To study the site of medial rectus (MR) insertion in surgical candidate children with esotropia and its relation to the angle of deviation.

Methods: A prospective study that had been done on 110 children scheduled for surgical management of esotropia. We divided them, according to age, into 3 groups: below 2 years, from 2 to 6, and from 6 to 12. We documented the angle of deviation. During surgery, we measured the distance between the MR insertion and the limbus using the caliber viewing by microscope. We created similar control age groups of 98 non-strabismic children. They were admitted to the operating theatre for other reasons. After written permission, we measured the MR insertion site.

Results: The mean insertion site in control group 1 (age below 2) was 4.33 ± 0.39 . While it was significantly less in patient group 1 ($P < 0.001$), 3.81 ± 0.48 and 3.78 ± 0.56 for right and left eyes. For group 2, it was 4.63 ± 0.48 in the control group. While it was significantly less in esotropia ($P < 0.001$), 3.99 ± 0.38 and 3.98 ± 0.40 for right and left eye. For group 3 (6 to 12 years), it was 5.27 ± 0.24 in control and 4.91 ± 0.46 and 4.26 ± 0.47 in esotropia ($P < 0.001$). There was a significant negative correlation between the angle of deviation and the MR insertion site ($P < 0.001$) in all age group patients.

Conclusions: From this study, we can conclude that the medial rectus is significantly closer to the limbus in children with esotropia than in non-strabismic individuals. Also, there is a negative correlation

between the MR insertion site and the severity of esotropia.

Panel No.: POS-0846

Mirror Image Esotropia, Amblyopia and Refractive Error in Monozygotic Identical Twins

First Author: Moustafa ABDELHAFEZ

Co-Author(s): Mahmoud ABDELHAFEZ

Purpose: To record esotropia, amblyopia, and refractive error in identical twins.

Methods: Our patients are 7-year-old boys, identical twins. They had esotropia of 25 to 30 prism diopters. Child number (1) showed esotropia in the right eye. Meanwhile, child (2) showed esotropia in the left eye. Visual acuity, without correction, was 20/150 in the right eye and 20/40 in the left eye in child (1) and 20/30 in the right eye and 20/150 in the left eye in child (2). Cyclorefraction was $+4.00/-3.00 \times 10$ in the right eye and $+1.50/-1.50 \times 165$ in the left eye. In child (2), it was $+1.25/-1.00 \times 10$ in the right eye and $+3.75/-3.00 \times 170$ in the left eye. Vision with glasses, for child (1), was 20/80 in the right eye and 20/28 in the left eye. While in child (2), it was 20/25 in the right eye and 20/80 in the left eye. We started patching the left eye in child (1) and the right eye in child (2). We diagnosed child (1) as esotropia, astigmatism, and amblyopia in the right eye and the same diagnosis for child (2) in the left eye.

Results: Twins are receiving the same treatment for glasses and treatment of amblyopia. But it happens in the opposite eye.

Conclusions: Monozygotic twins may have mirror-image eye disorders, such as esotropia, amblyopia, and refractive error.

Abstract No.: 204420

Mitigating Severe Myopia: The Synergistic Effect of Medicago Sativa Extract and Low-Dose Atropine on Oxidative Stress and Axial Length Progression

First Author: Aryani Atiyatul AMRA

Co-Author(s): Aznan LELO, Rodiah Rahmawaty LUBIS, Lambok SIAHAAN

Purpose: Severe myopia, characterized by excessive axial elongation of the eyeball, poses significant risks to vision. This condition is closely linked to oxidative stress, where reactive oxygen species damage ocular tissues, exacerbating disease progression. Malondialdehyde (MDA) serves as a key biomarker for lipid peroxidation and oxidative damage. This study evaluates the impact of Medicago sativa extract (EMS)

combined with 0.01% atropine eyedrops on MDA levels and axial length progression in severe myopia

Methods: A double-blind randomized controlled trial involved 40 adolescents (aged 13-18) with severe myopia (n=20 EMS group; n=20 placebo). EMS (or placebo) was given orally for 6 months alongside atropine. Plasma MDA was measured at baseline, 3 months, and 6 months using ELISA. Axial length was assessed via optical biometry. Data analyzed with repeated ANOVA and post-hoc tests ($p < 0.05$ significant)

Results: Baseline MDA was higher in EMS ($28.81 \pm 6.85 \mu\text{mol/L}$) vs. placebo ($24.05 \pm 6.00 \mu\text{mol/L}$; $p = 0.025$). At 6 months, EMS MDA decreased to $17.16 \pm 3.77 \mu\text{mol/L}$ ($p < 0.001$), while placebo increased to $29.96 \pm 5.03 \mu\text{mol/L}$ ($p < 0.001$). Axial elongation was minimal in EMS (0.05 mm OD/OS) vs. significant in placebo (0.45-0.49 mm)

Conclusions: The combination of EMS and 0.01% atropine significantly reduce plasma MDA levels. These findings highlight EMS as a promising adjunctive therapy, offering a dual approach to managing myopia by addressing both structural and biochemical aspects

More than Meets the Eye: Ocular Manifestations of Toxoplasmosis in Costa Rican Children

First Author: Leslie ARGUELLO

Co-Author(s): Otana JACKPOR, Carlos VILLALOBOS

Purpose: We aim to characterize the presentation of pediatric ocular toxoplasmosis in Costa Rica. To our knowledge, this is the first study to do so.

Methods: Chart review was performed to identify patients <12 years old with positive Toxoplasma IgG or IgM, seen by the ophthalmology service of a Costa Rican tertiary hospital from 2020 to 2023. Hospital protocol is to refer all toxoplasmosis patients for eye exams, though this does not always take place. Patients were excluded if they had prior eye trauma or malignancy, other congenital disease, other positive TORCH serology, or excess missing data.

Results: Out of 80 patients, 32 (40%) had abnormalities on initial eye exam, half of whom had active lesions. The most common abnormal exam finding was chorioretinitis/posterior uveitis (30%, 24 patients). Though 31 patients were asymptomatic, 6 of these (19%) had exam abnormalities. 17 patients received treatment, 14 of whom (82%) had active lesions on initial exam. In 8 of these patients (57%), active lesions resolved by follow-up about 1-3 months later.

Conclusions: There is likely a high rate of eye findings in Costa Rican children with toxoplasmosis. The absence of symptoms does not rule out eye involvement.

Muscle Transplantation in Large-Angle Sensory Exotropia: A Case Report

First Author: Katherine Marl FERRER

Co-Author(s): Fay Charmaine CRUZ

Purpose: Large-angle sensory exotropia presents a significant surgical challenge, necessitating correction involving three to four horizontal rectus muscles. Despite adherence to maximal correction parameters, results are frequently suboptimal. Muscle transplantation has emerged as a promising alternative, particularly in revision cases. This technique enables greater muscle lengthening and stronger recession effect while preserving ocular motility. In contrast to supramaximal recessions—where the muscle is reinserted posterior to the equator, potentially restricting movement—transplanted segments are positioned anterior to the equator, maintaining full range of motion. Moreover, using autologous grafts avoids complications associated with synthetic materials, such as foreign body reaction or rejection.

Methods: We present the first locally documented case of muscle transplantation for strabismus correction. A 38-year-old woman presented with longstanding right eye outward deviation following congenital cataract extraction via lensectomy without intraocular lens implantation. She was lost to follow-up, resulting in progressive exotropia. Initial surgery involved secondary IOL implantation, followed by an 11.0mm supramaximal right lateral rectus recession and 6.5mm right medial rectus plication to address a 65PD exotropia. Due to residual exotropia (18–65 PD), re-operation was performed.

Results: In the second procedure, a 2.0mm autologous graft—harvested from a 6.0mm left medial rectus resection—was transplanted to the right lateral rectus. This was combined with a 6.0mm left lateral rectus recession and a 3.0mm right medial rectus resection. The patient achieved stable orthophoria at 2.5 and 6 months postoperatively.

Conclusions: This case supports muscle transplantation as an effective and safe approach for managing large-angle exotropia.

Myopia Progression Patterns in Filipino Children and Adolescents Wearing Single Vision Lenses in a Single Center

First Author: Kimberly Amanda COMIA

Co-Author(s): Joanne BOLINAO, James Abraham LEE

Purpose: The aim of this study is to describe the progression of myopia in Filipino children who received single-vision lenses.

Methods: This study analyzed the electronic medical records of children aged 5 to 18 years old between 2010 to 2024 who received single vision lenses for myopia in this single-center retrospective cohort study. Included patients had at least 5 visits throughout the observation period. Myopia progression rates were calculated based on age, sex, refractive status, and severity at baseline, and whether the patient was seen before the COVID-19 lockdowns or after. The cumulative risk of progression and the correlation between age at first consultation and the rate of progression were calculated.

Results: Myopia progression rates were most rapid in the youngest (5-7 years old) age group (mean progression rate -0.84 D/year, SE 0.03, [-0.90, -0.79], $p < 0.0001$), as well as in females (mean progression rate -0.82 D/year, SE 0.04, [-0.89, -0.75], $p = 0.044$). Progression was fastest among patients who were emmetropic and hyperopic at baseline, and there was no statistically significant difference between the nonpandemic and pandemic cohorts. A direct but weak correlation between age at first consult and myopia progression rate was observed.

Conclusions: The mean progression rates of myopia observed may help clinicians better predict refractive outcomes and manage myopia among Filipino children. Younger children below 10 years old exhibiting continued myopia progression may benefit from early intervention, regardless of refractive status at baseline.

Abstract No.: 204632

Ocular Manifestations in Children With Acute Leukemia Undergoing Chemotherapy and Their Correlation With Hematological Parameters

*First Author: Yunanda Rizki Amalia **HARAHAP**
Co-Author(s): Fithria **ALDY**, Bobby Ramses Erguna **SITEPU***

Purpose: Acute leukemia, the most common childhood cancer, frequently causes ocular manifestations due to hematological abnormalities or direct leukemic infiltration. This study aimed to determine the relationship between hematological parameters (hemoglobin, leukocytes, platelets) and ocular manifestations in children with acute leukemia undergoing chemotherapy.

Methods: A cross-sectional study was conducted on 50 children (5–18 years) with acute leukemia receiving chemotherapy at Medan Pediatric Oncology Foundation (August 2024–January 2025). Data were collected through interviews and comprehensive ophthalmologic examinations that assessed both the anterior and posterior ocular segments. Hematological parameters measured hemoglobin levels, leukocyte counts, and platelet counts.

Results: Twenty-seven (54%) were male, and 23 (46%) were female, with a mean age of 10.48 years. Forty-one children (82%) had acute lymphoblastic leukemia (ALL), and nine (18%) had acute myeloid leukemia (AML). The most frequent anterior segment manifestation was subconjunctival hemorrhage (8%), while the most common posterior segment findings were Roth spots and retinal exudates (7%). The median levels of hemoglobin, leukocytes, and platelets among patients with posterior segment involvement were 7 g/dL, $12 \times 10^3/\mu\text{L}$, and $69.5 \times 10^3/\mu\text{L}$, respectively, and with anterior segment involvement were 8g/dL, $13 \times 10^3/\mu\text{L}$, and $100 \times 10^3/\mu\text{L}$. A statistically significant association was found between ocular manifestations and hemoglobin and platelet levels, but not leukocyte count.

Conclusions: Hemoglobin and platelet levels are critical predictors of ocular complications in pediatric leukemia. Routine ophthalmic evaluations should be integrated into leukemia management protocols to prevent vision-threatening outcomes.

Abstract No.: 200532

Panel No.: POS-0818

Orthokeratology in Children With Myopia and Intermittent Exotropia: The Nanjing Strabismus Cohort

*First Author: Tianxi **LI**
Co-Author(s): Hu **LIU**, Zijin **WANG***

Purpose: To assess the impact of orthokeratology on myopia progression, exotropia conditions and visual function in children with myopia and intermittent exotropia.

Methods: This prospective cohort study recruited 60 children aged 7-12 years with myopia and intermittent exotropia who chose to wear either orthokeratology lenses or single-vision spectacles between February 2023 and December 2023. The primary outcome was change in axial length from baseline at 1 year. Secondary outcomes included changes from baseline in exotropia conditions, monocular function, and binocular vision at 1 year.

Results: At 1 year, the Ortho-K group had slower axial length elongation than the SVS group (0.22 mm vs. 0.42 mm; $P < .001$). In the Ortho-K vs. SVS group, respectively, the mean change was -4.78 PD vs. 1.50 PD ($P < .001$) in distant exodeviation, -4.28 PD vs. 0.57 PD ($P = .02$) in near exodeviation, -0.19 vs. 0.15 ($P = .22$) in distant control, and -0.23 vs. 0.23 ($P = .04$) in near control at 1 year. Improved accommodative functions were observed in the Ortho-K group at 1 year, including monocular accommodative facility ($P = .007$), negative relative accommodation ($P = .03$), and positive relative accommodation ($P = .04$). Ortho-K exhibited no significant effect on binocular vision or adverse effects over 1 year ($P > .05$).

Conclusions: In children with myopia and intermittent exotropia, orthokeratology may be recommended for its efficacy in controlling myopia progression, and for its potential to improve or maintain exotropia conditions.

Abstract No.: 202258

Panel No.: POS-0833

Outcomes of Botulinum Toxin for Thyroid Eye Disease Strabismus: A Retrospective Review

First Author: Maverick Wenhao **WONG**

Co-Author(s): Janice **LAM**, Maria **THEODOROU**

Purpose: To evaluate outcomes of botulinum toxin injections for Thyroid Eye Disease (TED)-related strabismus.

Methods: Retrospective notes review of TED-strabismus patients who underwent botulinum toxin injection in a tertiary referral centre. Eyes were grouped into horizontal (medial/lateral rectus) or vertical (inferior rectus) injections. Primary outcomes were reduction in deviation and motility improvements. Deviation analysis was restricted to the plane of injection, and motility limitation was documented in four directions. Responders were defined as patients with any reduction in deviation magnitude.

Results: We analysed 29 patients (33 injected eyes). 21 patients (24 eyes) had horizontal injections, and 8 patients (9 eyes) had vertical injections. Horizontal injections reduced deviation by a mean of 25 Prism Dioptres (PD) at near (range 2-70PD) and 20PD at distance (range 2-80PD). 24% overcorrected for near and 16% for distance. Vertical injections reduced deviation by a mean of 9PD at near (range 2-18PD) and 17PD at distance (range 5-31PD). There were 12.5% overcorrections for near and 25% for distance. There were minor improvements in motility. There were no significant adverse events. Initial analysis suggested that patients with smaller baseline deviations were more likely to benefit, while demographic variables showed no consistent association.

Conclusions: Botulinum toxin has not been traditionally used in TED-strabismus due to its restrictive nature in severe disease. We demonstrated that this is a safe treatment option, with documented improvements in deviation and motility in our cohort. Our findings support its consideration as an alternative treatment option where surgery is contraindicated/undesired, or as adjunct to treat residual deviations post-surgery.

Abstract No.: 205975

Panel No.: POS-0888

Outcomes of Early Delivery and Retinal Screening at Birth in Siblings of Patients With Familial Exudative Vitreo-Retinopathy (FEVR)

First Author: Subhadra **JALALI**

Co-Author(s): Akash **BELNJE**

Purpose: To report phenotypes and treatment outcomes of a novel protocol of early delivery and early retinal screening, in siblings of familial exudative vitreoretinopathy (FEVR) probands.

Methods: Once a proband was diagnosed clinically to have FEVR, the family was counselled regarding the risk of blindness in the next child. Elective delivery was planned at 37 weeks of gestational age in consultation with an experienced obstetrician after strict antenatal monitoring. Retinal screening was advised to be done within 1-2 days of delivery. Fundus details were evaluated, and appropriate treatments were done in case FEVR was detected. Patients were divided into group 1: compliant with protocol and group 2: non-compliant with protocol. Treatment outcomes were evaluated at the last follow-up.

Results: Twelve families with probands with significant low vision adopted the protocol. 24 eyes of 12 siblings were included. Six eyes (50%) in group 1 were diagnosed to have FEVR (66.6% had stage II, 0% had Stage V) as compared to 10 eyes (83.3%) in group 2 (33.3% had stage II, 33.3% had stage V). Treatment was required in all eyes diagnosed with FEVR in both groups. Anatomical outcome was classified as good (attached retina without drag or folds) in 83.3% (n=4/6) in group 1 and 40% (n=4/10) in group 2.

Conclusions: Delivery earlier by 3-4 weeks of the expected date and immediate retinal management provided a window of opportunity to treat a rapidly progressive blinding disease of newborns. Our protocol will need validation with larger cohorts.

Abstract No.: 203480

Panel No.: POS-0856

Outdoor Artificial Light at Night Exposure and Risk of Myopia: A Cross-Sectional and Prospective Cohort Study Among Hong Kong Children

First Author: Yingan **LI**

Purpose: Outdoor artificial light at night (ALAN) has emerged as a significant source of environmental pollution, yet epidemiological evidence on its impact in childhood myopia development remains limited. Therefore, this study aimed to investigate the association between outdoor ALAN exposure and myopia development.

Methods: Data were obtained from the Hong Kong Children Eye Study (HKCES), a population-based cohort

with a 3-year follow-up. Outdoor ALAN exposure (nW/cm²/sr) within 500 m of each residence was estimated using time-varying satellite data. Multivariable logistic regression models were employed in cross-sectional and prospective cohort analyses.

Results: A total of 19,114 children (mean [SD] age, 7.40 [1.10] years; 52.8% boys) were included, of whom 5,153 (27.0%) had myopia at baseline. In the cross-sectional analysis, each interquartile range (IQR) increase in outdoor ALAN exposure was associated with an 8% higher myopia rate (OR, 1.08; 95% CI, 1.02-1.15). In the prospective cohort (n=2,558 without baseline myopia and completed follow-up), each IQR increase was associated with a 37% higher risk of incident myopia over 3 years (OR, 1.37; 95% CI, 1.16-1.61). Compared with the lowest quartile, children in the highest quartile of outdoor ALAN exposure also had a greater risk of developing myopia in both cross-sectional (OR, 1.16; 95% CI, 1.03-1.29) and prospective cohort analyses (OR, 1.56; 95% CI, 1.14-2.12). Restricted cubic splines further indicated linear associations for both myopia rate and incidence.

Conclusions: Outdoor ALAN exposure is positively associated with childhood myopia development, identifying it as a modifiable environmental risk factor to target in future prevention strategies.

Abstract No.: 206099

Panel No.: POS-0892

Paediatric Cataract Surgery in Small Eyes: Preoperative Predictors and Outcomes

First Author: Kavitha KALAIVANI

Co-Author(s): Satya Swapnika Y

Purpose: To evaluate the clinical profile, surgical outcomes, and refractive predictability of cataract surgery in short axial length eyes in children.

Methods: This retrospective study included 123 eyes of 70 patients with small eyes undergoing cataract surgery over the last 5 years. Demographics, ocular biometry, surgical technique, ocular/systemic associations, and refractive outcomes were analysed.

Results: Zonular cataract (39.84%) is the most common presentation, and 19 eyes (15.45%) presented with total cataract. (71%) presented within 1 year of age. Ocular associations (ROP, PHPV) were noted in 22% of eyes. The mean axial length was 18.5 ± 1.1 mm, horizontal corneal diameter 11.0 ± 0.8 mm, and vertical keratometry 10.7 ± 0.8 mm. Surgical procedures were lensectomy with anterior vitrectomy in 53% (65 eyes) and primary intraocular lens implantation in 47% (58 eyes). Refractive analysis in 58 eyes with primary intraocular lens implantation, 42 eyes (72.4%) achieved refraction more hyperopic than the intended target. Glaucoma was a complication in 7.3 % (9 eyes) at the final follow-up.

Conclusions: Paediatric cataract surgery in small eyes is characterized by early presentation, biometric variability, and frequent ocular associations. Despite surgical modifications, refractive outcomes often overshoot the intended hyperopic target. Glaucoma remains a significant postoperative concern, underscoring the need for careful planning and vigilant follow-up.

Panel No.: POS-0837

Paediatric Non-Infectious Uveitis – Retrospective Review From a Local Tertiary Eye Center

First Author: Yik To HO

Co-Author(s): Emily Suhan WONG

Purpose: To describe the demographics, clinical features, treatment, and visual outcomes of paediatric non-infectious uveitis at a local tertiary eye center in Hong Kong.

Methods: A retrospective cohort study was conducted on patients aged ≤ 18 years with non-infectious uveitis managed at the Hong Kong Children's Hospital joint ophthalmology-rheumatology clinic from November 2020 to February 2025. Inclusion required a minimum follow-up duration of 6 months (median 36 months). Data on demographics, uveitis classification, etiology, treatments, complications, and visual outcomes were extracted.

Results: The study included 37 patients (71 eyes), with a mean age of uveitis onset of 10±3.6 years (range 3–17) and a male-to-female ratio of 1:1.18. Anterior uveitis, with or without intermediate uveitis, was most common (73.0%), followed by panuveitis (24.3%). Most cases were idiopathic (89.2%). Steroid-sparing agents were required in 91.9% of patients, in which methotrexate was most commonly prescribed (86.5%). 51.4% of patients received adalimumab. More than two-thirds of patients (67.6%) experienced raised intraocular pressure requiring treatment. Cataract was another common complication (45.9%), followed by posterior synechiae formation (29.7%) and band keratopathy (10.8%). At the latest follow-up, 94.6% of patients maintained visual acuity ≥0.5, and 48.6% achieved steroid-free remission.

Conclusions: This study describes the clinical characteristics and management approach of paediatric non-infectious uveitis. Steroid-sparing agents are often required for disease control. With effective management, most patients were able to achieve favorable visual outcomes.

Abstract No.: 201858**Panel No.: POS-0831****Pediatric Vitreoretinal Surgery in Mongolia***First Author: Tsengelmaa CHULUUNBAT***Purpose:** To study of the outcome in the pediatric vitreoretinal surgery in Mongolia.**Methods:** Clinical History, diagnosis, age, sex, jurisdiction, eye examination, surgical details and indications, other tests, and information in medical history. Pre-and post-operative visual acuity was checked using a standard visual acuity chart with Log MAR.**Results:** A total of 59 surgeries in 48 cases were included in the study; 32 (67%) were male, and 16 (33%) were female. The mean age was 8.05 ± 4.79 (min years was 2 months of age, max years was 17 years of age). The more frequent clinical diagnoses were penetrating trauma in 15 (31.3%) patients, and 13 (86.7%) patients were male. The mean age of diagnosis in penetrating trauma patients was 9.8 ± 5.98 years of age. Thirty seven (77%) eyes were unilateral, 11 eyes (30%) were bilateral, preoperative visual acuity was 0.8-0.1 on the Logmar table in 4 cases (8.3%), improved postoperatively to 10 cases (20.8%), preoperative visual acuity was 0.01-0.09 in 11 cases (22.9%), postoperatively 15 cases (31.3%), which was statistically significant ($p=0.02$). A total of sixteen cases (27.1%) had pars plana vitrectomy and lensectomy surgery, while 43 (72.9%) had other combined vitrectomy surgeries performed, and the anatomical success and globe salvage rate was 58 eyes (98.3%).**Conclusions:** We have established the pediatric retinal surgery in NCMCH, Mongolia, and the anatomical success and globe salvage rate were 58(98.3%), and preoperative visual acuity was 15 (31.2%), while the postoperative visual acuity improved to 25 (52.1%), which was statistically significant ($p=0.02$).**Abstract No.: 207161****Panel No.: POS-0903****Plication-Augmented Modified Nishida's Procedure for Large-Angle Esotropia in Post-Traumatic Sixth Nerve Palsy- a Case Series***First Author: Disha AGARWAL**Co-Author(s): Vidhya***Purpose:** To report a series of three cases with large-angle esotropia (ET) secondary to chronic post-traumatic sixth nerve palsy corrected in a single stage with a plication-augmented modified Nishida's procedure.**Methods:** A retrospective case series reporting three cases with large-angle ET (>50 PDs) secondary to traumatic sixth nerve palsy corrected in a single stage with a modified Nishida's procedure and an MR recession augmented with an LR plication.**Results:** All three patients had a successful surgical outcome (ortho or ET <10 PD) with no evidence of anterior segment ischemia (ASI).**Conclusions:** The primary procedure of choice for a large-angle ET in sixth nerve palsy cases, nowadays, is a modified Nishida procedure, which is a no-split, no tenotomy transposition procedure. However, even with transposition surgeries, achieving a complete correction becomes a challenge in large-angle ETs with more than 50 PDs. If intraoperative tight MR is noted, the procedure can be combined with an MR recession or botulinum toxin injection. However, it does not give a single-staged correction for more than 50 PDs. Plication is safer in such cases to prevent ASI. Therefore, in our cases, we tried to minimize the risk of resurgery and ASI with an LR plication-augmented modified Nishida's procedure with MR recession. Thus, with a single procedure, the double vision was relieved, the abduction limitation improved, and the ocular alignment improved. We will, however, need prospective studies with a larger sample size to study the long-term effects of this modified surgical approach.**Abstract No.: 208526****Panel No.: POS-0909****Predictors of Chlamydia trachomatis Conjunctivitis in Neonates: A 10-Year Retrospective Study***First Author: Saadia FAROOQUI**Co-Author(s): Silpi BISWAS, Shazia KHAN***Purpose:** Ophthalmia neonatorum (ON) is a common neonatal ocular condition with potentially serious ocular and systemic complications. The spectrum of causative organisms varies by geographical regions, maternal health practices, and over time. This study aims to assess the local burden of Chlamydia trachomatis and identify clinical predictors.**Methods:** A 10-year retrospective review (2014–2023) of neonates with suspected ON at a tertiary paediatric eye centre in Singapore was conducted. Clinical and microbiological data were analysed to determine etiological trends and identify predictors of C. trachomatis conjunctivitis. Diagnostic methods included Gram stain, culture, immunofluorescence, and PCR testing. Multivariate logistic regression was used to assess associations.**Results:** A total of 797 neonates were included; 140 (17.5%) tested positive for Chlamydia trachomatis, followed by Staphylococcus aureus (10.2%) and MRSA (4.1%), while Neisseria gonorrhoeae was rare (0.75%). Ten-year trend showed a consistent pattern with Chlamydia trachomatis followed by Methicillin-sensitive Staphylococcus aureus. The presence of bloody discharge was the strongest predictor for Chlamydia infection (OR = 20.99, 95% CI: 6.09–72.29, $p < .001$), followed by vaginal delivery (OR = 17.63,

95% CI: 5.59–55.51, $p < .001$). Eyelid swelling and conjunctival redness were also significant.

Conclusions: Chlamydia trachomatis remains the leading cause of ON in our cohort. Key clinical predictors—bloody discharge, eyelid swelling, conjunctival redness, and unilateral involvement can assist clinicians in early recognition and timely initiation of targeted testing and therapy. These findings support the development of predictive diagnostic frameworks in settings with limited access to molecular diagnostics.

Preferred Practice in Non-Surgical Management of Myopia by Indian Ophthalmologists and Optometrists: A Questionnaire-Based Study

First Author: Shweta **DHIMAN**

Co-Author(s): Raj **KENIA**, Chitaranjan **MISHRA**, Jitendra **SAHOO**, Prolima **THACKER**

Purpose: To assess practice patterns, awareness, and barriers in non-surgical myopia management among Indian ophthalmologists and optometrists.

Methods: A cross-sectional, web-based study was conducted (May–July 2025). A 45-item questionnaire was completed by 300 respondents (70% ophthalmologists, 30% optometrists). Additionally, 142 ophthalmologists completed a supplementary 14-item survey providing deeper insights into clinical practice. Domains included pharmacological, optical, behavioral, monitoring, and digital strategies. Data were analyzed descriptively.

Results: Most respondents reported that 10–25% of pediatric patients were myopic, with therapy typically initiated before 8 years of age (78%). Pharmacological: Atropine 0.01% was prescribed by 85% and rated as the most effective and affordable treatment in the supplementary survey. Optical: Orthokeratology was prescribed by 21%; HALT/DIMS lenses were available to 34% but prescribed by only 26%, primarily due to cost and availability barriers. Multifocal contact lenses were used by 16%. Monitoring: 65% monitored axial length, while others relied on refraction. Typical follow-up was every 3–6 months. Lifestyle & Counseling: >95% recommended outdoor activity and >90% provided digital device counseling. Digital/AI Awareness: Only 23% were aware of AI-based prediction tools. Community Initiatives: 44% of ophthalmologists reported conducting school screenings or parental counseling.

Conclusions: Indian ophthalmologists and optometrists predominantly rely on low-dose atropine and lifestyle modification. Adoption of advanced optical interventions (HALT/DIMS, Ortho-K, multifocals) and digital/AI tools is limited, particularly among non-pediatric ophthalmologists, due to awareness, cost,

and access barriers. The dual-survey design offers both a broad overview and deeper insight, underscoring the need for training, national guideline implementation, and affordable technologies in non-surgical myopia management.

Panel No.: POS-0843

Prevalence of Refractive Errors Among Primary School Students Who Failed Vision Screening in the Philippines From 2022–2023

First Author: Jo Michael **MANIWAN**

Co-Author(s): Joanne **BOLINAO**, Patricia **CABRERA**, Anna Karen **LEE-ONG**

Purpose: The general objective of this study is to determine the prevalence of refractive errors among primary school children who failed vision screening from schools in the Philippines.

Methods: This is a retrospective, cross-sectional prevalence study on kinder and grade 1 students from schools in Marikina and Rizal from 2022 to 2023 who failed the vision screening using the vision screening kit with a LEA chart. The students were examined in the Rizal Medical Center for eye evaluation and cycloplegic refraction. The prevalence of undetected errors of refraction was computed for the sample population and for selected demographic variables (age, gender and location).

Results: Among 1,293 students, the prevalence for vision-screening failure was 23.36%. The most common refractive error among the subjects was hyperopia with astigmatism (43.11%). Among the 283 subjects who failed the vision screening, 168 (59.36%) were prescribed glasses.

Conclusions: Under one-fourth of kinder and grade 1 students from Marikina and Rizal failed vision screening. Hyperopia with astigmatism was the most common refractive error among the subjects, consistent with current data in the Philippines.

Profile of Retinopathy of Prematurity in North India: A Tertiary Care Experience

First Author: Nikita **DASH**

Co-Author(s): Deepak **CHOUDHURY**

Purpose: To study the demographics, risk factors, and pattern of retinopathy of prematurity (ROP) at a tertiary care center in North India.

Methods: This was a prospective, non-randomized, hospital-based study where neonates meeting screening criteria were screened for ROP from July 2023 to June 2025. Diagnosed cases were followed up till spontaneous regression or complete regression following treatment. Cases requiring treatment were

treated with laser photocoagulation and/or anti-VEGF injections as per the early treatment of ROP guidelines.

Results: Majority of the neonates screened were males (65.2%) and inborn babies (64.3%). ROP was detected in 125 neonates (38.5%) of which 81(64.8%) were males and 44(35.2%) were females. In the multivariate binary logistic regression analysis, three factors were identified as statistically significant independent predictors. Lower gestational age at birth was significantly associated with an increased risk of ROP (OR=0.83, 95% CI:0.71-0.97, $p=0.022$). Outborn status was a strong risk factor (OR=3.21, 95%CI: 1.77-5.81, $p<0.001$) with pre-term neonates born outside the center having a threefold higher odds of developing ROP. Neonates maintained on room air had substantially lower odds of developing ROP than those requiring assisted ventilation (OR=0.26, 95% CI: 0.13-0.50, $p<0.001$).

Conclusions: Higher incidence and disease severity are markers of subpar NICU practices that result in severe ROP in extremely premature and outborn cases. Factors that might cause pre-term births should be studied in depth to help identify at-risk cases and curb disease burden.

Prognostic Value of Fixation Stability for Functional Outcomes and Recurrence in Exotropia Surgery

First Author: Jingsen CHEN

Co-Author(s): Shuai CHANG, Junyi LIU, Jiangtao LOU, Xin MA, Jiahe NIE, Tong WU, Xinping YU

Purpose: This study aims to investigate the effect of strabismus surgery on fixational stability and evaluate whether any improvement in fixational stability correlates with the long-term stability of the surgical outcome and enhancement in visual function.

Methods: Fifty patients (31 intermittent exotropia, 19 constant exotropia; age 10–30) and 36 controls were studied to evaluate the effects of strabismus surgery on fixation stability, contrast sensitivity, prism diopter, stereoacuity, and binocular fusion. Postoperative assessments were conducted 2 months after surgery. Fixational stability was recorded with an eye tracker during monocular fixation, and quantified as the bivariate contour ellipse area (BCEA). Contrast sensitivity was tested across six spatial frequencies. Patients were subgrouped by BCEA improvement (post $\geq$ pre) and recurrence status (exodeviation $\leq 10^\Delta$, esodeviation $\leq 8^\Delta$).

Results: Preoperatively, fixation stability (BCEA) was significantly worse in the dominant eye than controls, with the non-dominant eye showing a near-significant reduction. Postoperatively, BCEA of both eyes was comparable to controls. Though not statistically

significant, the dominant eye tended to improve while the non-dominant eye tended to deteriorate. Patients with improved BCEA postoperatively showed better contrast sensitivity at 3 CPD and stereopsis at near, without differences in deviation angles or binocular fusion between improved and non-improved BCEA groups. Recurrence patients exhibited significantly worse preoperative dominant-eye BCEA than non-recurrence patients, whereas postoperative BCEA did not differ between groups.

Conclusions: Strabismus surgery improved fixation stability. Patients with postoperative BCEA gains showed better functional outcomes, while poor preoperative stability predicted recurrence, suggesting BCEA as a prognostic marker and linking fixational instability with reduced contrast sensitivity.

Rapidly Progressive Proptosis in a 2-Month-Old Infant With Capillary Hemangioma Mimicking As Rhabdomyosarcoma

First Author: Jill GENUINO

Co-Author(s): Ma.Rebecca ABES-SERVERA, Alex SUA, Clarissa Marie TADY, Honeylen Maryl TEO

Purpose: To report a case of a 2-month-old male preterm infant with retinopathy of prematurity who presents with a rapidly progressive protrusion of the left orbit mimicking an orbital rhabdomyosarcoma.

Methods: This is a case report.

Results: A 2-month-old preterm male infant sought consult due to rapid progressive protrusion of the left orbit. Clinical examination showed bluish discoloration on the middle 1/3 of the upper eyelid and axial proptosis exposing the lower palpebral conjunctiva. Contrast computed tomography (CT) scan of the brain and orbits requested by the previous attending physician described it as optic nerve glioma. However, contrasted magnetic resonance imaging (MRI) of the brain and orbits with fat suppression revealed more to be an orbital hemangioma measuring 2.5 cm. Oral propranolol 2.8mg/tablet was administered daily (at 1-2 mg/kg/day). The infant was monitored by the Pediatrics service. No side effects such as bradycardia were noted. A significant reduction of the proptosis was seen as early as one week, and a significant resolution was noted after six months of completion of oral propranolol.

Conclusions: This case report aims to describe that there are unusual presentations of the capillary hemangioma. We presented a 2-month-old infant with rapid progression of unilateral proptosis and contrast-enhancing retroorbital mass mimicking a malignant tumor like rhabdomyosarcoma. We should bear in mind that vascular lesions may also present acutely, and a therapeutic trial of propranolol is valuable in

the management of these vascular tumors, such as capillary hemangioma.

Research on Audiovisual Attention Function in Patients With Intermittent Exotropia

First Author: Tong WU

Co-Author(s): Jinsen CHAN, Shuai CHANG, Junyi LIU, Jiangtao LOU, Xin MA, Jiahe NIE, Xiping YU

Purpose: To investigate attentional resource allocation during audiovisual dual-tasking in intermittent exotropia (IXT) patients and evaluate attention functional improvement after strabismus surgery.

Methods: Thirteen IXT patients (preoperative and 2-month postoperative) and ten healthy controls performed auditory n-back tasks while maintaining fixation on a central target. Accuracy rates and reaction times were recorded. Three comparative analyses were conducted: 1) preoperative IXT vs controls, 2) IXT preoperative vs postoperative, and 3) postoperative IXT vs controls.

Results: Compared with the normal control group, preoperative IXT patients showed significantly lower accuracy in all levels of auditory tasks (0-back: 90.71% vs 99.17%, $P < 0.001$; 1-back: 76.60% vs 92.50%, $P < 0.001$; 2-back: 31.77% vs 55.57%, $P = 0.001$; 3-back: 22.12% vs 32.91%, $P = 0.04$), with no statistically significant differences in reaction times. Postoperatively, accuracy improved in 0-back to 2-back tasks (0-back: 90.71% $\rightarrow$ 94.55%, $P = 0.04$; 1-back: 76.60% $\rightarrow$ 85.26%, $P = 0.01$; 2-back: 31.77% $\rightarrow$ 45.05%, $P = 0.03$), while the 3-back task also showed an improving trend (22.12% $\rightarrow$ 32.69%, $P = 0.05$). No significant differences were found in reaction times. Compared with the normal group, postoperative IXT patients still had lower accuracy in 0-back to 2-back tasks (0-back: 94.55% vs 99.17%, $P = 0.01$; 1-back: 85.26% vs 92.50%, $P = 0.03$; 2-back: 45.05% vs 55.57%, $P = 0.02$), but no significant difference in the 3-back task (32.69% vs 32.91%, $P = 0.96$). No significant differences in reaction times were observed between the two groups.

Conclusions: IXT patients exhibit auditory attention deficits. Strabismus surgery effectively improves auditory attention function for low-to-moderate cognitive load tasks, but gaps persist compared to normal populations, suggesting that some auditory attention deficits may be persistent.

Abstract No.: 204999

Panel No.: POS-0872

Restoration of Binocular Single Vision in a Child With Residual Intermittent Exotropia and Secondary Convergence Insufficiency: A Case Report of Structured Orthoptic Training

First Author: Tsz Hin MAK

Co-Author(s): Kam Chuen CHAN, Sze Lok CHONG, Simon Tc KO, Peter Kc LEUNG, Ho On WONG, Patrick Kw WU

Purpose: Managing intermittent exotropia (IXT) with convergence insufficiency (CI) is clinically challenging. Although surgery can reduce deviation, functional binocular outcomes may remain suboptimal. This report describes the progression from absent to functional binocular single vision (BSV) in a child who underwent surgery followed by structured orthoptic training.

Methods: A 4-year-old female presented with IXT and secondary CI (20 Δ exo near, 25 Δ exo distance). Baseline findings included a Newcastle Control Score (NCS) of 7, visual acuity of 0.5 in each eye, absent stereopsis, alternating suppression, no fusional reserves, and convergence failure. At age 5, she underwent left lateral rectus recession and medial rectus resection, reducing deviation to 6 Δ exo near and 12 Δ exo distance. However, binocularity remained unchanged, with persistent suppression and convergence failure. She subsequently underwent 20 monthly sessions of structured orthoptic training, incorporating anti-suppression, convergence, and fusional vergence exercises.

Results: Sensory fusion (Worth 4 Dot) was first demonstrated at session 6, with measurable stereopsis emerging at session 8 (340" Frisby; 50" FD2). At age 7, deviation measured 12 Δ exo near and 10 Δ exo distance. Visual acuity improved (0.7 in each eye). Stable BSV was demonstrated at near and distance (85" Frisby, 240" TNO, 20" FD2). Fusional reserves improved (near: 4 Δ BO/4 Δ BI; distance: 2 Δ BO/2 Δ BI), convergence to 7 cm, and NCS reduced to 2.

Conclusions: Structured orthoptic training may achieve functional outcomes in cases where surgery alone is insufficient. This case represents one of the successful outcomes within our service, supporting the need for prospective studies to explore the effectiveness and optimal timing of intervention.

Results of the Analysis of Visual Functions in Children Who Have Had Brain Tumors

First Author: Igor **AZNAURYAN**Co-Author(s): Karmen **ARTENIAN**, Satenik **AGAGULIAN**, Victoria **BALASANYAN**, Elena **GLEBOVA**, Natalia **KURYSHEVA**, Alexander **LAVER**, Svetlana **RYCHKOVA**, Natalia **SHESTAK**, Alina **TOLMACHEVA**

Purpose: To study the structure of ophthalmopathology and the state of visual functions in patients with operated brain tumors in the period of remission.

Methods: The results of ophthalmological examination and outpatient card data of 224 children aged 7 to 17 (average 11.7 ± 0.6) years with operated brain tumors in remission were analyzed.

Results: Among children with PONA, there was a comparable proportion of emmetropic (33,3% of cases) and myopic (37,3% of cases) refractions. The predominant type of refraction in children without PONA was emmetropia (49,3% of cases). The number of children with strabismus was higher in the group of children with PONA than without PONA (39,2% vs 16,9% of cases, $p < 0.001$). Strabismus was most often observed in children with operated tumors of the cerebellum and the IV ventricle, probably as a symptom at a distance due to intracranial hypertension. The number of children with nystagmus was higher in the group of children with PONA (15,7 of cases) than without PONA (4,2% of cases). Pupillary disorders in the form of anisocoria and decreased pupillary reaction were detected in 9 (5,9%) children with PONA and were not observed in children without PONA. Retinal angiopathy and lagophthalmos with facial nerve insufficiency were observed in several children in both groups.

Conclusions: The results of the study indicate the need for regular, long-term and detailed monitoring of the state of visual functions (including visual memory and spatial perception) in children who have had a brain tumor.

Abstract No.: 205758

Panel No.: POS-0883

Risk Factors Associated With Early Recurrence Following the Recession-Plication Procedure for the Management of Basic Type Intermittent Exotropia in Children

First Author: Jingjing **JIANG**Co-Author(s): Di **CAO**, Li **LI**, Yuanyuan **REN**

Purpose: The study aimed to identify risk factors associated with early recurrence (within 6 months) following unilateral lateral rectus recession combined with medial rectus plication (RP) procedure for children with basic type intermittent exotropia (IXT).

Methods: The cohort study enrolled children with basic type IXT who underwent unilateral RP procedure between January 2022 and December 2023. Based on the postoperative ocular alignment at near (33 cm) 6 months postoperatively, patients were divided into the early recurrence group (exodeviation >10 PD) and the early success group (exodeviation or esodeviation ≤ 10 PD). Preoperative, early (1 week), mid-term (6 months), and long-term (>12 months) assessments included deviation at distance and near, fusion, and stereopsis. Multivariate logistic regression and ROC curve analyses identified predictors of recurrence and long-term motor outcomes.

Results: Ninety-one patients were enrolled, with a mean age of 8.10 ± 3.06 years and a mean follow-up of 16.81 months. At 6 months postoperatively, 31 patients were in the early recurrence group and 60 in the early success group. Univariate analysis showed significant differences in deviation at near and distance within 1 week postoperatively between the two groups ($P=0.004$ for distance; $P<0.001$ for near). Multivariate logistic regression identified deviation at near within 1 week postoperatively as an independent predictor of early recurrence (OR=0.738, 95% CI: 0.609–0.895, $P=0.002$). ROC curve analysis revealed a moderate predictive value of deviation within 1 week for early recurrence (AUC=0.7315, optimal cutoff value: -1.00 PD, sensitivity=67.74%, specificity=80.00%). For long-term outcomes, deviation at nearly 6 months postoperatively showed high predictive accuracy (AUC=0.8461, optimal cutoff value: -7.50 PD, sensitivity=85.71%, specificity=82.54%). At final follow-up, the patients in the early success group had a significantly higher proportion of fusion (95.00% vs. 77.42%, $P=0.011$).

Conclusions: Deviation at near within 1 week postoperatively is a predictive indicator of early recurrence following RP for basic type IXT in children, with mild overcorrection associated with a lower risk of early recurrence. Deviation at near 6 months postoperatively is a robust predictor of long-term motor outcomes. Follow-up within 6 months postoperatively is crucial for IXT patients.

Abstract No.: 204417

Panel No.: POS-0861

Risk Factors and Predictors of Botulinum Toxin Type A Re-Injection in Acute Acquired Concomitant Esotropia Patients

First Author: Jiayu **CHEN**Co-Author(s): Jing **FU**, Jie **HAO**

Purpose: To identify independent risk factors and predictors for repeat botulinum toxin type A (BTA) injections beyond 6 months in acute acquired concomitant esotropia (AACE) patients, providing a scientific foundation for risk-stratified clinical management.

Methods: A case-control study enrolled AACE patients treated at Beijing Tongren Hospital (July 2021–January 2025). All received initial BTA injections with 6-month follow-up; subset underwent reinjection post-6 months. Comprehensive ophthalmic examinations and questionnaires were administered at all timepoints. Binary logistic regression analyzed reinjection risk factors.

Results: Fifty-six (47.9%) required a second injection within 6 months. Although baseline characteristics were largely similar between groups, the presence of anisometropia (≥ 1.00 D) was significantly higher in the re-injection group. Multivariable analysis identified baseline anisometropia (OR=2.789) and postoperative distance deviation at 3 months (OR=1.315) as independent risk factors for re-injection. A prediction model incorporating the distance deviation at 3 months achieved an AUC of 0.810, with a cut-off value of >5.23 PD providing 82.0% specificity.

Conclusions: Anisometropia is a robust baseline predictor for repeat BTA injections in AACE. Residual distance deviation at 3 months postoperatively serves as a critical dynamic indicator of treatment response and reinjection risk, enabling early identification of high-risk patients.

Panel No.: POS-0814

Safety and Efficacy of Atropine 0.05% Versus 0.01% for Prevention of Myopic Progression in Children: A Randomized Clinical Trial

First Author: Siddharam JANTI

Co-Author(s): Kalpana MALI, Bhushan, Srividya, Hari Kumar S

Purpose: This study aimed to evaluate the effectiveness and safety of 0.01% and 0.05% atropine eye drops in managing myopia progression in children compared to a placebo.

Methods: This randomized interventional study was conducted from March 2022 to May 2023 at the Institute of National Importance, India. A total of 272 children aged five to 16 years, with myopia between -1.0 D and -6.0 D and annual progression greater than 0.5 D, were enrolled. Participants were randomly assigned into three groups: Group A ($n=88$, atropine 0.01%), Group B ($n=90$, atropine 0.05%), and Group C ($n=94$, placebo). Comprehensive ophthalmic examinations, including cycloplegic refraction, axial length measurement, and fundus evaluation, were performed at baseline, six weeks, 12 weeks, and at one year. Changes in refractive error, axial length, accommodation, and pupil size were analyzed.

Results: Both atropine treatments effectively slowed myopia progression compared to placebo. Atropine 0.05% significantly reduced refractive progression (0.263 ± 0.03 D) and axial elongation (0.138 ± 0.22

mm) versus placebo (0.759 ± 0.34 D and 0.367 ± 0.33 mm, respectively). The 0.01% atropine group showed a less pronounced but still significant reduction (0.319 ± 0.05 D and 0.241 ± 0.22 mm, respectively). Both atropine groups experienced increased near point of accommodation and pupil size, more notably in the 0.05% group. Mild adverse effects, including near vision difficulties and photophobia, were reported but did not significantly impact patient compliance.

Conclusions: Atropine 0.05% is more effective than 0.01% atropine and placebo in slowing myopia progression.

Abstract No.: 206636

Panel No.: POS-0897

Seeing the Difference: A Comparative Case Report on Clinical Characteristics of Unilateral and Bilateral Retinoblastoma in Children

First Author: Atika ANDIANTI

Co-Author(s): Primawita Oktarima AMIRUDDIN, Sesy CAESARYA, Irawati IRFANI, Feti KARFIATI, Mayasari Wahyu KUNTORINI

Purpose: Retinoblastoma is the most common malignant ocular tumor of childhood and one of the most common pediatric malignant tumors, which is associated with mutations in the RB1 gene. Retinoblastoma could be unilateral or bilateral. These case reports aim to explain the differences in clinical manifestations of unilateral and bilateral retinoblastoma.

Methods: The first case involved a 2-year-old boy who presented with a chief complaint of leukocoria of the right eye. He was diagnosed with Intraocular Retinoblastoma Group D Advanced in the right eye. The patient was planned to have enucleation of the right eye and staging. Second case presents a 2-month-old boy with chief complaint of leukocoria of right eye and esotropia, he was diagnosed with Intraocular Retinoblastoma Group D of right eye and Group B of left eye, the patient was planned for chemotherapy and followed by focal therapy.

Results: Hereditary cases of retinoblastoma are diagnosed in children under 1 year of age and mostly present with bilateral retinoblastoma. Sporadic cases are diagnosed between 1 and 3 years of age and usually present with unilateral retinoblastoma, even though bilateral cases are also possible. Bilateral cases present with multifocal tumors, while unilateral cases mostly present with a unifocal tumor. International Classification of Retinoblastoma (ICRB) of Shields/Philadelphia and Murphree/CHLA are used to determine retinoblastoma severity.

Conclusions: Cases without a family history have a chance to manifest unilateral or bilateral retinoblastoma. Clinical manifestations and adequate examinations are important to determine the severity

and management of retinoblastoma. Treatment in the early stages holds a good prognosis for survival and salvage of visual function.

Sequential Surgical Management of Unilateral Dissociated Vertical Deviation With Exotropia in an Adult With Anisoamblyopia

First Author: Rizqi Suryani PUTRI

Co-Author(s): Rozalina LOEBIS

Purpose: To describe diagnostic nuances and staged surgical management of unilateral dissociated vertical deviation (DVD) associated with exotropia in an anisoamblyopia adult patient.

Methods: A 36-year-old female with a history of upward and outward misalignment of the left eye (LE) since the age of four, with reduced vision in the LE but no diplopia. Best corrected visual acuity was 6/6 in the right eye (RE) and 6/9.5 in the LE. Examination revealed left exotropia and hypertropia with upward drift on occlusion. Prism cover test at distance (6m) showed 40 prism diopters (PD) exotropia and 14 PD vertical deviation. Initial horizontal alignment was addressed with left lateral rectus recession (8 mm) and medial rectus resection (6.5 mm). One month later, residual measured 20 PD vertical deviation and 8 PD exotropia, prompting planned superior rectus (SR) recession. Intraoperatively, dense cicatricial tissue was found on the superior rectus and released. A shorter SR recession of 7 mm was performed instead of the intended 9 mm. This was followed by a 4 mm inferior rectus resection.

Results: Staging the horizontal correction clarified the magnitude of the vertical dissociation. Postoperatively, the patient was attaining near orthophoria and a minimal residual distance deviation of 6 PD. This result made a tremendous psychosocial impact on the patient (Adult Strabismus Questionnaire score = 82.5).

Conclusions: DVD associated with exotropia in anisometropic amblyopia is uncommon. A sequential approach can unmask and more accurately quantify vertical dissociation after horizontal alignment, guiding tailored vertical muscle surgery. As a result, it significantly improve ocular alignment, visual function, patient's confidence and quality of life.

Single Muscle Nishida's Procedure for Large Angle Combined Horizontal and Vertical Deviations

First Author: Sowmya RAVEENDRA MURTHY

Purpose: To present a case series of paralytic squints (large angle combined horizontal and vertical

deviations) treated by the Single Muscle Modified Nishida's (SMN) procedure.

Methods: Retrospective analysis of 6 cases of paralytic strabismus treated with SMN procedure. This included two Cases of MED presenting with XT and hypotropia, and 4 cases of IR palsy with hypertropia (HT) with exotropia (XT) treated with a single muscle modified Nishida procedure were analysed. Four cases of IR palsy with hypertropia ranging from 40-55 pd and exotropia of 20-45 pd. Both underwent superior rectus recession with single muscle (LR or MR) modified Nishida's procedure and recession or plication of (LR or MR) to correct the XT. Two cases of MED with hypotropia of 16-20 and XT of 16-55 pd. Both underwent LR SMN procedure with unilateral or bilateral MR plication to correct XT and HoT.

Results: Lateral rectus SMN was done in 5 cases, and Medial rectus in one case. The vertical deviation reduced from 16-45 pd to 0 to 12 pd with the correction obtained from SMN ranging between 20 to 25 pd. Further, it spared one horizontal recti that could be used in the correction of horizontal deviation (XT) in the same sitting. The SMN procedure used one horizontal rectus muscle to correct the vertical and the other to correct the horizontal deviation.

Conclusions: This is the first case report of SMN procedure for vertical deviation in paralytic strabismus. Seems to be useful option in cases where there is a higher risk of anterior segment ischemia

Six-Year Evolution of Paediatric Optic Disc Drusen-Associated Anterior Ischaemic Optic Neuropathy

First Author: Ka Lam Janice WU

Co-Author(s): Tin Kin Jonathan CHAN, Gerard LYDON

Purpose: To describe a six-year clinical course of optic disc drusen-associated anterior ischaemic optic neuropathy (ODD-AION) in a paediatric patient, emphasising the value of longitudinal structural and functional monitoring. Paediatric ODD-AION is extremely rare, and this case provides insight into its early evolution, progression, and management.

Methods: A 9-year-old girl was referred to ophthalmology with asymptomatic right optic disc swelling. She underwent serial ophthalmic assessments over six years, including visual field testing, optical coherence tomography (OCT), magnetic resonance imaging (MRI), and fundus autofluorescence.

Results: Between ages 11-13, progressive inferior arcuate scotoma and retinal nerve fiber layer thinning developed in the right eye, with stable vision. At age 15, she presented with sudden right visual loss, an inferior altitudinal defect, and a relative afferent pupillary defect. Bilateral optic disc drusen were

confirmed on autofluorescence and ultrasound. OCT demonstrated diffuse retinal nerve fiber layer and ganglion cell layer thinning in the right eye. MRI and blood investigations were unremarkable. Hydration counselling and observation were advised. At six months, visual acuity partially recovered (LogMAR 0.6 right, 0.1 left) with a stable field defect.

Conclusions: This case demonstrates that paediatric ODD-AION may follow a prolonged, clinically silent course before acute vision loss. Serial OCT and perimetry are essential for detecting progressive optic nerve damage, even in asymptomatic patients. Careful long-term monitoring is warranted, as apparent visual stability may mask ongoing structural change and risk of ischaemic events.

Social Impact of Strabismus

First Author: Tasnima RAHMAN

Co-Author(s): Mostafa HOSSAIN, Nabila RAHMAN

Purpose: This study aims to explore the social and psychological consequences of untreated squint and to highlight the importance of timely intervention through the combined efforts of parents, teachers, and healthcare providers.

Methods: A review of multiple case scenarios was undertaken to assess the challenges faced by individuals with squint. The cases illustrated the impact of untreated squint on education, career opportunities, interpersonal relationships, and self-image. Information was gathered through clinical encounters, focusing on both the social difficulties and the improvement observed after medical and surgical management.

Results: The findings revealed that untreated squint often leads to low self-esteem, social isolation, and bullying during childhood. Many patients reported limitations in career prospects and challenges in forming social or marital relationships. Case examples included unemployed adults, students with reduced confidence, and homemakers experiencing social stigma. Conversely, individuals who received timely diagnosis and treatment demonstrated improved psychological well-being, enhanced social acceptance, and better professional opportunities. The supportive roles of parents in early recognition, teachers in addressing classroom challenges, and doctors in dispelling myths and providing effective treatment were identified as crucial in improving outcomes.

Conclusions: Squint, if left untreated, imposes significant social, psychological, and professional burdens. Early detection and timely management, combined with strong emotional and social support systems, are essential to improving the lives of affected individuals. Raising awareness and encouraging prompt medical consultation can transform the long-term

social impact of squint into positive and fulfilling life outcomes.

Panel No.: POS-0873

Structured Orthoptic Binocular Vision Training in Pediatric Intermittent Exotropia: A Four-Year Retrospective Analysis

First Author: Ho On WONG

Co-Author(s): Kam Chuen CHAN, Sze Lok Gabriela CHONG, Simon Tc KO, Peter LEUNG, Tsz Hin MAK

Purpose: Intermittent exotropia (IXT) is a prevalent childhood strabismus with varied management approaches. Historically, surgery has been the mainstay of treatment, particularly for patients with poor control or significant deviations. However, evidence supporting the efficacy of structured orthoptic training remains limited, especially among Asian populations. This study evaluated the clinical outcomes of a 4-year structured orthoptic training program in children with IXT.

Methods: A retrospective analysis was conducted on 120 patients (aged 3–18 years) diagnosed with basic IXT who completed structured orthoptic training between 2020 and 2024. Outcomes were compared with 120 age-matched controls who declined training and received monitoring only. This program comprised anti-suppression, convergence, and fusional vergence exercises delivered in the clinic and at home. Primary outcome measures included Newcastle Control Score (NCS), angle of near deviation (AoND), angle of distance deviation (AoDD), and fusional vergence ranges.

Results: Significant improvements were observed across all measured parameters in the training group. Mean NCS improved from 4.2 ± 1.95 to 2.0 ± 1.97 ($p < 0.001$). AoND reduced from 15.2 ± 7.4 PD to 10.9 ± 6.3 PD ($p < 0.001$), and AoDD from 20.5 ± 7.2 PD to 13.0 ± 7.2 PD ($p < 0.001$), with 59.8% achieving a reduction of >5 PD. Near base-out fusional reserves increased from 10.5 ± 7.1 PD to 19.6 ± 8.9 PD ($p < 0.001$), while distance base-out reserves improved from 2.5 ± 4.6 PD to 13.0 ± 7.7 PD ($p < 0.001$).

Conclusions: Structured orthoptic training was associated with meaningful improvements in IXT control, deviation magnitudes, and fusional reserves. Importantly, over two-thirds (69%) of patients reported no intention to pursue surgery, indicating a potential role in reducing surgical demand. Larger prospective studies are warranted to confirm the long-term stability and effectiveness of this program.

Abstract No.: 203022**Panel No.: POS-0849****Study on the Impact of Early Intervention on Retinopathy of Prematurity***First Author: Yamei LIN*

Purpose: Exploring the impact of early intervention on retinopathy of prematurity, providing evidence for early intervention in premature infants.

Methods: A total of 207 cases from our hospital in the past two years were randomly selected as the premature follow-up group, and an early intervention plan using ranibizumab injection was adopted. These cases were compared with 69 premature children who were lost to follow-up and 138 premature children who were similar to the follow-up group. The incidence of adverse reactions, screening duration, and follow-up compliance during the screening period were observed in the three groups.

Results: The differences between the premature intervention group and the premature loss-to-follow-up group were significant ($P < 0.05$), and the premature follow-up group was significantly better than the premature loss-to-follow-up group ($P < 0.05$).

Conclusions: Early intervention can significantly promote the recovery of retinopathy of prematurity and improve the health of affected infants.

Abstract No.: 204091**Panel No.: POS-0859****Subconjunctival Versus Combined Subconjunctival and Subscleral Flap Mitomycin C in Pediatric Trabeculectomy: A Randomized Clinical Study***First Author: Ahmed ALI*

Purpose: To compare the safety and efficacy of trabeculectomy augmented by subconjunctival application of Mitomycin C (MMC) versus combined subconjunctival and subscleral flap MMC application in primary congenital glaucoma (PCG).

Methods: This prospective, randomized, interventional study included children aged Results: At 12 months, the percent IOP reduction for group A was 45.6% and for group B 46.8%. Qualified success was achieved in 68% and 72% of eyes in groups A and B, respectively. Failure tended to occur earlier in group B. Kaplan-Meier analysis for complete success showed a cumulative probability of survival of 53% for group A and 40% for group B (P -value=0.38). Needling was more successful in group B with 60 % total success compared to 33.3% in group A (P -value=0.39).

Conclusions: The subscleral flap application of MMC in conjunction with subconjunctival MMC application in pediatric trabeculectomy does not appear to result in additional benefit regarding safety or efficacy, when compared to subconjunctival application alone.

Abstract No.: 206874**Panel No.: POS-0902****Successful Inferior Rectus Advancement for Managing Vertical Diplopia in Traumatic Extraocular Muscle Rupture: A Case Report***First Author: Gusti Gede SUARDANA**Co-Author(s): Devina Nur ANNISA, Hasiana LUMBAN GAOL*

Purpose: To report a successful inferior rectus (IR) muscle advancement to manage vertical diplopia in traumatic IR rupture.

Methods: A 43-year-old woman presented with a chief complaint of binocular vertical diplopia and a higher position of her left eye (LE) that had persisted for nine months prior to admission. She reported a history of ocular trauma preceding the onset of symptoms. Ophthalmological examination revealed 20 degrees of hypertropia in the LE, along with a limitation of downward gaze. Intraoperative exploration revealed a new insertion of the IR muscle located approximately 3.5 mm posterior to its original insertion site. The IR muscle was then sutured 3 mm posterior to its new insertion point, disinserted, and advanced to 6.5 mm behind the limbus.

Results: Postoperatively, the patient achieved orthophoria in primary gaze and reported no residual diplopia.

Conclusions: Extraocular muscle rupture can result from trauma or injury and may presents as incomitant strabismus. Thorough examination and intraoperative assessment are essential to identify the affected muscles and achieve good surgical outcomes to manage patient's symptoms.

Abstract No.: 200650**Panel No.: POS-0819****Surgical Approaches to Secondary Gaze Diplopia: A Case Series***First Author: Juan Lorenzo SIMPAO**Co-Author(s): Toshiaki GOSEKI, Hiromi ONOUCHI*

Purpose: We report a series of cases in which residual diplopia in secondary gaze persisted despite successful alignment in the primary position following strabismus surgery. These cases required additional surgical intervention to address the diplopia in secondary gaze.

Methods: Case series.

Results: Case 1: A 70-year-old female with right superior oblique palsy underwent a 2mm recession with nasal transposition of the left inferior rectus, which improved diplopia in primary gaze. Residual diplopia in left gaze persisted postoperatively and was resolved with 4mm recession of the right medial rectus. Case 2: A 57-year-old female with both thyroid eye disease and myasthenia gravis underwent steroid therapy and orbital decompression. To treat

residual diplopia, 4.5mm inferior rectus recession and 6.5mm medial rectus recession on the right eye were performed, resolving diplopia in primary gaze. Persistent diplopia in right gaze improved after 4mm medial rectus recession in the left eye. Case 3: A 42-year-old male underwent bilateral lateral rectus recession and medial rectus resection on the right eye for intermittent exotropia. Although ocular alignment in primary gaze improved, diplopia was noted in right gaze postoperatively. Medial rectus recession 3.5mm on the left eye was performed, leading to symptomatic improvement.

Conclusions: Diplopia limited to secondary gaze is not typically considered an indication for surgical intervention when alignment in the primary position is satisfactory. However, in selected cases where residual symptoms interfere with daily activities, additional surgery targeting the secondary gaze deviation can be beneficial. Accurate assessment of ocular motility and individualized evaluation of visual needs are essential for optimal management.

Abstract No.: 200274

Panel No.: POS-0817

Surgical Considerations for the Management of Unilateral Pediatric Cataract

First Author: Rebecca MURTAZA

Purpose: Cataract surgery in younger children possesses different challenges and potential complications compared to those encountered in the adult population. To discuss the clinical profile and presentation of children with unilateral cataract.

Methods: A video will be presented of different unilateral cataract surgeries.

Results: Video presentation.

Conclusions: The pediatric age group with unilateral cataract requires special surgical considerations.

Abstract No.: 204837

Panel No.: POS-0867

Surgical Outcomes of Two-Muscle Versus Three- or Four-Muscle Procedures in Large-Angle Exotropia: A Systematic Review and Meta-Analysis

First Author: Christy MAGDALENA

Co-Author(s): Anna Puspitasari BANI

Purpose: Large-angle exotropia (XT) significantly impairs binocular vision and quality of life, and surgical correction remains the mainstay of treatment. Two-muscle procedures are commonly performed but may be insufficient for large deviations, prompting the use of three- or four-muscle surgeries. This review compares the outcomes of these approaches in large-angle XT.

Methods: A systematic search of PubMed, ProQuest, Scopus, and ScienceDirect was conducted through July 2025. Eligible studies included case series or cohorts reporting primary XT of at least 50 PD managed with two-, three-, or four-muscle procedures. The primary outcome was motor success, with complications as secondary outcomes. Pooled success rates were calculated using meta-analysis in R.

Results: Nine studies met the inclusion criteria: six evaluated two-muscle procedures (261 patients) and three evaluated three- or four-muscle procedures (80 patients). Two-muscle surgeries yielded a pooled success rate of 71% (95% CI: 62%-81%) with substantial heterogeneity ($I^2 = 62\%$, $p = 0.02$). Sensitivity analysis improved the success rate and heterogeneity to 77% (95% CI: 71%-82%; $I^2 = 0\%$, $p = 0.95$). Three- or four-muscle surgeries showed a higher success rate, 83% (95% CI: 75%-91%; $I^2 = 0\%$, $p = 0.55$). Abduction deficit was the most common complication following two-muscle surgeries.

Conclusions: Both approaches are effective. Two-muscle surgery is a practical first-line option for deviations up to ~60 PD, especially in resource-limited settings. Three- or four-muscle procedures offer higher success for larger deviations. Surgical planning should be individualized, balancing deviation magnitude, risk of abduction deficits, and available resources.

Abstract No.: 203244

Panel No.: POS-0852

Surgical Treatment Experience of a Case of Childhood Acute B-Lymphoblastic Leukemia Complicated With Bilateral Vitreous Hemorrhage

First Author: Fang CHAI

Co-Author(s): Xiquan ZHAO

Purpose: Cases of childhood acute leukemia complicated with bilateral vitreous hemorrhage are clinically rare. Through a retrospective study of one case and a review of recent literature reports, we systematically analyzed the pathogenesis and clinical manifestations of fundus hemorrhage associated with acute leukemia in children.

Methods: A female patient, 3 years old, presented to the Ophthalmology Department of Xi'an People's Hospital (Xi'an Fourth Hospital) due to the inability to see with both eyes for 1 month. Examinations, including binocular visual acuity, intraocular pressure, slit-lamp examination, and ocular B-scan ultrasound, were performed to confirm the diagnosis.

Results: One month prior, the child was diagnosed with Acute B-lymphoblastic leukemia. Ocular B-scan suggested: Bilateral vitreous hemorrhage; retinal detachment could not be ruled out. Staged surgeries were scheduled: the right eye underwent vitrectomy combined with silicone oil tamponade, and the left

eye underwent vitrectomy combined with sterilized air tamponade. Silicone oil removal was performed in the right eye 8 months postoperatively. At a follow-up visit 1 year after oil removal, the child's visual acuity was 0.6 in both eyes, and the fundus condition was stable.

Conclusions: The clinical symptoms of leukemia infiltrating the eye are becoming increasingly diverse. Tumor cells can invade almost all ocular structures. Understanding the ocular manifestations of leukemia is of great significance for the diagnosis and treatment of eye diseases. Under stable systemic conditions, ocular vitrectomy can effectively control the ocular condition and restore the patient's vision.

Abstract No.: 203885

Panel No.: POS-0858

The Association Between Refractive Error and Control in Intermittent Exotropia: A Prospective Cross-Sectional Study

First Author: Tsz Him YAU

Co-Author(s): Gabriela Sze Lok CHONG, Ka Wai KAM, Wai Hing TAM

Purpose: Intermittent exotropia (IXT) is a prevalent pediatric eye condition. Although refractive errors are common among children, their association with IXT control remains unclear. Previous research focused on convergence and stereopsis, few studies have directly examine the direct relationship between IXT control and refractive error types and magnitude. This prospective, cross-sectional and observational study aims to determine how refractive error of the participants with IXT is associated with the control of their deviation.

Methods: This study recruited 60 children with IXT from two orthoptic clinics in Hong Kong. Participants underwent a comprehensive orthoptic assessment. Habitual refractive corrections were assessed using focimetry, and IXT control was measured using the office-based control score. Spherical equivalent (SE) were used to classify participants into hypermetropia, emmetropia, and myopia groups. The Kruskal-Wallis test, correlation and multiple linear regression analyses were used to explored associations between SE and IXT control, adjusting for potential confounders.

Results: No significant differences in total, near, or distance control scores among the refractive error groups. SE also showed no significant correlation with office-based control scores. Multiple linear regression confirmed no association between refractive error and IXT control. Conversely, older age was significantly correlated with improved control scores ($p=0.44$, $p=.003$; $B=-0.33$, $p=0.04$).

Conclusions: In this Chinese cohort, types and severity of refractive error were not associated with IXT control, whereas older age predicted better control. These findings address a notable gap in Asian IXT literature

and suggest future research should prioritise other prognostic factors.

Abstract No.: 205390

The Binocular Visual Imbalance in Preoperative Intermittent Exotropia

First Author: Jiangtao LOU

Co-Author(s): Shuai CHANG, Jingsen CHEN, Rong JIANG, Junyi LIU, Xin MA, Jiahe NIE, Tong WU, Xinping YU

Purpose: To quantify and characterize the binocular visual imbalance in patients with intermittent exotropia (IXT) prior to surgical intervention.

Methods: This prospective study included 34 preoperative IXT patients and 19 matched healthy controls. A binocular orientation combination task was used to assess binocular visual imbalance across central, nasal, and temporal visual fields referenced to the sensory dominant eye at two spatial frequencies (1.5 and 6 cycles/degree, cpd). The sensory dominant eye was confirmed in the central visual field at two spatial frequencies. Binocular visual imbalance was quantified using the log contrast ratio between the non-dominant and dominant eyes, denoted as lgBP. The extent of binocular imbalance was quantified with the absolute value of lgBP, denoted as |lgBP|.

Results: In the central visual field, both controls and IXT patients tended to be dominated by the dominant eye, with IXT patients experiencing more pronounced imbalance at 1.5 cpd (0.15 vs. 0.22, $P=0.024$). In the nasal visual field, both controls and IXT patients favored the non-dominant eye. In the temporal visual field, controls still favored the non-dominant eye, whereas IXT patients favored the dominant eye (1.5cpd: -0.07 vs. 0.09, $P=0.036$; 6cpd: -0.20 vs. 0.01, $P=0.031$). Additionally, IXT patients showed significantly greater binocular visual imbalance than controls in the peripheral visual fields at the low spatial frequency (1.5 cpd, all $P<0.05$).

Conclusions: The eye dominance pattern in the temporal visual field of IXT patients was different from that of healthy controls. Patients with IXT exhibit more pronounced binocular visual imbalance at low spatial frequencies.

Abstract No.: 202399

Panel No.: POS-0835

The New Method for Calculating Surgical Treatment of Nystagmus Using the Computer Modelling System

First Author: Igor **AZNAURYAN**

Co-Author(s): Victoria **BALASANYAN**, *Evgenii* **MORDYUKOV**, *Magomed* **UZUEV**

Purpose: Nystagmus, characterized by involuntary rhythmic eye oscillations, is a severe pathology with a prevalence of 1:2000. It leads to significantly reduced visual acuity, oscillopsia, abnormal head posture, and serious social limitations, necessitating the development and refinement of effective treatment strategies. To present a novel comprehensive approach to the diagnosis and treatment of patients with nystagmus, focusing on modern surgical techniques aimed at reducing oscillation amplitude and improving visual functions.

Methods: The diagnostic algorithm included a comprehensive examination: standard and null-zone visual acuity assessment, cycloplegic refraction, videonystagmography for quantitative analysis of nystagmus parameters and precise identification of the null zone, as well as OCT and electrophysiological testing (VEP, ERG). Surgical intervention was performed using the proprietary "STRABO" mathematical modeling program to calculate the precise dosage of the operation on the extraocular muscles.

Results: The application of mathematical modeling enabled the precise dosing of surgery on the extraocular muscles to create a new null zone in the primary position. This resulted in a significant reduction in nystagmus amplitude, elimination of abnormal head posture, improvement of visual acuity, and, consequently, a marked enhancement in the patients' quality of life.

Conclusions: The proposed comprehensive approach, based on meticulous diagnostics and personalized surgical planning utilizing the «STRABO» software, represents a highly effective method for managing nystagmus. It allows for achieving stable functional and cosmetic outcomes, offering new possibilities for treating patients with this challenging condition.

The Potential of Lutein-in-Extra-Virgin-Olive-Oil as an Oral Intervention for Retinopathy of Prematurity

First Author: Xiaoyuan **YE**

Co-Author(s): Wai-ching **LAM**, *Amy Cheuk Yin* **LO**

Purpose: Retinopathy of prematurity (ROP) is a leading cause of childhood blindness driven by oxidative stress and inflammation. While lutein shows therapeutic potential due to its antioxidant and anti-inflammatory

properties, its clinical efficacy remains controversial. We proposed that extra virgin olive oil (EVOO) could enhance lutein absorption and aimed to evaluate the effects of lutein-in-EVOO (LEVOO) in a mouse ROP model.

Methods: The mouse oxygen-induced retinopathy (OIR) model was employed. Neonatal C57BL/6J mice were exposed to 75% oxygen from postnatal day 7 (P7) to P12, followed by daily gavage of LEVOO (0.4, 1.8, and 3.6 mg/kg). Retinal function was evaluated on P17 using scotopic electroretinography (ERG). Retinal vasculature and microglia were assessed via immunohistochemistry. Proteomic analysis was performed to investigate changes in the retinal proteome.

Results: LEVOO at 3.6 mg/kg significantly improved retinal function, increasing b-wave amplitudes, and reduced both avascular and neovascular areas compared to those receiving EVOO alone. The number of activated microglia in avascular regions significantly decreased. GO enrichment analysis of differentially expressed proteins (DEPs) revealed clusters related to angiogenesis and cell adhesion between the OIR-challenged and control groups. DEPs between LEVOO-treated and OIR-challenged groups primarily focused on the negative regulation of macrophage chemotaxis.

Conclusions: LEVOO administration improved retinal function, suppressed pathological neovascularization, and reduced inflammation in the OIR model. Proteomic findings provided mechanistic insights into LEVOO's benefits, reinforcing lutein's anti-inflammatory as well as neuro- and vascular-protective roles. This study supported LEVOO as a promising intervention for ROP.

Abstract No.: 200754

Topical and Oral Carbonic Anhydrase Inhibitor Combination Therapy in Juvenile Retinoschisis: A Case Report

First Author: Maria Christine **DY**

Co-Author(s): Michelle **DAGTA**, *John Vyle* **PASCARAN**

Purpose: To report a clinically diagnosed case of juvenile retinoschisis managed with short-term topical and oral carbonic anhydrase inhibitor combination therapy.

Methods: A ten-year-old male with chronic progressive blurring of vision of the left eye was seen at a Philippine tertiary government hospital. Medical and family histories were unremarkable. Visual acuity was 20/25 on the right and counting fingers on the left. Cyclorefraction showed anisometropia of +0.50 and +6.50 spherical equivalents, respectively. 30 prism diopter left exodeviation was also noted. Anterior segment findings were normal. Spoke-wheel foveal streaks and a dome-shaped inferotemporal retinal elevation with atrophic edges consistent

with retinoschisis were seen on each eye on clinical exam. These were further confirmed with diagnostic procedures. The patient was referred for genetic counseling; gene and electrophysiologic tests are pending.

Results: Dorzolamide eyedrops and oral acetazolamide were started thrice a day with regular follow-ups and electrolyte monitoring. Three months on treatment, vision on the left improved to 20/200 with no reported side effects. Repeat diagnostic imaging showed a relative decrease in central subfield thickness with smaller cystic spaces. Long-term response to medications, regular funduscopy, and serial refraction were continuously monitored.

Conclusions: Juvenile retinoschisis is an X-linked recessive disorder and is the most common macular dystrophy among young males. Since there is no proven effective treatment, amblyopia and low vision rehabilitation are important. Despite its progressive nature, studies have shown the potential efficacy and safety of carbonic anhydrase inhibitors in terms of visual and anatomical improvement.

Abstract No.: 200187

Panel No.: POS-0815

Unilateral Retinopathy of Prematurity: Rare Cases Challenging Bilateral Assumptions

First Author: Khushbakht PETERS

Purpose: To highlight the occurrence and clinical course of unilateral retinopathy of prematurity (ROP), a rare presentation, through two distinct case studies. This report aims to emphasise the importance of vigilant follow-up in cases with seemingly initial symmetric retinal vascular development.

Methods: Two preterm infants undergoing routine ROP screening were reviewed. Case 1: A preterm infant with bilateral immature retinal vascularisation till Zone 2 was observed at baseline. On subsequent follow-up, he progressed to Stage 2 Zone II ROP in one eye while the fellow eye showed complete vascularisation. Case 2: A preterm infant presented with Stage 1 Zone II ROP unilaterally on the first screening, with the contralateral eye showing only immature vascularisation till Zone 2. Both infants were followed at regular intervals, and fundus findings were documented using indirect ophthalmoscopy.

Results: Case 1: Progression to ROP occurred unilaterally despite initial bilateral immature vascularisation, with no subsequent disease development in the fellow eye. Case 2: ROP was noted only in one eye from the first screening visit, with the opposite eye showing no signs of disease throughout follow-up. Neither case progressed to Type 1 ROP. Both cases showed spontaneous regression.

Conclusions: Although ROP is typically a bilateral disease, unilateral presentations can occur and may be

under-recognized. These cases underscore the need for vigilance during screening and follow-up.

Panel No.: POS-0880

Unveiling Cerebrotendinous Xanthomatosis Through the Eye: Clinical and Genetic Insights

First Author: Bhargavi PIDUGU

Purpose: Cerebrotendinous Xanthomatosis (CTX) is a rare autosomal recessive lipid storage disorder caused by biallelic pathogenic variants in the CYP27A1 gene, leading to defective bile acid synthesis and accumulation of cholestanol in multiple tissues. Early diagnosis is essential, as treatment with chenodeoxycholic or cholic acid can prevent or reverse disease progression.

Methods: This case series presents three children (ages 5, 9, and 10 years) who presented with bilateral posterior subcapsular granular cataracts. Systemic clues included recurrent diarrhoea, ataxia, and jaundice. Based on the distinctive cataract morphology and clinical history, CTX was suspected and confirmed by genetic testing.

Results: Two patients carried homozygous pathogenic variants in CYP27A1 (c.526del and c.380G>A), while one had compound heterozygous variants (c.526delG and c.1263+1G>A). All were started on oral ursodeoxycholic acid. Five of six eyes underwent cataract surgery, while one showed spontaneous resolution with supplementation. Postoperative visual improvement was significant, with one patient's vision improving from 20/200 to 20/20.

Conclusions: Bilateral developmental cataracts, particularly granular posterior subcapsular types, should prompt suspicion for CTX when accompanied by systemic signs such as diarrhea or tendon xanthomas. Genetic confirmation enables timely intervention, potentially halting or reversing systemic and ocular manifestations

Abstract No.: 202636

Use of Soft Contact Lenses in Anisometropia Amblyopia Treatment: A Case Series

First Author: Nguyet Anh NGUYEN

Purpose: Anisometropia is a leading cause of amblyopia in children. Optical correction plays a crucial role in the management of anisometropic amblyopia. Moreover, soft contact lenses can minimize image size differences caused by anisometropia. This study aimed to evaluate the effectiveness of soft contact lenses in the treatment of amblyopia and related factors.

Methods: A retrospective case series was conducted on 7 amblyopia children who wore soft contact lenses at VIVISION KID – Children's Eye Clinic System

(2022–2024), after amblyopia therapy of spectacles and occlusion therapy had been tried. Data collected included demographics, refractive error, best-corrected visual acuity (BCVA) before and after soft contact lens wear, duration of lens wear, and reasons for discontinuation.

Results: Seven children (5 females, 2 males), aged 5–12 years (mean age: 6.8 years), were included. Six had anisometropic myopia (anisometropia ranging from 7.00 to 11.75 D), and one had anisometropic hyperopia (anisometropia of 5.00 D). Baseline BCVA ranged from 0.8 to 1.1 logMAR. After treatment with soft contact lenses, visual acuity improved on average by 0.254 logMAR after 6 months and 0.19 logMAR after 1 year. Two children improved by 4–5 logMAR lines after 1.5 years of contact lens wear. Regarding compliance, one child discontinued after 6 months due to keratitis, and three discontinued after 1 year for geographic or financial reasons.

Conclusions: Soft contact lenses provided significant improvement in visual acuity for the treatment of anisometropic amblyopia. However, risks of infection and compliance issues require long-term monitoring.

Video-Oculography vs. Standard Diagnostic Methods in Binocular Vision Assessment: A Comparative Study

First Author: Igor **AZNAURYAN**

Co-Author(s): Satenik **AGAGULIAN**, Victoria **BALASANYAN**, Evgenii **KUZNETSOV**, Evgenii **MORDYUKOV**

Purpose: To retrospectively analyze and compare the angle of deviation measurements obtained from the videooculograph, non-contact autorefractor, and synoptophore in a cohort of non-amblyopic patients with divergent strabismus.

Methods: This study retrospectively analyzed data from 22 patients (aged 5–38 years, mean age 12.2 ± 7.1 years, 12 females/10 males) with divergent strabismus (type 2) to compare angle measurements across three diagnostic devices: videooculograph, non-contact autorefractor, and synoptophore. All patients had a cyclotropia value ranging from -7 to -40 prism diopters. Best-corrected visual acuity was normal (0.0 logMAR) in both eyes for all subjects, and no amblyopia was documented.

Results: The mean angle of deviation measured by the videooculograph was -16.0 ± 6.2 degrees, the non-contact autorefractor showed -14.8 ± 5.4 degrees, and the Synoptophore measured -15.6 ± 6.7 degrees. Differences between devices were not statistically significant ($p > 0.05$), though individual variability was observed, particularly in cases with higher cyclotropia. Refractive errors, expressed as spherical equivalents,

varied widely among patients (range: -6.875 to +2.125 D), with anisometropia present in 8 cases.

Conclusions: The results indicate good overall agreement between the three methods in quantifying divergent strabismus angles in non-amblyopic patients. However, device-specific discrepancies highlight the importance of standardized measurement protocols in clinical practice. This study supports the use of multiple complementary techniques for accurate strabismus assessment, especially in patients with significant cyclodeviation or anisometropia. Further research with larger samples is warranted to evaluate device reliability in more complex clinical scenarios.

Visual Rehabilitation Outcomes in Pediatric Patients with Multiple Disabilities and Visual Impairment (MDVI): A Retrospective Study in a Tertiary Eye Hospital

First Author: Aura **ARIAPUTRI**

Co-Author(s): Joan Sherlone T. **HUTABARAT**, Ine Renata **MUSA**, Karmelita **SATARI**, Susanti Natalya **SIRAIT**

Purpose: To present the rationale, methods, and outcomes of visual rehabilitation in pediatric patients with multiple disabilities and visual impairment (MDVI) at Cicendo Eye Hospital in 2023, emphasizing the importance of early intervention in this vulnerable group.

Methods: A retrospective cross-sectional study was conducted using medical records of pediatric patients with MDVI who underwent visual rehabilitation at the Pediatric Ophthalmology and Strabismus Clinic and Low Vision Clinic at the National Eye Center, Cicendo Eye Hospital, from January to December 2023. Inclusion criteria were all MDVI-diagnosed pediatric patients who completed rehabilitation. Exclusion criteria included incomplete records, absence of visual acuity or objective refraction data, and loss to follow-up.

Results: Seventy-one patients (142 eyes) were included. Most patients were male (60.56%), aged 0–3 years (71.83%), and residing in West Java (95.77%). Common ocular diagnoses included nystagmus (32.29%), strabismus (19.71%), and cortical visual impairment (16.90%). Systemic comorbidities were global developmental delay (29.57%), cerebral palsy (21.12%), and epilepsy (19.71%). Visual stimulation was the primary rehabilitation method (74.65%). Improvements in visual function were observed, with 6/24 visual acuity increasing from 9.86% to 23.94%, and fix-and-follow ability from 22.4% to 36.62% after therapy.

Conclusions: Structured visual rehabilitation led to meaningful improvements in functional vision among children with MDVI. These findings support the implementation of early, comprehensive rehabilitation

to enhance visual and developmental outcomes in this population.

"10-10" Monocular Surgical Correction in Moderate to Large Angle Exotropia: A Case Series

First Author: Ashfaque Rahman KHAN

Co-Author(s): Syeed Mehbub Ul KADIR

Purpose: Exotropia is a form of strabismus characterized by outward deviation of one eye. This condition may result in impaired binocular vision, cosmetic disfigurement, and psychosocial issues. To evaluate the outcomes of the <10-10> monocular surgical technique for correcting moderate-to-large angle alternative exotropia.

Methods: Alternate exotropia can be challenging to correct in moderate-to-large angle deviations. Traditional surgical options vary, but the need for a precise, balanced technique has led to interest in the <10-10> monocular resection-recession approach. This involves recessing the lateral rectus and resecting the medial rectus by 10 mm in the deviating eye.

Results: A total of thirty-five patients (ages 12–36 years) with alternative exotropia >60 PD and absent binocular single vision were included. Preoperative evaluation involved visual acuity testing, prism cover testing, cycloplegic refraction, orthoptic evaluation, and fundus examination. All patients underwent 10 mm recession of the lateral rectus and 10 mm resection of the medial rectus in the deviating eye (monocular correction). Postoperative outcomes revealed successful alignment in all cases, with no major complications or resurgeries needed.

Conclusions: The 10-10 monocular resection-recession technique offers a reliable and balanced surgical approach to correcting large-angle alternate exotropia. It minimizes the risks of over- or undercorrection and is effective for the patient's visual outcome, cosmesis, and helps overcome the social stigma.

"Beyond-the-Bag" Intraocular Lens Capture in Complicated Pediatric Cataract Surgery

First Author: Rabeeah ZAFAR

Purpose: To compare the learning curve of two surgeons performing lensectomy and posterior optic capture of a multipiece intraocular lens (IOL) in complicated congenital cataracts in children.

Methods: A retrospective comparative analysis was performed on the first 50 cases of posterior optic capture of IOL in pediatric eyes with anterior chamber

abnormalities, carried out by two surgeons: Surgeon 1 (S1), a proficient senior pediatric ophthalmologist, and Surgeon 2 (S2), a trainee pediatric ophthalmologist. The outcomes of the surgery were measured in terms of successful posterior capture of IOL, perioperative and postoperative complications, as assessed by an independent observer using SPSS version 26.0.

Results: The mean age of the patients was 4 ± 2.7 years for S1 and 5 ± 3.1 years for S2. S1 completed the first 50 cases in 5 months, while S2 completed them in 7 months. Successful optic capture was achieved in 48 (96%) cases by S1 and 45 (90%) cases by S2. Complications were observed in 2 cases (4%) for S1 and 5 (10%) cases for S2 ($P < 0.05$). Statistically, there was no significant difference in the learning curve between the surgeons in terms of duration and surgical outcomes ($p < 0.05$).

Conclusions: Posterior optic capture of IOL is an effective and promising modality in pediatric cataracts with anterior segment abnormalities, requiring meticulous tissue handling in small eyes. Despite a steep learning curve noted in existing literature, junior surgeons can quickly learn and master this technique with minimal complications when performing under the direct supervision of an experienced senior surgeon.

Amblyopia Treatment Efficacy in Children: The Advantage of Early Refractive Management

First Author: Igor AZNAURYAN

Co-Author(s): Karmen ARTENIAN, Satenik AGAGULIAN, Victoria BALASANYAN

Purpose: Amblyopia is a neurodevelopmental disorder of vision and a leading cause of preventable monocular visual impairment in children. While conventional treatments such as optical correction, patching, and pharmacological penalization remain standard, emerging evidence emphasizes the critical importance of early refractive management as a foundational therapeutic step.

Methods: Timely optical correction alone can resolve amblyopia in a significant proportion of patients, especially when implemented during the critical period of visual development. Studies demonstrate that providing accurate glasses or contact lenses before initiating occlusion or penalization allows the visual cortex to begin processing clearer input, thereby enhancing neural plasticity. This approach often reduces the duration and intensity of additional therapies required. In cases where amblyopia persists

despite refractive adaptation, subsequent patching or atropine treatment tends to be more effective due to the established optical foundation.

Results: Key outcomes supporting early refractive intervention include improved binocular visual acuity, greater stereoacuity gains, and higher long-term stability of visual function.

Conclusions: Moreover, early correction mitigates the risk of persistent amblyopia and promotes better compliance with combined treatment regimens. The evidence underscores that refractive management should not be regarded merely as a preliminary step, but as a core, active component of amblyopia therapy. Thus, prioritizing early and precise optical correction is essential for maximizing visual outcomes and reducing the burden of care in children with amblyopia.

Analysis of Preoperative Risk Factors for Corneal Ectasia After Small Incision Lenticule Extraction (SMILE)

*First Author: Tie Pei **ZHU***

*Co-Author(s): Hongying **JIN**, Hai Xiu **WU***

Purpose: To investigate the preoperative characteristics and risk factors of corneal ectasia after small incision lenticule extraction (SMILE) through a case series analysis.

Methods: A retrospective case series study was conducted on 9 patients (13 eyes) diagnosed with corneal ectasia following SMILE surgery at the Eye Center of the Second Affiliated Hospital of Medical College of Zhejiang University between January 2014 and December 2022. The study consisted of 5 males and 4 females, with a mean age of 19.9 ± 3.7 years (range: 17–28 years). Preoperative corneal topographic parameters, including mean keratometry (Km), Belin/Ambrosio Deviation (BAD-D) value, and corneal diameter, were collected. Intraoperative parameters such as lenticule thickness (LT), residual stromal bed (RSB) thickness, and optical zone diameter were recorded. Percentage tissue altered (PTA), lenticule thickness index (LTI), and Ectasia Risk Score System (ERSS) score were calculated to summarize the preoperative and intraoperative characteristics of these cases.

Results: Among the nine patients, 75% were younger than 21 years. The mean preoperative spherical equivalent was -5.58 ± 1.64 D. The mean corneal diameter was 11.87 ± 0.22 mm, LT was 106.2 ± 28.3 μ m, RSB thickness was 310.8 ± 26.2 μ m, and LTI was $20.0 \pm 5.2\%$. Some cases presented with large corneas (≥ 12 mm, 4/13 eyes), thin corneas (< 510 μ m, 4/13 eyes), and mildly elevated BAD-D values (1.59 ± 0.46). According to the ERSS, 76.9% (10/13) of eyes were classified as high risk. Compared with previously

reported international cases, this study demonstrated a significantly younger mean age ($u = 8.6$, $P = 0.0065$).

Conclusions: Post-SMILE ectasia was observed predominantly in younger patients, often accompanied by features such as large corneal diameter, thin cornea, and high ERSS scores, even in the absence of typical topographic abnormalities. Preoperative screening should carefully consider the possibility of concurrent risk factors, including large cornea, thin cornea, potentially false-negative BAD-D, and high ERSS scores.

Panel No.: REF-0925

Analysis of the Effects of Perioperative Intervention With Quguang Jueming on Ocular Surface Inflammatory Factors Following TransPRK Surgery

*First Author: Dian **ZHAO***

Purpose: To analyze the effect of perioperative administration of Quguang Jueming on postoperative changes in ocular surface inflammatory factor levels during TransPRK, and to explore the potential mechanism of action of traditional Chinese medicine (TCM) intervention based on the “liver-lung theory” during the perioperative period of laser refractive corneal surgery.

Methods: Prospective study. Cases undergoing TransPRK surgery at the Refractive Surgery Department of Ineye Hospital of Chengdu University of Traditional Chinese Medicine between January 1, 2024, and January 31, 2025, meeting inclusion criteria were enrolled. Subjects were assigned to Group A or Group B based on receipt of TCM intervention. Group A (TCM intervention group) received standard perioperative management for TransPRK plus additional TCM intervention: daily oral administration of Quguang Jueming from 1 day preoperatively to 7 days postoperatively. Group B (non-intervention group) followed routine perioperative management. Patient demographics, preoperative refractive error, preoperative best-corrected visual acuity (BCVA), and uncorrected visual acuity (UCVA) at postoperative 1 week, 1 month, and 3 months were collected. Tear samples were obtained preoperatively and at postoperative 1 day, 4 days, and 7 days. Changes in postoperative UCVA and tear levels of TGF- β 1, PGE2, IL-6, and TNF- α were compared between groups.

Results: Both groups showed significant postoperative improvements in uncorrected visual acuity (UCVA) compared to preoperative levels (all $P < 0.001$). TGF- β 1 levels exhibited a decreasing trend at 1 day, 4 days, and 1 week postoperatively in both groups. TGF- β 1 levels at all postoperative time points were significantly lower in Group A than in Group B, while the change in TGF- β 1 levels (Δ TGF- β 1) at all postoperative time points was higher in Group B than in Group A (all $P < 0.001$). Group B showed increased IL-6 levels at 1

day, 4 days, and 1 week postoperatively compared to preoperative levels ($P < 0.001$). Both groups exhibited a decreasing trend in IL-6 at these time points, with Group A showing significantly lower IL-6 levels than Group B at each postoperative time point (all $P < 0.001$). Group B's Δ IL-6 at postoperative days 1, 4, and 1 week was higher than Group A's ($P < 0.001$). PGE2 levels in both groups showed a decreasing trend at postoperative days 1, 4, and 1 week, with Group A's PGE2 levels at these time points significantly lower than Group B's (all $P < 0.001$); Group B's Δ PGE2 at postoperative day 1 was significantly higher than Group A's. Group A's Δ PGE2 reduction at postoperative week 1 was significantly greater than Group B's. Δ PGE2 in both groups decreased at postoperative days 4 and week 1 compared to day 1 (all $P < 0.001$). Group A showed elevated TNF- α levels at 1 day and 4 days postoperatively compared to preoperative levels, while TNF- α decreased at 1 week postoperatively ($P < 0.001$, $P < 0.001$, $P = 0.007$). TNF- α levels at all postoperative time points in Group A were significantly lower than those in Group B ($P < 0.001$). The change in TNF- α levels at all postoperative time points in Group B was greater than that in Group A ($P < 0.001$).

Conclusions: The perioperative use of Quguang Jueming in TransPRK effectively reduces postoperative levels of inflammatory mediators such as TGF- β 1, PGE2, IL-6, and TNF- α in the ocular surface, thereby alleviating postoperative complications, including pain, haze, and dry eye.

BIOPTIC Technique to Treat High MYOPIC Refractive Errors

First Author: Sami ALRABIAH

Purpose: To evaluate the refractive surgery outcome for patients who have relative corneal thickness insufficiency to correct a relatively high refractive myopic error, using the Biopic technique.

Methods: This study includes 22 patients, 14 female, 8 male, who had refractive error ranging from -7.50 to -9.50 diopters, Corneal thickness ranging from 505-542 microns, and all clinical examinations were within normal limits (Topography, Tomography, Pachmetry, Corneal Biomechanics, and best corrected vision). 1- First step is Femtolasik treatment to correct as much as possible without jeopardizing safety and quality 2- Second step after 6 months, Transepithelial wave front guided PRK on the flap surface, aiming for correction A- residual refractive error as well as B- induced high-order aberrations

Results: All patients could reach the best corrected vision, with almost no or minimal higher-order aberrations.

Conclusions: Biopic technique is not only a method to correct the total refractive power on two stages, but safety is also kept in mind. As second stage is on the flap that has no influence over corneal stability and power. So no harmful effect regarding the stromal thickness, but also it reduces all wave front errors that were induced by regular femto-Lasik, and gives us a much better quality of vision that is comparable to a single treatment for lower degrees of refractive errors

Abstract No.: 204218

Binocular Vision Across All Distances: Six-Month Results of PRESBYOND Laser Vision Correction

First Author: Olesia ZIIATDINOVA

Co-Author(s): Chun Chun HE, Lina ZHOU

Purpose: To evaluate the visual and refractive outcomes of PRESBYOND laser vision correction in patients with presbyopia.

Methods: A retrospective analysis was conducted on 32 patients with presbyopia who underwent bilateral PRESBYOND laser vision correction. Inclusion criteria included age within the presbyopic range, mean spherical error and astigmatism within the treatment range, and adequate corneal thickness. All patients tolerated a -1.50 D anisometropia test prior to surgery. Femtolasik flaps were created using the VisuMax 500 femtosecond laser, and excimer ablation was performed with the MEL 90 using the PRESBYOND software module. Postoperative assessments were performed at 1 day, 1 week, 1 month, 3 months, and 6 months, including autorefractometry, uncorrected visual acuity (UCVA), manifest visual acuity (MVA), and Pentacam measurements.

Results: A high percentage 89% of patients achieved the targeted postoperative refraction. Mean postoperative sphere ± 0.65 D and cylinder ± 0.56 D were within of target at all follow-up visits. The majority of patients reached their target refraction within the first few months after surgery. No patients required enhancement procedures during the 6-month follow-up. Postoperative corneal spherical higher-order aberrations (HOAs) increased within an acceptable range, with a stable mean value at 6 months.

Conclusions: PRESBYOND laser vision correction provides effective binocular vision across all distances in presbyopic patients without signs of cataract, demonstrating good safety, predictability, and stability.

Can Biomechanics Be a Surrogate Marker for Lysyl Oxidases Expression in Patients Undergoing Lenticular Extraction?

First Author: Shweta DEV

Co-Author(s): Apurva BANSOD, Abhijit SINHA ROY, Nimisha

Purpose: Lysyl oxidases (LOXs) are enzymes that enhance corneal tissue strength by cross-linking collagen. This study aimed to identify biomechanics parameters that correlated with LOXs expression as potential surrogate markers.

Methods: In these prospective eyes, 106 eyes undergoing lenticular extraction were included. Each patient underwent scans using Pentacam, Corvis, and polarization-sensitive OCT (PSOCT). The lenticule extracted during surgery was analyzed for LOXs expression using quantitative PCR. Patients were divided into three groups based on LOXs levels. Random Forest AI models were used to correlate LOXs with 24 corneal biomechanics and PSOCT parameters.

Results: LOXs and Cola1 increased from group 1 to 3. In group 3, CBI and SP-A1 values showed significant correlation.

Conclusions: This study aids in determining the need for the Xtra procedure based on biomechanics values alone.

Panel No.: REF-0924

Clinical Outcomes of RIL: A No-Central Hole Unique Model Phakic Intraocular Lens

First Author: Ankeeta THALI

Co-Author(s): Jagadeesh REDDY, Vandhana SUNDARAM

Purpose: To evaluate the clinical outcomes of a novel refractive implantable lens (RIL) in patients with refractive error, corneal ectasia, and post-deep anterior lamellar keratoplasty (DALK).

Methods: This retrospective analysis included 60 eyes of 40 patients who underwent implantation of RIL with four peripheral holes and no central hole, eliminating the need for peripheral iridotomy and avoiding potential glare from a central hole. The lens is available in a wide range of powers (-1 to -23 diopters [D], up to +10 D, and cylindrical powers up to 16 D). Clinical records were reviewed over 12 months. Parameters assessed included uncorrected visual acuity (UCVA), best-corrected visual acuity (BCVA), intraocular pressure (IOP), vault, lens rotation, and endothelial cell count.

Results: Significant improvement was observed in visual and refractive outcomes from preoperative values to 1 month postoperatively ($P < 0.05$). Mean

logMAR UCVA improved from 1.1 ± 0.1 to 0.3 ± 0.1 . Spherical error reduced from 5.4 ± 3.8 D to 0.3 ± 0.1 D, and cylindrical error reduced from 5.4 ± 3.2 D to 0.8 ± 0.7 D. Postoperative complications occurred in only 3 of 60 eyes: one cataract, one case of severe inflammation (resolved with treatment), and one IOL rotation (repositioned). No other complications were noted.

Conclusions: This unique RIL design provides effective visual rehabilitation and appears to be a safe and reliable option for correcting high ametropia, including in complex corneal conditions.

Abstract No.: 202612

Panel No.: REF-0918

Comparison of the Correction Effects of Different Corneal Laser Surgeries for Asymmetric Corneal Astigmatism

First Author: Riping ZHANG

Co-Author(s): Yi ZHANG

Purpose: To compare optical zone decentration and corneal high-order aberrations (HOAs) after selective corneal wavefront aberration-guided femtosecond laser-assisted in situ keratomileusis (CW-FS-LASIK), aberration-free FS-LASIK (AF-FS-LASIK), and small incision lenticule extraction (SMILE).

Methods: A retrospective analysis included 58 eyes treated with CW-FS-LASIK, 67 with AF-FS-LASIK, and 106 with SMILE at Joint Shantou International Eye Center between 2018 and 2024. Patients had myopia (-1.00 to -6.00 D) and asymmetric corneal astigmatism (corneal topography with inferior-superior dioptric difference ≥ 1.00 D within the central 3 mm). Visual acuity, refraction, and corneal topography were evaluated preoperatively and 1 month postoperatively. HOAs were measured over 4 mm and 6 mm zones using Pentacam, and tangential curvature difference maps were processed in ImageJ for effective optical zone diameter (EOZ) and decentration. Statistical comparisons used ANOVA and Kruskal-Wallis tests.

Results: Preoperative parameters and HOAs were comparable. Postoperative visual acuity was comparable. The SMILE group showed a larger EOZ than both FS-LASIK groups ($P < 0.001$) with no significant difference in decentration. At 4 mm zone, CW-FS-LASIK showed the lowest HOAs, vertical and total coma. At 6 mm zone, CW-FS-LASIK had the lowest vertical and total coma ($P < 0.001$), while SMILE demonstrated the lowest spherical aberration ($P < 0.05$).

Conclusions: In asymmetric corneal astigmatism, CW-FS-LASIK reduces HOAs and coma, whereas SMILE better controls spherical aberration and enlarges EOZ. Surgical choice should consider astigmatism patterns and visual quality.

Abstract No.: 206685

Panel No.: REF-0932

Comparisons of Visual Function Under Different Optical Zone Ranges in TransPRK Surgery

First Author: Fanfei MA

Purpose: To evaluate the efficacy of large optical zones (OZ) in TransPRK for correcting low-to-moderate myopia in patients with large dark pupil diameters (≥ 7 mm).

Methods: A retrospective study included 145 myopic eyes (-0.50 to -6.00 D) from 80 patients (17–36 years) undergoing TransPRK. Eyes were divided into Group A (pupil diameter ≥ 7 mm, $n = 72$) and Group B (< 7 mm, $n = 73$). OZ sizes (6.5–7.3 mm) varied between groups, with Group A having more eyes treated with OZ ≥ 7.0 mm (40/72 vs. 11/73 in Group B). Preoperative and 3-month postoperative assessments included visual acuity, intraocular pressure (IOP), corneal spherical aberration (SA), corneal higher-order aberrations (HOAs), total higher-order aberrations (THOAs), total coma (T.Coma), and modulation transfer function (MTF). Statistical analyses included linear mixed-effects models (LMMs, random intercepts for patient ID and eye nested within patient) for within-group (preoperative vs. postoperative) and between-group comparisons. Exploratory cluster-robust Pearson correlation analyses were performed within the Generalized Estimating Equations (GEE) framework with Benjamini–Hochberg false discovery rate (BH-FDR) correction. Exploratory backward stepwise multivariate linear mixed-effects regression (patient ID as random intercept) suggested factors associated with postoperative HOAs, with variance inflation factor (VIF) tests ($VIF < 5$) to exclude multicollinearity.

Results: Both groups showed significant improvements in MTF(Total) postoperatively (Group A: 15.47% vs. 43.67%, $P < 0.001$; Group B: 15.84% vs. 45.95%, $P < 0.001$). In group B, MTF(HO) decreased (76.28% vs. 63.20%, $P < 0.001$), while T. Coma increased (Group A: 0.18 vs. 0.27 μm , $P = 0.004$; Group B: 0.19 vs. 0.30 μm , $P < 0.001$). Cluster-robust correlation analyses showed HOAs were strongly correlated with THOAs ($r = 0.432$, BH-FDR $q = 0.0008$), T.Coma ($r = 0.389$, BH-FDR $q = 0.0008$), and MTF(HO) ($r = -0.295$, BH-FDR $q = 0.0008$). MTF(HO) was positively associated with OZ size ($r = 0.218$, BH-FDR $q = 0.024$), while THOAs showed no significant association with OZ after FDR correction ($r = -0.172$, BH-FDR $q = 0.082$). Exploratory multivariate linear mixed-effects regression confirmed OZ size was negatively associated with postoperative HOAs in Group A ($\beta = -0.215$, robust SE = 0.084, BH-FDR $q = 0.0195$; adjusted $R^2 = 0.386$), but not in Group B ($\beta = -0.082$, BH-FDR $q = 0.3725$).

Conclusions: TransPRK effectively corrects low to moderate myopia in patients with large pupils, with stable postoperative visual function. Within the scope

of this study, the postoperative objective optical indicators (e.g., MTF, HOAs) in Group A treated with larger OZs show no statistically significant difference from those in Group B.

Abstract No.: 205364

Panel No.: REF-0929

Corneal Asphericity Preservation via Spatially-Selective Peripheral Stromal Volume Ablation Following Ray-Tracing-Guided LASIK

First Author: Bo YUAN

Co-Author(s): Jingwen CHAI, Xuzhao GUO, Xia HUA, Bo ZHAO

Purpose: To quantitatively appraise postoperative visual quality and to delineate the spatial corneal morphological changes occurring within the central and pericentral optical zones subsequent to ray-tracing-guided laser-assisted in situ keratomileusis (RT-LASIK) compared to Q-value-guided LASIK (Q-LASIK).

Methods: Sixty patients were enrolled. The means of preoperative spherical equivalent (SE) were -5.029 ± 1.532 D in the RT-LASIK group and -5.279 ± 1.779 D in the Q-LASIK group ($n=30$ each). The cornea was partitioned into three vertex-centered concentric regions: a central 0–3 mm optical zone, a paracentral 3–5 mm annulus, and a pericentral 5–7 mm annulus. The corneal ablation ratio (CAR) was calculated as the quotient of the preoperative-to-postoperative reduction in either corneal thickness (tCAR) or stromal volume (vCAR) divided by the absolute value of the preoperative SE.

Results: The RT-LASIK group exhibited significantly superior UDVA, SE, and 3-mm Strehl ratio post-operatively. Concurrently, RT-LASIK yielded markedly steeper corneal curvature in the nasal and temporal sectors of the 3–5 mm paracentral annulus. vCAR within the same 3–5 mm zone was also significantly elevated in the RT-LASIK group, whereas tCAR did not differ between groups. Furthermore, RT-LASIK was associated with a significantly attenuated post-operative change in Q-value within the 5-mm zone, a more pronounced reduction in spherical aberration across the 3-, 5-, and 7-mm optical zones, and a comparatively greater increase in coma aberration within the 5-mm zone.

Conclusions: RT-LASIK conferred superior post-operative visual performance by conserving native corneal asphericity and reducing SA. This optical advantage was mediated by a proportionally greater ablation of stromal volume within the paracentral 3–5 mm annulus.

Abstract No.: 207832

Panel No.: REF-0935

Design of Progressive Addition Lens for Presbyopia: A Systematic Review

First Author: Jijing LI

Co-Author(s): Mingguang HE, Yue WU

Purpose: This systematic review synthesizes recent evidence (2015 - 2025) on the technical design of Progressive Addition Lenses (PALs) for presbyopia, focusing on key developments in design methodologies, performance evaluation, and emerging lens concepts.

Methods: A systematic search of six databases (PubMed, Embase, Web of Science, Cochrane Library, Scopus, SPIE Digital Library) was conducted following PRISMA guidelines. Eligible studies included original research on PALs' design principles, optimization algorithms, evaluation techniques, or novel optical concepts. Study quality was assessed using a customized 12-dimensional framework.

Results: The review included 17 eligible studies. Three major thematic areas of advancement were identified: the maturation of freeform surface design as the primary method for creating complex optical surfaces; the development of advanced optical evaluation techniques enabling objective quantification of lens performance; and the emergence of novel lens concepts expanding design possibilities beyond conventional refractive approaches. Key progress was noted in algorithmic optimization for astigmatism control and the shift from subjective assessment to data-driven performance validation.

Conclusions: PALs design has evolved significantly toward customized, algorithm-driven solutions. However, challenges remain in standardizing clinical fitting, understanding neural adaptation, and developing personalized designs for diverse presbyopic subpopulations. Future progress will hinge on deeper interdisciplinary integration to evolve PALs from standardized corrections into adaptive visual wearables.

Diagnosis and Management of Bacterial Keratitis Following Transepithelial Photorefractive Keratectomy: A Case Report

First Author: Aiqin NIE

Purpose: To describe the clinical presentation, diagnostic approach, and management of bacterial keratitis following transepithelial photorefractive keratectomy (TransPRK), and to highlight strategies for improving outcomes in this serious postoperative complication.

Methods: A retrospective case analysis was performed on a 36-year-old male who developed acute bacterial

keratitis in the left eye 18 days after undergoing bilateral TransPRK. The patient presented with a sudden onset of ocular redness, pain, and decreased vision. Diagnosis was established based on clinical history, examination findings, and ancillary testing. Upon admission, the patient received intensive topical and systemic antimicrobial therapy, anti-inflammatory agents, and mydriatics. Treatment was adjusted according to clinical response.

Results: At presentation, the left eye exhibited central corneal stromal opacity with hypopyon. Intensive topical vancomycin (50 mg/ml), levofloxacin, tobramycin, subconjunctival vancomycin injection, and systemic ceftazidime were administered. Hypopyon resolved within two days, visual acuity improved to 0.15 by day four, and reached 1.0- by day ten. At 1.5 months post-treatment, both eyes achieved good visual acuity, with a residual central corneal opacity in the left eye.

Conclusions: Bacterial keratitis following TransPRK is characterized by rapid onset and progression. Early recognition and prompt, standardized antimicrobial therapy are critical for favorable outcomes. While medical management is the first-line approach, surgical intervention should be considered in refractory or severe cases. Postoperative care should emphasize corneal epithelial healing and mitigation of infection risk factors.

ELITA vs VisuMax 800: A Clinical Comparison for Astigmatic Keratorefractive Lenticule Extraction

First Author: Chen-cheng CHAO

Co-Author(s): Chao-kai CHANG, Chien-cheng CHIEN, Yu-hsuan LU, You-ci OU

Purpose: To compare the clinical outcomes of astigmatism correction following keratorefractive lenticule extraction (KLEx) performed with the VisuMax 800 (Carl Zeiss) and ELITA (Johnson and Johnson).

Methods: This was a retrospective, non-randomized, multi-center clinical study of patients undergoing KLEx surgery for myopic astigmatism using the VisuMax 800 and ELITA. Patients with moderate to severe astigmatism (≥ 1.50 D) were included. The data were collected from one eye of each patient. The uncorrected visual acuity, best-corrected visual acuity, and residual refractive error were measured 1 month postoperatively.

Results: A total of 50 and 58 eyes were categorized into the ELITA and VisuMax 800 groups, respectively. Visual acuity, refraction, topographic parameters, and surgical indices were recorded. Independent t-tests were used to compare the postoperative uncorrected distance visual acuity (UDVA), spherical equivalent (SE), and residual astigmatism between the two groups. The

difference in UDVA was not significant 1 month after KLEx surgery ($p = 0.513$), and the SEs 1 month after surgery were also similar between the two groups ($p = 0.440$). There was also no significant difference in residual astigmatism between the groups ($p = 0.341$).

Conclusions: ELITA and VisuMax 800 provided excellent visual and refractive outcomes for subjects with myopic astigmatism. The VisuMax 800, using Oculign and Centralign aids, demonstrated similar accuracy when correcting cylinder ≥ 1.50 D compared to the ELITA using manual cyclotorsion compensation.

Early Corneal Epithelial Thickness Changes in the Optical Zone Following Small Incision Lenticule Extraction for High Myopia

First Author: Aiqin **NIE**

Co-Author(s): Xingtao **ZHOU**

Purpose: To investigate the early changes in corneal epithelial thickness in the optical zone after small incision lenticule extraction (SMILE) for myopia correction.

Methods: A total of 60 patients (24 males, 36 females; aged 18–40 years) who underwent SMILE for myopia or myopic astigmatism since April 2023 were enrolled. Patients were divided into two groups based on refractive error: Group A (high myopia, 30 eyes) and Group B (mild to moderate myopia, 30 eyes). Preoperative and postoperative examinations included visual acuity, refraction, Pentacam, and anterior segment optical coherence tomography (OCT; RTVue, Optovue) to measure corneal epithelial thickness in the central 0–2 mm, 2–5 mm, 5–7 mm, and 7–9 mm zones. All patients underwent standard SMILE and were followed for 3 months. Statistical analysis was performed using SPSS 26.0, with $P < 0.05$ considered significant.

Results: Preoperatively, corneal epithelial thickness did not differ significantly between groups. At 3 months postoperatively, Group B showed significant epithelial thickening in the central 0–2 mm, 2–5 mm, and 5–7 mm zones ($P < 0.05$), while Group A exhibited more pronounced thickening in these zones ($P < 0.05$). The increase in epithelial thickness was significantly greater in the high myopia group compared to the mild to moderate group ($P < 0.05$).

Conclusions: Corneal epithelial remodeling occurs after SMILE, with significant thickening in the optical zone. The degree of thickening is more pronounced in eyes with higher myopia.

Efficacy and Safety of Toric Implantable Collamer Lens Implantation in Myopic Eyes with Asymmetric Bow-Tie Corneal Astigmatism: A Prospective Comparative Study

First Author: Xue **DING**

Co-Author(s): Shaowei **LI**, Wenjuan **WANG**, Dan **WEI**

Purpose: To evaluate the efficacy and safety of toric implantable collamer lens (Toric ICL) implantation for myopia with asymmetric bow-tie corneal astigmatism.

Methods: In this prospective cohort study, 25 eyes of 16 patients with asymmetric bow-tie astigmatism and 41 eyes of 24 patients with symmetric bow-tie astigmatism underwent Toric ICL implantation. Pentacam HR was used for corneal topography. Uncorrected and corrected distance visual acuities (UDVA and CDVA), refraction, astigmatic changes (vector analysis), and higher-order aberrations (HOAs) were evaluated preoperatively and at 1, 3, and 6 months postoperatively.

Results: Preoperative astigmatism was -2.24 ± 0.85 D in the asymmetric group and -2.11 ± 0.92 D in the symmetric group. Postoperatively, 100% of eyes in both groups achieved UDVA $\geq 20/20$ and UDVA equal to or better than preoperative CDVA. Spherical equivalent within ± 0.50 D was achieved in 80% (asymmetric) and 83% (symmetric) of eyes. Mean residual astigmatism at 6 months was -0.60 ± 0.41 D (asymmetric) and -0.47 ± 0.35 D (symmetric) (both $P < 0.01$ vs. baseline), with no significant inter-group difference. Vector analysis showed correction indices of 0.87 ± 0.26 and 0.95 ± 0.19 , respectively ($P > 0.05$). HOAs increased comparably in both groups. No complications occurred.

Conclusions: Toric ICL implantation effectively and safely corrects asymmetric bow-tie corneal astigmatism, with refractive and visual outcomes comparable to those in symmetric bow-tie astigmatism.

Epithelial Regrowth and Epithelial Refractive Outcomes After cTen™: A Ray-Tracing

First Author: Yue **FENG**

Co-Author(s): Mule' **GIULIO**, Xue-min **LI**, Aleksandar **STOJANOVIC**

Purpose: To evaluate the morphological and refractive changes in the corneal epithelium following cTen™ customized TPRK and assess the role of a constant gradient of curvature in promoting homogeneous epithelial regrowth.

Methods: This study analyzed patients with regular corneas undergoing TPRK using the iVis laser Suite (iVIS Technologies, Taranto, Italy) for myopic/astigmatic

refractive error. Preoperative and postoperative epithelial thickness and ray-tracing refractive power were measured within the central 6.0 mm diameter using the Preciso® 2 tomographer at 1, 3, and 6 months.

Results: Thirty-one eyes in 31 patients were included in this study, with a mean age of 36.6 ± 7.98 years, with average refractive error: spherical -3.25 ± 1.88 D; cylinder -1.17 ± 1.14 D. Postoperatively, the average epithelial thickness decreased by $5.6 \mu\text{m}$ (11%) at 1 month but nearly returned to preoperative values by 6 months. A transient hyperopic shift of 0.4 D (37%) was observed at 1 month, resolving completely by 6 months. The standard deviation of epithelial thickness and refractive power increased at 1 month but trended toward preoperative values over time, indicating reduced variability and improved predictability. UCVA improved significantly, with 19 eyes achieving 20/20 or better at 1 month and 26 eyes at 6 months.

Conclusions: The study demonstrates that cTen® surgery, combined with a customized ablation profile ensuring a constant gradient of curvature, facilitates smooth epithelial regrowth and restoration of preoperative epithelial properties within 6 months. This contributes to stable refractive outcomes and long-term success, underscoring the importance of epithelial remodeling in optimizing visual results.

Improved Surgical Efficiency and Vision With Optimized Phacoemulsification Settings

First Author: Cindy Prajna **METTA**

Co-Author(s): Ruth **ANASTASIA**, *Clarissa* **LISTER**, *Laksono Bagus* **SASMITO**

Purpose: Efficient phacoemulsification requires minimizing surgical time and ultrasound energy while preserving optimal visual outcomes. Refinement of phaco modulation parameters may directly influence both intraoperative performance and postoperative recovery. This study compared two modulation settings in mature cataract surgery.

Methods: Twenty eyes with mature cataracts that underwent phacoemulsification between February and March 2025 were included. Patients were randomized to Group 1 (power 50%, vacuum 400 mmHg) or Group 2 (power 50%, vacuum 350 mmHg, DC 70%, PPS 50). Outcomes included surgical duration, absolute phaco time (APT), effective phaco time (EPT), and one-week postoperative visual acuity (VA, logMAR). Independent t-tests were used, with significance defined as $p < 0.05$.

Results: Group 1 achieved significantly shorter surgical duration (4.62 vs. 6.03 minutes, $p = 0.005$) and better postoperative VA (0.25 vs. 0.56 logMAR, $p = 0.006$). Although differences in APT (67.17 vs. 68.17 seconds, $p = 0.48$) and EPT (19.62 vs. 24.70 seconds, $p =$

0.09) were not statistically significant, both favored Group 1. These findings indicate that higher vacuum with standard duty cycle can improve efficiency and accelerate early visual recovery without increasing ultrasound energy use.

Conclusions: Phaco modulation parameters significantly influence both surgical efficiency and visual outcomes. A higher-vacuum setting enhanced intraoperative performance and postoperative vision in mature cataracts. Optimizing phaco settings may represent a simple yet effective strategy to enhance surgical outcomes in mature cataracts.

Integrative Transcriptome and Machine Learning Identify Molecular Drivers of Corneal Epithelial Hyperplasia in Postoperative Refractive Regression and Novel Therapeutic Candidates

First Author: Chuzhi **PENG**

Co-Author(s): Xi **CHEN**, *Keming* **YU**, *Jing* **ZHUANG**

Purpose: Postoperative refractive regression following corneal laser surgery is frequently associated with aberrant corneal epithelial hyperplasia (CEH), yet its underlying molecular mechanisms remain poorly elucidated. This study aims to delineate the transcriptomic landscape and identify key pathogenic drivers and potential therapeutic agents for this condition.

Methods: We performed comprehensive transcriptome sequencing on corneal epithelial samples from patients exhibiting regression versus controls. Bioinformatic analyses, including differential expression, pathway enrichment, and network analysis, were integrated with advanced machine learning algorithms to pinpoint core regulatory genes. Candidate small-molecule therapeutics were predicted via computational drug repurposing platforms and validated through a series of in vitro and ex vivo functional assays.

Results: Transcriptome profiling identified a signature of 152 significantly dysregulated genes in the regression cohort. Critical pathways were markedly enriched, including p53 signaling, cell cycle progression, and ECM-receptor interaction. Machine learning pinpointed a core regulatory network centered on genes such as CDK1, CCNB1, AURKB, and ITGA2. A top-ranked predicted compound, Toceranib, effectively suppressed hyperproliferation and downregulated these key targets in validation assays. Subsequent animal experiments confirmed its efficacy in suppressing pathological epithelial hyperproliferation in relevant models.

Conclusions: This study delineates the molecular characterization of CEH-driven postoperative refractive regression, uncovering critical pathogenic networks and regulatory hubs. The identification and preliminary

validation of candidate therapeutics provide a foundational framework for developing novel strategies to prevent or treat this postsurgical complication.

Late Sterile Subflap Inflammation After FS-LASIK Treated With 0.05% Cyclosporine Eye Drops: A Case Report

First Author: Luo HUI HUI

Co-Author(s): Qu HAO KUN, He JING XIN, Liang XIAN JUN, Lin YING JIE

Purpose: A 27-year-old man had bilateral FS-LASIK on 20 Dec 2024. Surgery revealed bilateral epithelial erosions and heavy surface lipid. Careful subflap irrigation and bandage lenses were applied. 1st day after surgery, visual acuity (VA): 1.5 OD, 1.0 OS. Moderate lipid lay beneath the mid-lower left flap, sharply demarcated. Bandage lenses were removed; both eyes received tobramycin-dexamethasone and hyaluronate 4 times/day. 1 week after surgery, VA: 1.5 OU, and the patient was satisfied. Left flap lipid unchanged. Tobramycin-dexamethasone stopped; both eyes switched to 0.1 % flumetholone 3 times/day (TID), tapered weekly, and ceased 1 month after surgery. 1.5 months after surgery, the patient complained a decrease VA in the left eye, with VA 1.5 OD, 0.8 OS. The left cornea showed mild, diffuse lipid-related turbidity, causing sterile inflammation and vision loss.

Methods: Left eye received 0.05% cyclosporine TID. 3 months after surgery, the left-eye vision remained poor, with VA 1.5 OD, 1.0 OS, and the left mid-lower flap turbidity unchanged. The epithelial thickness of the left eye was checked with intalight OCT, and the result showed central-lower epithelium thinned, worse temporally. Irrigation was advised but refused due to prior epithelial erosion; cyclosporine TID continued.

Results: Six months after surgery, VA was 1.5 OU, and the patient was pleased! Left flap turbidity resolved, and lipid margins cleared.

Conclusions: Late sterile FS-LASIK subflap inflammation with vision loss may respond to 0.05 % cyclosporine drops, the recommended course is 3–6 months.

Long-Term Clinical Outcomes of Posterior Chamber Phakic Intraocular Lenses Implantation for the Treatment of Refractive Errors Patients

First Author: Tuan VU-ANH

Co-Author(s): Quynh Anh NGUYEN PHUONG, Trang PHAM- THU

Purpose: To describe the clinical demography and the long-term efficacy, safety outcomes, and the adverse

events after implanting the posterior chamber phakic intraocular lenses.

Methods: This study evaluated 122 eyes of 62 patients who underwent posterior chamber phakic intraocular lens implantation from 1/2017 to 12/2018. The results were recorded before surgery, after surgery 1 day, and after surgery 7 years. The data collected included: the uncorrected distance visual acuity (UDVA); best-spectacle corrected visual acuity (BCVA) in Snellen and Logmar scale; efficacy index (post-operative UDVA/preoperative CDVA); spherical equivalent (SE); endothelial cell density (ECD), and intra-ocular pressure (IOP) and incidences of adverse events.

Results: The mean age of patients in surgery is 24.89 ± 5.2 . The mean preoperative SE was $-8.51 \pm 2.91D$, the mean preoperative sphere was $-7.90 \pm 2.91D$. After 1 day postoperative, 94% of the patients had UDVA better than 20/30 (Snellen scale). The means of UDVA after surgery on day 1 and the BCVA before surgery do not differ. The mean UDVA after 7 years and BCVA before surgery are 0.14 ± 0.2 and $0.03 \pm 0.1 \log MAR$, respectively. So the mean logMAR UDVA after 7 years decreased by 1 line than the mean BCVA before surgery. These comparisons pair test demonstrated significant differences with $p < 0.001$. The mean endothelial cell density loss was $3.89\% \pm 5.78$. The mean vault is $465 \pm 217 \mu m$. After 7 years, there are no patients who need to exchange lenses because of the rotation of lenses. Increased intraocular pressure was found in 3 eyes (2.34%) that need to do laser iridectomy, and two out of three eyes (1.6%) require additional eye drops to lower eye pressure. Two eyes (1.6%) were found to have cataract and oval iris. The mean efficacy index is 0.84.

Conclusions: Over 7 years of follow-up, the Implantation of posterior chamber phakic intraocular lenses is an effective surgery for the treatment of high myopia and has stable efficacy.

Abstract No.: 204669

Navigating Femtosecond LASIK in the Presence of Bilateral Asteroid Hyalosis: A Case Report Highlighting Surgical Planning and Intraoperative Challenges

First Author: Tommy TRI ATMAJA

Co-Author(s): Chairunnisa KARIM CHAN

Purpose: To report a rare case of high myopia with bilateral asteroid hyalosis (AH) undergoing femtosecond LASIK, emphasizing preoperative planning, intraoperative considerations, and postoperative outcomes.

Methods: A 38-year-old female with high myopia and bilateral AH presented for refractive surgery to achieve spectacle independence. Preoperative assessment included uncorrected distance visual acuity (UCVA),

best-corrected distance visual acuity (BCVA), manifest refraction, corneal tomography and topography using the Schwind Sirius, and a comprehensive fundus examination to evaluate asteroid body density and location. Measurements were repeated to ensure accuracy and stability. The procedure utilized the Victus femtosecond laser for flap creation and the Schwind Amaris 750s for excimer laser ablation. Preoperative and postoperative UDVA, BCVA, and intraoperative observations were documented.

Results: Preoperatively, UCVA was 3/60 in both eyes. The BCVA was 20/20 with a manifest refraction of -5.00 sphere in the right eye (OD) and -4.50 sphere with -0.50 cylinder at 90° in the left eye (OS). Fundus examination revealed mild-to-moderate asteroid deposits with clear visualization of the optic disc and retinal vasculature. Corneal imaging remained accurate and reproducible despite AH. The surgery proceeded uneventfully with no suction loss, flap irregularities, or pupillary tracking errors. At one week postoperatively, UDVA improved to 20/15 in OD and 20/20 in OS. The patient reported excellent visual satisfaction, stable refraction, and rapid recovery with no intraoperative or postoperative complications.

Conclusions: Femtosecond LASIK can be safely performed in mild-to-moderate AH with careful planning and monitoring. Dense asteroid deposits may reduce image quality, affecting surgical precision and outcomes, requiring thorough evaluation and technique adjustments.

Prediction of Ultrasound Biomicroscopy-Based Horizontal Sulcus-to-Sulcus Distance Using Non-Contact Anterior Segment Parameters

First Author: Ruofan LI

Co-Author(s): Xuemin LI, Haocheng XIAN

Purpose: To develop and validate a formula for predicting Horizontal Sulcus-to-Sulcus (H-STs) measured via Ultrasound Biomicroscopy (UBM) using non-invasive optical parameters to facilitate preoperative planning.

Methods: This study enrolled high myopia patients scheduled for intraocular lens implantation at Peking University Third Hospital. Preoperative UBM and multimodal imaging parameters from anterior segment optical coherence tomography (AS-OCT), IOL-Master, and Sirius were collected. A prediction model was developed through multiple linear regression and evaluated by the coefficient of determination (R^2), root mean square error (RMSE), and mean absolute error (MAE).

Results: The data analysis was based on 1,946 high myopia patients (3,892 eyes). Seven parameters were

incorporated into the final model: angle-to-angle distance (ATA) and crystalline lens rise (CLR) from AS-OCT; corneal volume, iridocorneal angle (IC angle), and flat keratometry (K1) from Sirius; axial length (AL) and white-to-white distance (WTW) from IOL-Master. The model achieved an R^2 value of 0.501. Bootstrap validation yielded an RMSE of 0.370 (95% CI: 0.370–0.372) and an MAE of 0.288 (95% CI: 0.286–0.289). External validation on 1,166 eyes indicated consistent performance ($R^2=0.496$, RMSE=0.378, MAE=0.292). Bland–Altman analysis demonstrated excellent agreement with a mean difference of 0.010 mm.

Conclusions: The prediction model based on seven routinely measured optical parameters provides an accurate and clinician-friendly method for estimating post-operative H-STs before surgery. This approach may reduce unnecessary UBM examinations and refine intraocular lens selection.

Rotational Stability, and Visual Outcomes of Toric Implantable Collamer Lenses (EVO-TICL) in Eyes With Non-Horizontal Implanting Orientation: A Prospective Observational Study

First Author: Xiaoe FAN

Co-Author(s): Teruko Fukuyam

Purpose: To evaluate the short-term rotational stability and visual outcomes of EVO-TICL with non-horizontal implantation orientation.

Methods: Seventy-seven eyes of 51 patients were enrolled in this prospective study. There were 36 eyes with non-horizontal orientation and 41 eyes with horizontal orientation of the TICL. Visual acuity, refractive parameters, and axial position of the EVO-TICL were measured preoperatively at 1week, 1month, and 3 months postoperatively.

Results: Postoperatively, there were no statistically significant differences between the two groups in UDVA ($p = 0.940$), spherical equivalent ($p = 0.283$), cylinder ($p = 0.156$), or rotation degree ($p = 0.385$). In the non-horizontal group at final follow-up, the safety index was 1.22 ± 0.21 , and the efficacy index was 1.17 ± 0.15 . The best-fitting curve of attempted versus achieved correction was $y = 1.02x + 0.01$. Mean spherical equivalent improved from -8.74 ± 3.17 D preoperatively to -0.14 ± 0.50 D at 3 months postoperatively, with mean surgically induced astigmatism of -0.33 ± 0.32 D. The absolute rotation was $2.69 \pm 2.11^\circ$ (range $0-10^\circ$) at 1 month and $3.15 \pm 2.85^\circ$ (range $0-11^\circ$) at 3 months. Expected astigmatism was -0.11 ± 0.03 D compared to actual astigmatism of -0.33 ± 0.32 D at 3 months. For refractive outcomes, 88.89% of eyes were within ± 0.50 D of expected SE and 100% within ± 1.00 D, while 71.7% had astigmatism correction within ± 0.50 D and 96.22% within ± 1.00 D of attempted correction.

Conclusions: EVO-TICL with non-horizontal implantation orientation demonstrates good safety, efficacy, predictability, and stability, with a relatively stable axial position postoperatively.

Seven-Year Clinical Outcomes of Implantable Collamer Lens Implantation Versus KLEx for Myopia Correction: A Contralateral Eye Analysis

First Author: Mingrui **CHENG**

Co-Author(s): Xiaoying **WANG**

Purpose: This study aims to compare the seven-year clinical outcomes of Implantable Collamer Lens (ICL) implantation and Keratorefractive Lenticule Extraction (KLEx) for the correction of myopia in patients with anisometropia, with a focus on evaluating long-term refractive stability, visual quality, and patient satisfaction.

Methods: A contralateral eye analysis was conducted on 25 patients with stable myopia. Comprehensive preoperative evaluations included assessments of visual acuity, refractive error, corneal topography, and endothelial cell density. ICL V4c implantation and KLEx were performed following standardized surgical protocols. Postoperative follow-up evaluations at 1 month and 7 years included measurements of visual acuity, refractive stability, wavefront aberrations, retinal image quality, and patient-reported visual disturbances.

Results: A contralateral eye analysis was conducted on 25 patients with stable myopia. Comprehensive preoperative evaluations included assessments of visual acuity, refractive error, corneal topography, and endothelial cell density. ICL V4c implantation and KLEx were performed following standardized surgical protocols. Postoperative follow-up evaluations at 1 month and 7 years included measurements of visual acuity, refractive stability, wavefront aberrations, retinal image quality, and patient-reported visual disturbances.

Conclusions: Both ICL and KLEx are effective for long-term myopia correction, with ICL offering superior visual quality and stability, particularly in patients with high myopia. The combination of these techniques in anisometropic patients is feasible and provides a personalized treatment approach, ultimately enhancing overall visual outcomes and patient satisfaction.

Toric Versus Non-toric Implantable Collamer Lens Implantation for Low Myopic Astigmatism: 12-month Follow-up

First Author: He **HAIYAN**

Purpose: To evaluate and compare the visual and refractive outcomes of TICL and ICL implantation in patients with low myopic astigmatism.

Methods: This retrospective study included 64 eyes of 64 patients with low myopic astigmatism who underwent TICL or ICL implantation. Visual acuity, refractive outcomes, visual quality, and ocular parameters were assessed at baseline, 3 months, and 12 months postoperatively. The surgical results were evaluated using statistical and astigmatism vector analysis methods.

Results: The safety index was 1.24 ± 0.17 for TICL and 1.21 ± 0.17 for ICL ($p = 0.534$). The efficacy index was 1.19 ± 0.18 for TICL and 1.07 ± 0.16 for ICL ($p = 0.003$). The uncorrected visual acuity at 12 months was -0.07 ± 0.06 in the TICL group and -0.02 ± 0.07 in the ICL group, respectively ($p = 0.006$). The postoperative astigmatism was -0.05 ± 0.18 D in the TICL group, and -0.44 ± 0.38 D in the ICL group ($p < 0.001$). Both groups exhibited good predictability ($R^2 > 0.98$) and long-term stability for postoperative refraction, as well as a significant increase in visual quality ($p < 0.001$). The correction index was 0.95 and 0.48 in the TICL and ICL groups, respectively.

Conclusions: TICL and ICL demonstrated favorable safety, predictability, and comparable improvement in visual quality for low astigmatic patients in the long term. Nevertheless, compared to ICL, TICL presented superior efficacy, stability, postoperative visual acuity, as well as better astigmatism correcting outcomes.

Visual, Refractive and Satisfaction Outcomes Following Myopic Presbyond Treatment in the Philippines: A Retrospective Cohort Study

First Author: Cristina Erika **ELAZEGUI**

Co-Author(s): Nicolette **CHUA**, Reginald **TAN**

Purpose: To evaluate the visual, refractive, and patient satisfaction outcomes of Presbyond laser blended vision (LBV) in Filipino myopic presbyopes.

Methods: This retrospective cohort study included 46 eyes from 23 patients who underwent Presbyond femtosecond LASIK at a tertiary hospital in the Philippines between August 2023 and January 2025. Patients were ≥ 39 years with preoperative corrected distance visual acuity (CDVA) of 20/25 or better. Outcomes at 6 months included uncorrected distance visual acuity (UDVA), CDVA, predictability, stability,

and astigmatic correction. Patient satisfaction was measured using a validated 0–100 scale.

Results: At 6 months, 96% of eyes achieved UDVA of 20/20 or better, and UDVA was within 1 line of preoperative CDVA in 96% of cases. No eye lost >2 lines of CDVA, and 15% gained 1 line. Predictability was high, with 91% of eyes within ± 0.50 D and 100% within ± 1.00 D of target refraction. Astigmatic correction was precise, with 96% of eyes ≤ 0.50 D and 92% aligned within $\pm 15^\circ$ of the intended axis. Refractive stability was achieved by 6 months. Overall satisfaction scores were high, with most patients reporting spectacle independence at distance and near.

Conclusions: Presbyond LBV is a safe, effective, and predictable option for presbyopia correction in myopic Filipino patients, demonstrating excellent refractive accuracy, stability, and high patient satisfaction.

A Case Report of Late-Onset Alström Syndrome

First Author: Zhen FANGYUAN

Co-Author(s): Zhou XIAOLAI, Hu

Purpose: Alström syndrome is a rare autosomal recessive genetic disorder characterized primarily by retinal dystrophy, with a wide range of accompanying systemic manifestations. This paper reports a patient with a compound heterozygous variant in the ALMS1 gene (c.10831_10832del, p.Arg3611AlafsTer and c.1238-20A>G). This variant combination has not been reported previously, and the patient was diagnosed with Alström syndrome.

Methods: Ophthalmic assessments included visual acuity examination, refraction, slit-lamp examination, optical coherence tomography (OCT), and electroretinography (ERG). Genetic analysis was performed using whole-exome sequencing.

Results: The patient experienced vision loss at age 50 and became blind at age 60. Ophthalmic assessments revealed diffuse bilateral retinal pigmentary changes, and ERG results showed cone-rod dystrophy. However, rod cell function was only mildly affected, while cone cell function was completely lost. Genetic testing of this patient revealed a compound heterozygous variant in the ALMS1 gene, which includes a known pathogenic variant (c.10831_10832del) and a variant of uncertain significance (c.1238-20A>G).

Conclusions: The age of onset in this case is different from typical Alström syndrome, presenting as a rare late-onset phenotype. Although the second variant is classified as a variant of uncertain significance, the

clinical and electrophysiological data from this case strongly support its co-pathogenic role with the known pathogenic variant, giving rise to a unique late-onset phenotype. This provides new insights into the genetic and phenotypic heterogeneity of the disease.

A Cohort Study on Prepartum and Postpartum Changes in Retinal Choroidal Microcirculation in Patients With Hypertensive Disorders of Pregnancy

First Author: Jiulin NI

Co-Author(s): Shuting LI, Wan LI, Min QIU

Purpose: To investigate changes in choroidal microcirculatory blood flow and structure in patients with hypertensive disorders of pregnancy (HDP) before and after delivery using swept-source optical coherence tomography angiography (SS-OCTA).

Methods: Thirty-seven women with HDP (64 eyes) underwent SS-OCTA in late pregnancy and at 6 weeks postpartum. Choroidal thickness (CT) and choriocapillaris vascular density (CCVD) in macular and peripapillary regions were analyzed. Paired t-tests and Pearson correlations were applied to observe changes in choroidal parameters and their correlations with various clinical indicators.

Results: Patients had a mean age of 29.03 ± 3.66 years and gestational age of 36.93 ± 2.59 weeks. Postpartum, blood pressure and body weight decreased significantly. Macular CT was higher prepartum in the central and inferior regions, while peripapillary CT was reduced only in the superior quadrant. Central macular CCVD was higher prepartum, whereas inferior macular CCVD was lower; peripapillary CCVD showed no significant changes. Correlation analysis revealed associations of inferior macular CCVD with diastolic pressure change, 24h urinary protein, and PI, and of superior macular CCVD with 24h urinary protein. The outer macular CT correlated with 24h urinary protein, RI, and biparietal diameter.

Conclusions: HDP patients predominantly demonstrated postpartum reductions in CT and increases in CCVD, with region-specific correlations to systemic and obstetric indicators. SS-OCTA provides valuable insights into ocular changes associated with HDP.

Abstract No.: 204647**Panel No.: RME-0998**

A Diagnostic Dilemma: Ischemic Maculopathy or Macular Dystrophy in a Post-Preeclampsia Patient

*First Author: Kaveri BIRLA**Co-Author(s): Prince ABU AAMIR, Neha CHAWLA GULIANI, Afsana IDRISHI*

Purpose: To highlight the diagnostic challenge in differentiating ischemic maculopathy secondary to pre-eclampsia from heredomacular dystrophies in a patient with bilateral long-standing visual impairment.

Methods: We report the case of a 41-year-old female who developed sudden, painless, bilateral diminution of vision during the ninth month of pregnancy 18 years ago. Visual function worsened initially, prior to delivery. Partial recovery was documented two weeks postpartum, and it has been stable thereafter. There were no systemic comorbidities or family history of ocular disease. Comprehensive ocular examination, multimodal imaging including fundus photography, OCT, and OCTA were performed.

Results: Fundus evaluation revealed arteriolar attenuation, collateral vessels, flecks at the macula with pigmentary changes, and Elschnig's spots. OCT demonstrated severe inner retinal atrophy with markedly reduced central macular thickness (117–126 μm). Hence, differential diagnosis of ischemic maculopathy related to pre-eclampsia versus macular dystrophies such as Stargardt disease or pattern dystrophy was incorporated. However, the acute onset during pregnancy, presence of hypertensive complications, and fundus features of choroidal ischemia favour a vascular etiology. Therefore, we suggest a final diagnosis of post-pre-eclampsia bilateral ischemic maculopathy.

Conclusions: Ischemic maculopathy is an uncommon but vision-threatening sequelae of pre-eclampsia. Its fundus findings can mimic macular dystrophies, especially in chronic stages with macular flecks and atrophy. Detailed obstetric history, including sequential timeline and multimodal imaging, is essential to distinguish vascular ischemic damage from hereditary macular disorders and interim guide prognosis.

A Probable Case of Bullous Central Serous Chorioretinopathy Treated with Intravitreal Bevacizumab

*First Author: Robbie Alyssa MALIWAT**Co-Author(s): Kristine CORPUS-VELASQUEZ, Juan LOPEZ*

Purpose: To present a probable case of bilateral bullous central serous chorioretinopathy (bCSCR) treated with

intravitreal injection of bevacizumab (IVB) in one eye in a patient with multiple comorbidities.

Methods: This is a case report.

Results: A 50-year-old male with diabetes and chronic kidney disease presented with sudden-onset painless blurring of vision on the right eye then subsequently the left eye. Initial best corrected visual acuity (BCVA) was counting fingers at 1 foot on the right and 20/150 on the left. Fundoscopy revealed a broad-based shallow retinal detachment and a doughnut-shaped subretinal patch in the macula of the right eye and an inferior bullous retinal detachment with positive shifting fluid sign but no visible breaks, and an ovoid-shaped yellow subretinal patch on the left eye. Macular optical coherence tomography (OCT-M) revealed exaggerated neurosensory retinal detachment in both eyes disproportionate to fundoscopic findings. Trial of IVB was done on the right eye. One-month post IVB revealed significant improvement of BCVA 20/40 on the right and 20/120 on the left. There was significant resolution of the retinal detachment and subretinal patches in both eyes. Fluorescein angiography and OCT-M showed pooling and prominent resolution of retinal detachment, respectively. Uveitis referral and work-up revealed incidental positive interferon-gamma release assay without other findings pertinent to ocular tuberculosis.

Conclusions: In cases of bilateral non-rhegmatogenous, noninfectious, exudative retinal detachment, bCSCR should be in the differential diagnoses. Multi-modal imaging and multi-specialty collaboration is paramount. IVB may have a potential role in the treatment of bCSCR.

Abstract No.: 204636**Panel No.: RME-0999**

A Rare Case of Ocular Sarcoidosis Presenting as Chronic Granulomatous Conjunctivitis

*First Author: Faouzia SULTANA**Co-Author(s): Hasan JAWAD*

Purpose: To report a rare case of ocular sarcoidosis initially presenting as chronic granulomatous conjunctivitis, highlighting the diagnostic challenges in tuberculosis-endemic regions.

Methods: A case report of a 60-year-old Bangladeshi male with persistent conjunctival redness, swelling, and nodules in the left eye. Clinical findings, laboratory investigations, imaging, histopathology, and multidisciplinary management were reviewed.

Results: Initial treatment as idiopathic conjunctivitis failed. Examination revealed conjunctival granulomas, cataract, and secondary glaucoma without posterior uveitis. Systemic workup excluded tuberculosis with negative Mantoux and QuantiFERON-TB Gold tests. Chest imaging revealed basal consolidation and inflammatory changes. Conjunctival biopsy confirmed

non-caseating granulomas, consistent with sarcoidosis. The patient was treated with systemic corticosteroids, topical anti-inflammatory and antiglaucoma medications, and supportive systemic therapy. Atrial fibrillation and poorly controlled diabetes required cardiology and endocrinology input. Clinical improvement was noted under a multidisciplinary approach.

Conclusions: Ocular sarcoidosis rarely presents as chronic granulomatous conjunctivitis. In TB-endemic regions, it is often misdiagnosed, delaying appropriate management. Histopathology remains the cornerstone of diagnosis in distinguishing sarcoidosis from infectious granulomatous disease. This case emphasizes the importance of clinical suspicion, biopsy confirmation, and coordinated multidisciplinary care to prevent vision loss and systemic complications.

Abstract No.: 201669

A Rare Glimpse into Darkness: A Devastating Ocular Complication of Systemic Lupus Erythematosus in a 23-year-old Filipino Female

First Author: Richard VILLAMOR

Co-Author(s): Karen CABRERA

Purpose: To report a case of a 23-year-old Filipino female presenting with sudden, painless vision loss in the left eye. Examination revealed a cherry-red spot, RAPD, and OCT showed inner retinal thickening, which is consistent with diagnosis of Central Retinal Artery Occlusion (CRAO). CRAO is a rare ophthalmic emergency in young patients, typically linked to non-atherosclerotic causes.

Methods: Systemic workup was done to determine possible etiology.

Results: Systemic workup revealed positive ANA and anti-dsDNA, confirming a diagnosis of systemic lupus erythematosus (SLE). CRAO is an uncommon ocular manifestation of SLE, especially without a known hypercoagulable state. Patient underwent hyperbaric oxygen therapy and resulted into improvement of visual acuity.

Conclusions: This case highlights the importance of considering autoimmune diseases in young patients with CRAO and the need for early multidisciplinary intervention to manage systemic involvement.

Altered m6A Epitranscriptome of mRNAs in Retinal Ischemia-Reperfusion

First Author: Jingying LIANG

Co-Author(s): Yingting ZHU, Yehong ZHUO

Purpose: Retinal ischemia-reperfusion (RIR) injury, characterized by irreversible degeneration of retinal ganglion cells, underlies the pathological mechanisms of glaucoma and diabetic retinopathy. Epitranscriptomic regulation by N6-methyladenosine (m6A) has emerged as a key modulator of RNA stability and translation, yet its role in pathological retinal ischemia-reperfusion remains unclear. Here, we investigated transcriptome-wide m6A modifications of mRNAs in a mouse model of RIR.

Methods: Retinal tissues from RIR and sham mice were subjected to Methylated RNA Immunoprecipitation sequence and RNA-seq analysis.

Results: RT-qPCR demonstrated that the expression of the m6A methyltransferase Mettl3 was elevated on day 3 after RIR injury, suggesting an active involvement of the m6A modification in pathogenesis. A total of 7,495 mRNAs (3,871 hypermethylated and 3,624 hypomethylated) exhibited significant alterations in m6A methylation. A total of 7495 mRNAs (3871 hypermethylated, 3624 hypomethylated) showed significant alterations in m6A methylation. Gene ontology analysis revealed that hypermethylated transcripts were enriched in cellular process, cellular anatomical entity, binding, whereas hypomethylated transcripts were associated with regulation of synaptic signaling, synapse, gated channel activity. KEGG pathway analysis indicated that hypermethylated mRNAs were involved in tight junction, Hippo signaling pathway, and PI3K-Akt signaling pathways, while hypomethylated mRNAs were linked to neuroactive ligand-receptor interaction and glutamatergic/cholinergic synapses.

Conclusions: Our study suggested that m6A methylation levels are significantly altered in retinal ischemia-reperfusion. The possible roles of m6A modification in RIR were predicted by bioinformatics analysis. The results implied that the m6A modification might be involved in RIR and considered as potential therapeutic targets.

Anatomical and Patient-Reported Outcomes of Bevacizumab Versus Ranibizumab in Wet Age-Related Macular Degeneration: A Multi-Center, Randomized, Double-Blind, Active-Controlled, Phase III Trial (AURA-1)

First Author: Jingjing **SHEN**Co-Author(s): Paul **CHANG**, Malcolm **NGIAM**, Na **XU**, Qi **XUE**

Purpose: High-level evidence from large randomized controlled trials (RCTs) on bevacizumab for wet age-related macular degeneration (wAMD) in the Chinese population has been lacking. AURA-1, as the first and only large-scale RCT in Chinese wAMD patients, aimed to address this gap by providing robust evidence on the efficacy of bevacizumab. The current research compared the anatomical and patient-reported outcomes of bevacizumab versus ranibizumab in patients with wAMD.

Methods: In this multicenter, randomized, double-blind, active-controlled, phase III trial, 407 patients were randomized to receive intravitreal injections of bevacizumab (1.25 mg/eye) or ranibizumab (0.5 mg/eye) every 4 weeks for 48 weeks. Statistical analyses included t-tests and mixed-model repeated measures (MMRM). AURA-1 was registered (NCT05003245).

Results: Bevacizumab demonstrated significant improvements from baseline in anatomical and patient-reported outcomes, with no statistically significant differences compared to ranibizumab. Bevacizumab showed robust efficacy from baseline: fluorescein angiography (FA) leakage area reduction of -3.32 mm^2 ($p < 0.001$), choroidal neovascularization (CNV) total area reduction of -0.99 mm^2 ($p = 0.001$), central retinal thickness (CRT) reduction of $-129.8 \mu\text{m}$ ($p < 0.001$), and Visual Function Questionnaire-25 (VFQ-25) score improvement of $+2.60$ points ($p = 0.0036$). The differences between the bevacizumab and ranibizumab groups were not significant for FA leakage area (0.468 mm^2 , $p = 0.544$), CNV total area (-0.40 mm^2 , $p = 0.196$), CRT ($14.80 \mu\text{m}$, $p = 0.333$), and NEI VFQ-25 scores (-1.58 points, $p = 0.207$). Sensitivity analyses using MMRM showed similar results.

Conclusions: Bevacizumab demonstrated significant efficacy in reducing anatomical lesions and improving the quality of life in Chinese wAMD patients. Its comparable profile to ranibizumab supports its use as a cost-effective alternative treatment.

Anti-VEGF Combined With Ocular Corticosteroids Therapy Versus Anti-VEGF Monotherapy for Diabetic Macular Edema: Meta-Analysis and OCT-Based Biomarkers in Response to Treatments

First Author: Jing **HAN**

Purpose: Anti-VEGF is the first-line treatment for diabetic macular edema (DME), a key pathological condition of DR, and also a major cause of visual impairment in the global working population. As anti-VEGF monotherapy shows suboptimal efficacy in some DME patients and requires frequent administration, other therapeutic options, including corticosteroids alone or in combination with anti-VEGF, might produce a beneficial effect in these patients. The purpose of the study is to compare the effect and OCT-based biomarkers between the anti-VEGF combined with ocular corticosteroids therapy and anti-VEGF monotherapy for the treatment of DME.

Methods: 1) Meta-analysis: Databases were searched up to April 5, 2023, data were extracted and analyzed using STATA 15.1 according to the PROSPERO protocol (CRD42023408338). Best corrected visual acuity (BCVA) and central macular thickness (CMT) were compared between the groups. 2) Retrospective analysis: Medical records of DME patients at the Ophthalmology Department of Tangdu Hospital (2018–2025) were reviewed, divided into a combined group and a monotherapy group, with OCT image differences analyzed via SPSS 26.0.

Results: Meta-analysis outcomes revealed that combined therapy was superior in improving BCVA and reducing CMT at 1–3 months (peak at 3 anti-VEGF injections) but not at 6–12 months, with higher adverse event risks. In retrospective analysis, combined therapy better reduced HRF, restored ELM/EZ, decreased SRF and DRIL (3–6 months).

Conclusions: Anti-VEGF combined with ocular corticosteroids demonstrates superior efficacy within 3 months of DME treatment (but not after 6 months), and is more effective in the change of OCT biomarkers, including reducing HRF, restoring EZ integrity, and alleviating SRF accumulation.

Assessing a 36-Week Refill-Exchange Regimen for Port Delivery Platform With Ranibizumab in Patients With Up to Two Years' Diagnosis of Neovascular Age-Related Macular Degeneration: Phase-3b Sightspire Trial

First Author: Christopher Seungkyu LEE
Co-Author(s): Richard H. FOXTON, Frank G. HOLZ, Thanapong SOMKIJRUNGROJ, Kailin TIAN

Purpose: PDS (Port Delivery Platform with ranibizumab), a drug delivery system continuously delivering ranibizumab into the vitreous, is approved in the US for nAMD (neovascular age-related macular degeneration) with refill exchanges Q24W (every-24-weeks). We report the study design of the ongoing, global, phase-3b Sightspire trial assessing PDS Q36W in nAMD patients.

Methods: The single-arm Sightspire (NCT06847542) trial assesses the effectiveness, safety, and PROs (patient-reported outcomes) of PDS Q36W and Q24W in nAMD patients. Eligibility criteria: nAMD diagnosis ≤ 24 months, prior anti-vascular endothelial growth factor response, BCVA (best-corrected visual acuity) ≥ 34 -letters (20/200 Snellen). At W24 (week 24), disease activity (BCVA: ≥ 5 letter decrease vs last 2 measures, ≥ 10 letter decrease from best recorded, CST [central subfield thickness]: $\geq 75\mu\text{m}$ increase vs last 2 measures, $\geq 100\mu\text{m}$ increase vs lowest measure, or new macular hemorrhage) will be assessed; patients without activity are assigned to Q36W cohort; patients with activity are assigned to Q24W cohort.

Results: Primary endpoint: change from baseline in BCVA, averaged over W68 and W72 (Q36W cohort). Secondary outcomes: change in BCVA scores, center point thickness, CST over time, treatment, and visit burden (Q36W cohort). PROs: patient preference for PDS vs intravitreal injections and recovery experience. Sightspire also explores caregiver burden and whether PDS can help reduce it. Safety: incidence and severity of ocular and systemic adverse events.

Conclusions: Sightspire uniquely evaluates PDS treatment adaptability, visit flexibility, and clinical outcomes across a diverse patient population, supporting individualised treatment for patient and caregiver benefit.

Panel No.: RME-0946

Assessment of Outcome Measures to Detect Disease Progression in Bietti Crystalline Dystrophy

First Author: Yusuke MURAKAMI
Co-Author(s): Manabu MIYATA, Akio OISHI, Koh-hei SONODA, Kazushige TSUNODA, Huanyu ZHAO

Purpose: To characterize the natural history of Bietti crystalline dystrophy (BCD), and to identify sensitive outcome measures for detecting disease progression.

Methods: This multi-center, prospective study included patients with BCD carrying biallelic pathogenic variants in the CYP4V2 gene, recruited from four academic centers in Japan. Multimodal imaging and functional assessments included best-corrected visual acuity (BCVA), static perimetry (Humphrey 10-2), fundus autofluorescence (FAF), and optical coherence tomography (OCT). The primary outcome was the longitudinal changes in BCVA. Secondary outcomes included changes in the hypo-autofluorescent (hypo-AF) area, and static perimetry parameters, such as mean deviation (MD), absolute scotoma points (ASP), and transitional zone retinal sensitivity (TZRS).

Results: Thirteen patients with genetically confirmed BCD were followed prospectively over a median of 2.5 years (range: 2.5-3 years). Longitudinal analysis showed progression in hypo-AF area ($11.8 \text{ mm}^2/\text{year}$, 95% CI: 5.25–18.34, $P = 0.003$) and TZRS decline (-2.32 dB/year , 95% CI: -4.06 to -0.59 , $P = 0.015$) and BCVA decline (0.04 logMAR/year , $P = 0.008$). Hypo-AF area showed the biggest annual change rate (18.4%) and highest SNR (1.10; signal-to-noise ratio) among all parameters. LMM revealed that hypo-AF area progression was significantly associated with faster loss of MD ($P = 0.011$) and ASP ($P = 0.017$), but not with BCVA or TZRS changes.

Conclusions: This prospective natural history study suggests that hypo-AF area may serve as a useful structural measure for detecting disease progression in BCD clinical trials, warranting further validation in larger prospective studies.

Abstract No.: 203370
Panel No.: RME-0984

Association Between Mean Ocular Perfusion Pressure and Proliferative Diabetic Retinopathy in a Northern Chinese Population

First Author: Juping LIU
Co-Author(s): Han BO, Chen CHEN, Fei GAO, Liying HU, Xiaorong LI, Emmanuel Eric PAZO, Yu SHI, Xiuqing ZHU

Purpose: To evaluate the association between mean ocular perfusion pressure (MOPP), pulse pressure (PP), systolic blood pressure (SBP), and the proliferative

diabetic retinopathy (PDR) in patients with type 2 diabetes in a northern Chinese population.

Methods: A retrospective cross-sectional study was conducted using 1,119 patient data from the Beichen Eye Study and 204 electronic medical records from the Tianjin Medical University Eye Hospital. The participants were categorized into no diabetic retinopathy (NDR), non-proliferative diabetic retinopathy (NPDR), PDR groups. SBP, diastolic blood pressure (DBP), and intraocular pressure (IOP) were measured. MOPP was calculated using the formula: $MOPP = 2/3 [DBP + 1/3 (SBP - DBP)] - IOP$.

Results: When the PDR group was set as the reference, the odds ratio (OR) value of MOPP (NDR: OR, 0.92, 95% confidence intervals [CI], 0.89-0.95; NPDR: OR, 0.94, 95% CI, 0.91-0.98) was lower than that of SBP and PP. In a model with MOPP, SBP, and PP simultaneously as covariates, the OR value of MOPP (NDR: OR, 0.83, 95% CI, 0.77-0.89; NPDR: OR, 0.89, 95% CI, 0.83-0.96) was lower than PP, while SBP was not statistically significant. The OR trend for these three parameters remained consistent following tertile classification. Except for PP (P for likelihood test = 0.046), MOPP and SBP have no threshold effects for the association of PDR.

Conclusions: MOPP outperforms SBP and PP in predicting PDR risk, underscoring the synergistic role of IOP and blood pressure in disease development.

Abstract No.: 201913

Panel No.: RME-0954

Atypical Retinitis Pigmentosa Associated With CERKL Mutation Mimicking Gyrate Atrophy

First Author: Vinit TANWAR

Co-Author(s): Manasi TRIPATHI

Purpose: To report the unique multimodal imaging findings in a genetically confirmed case of Atypical Retinitis Pigmentosa (RP) due to a CERKL mutation, which presented with a rare phenotype mimicking Gyrate Atrophy, and to highlight the diagnostic importance of genetic testing.

Methods: A case report. A patient presenting with features of a progressive retinal dystrophy underwent a comprehensive ophthalmic evaluation. This included color fundus photography, fundus autofluorescence (FAF), and spectral-domain optical coherence tomography (SD-OCT). Subsequent genetic testing was performed via next-generation sequencing to identify the underlying causative mutation.

Results: Fundus examination revealed widespread, well-circumscribed chorioretinal atrophic patches in the periphery, along with significant pigmentary changes involving the macula, a pattern highly suggestive of Gyrate Atrophy. FAF imaging showed hypofluorescence corresponding to these atrophic

areas. SD-OCT demonstrated severe outer retinal atrophy, loss of the ellipsoid zone, and foveal thinning. Contrary to the clinical appearance, genetic analysis identified a homozygous pathogenic variant in the CERKL gene (c.967_968del, p.Met323ValfsTer20), confirming a diagnosis of Atypical Retinitis Pigmentosa (RP26).

Conclusions: Retinal dystrophies associated with CERKL mutations exhibit significant phenotypic variability. This case demonstrates a rare presentation that can masquerade as other chorioretinal degenerations like Gyrate Atrophy. Multimodal imaging is essential for characterization, but genetic testing is indispensable for reaching a definitive diagnosis, which is critical for accurate prognostication and patient counseling.

Abstract No.: 203857

Panel No.: RME-0986

Baseline Associations Between Visual Function and Inflammatory Markers in the Registry of Retinitis Pigmentosa

First Author: Kaho YAMAMOTO

Co-Author(s): Takahiro HISAI, Yasuhiro IKEDA, Kazunori MIYATA, Yusuke MURAKAMI

Purpose: To examine the relationship between visual function and inflammatory markers at baseline in the Retinitis Pigmentosa Progression and Inflammatory Marker Registry (RP-PRIMARY Study); a prospective registry of moderate-stage RP.

Methods: Sixty-seven patients with moderate-stage RP were analyzed cross-sectionally. Examinations included ETDRS best-corrected visual acuity (BCVA), Humphrey Field Analyzer 10-2 mean deviation (MD), retinal sensitivity (RS Cent 4'/12'), ellipsoid zone (EZ) length, central fovea thickness (CFT), and hyper-autofluorescence (AF) ring area. Aqueous flare was quantified by laser flare photometry, and systemic markers were measured by blood tests. Associations were analyzed using correlation and multiple linear regression models.

Results: Aqueous flare correlated negatively with BCVA ($p = -0.35$, $p = .004$), RS Cent 12' ($p = -0.32$, $p = .008$), EZ length ($p = -0.28$, $p = .023$), and AF ring area ($p = -0.31$, $p = .016$). No systemic associations were found. Intraocular lens (IOL) eyes showed higher flare (15.6 vs. 8.0 pc/ms, $p < .001$) and worse visual outcomes, including lower BCVA ($p = .004$), RS Cent 12' ($p = .005$), RS Cent 4' ($p = .010$), reduced CFT ($p = .001$), and shorter EZ length ($p = .011$). In multivariate regression, IOL implantation remained an independent predictor of increased aqueous flare ($\beta = 0.262$, $p < .001$).

Conclusions: At baseline, aqueous flare was inversely correlated with visual function, and IOL implantation was most strongly associated with increased aqueous flare in patients with moderate-stage RP.

Abstract No.: 204612

Panel No.: RME-0996

Biallelic Heterozygous Mutations in Crumbs Homolog-1 Gene Associated With Macular Retinoschisis and Angle-Closure Glaucoma

First Author: Xu HOU

Co-Author(s): Dan HU, Xiaojin SONG, Jiaying SUN, Yusheng WANG, Jian ZHOU

Purpose: To investigate clinical features, including macular retinoschisis, Coats-like vasculopathy, short axial length, and angle-closure glaucoma (ACG) in a patient with mutations in the crumbs homolog-1 (CRB1) gene.

Methods: A girl with a complaint of poor visual acuity of both eyes was admitted and had both general physical examination and ocular examination on her first visit at 7 years old. Clinical features, including BCVA, IOP, OCT, AF, FFA, ERG, and VEP were performed. DNA samples were screened to detect mutations in the most frequently involved genes in retinal diseases. Initial treatment involved the combined medications and LPI. Trabeculectomy and secondary surgery, including phacoemulsification, intraocular lens implantation, and anterior vitrectomy, were performed in both eyes during the next 10-year follow-up.

Results: The abnormal ocular phenotype included bilateral anterior angle closure, short axial length, optic atrophy, macular retinoschisis, and Coats-like response in the peripheral retina. The genetic testing showed a combined heterozygous missense mutation (paternal p.C469G and maternal p.R905Q) in CRB1 in the affected girl. The BCVA was 20/400 in both eyes, and the IOP was 18 mmHg in the right and 17 mmHg in the left at the last follow-up. OCT revealed more serious cystoid changes and disrupted structures of the outer retina within the macula, as well as excavation of the optic disk.

Conclusions: CRB1 mutations could result in a combined manifestation in the anterior and posterior segments. It also highlights the crucial role of CRB1 in eyeball development.

Abstract No.: 206403

Panel No.: RME-1022

Bilateral Central Retinal Vein Occlusion in Young Adults With Hypertensive Retinopathy: A Rare Case Report

First Author: Andika Adiputra WITONO

Co-Author(s): Eugeni SUMANTI, Salam SURBAKTI, Dyana WATANIA

Purpose: To report a rare case of bilateral central retinal vein occlusion (CRVO) in a young adult with uncontrolled hypertension and hypertensive retinopathy, emphasizing diagnostic findings, management, and treatment outcomes.

Methods: A 20-year-old female with a 10-year history of uncontrolled hypertension presented with blurred vision in her left eye. Clinical evaluation included visual acuity testing, fundus examination, and optical coherence tomography (OCT), confirming bilateral CRVO. Management consisted of systemic anti-hypertensive therapy and intravitreal Ranibizumab injection in the left eye, followed by close monitoring.

Results: On presentation, visual acuity was 1/300 in the right eye and 1/60 in the left eye, with characteristic funduscopic findings of bilateral CRVO. After intravitreal Ranibizumab injection, the patient remained stable at one-week follow-up, with unchanged visual acuity, controlled intraocular pressure, and no reported complications. Further injections were planned for continued management.

Conclusions: Although uncommon in young adults, bilateral CRVO can occur in association with chronic uncontrolled hypertension. Early recognition and timely initiation of anti-vascular endothelial growth factor therapy, combined with systemic blood pressure control, are crucial to preserve vision and prevent disease progression. Continuous follow-up is mandatory to optimize long-term outcomes.

Bilateral Serous Retinal Detachment As the Initial Presentation of HELLP Syndrome in an Undiagnosed Pregnancy: A Case Report

First Author: Rinprapa CHUCHAROEN

Co-Author(s): Taniya BHOOPAT

Purpose: To describe a rare case of HELLP syndrome initially presenting with bilateral serous retinal detachment (SRD) in a previously undiagnosed pregnancy.

Methods: A 33-year-old woman presented with progressive bilateral blurred vision for three weeks. Initial examination showed bilateral SRD, leading to a misdiagnosis of Vogt-Koyanagi-Harada disease and initiation of high-dose corticosteroid therapy. She was subsequently referred to a tertiary center for further evaluation.

Results: At referral, fundus examination revealed optic disc and macular edema with retinal arteriolar narrowing and serous retinal detachment. Hypertensive retinopathy was suspected. Blood pressure was markedly elevated at 227/125 mmHg. Systemic evaluation unexpectedly identified a 33-week intrauterine pregnancy with laboratory findings consistent with HELLP syndrome. An emergency cesarean section was performed.

Conclusions: Bilateral SRD may represent the initial ocular manifestation of HELLP syndrome and can mimic VKH disease. In women of reproductive age presenting with bilateral SRD, hypertensive disorders of pregnancy

should be included in the differential diagnosis. Early recognition and multidisciplinary management are critical to optimize maternal and fetal outcomes.

Abstract No.: 204304

Calcium Signaling Dysregulation in Aged Retinal Pigment Epithelium: Therapeutic Potential of Calmodulin Inhibition

First Author: Junying WU

Co-Author(s): Xiuxing LIU, Wenru SU, Yehong ZHUO

Purpose: Age-related retinal pigment epithelium (RPE) degeneration is central to dry age-related macular degeneration (AMD). This study aimed to elucidate molecular mechanisms of aged RPE vulnerability and to assess the therapeutic potential of targeting calcium signaling and oxidative stress.

Methods: Single-cell RNA sequencing of young and aged mouse retinæ was analyzed using Seurat, focusing on RPE subpopulations. Differential gene expression and pathway enrichment highlighted signaling abnormalities. Functional validation was performed in cultured RPE cells treated with lipopolysaccharide (LPS), with or without W-7 hydrochloride (calmodulin inhibitor) or pyrroloquinoline quinone (PQQ). Cytotoxicity, apoptosis, reactive oxygen species (ROS), and inflammatory cytokines were quantified. In vivo, a sodium iodate-induced retinal degeneration model was used to evaluate W-7 delivered via intraperitoneal injection and topical eye drops.

Results: Aged RPE cells showed upregulation of calcium signaling genes (Calmd1), oxidative stress mediators (Nox4, Hmox1), and pro-inflammatory factors (Il1b, Tnf). W-7 significantly reduced LPS-induced apoptosis, ROS accumulation, and ERK/p38 activation, thereby decreasing IL-6, IL-1 β , and TNF- α expression. PQQ exhibited antioxidant protection but less pronounced anti-inflammatory effects. In vivo, W-7 preserved retinal architecture and RPE layer integrity against NaIO₃-induced damage, indicating functional protection.

Conclusions: This study demonstrates that aberrant calcium signaling, oxidative stress, and inflammation collectively drive age-associated RPE degeneration. Pharmacological inhibition of calmodulin by W-7 confers robust protection both in vitro and in vivo, supporting its therapeutic promise for dry AMD. PQQ may serve as an adjunct antioxidant strategy.

Abstract No.: 205148
Panel No.: RME-1003

Clinical Association of Diabetic Neuropathy With Diabetic Retinopathy and Choroidopathy

First Author: Kiyoun KIM

Purpose: This study aims to investigate the clinical correlation between diabetic retinopathy (DR), choroidopathy, and neuropathy through a longitudinal follow-up in a diabetic cohort.

Methods: Participants were patients diagnosed with diabetes and no DR or mild NPDR, who had available ophthalmologic follow-up for at least five years. Autonomic nerve function was scored from 0 to 10 based on five standardized tests. Peripheral nerve function was assessed using nerve conduction velocities. The annual rate of macular GCIPL thinning was obtained using the OCT's built-in software. We also quantified choroidal circulation using choroidal thickness maps and CVI maps, and tracked changes over 5 years.

Results: A total of 312 patients were included, with a mean age of 59.1 and a mean diabetes duration of 13.5 years. DR progression was observed in 25.5%. The average mGCIPL thickness decreased from 78.5 μ m to 76.4 μ m over the study period. In regression analysis, the autonomic nerve function score was significantly associated with DR progression ($B = 0.463$, $P = 0.004$). The rate of mGCIPL thinning was significantly correlated with sural sensory nerve conduction velocity ($P = 0.03$). Notably, both the 12x12mm field mean CVI and the DCP vessel density significantly declined over 5 years. Worse autonomic nerve function was significantly associated with greater decreases in CVI over 5 years, but not with retinal vessel density.

Conclusions: Peripheral neuropathy is associated with retinal neurodegeneration in the posterior pole. Autonomic neuropathy reduces choroidal vascularity, which accelerates DR progression. Choroid and photoreceptors are likely key players in early pathogenesis, highlighting the need for further imaging research.

Clinical Indications and Outcomes of Intravitreal Faricimab in Indian Eyes: A Real-World Experience

First Author: Vishal RAVAL

Co-Author(s): Shreeya JAIN

Purpose: To study the patient demography, clinical indications, and treatment outcomes of patients treated with intravitreal faricimab injection in Indian patients.

Methods: This retrospective hospital-based study included all patients with treatment-naïve or refractory retinal disease who received faricimab from January to December 2024. Patient demographics, treatment indications, change in LogMAR BCVA, and central macular thickness (CMT) were the primary outcomes. Secondary outcomes included the mean number of injections, the mean interval between injections, and OCT biomarkers.

Results: A total of 68 patients (80 eyes) with a mean age of 69 +/- 11 years and 74% males were included. Treatment indications included choroidal neovascular membrane (34, 43 %), diabetic macular edema (DME) (23, 29%), polypoidal choroidal vasculopathy (8, 10%), retinal vascular occlusion (13, 16%), and pseudophakic macular edema and vasculitis (one each). Of the 80 eyes, 27 (34%) were treatment-naïve. The switch to faricimab was prompted by recurrent subretinal fluid (19, 24%), non-resolving intraretinal fluid (14, 17.5%), recalcitrant DME (16, 20%), and chronic cysts (4, 5%). Mean LogMAR BCVA improved by -0.11 units ($p = 0.002$), and the mean CMT reduced by 125 (+/- 181) microns, ($p < 0.05$) across all study groups, reflecting a significant anatomical response. Patients received a mean of 1.80 +/- 0.91 injections with a mean interval of 9.60 +/- 5.91 weeks. No adverse events or endophthalmitis were reported.

Conclusions: Real-world use of faricimab in Indian eyes demonstrated significant visual and functional improvement with a favorable safety profile highlighting its durability and potential to lower the treatment burden.

Panel No.: RME-0977

Clinical Observation of Retinal Vasoproliferative Tumor

First Author: Panpan YE

Co-Author(s): Mingzhi SU, Weixin ZHENG

Purpose: To investigate the clinical and imaging characteristics of retinal vasoproliferative tumor (RVPT) and evaluate the efficacy of individualized treatment strategies.

Methods: Twelve RVPT patients from two centers (February 2022-May 2025) underwent comprehensive examinations (fundus photography, fundus fluorescein angiography (FFA), optical coherence tomography (OCT)) with histopathological analysis in two cases. Individualized treatments included anti-vascular endothelial growth factor (anti-VEGF) injections, laser photocoagulation, and vitrectomy based on lesion characteristics.

Results: The cohort included nine females and three males (mean age 52, range 17-78 years). Eleven cases were primary RVPT; one was secondary to uveitis. Lesions were predominantly solitary, located in the

inferotemporal retinal periphery as irregular masses. FFA demonstrated abnormal surface capillaries with early hyperfluorescence and late leakage. OCT revealed ill-defined nodular lesions with hyperreflective foci, without choroidal excavation; secondary macular detachment occurred in three eyes, retinal detachment in two eyes, and pseudocyst formation was detected by B-Scan in one eye. Treatments included local laser photocoagulation ($n=9$), transpupillary thermotherapy ($n=1$), combined intravitreal anti-VEGF for macular detachment ($n=2$), pars plana vitrectomy with tumor excision for complicated cases including macular hole, retinal detachment, and uveitis-associated RVPT ($n=3$). All lesions regressed or stabilized post-treatment, with improved or maintained visual acuity.

Conclusions: RVPT is typically a unilateral, primary peripheral retinal tumor in middle-aged adults, presenting with diverse manifestations. Key indicators of activity include vascular engorgement and exudative changes. A thorough assessment of imaging findings, lesion activity, and systemic health is essential for developing effective, individualized treatment.

Clinico-Demographic Characteristics of Patients With Optical Coherence Tomography-Detected Macular Thickening and Thinning in a Level Three Private Hospital

First Author: Eric Nathaniel REYES

Co-Author(s): Carlo LADORES

Purpose: This study aims to analyze the clinico-demographic characteristics associated with OCT-detected macular thickening and thinning among Filipinos in a tertiary hospital in Manila.

Methods: A retrospective observational study was conducted using OCT macular scans and corresponding medical records of patients at the University of Santo Tomas Hospital from January 2022 to December 2024. A minimum sample size of 84 patients was used. Descriptive and inferential statistical analyses, including t-tests, ANOVA, multiple linear regression, and correlation analysis, were used to determine associations between macular thickness and demographic/clinical variables.

Results: Sex showed a significant difference in distribution, with thinning more common among females and thickening more common among males ($\chi^2 = 4.268$, $p < 0.05$). Atherosclerotic cardiovascular disease was noted in 8 patients (4.3%), all of whom fell under the thinning category, producing a significant association with macular thinning. ($\chi^2 = 5.424$, $p < 0.05$). Other comorbidities such as hypertension, diabetes, dyslipidemia, chronic kidney disease, and autoimmune disease showed no significant associations with macular thickness ($p > 0.05$). ANOVA showed that

LogMAR differed ($p < 0.05$) and signal strength differed ($p < 0.05$), while CFT ($p > 0.05$) and IOP ($p > 0.05$) did not; group means by age bracket were not present in the output.

Conclusions: Macular thinning is the more common OCT phenotype in a Filipino tertiary population and that it carries functional consequences, particularly in women and in patients with cardiovascular disease. Thickening, though less frequent, tended to preserve visual acuity and aligns with processes such as macular edema. Intraocular pressure and co-morbidities such as hypertension, diabetes, dyslipidemia, chronic kidney disease, autoimmune conditions, thyroid disease, and pulmonary tuberculosis were not statistically linked to macular thickening or thinning.

Clinico-Microbiological Profile and Treatment Outcomes of Endophthalmitis Following Intravitreal Injection – a Retrospective Analysis of 27 Eyes

First Author: Bhavani **SANKARAN**

Co-Author(s): Naresh Babu **KANNAN**, Kim **RAMASAMY**, Muthukrishnan **VALLINAYAGAM**

Purpose: To evaluate the incidence, clinical characteristics, microbiological profile, and management outcomes of endophthalmitis following intravitreal injections of various AntiVEGF drugs (Bevacizumab, Ranibizumab and its biosimilars, Aflibercept, Brolucizumab) and corticosteroids (Triamcinolone acetonide and Dexamethasone implant) in a tertiary care eye hospital in South India over a 7-year period.

Methods: Retrospective single-centre study involving the review of medical records of 66,999 intravitreal injections that were administered over a period of 7 years between January 2017 and December 2023. 27 patients with clinical signs of acute endophthalmitis were included. 3 eyes underwent vitreous tap with intravitreal antibiotics, and 24 eyes underwent core vitrectomy with intravitreal antibiotics. The incidence, clinical and microbiological characteristics, and treatment outcomes of endophthalmitis following various intravitreal injections were analysed over a minimum follow-up period of 3 months.

Results: Intravitreal injections were administered in 66,999 eyes, of which 27 developed endophthalmitis. This accounts for an overall incidence of 0.04%. 26 patients (96.3%) presented within 7 days of the onset of symptoms. The mean follow-up after diagnosis was 473.48 days (range 3 months to 6 years). Mean visual acuity (logMAR) at the time of presentation was 1.75 ± 0.49 , which improved to 0.88 ± 0.59 at 3 months follow-up period ($p < 0.001$, Paired t-test). Culture positivity was observed in 18 subjects (66.67%) and revealed Gram-positive bacteria in all cases. The most

common organisms isolated were Staphylococcus haemolyticus and Staphylococcus epidermidis. Staphylococcus arlettae was a unique organism isolated in 1 patient. 3 eyes (11.11%) underwent vitreous tap with intravitreal antibiotics, and 24 eyes (88.89%) underwent core vitrectomy with intravitreal antibiotics.

Conclusions: There was no difference in clinical outcome based on the type of intravitreal injection. All the culture positive cases revealed gram positive bacteria and most were Staphylococci. Staphylococcus arlettae has never been reported hitherto, as a causative of endophthalmitis in extant literature. Poor visual outcome can be attributed to cataract, epiretinal membrane and macular hard exudates.

Combination Therapy of Intravitreal Ranibizumab and Sub-Tenon Triamcinolone for the Treatment of Diabetic Macular Edema: A Systematic Review and Meta-Analysis

First Author: Julsyawiah Novthalia

Co-Author(s): Nihayah Lukman, Safira Nurfadila **HARAHAP**

Purpose: This study aimed to evaluate the efficacy of intravitreal ranibizumab (IVR) combined with posterior sub-Tenon injection of triamcinolone acetonide (PSTA) for the treatment of diabetic macular edema.

Methods: This study employed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses. PubMed, Scopus, Google Scholar, and ScienceDirect were searched for systematic reviews of randomized controlled trials (RCTs). Primary outcomes were changes in central macular thickness (CMT) and best corrected visual acuity (BCVA). Risk of bias was assessed using the Cochrane risk assessment tool. Meta-analysis was performed using RevMan version 5.4.1, generating pooled effect estimates for mean difference (MD) and risk ratio (RR), two-sided p-values, and 95% confidence intervals (CIs).

Results: Nine RCTs including 611 participants were included. Combination therapy with intravitreal ranibizumab and posterior sub-Tenon injection of triamcinolone acetonide showed no significant reduction in CMT compared with intravitreal ranibizumab alone (MD = 42.10; 95% CI: -121.65 to 205.84; $p = 0.61$; $I^2 = 100\%$). Similarly, the combination therapy did not result in a significant improvement in BCVA compared with ranibizumab monotherapy (MD = 0.01; 95% CI: -0.03 to 0.06; $p = 0.59$; $I^2 = 58\%$). Funnel plots showed symmetrical distribution, suggesting a low risk of publication bias, and no evidence of publication bias was observed based on the funnel plot and Egger's test.

Conclusions: Combined intravitreal ranibizumab and posterior sub-Tenon triamcinolone acetonide does not

appear to provide additional benefit in improving BCVA or CMT compared with intravitreal ranibizumab alone in patients with diabetic macular edema.

Comparison of 0.1% Nepafenac and 0.3% Nepafenac Eye Drops in Reduction of Macular Thickness and Improvement of Visual Acuity in Patients with Diabetic Macular Edema – A Randomized Controlled Trial

First Author: Amit Kumar DEB
Co-Author(s): Sandip SARKAR

Purpose: Topical NSAIDs are the preferred treatment for patients with diabetic macular edema (DME) and good visual acuity. Among all NSAIDs, Nepafenac exhibits the highest penetration ability. This study aimed to compare the efficacy of Nepafenac 0.3% ophthalmic solution with Nepafenac 0.1% ophthalmic solution in terms of reducing central sub-field (CSF) macular thickness and improvement of visual acuity.

Methods: We conducted a prospective randomized controlled study involving 73 patients diagnosed with DME and good visual acuity. After randomization, group 1 received Nepafenac 0.1% eye drops three times a day, while group 2 received Nepafenac 0.3% eye drops once daily. BCVA and central sub-field foveal thickness (CSF) were recorded using. Patients were followed for 6 months.

Results: At baseline, the mean BCVA was 40.74 (± 2.98) letters and 40.83 (± 3.49) letters for the Nepafenac 0.1% and Nepafenac 0.3% groups, respectively. At the last follow-up at six months, BCVA improved to 42.37 (± 2.88) letters and 43.03 (± 2.22) letters ($P > 0.005$) for the Nepafenac 0.1% and Nepafenac 0.3% groups, respectively. The mean baseline CSF was 391.71 (± 121.02) microns and 324.77 (± 75.60) microns for the Nepafenac 0.1% and Nepafenac 0.3% groups, respectively, and reduced to 287.11 (± 92.97) microns and 233 (± 25.63) microns ($P > 0.005$) for the Nepafenac 0.1% and 0.3% groups, respectively. No adverse effects were found in our study.

Conclusions: Nepafenac 0.3% topical eye drops are equally effective in reducing the central sub-foveal thickness and improving best-corrected visual acuity compared to Nepafenac 0.1% eye drops.

Comparison of Subretinal Fibrosis Development Between Aflibercept and Faricimab Treatment in Neovascular Age-Related Macular Degeneration

First Author: Kenichiro MORI
Co-Author(s): Keijiro ISHIKAWA, Shoji NOTOMI, Satomi SHIOSE, Koh-hei SONODA

Purpose: To compare the incidence of subretinal fibrosis (SF) one year after initiation of intravitreal aflibercept (IVA) or intravitreal faricimab (IVF) in treatment-naïve patients with neovascular age-related macular degeneration (nAMD).

Methods: This retrospective study included 320 eyes of 320 nAMD patients who received IVA or IVF between January 2013 and October 2023 at Kyushu University Hospital. Patients had no evidence of subretinal fibrosis before treatment and were followed for at least one year. Baseline variables assessed for association with SF were age, sex, logMAR visual acuity, central retinal thickness (CRT), macular neovascularization (MNV) subtype, retinal hemorrhage, subretinal hyperreflective material (SHRM), intraretinal fluid (IRF), subretinal fluid (SRF), and retinal pigment epithelium (RPE) disruption. Propensity score matching (PSM) was applied to balance baseline characteristics, and SF incidence was compared between IVA and IVF groups.

Results: At 1 year, SF developed in 17% (53 eyes). Significant risk factors in univariate analysis included baseline logMAR visual acuity, CRT, MNV subtype, retinal hemorrhage, SHRM, IRF, and RPE disruption. After 1:1 PSM, 35 eyes were analyzed in each group. The IVF group showed a lower incidence of SF compared with the IVA group (8.6% vs. 20.0%; odds ratio: 0.38; 95% CI: 0.088–1.59; $p = 0.17$).

Conclusions: The incidence of subretinal fibrosis after anti-VEGF therapy for nAMD may differ between agents. Faricimab tended to reduce the risk of fibrosis compared with aflibercept, suggesting that the drug choice should consider the fibrosis risk.

Comparison of the Efficacy of Subthreshold Micropulse Laser Versus Intravitreal Anti-VEGF Therapy for Central Serous Chorioretinopathy

First Author: Li JINYU
Co-Author(s): Chen ZHIQING

Purpose: To compare the therapeutic ability between 577-nm subthreshold micropulse laser (SML) and intravitreal anti-VEGF injection (IVA) in the central serous chorioretinopathy (CSCR) treatment.

Methods: The medical records of 50 eyes of 49 patients who underwent IVA injection (30 eyes) or SML (20 eyes) for the treatment of CSCR were reviewed. All participants were followed up for six months. The changes in best-correct visual acuity (BCVA), central retinal thickness (CRT), subretinal fluid (SRF) and subfoveal choroidal thickness (SFCT) values from OCT at 1st month, 3rd month and 6th month of follow-up visit were evaluated among the groups.

Results: The baseline characteristics (age, gender, type of leakage in FA, BCVA, CRT, SRF, SFCT) of the patients were not significant between the groups (all $p > 0.05$). The mean $\pm$ SD of SML sessions and IVA injection were 1.67 ± 0.80 and 1.75 ± 0.97 , respectively ($p > 0.05$). In comparison to the baseline values, the BCVA at the 6th months after treatment showed considerable improvement in both groups ($p < 0.05$), while the CRT, SRF and SFCT values prominently decreased at the final evaluation visit (all $p < 0.05$). No statistically significant difference was revealed in the BCVA and CRT data of all time points between the two groups (all $p > 0.05$). At baseline, 1st, and the 3rd month, there was no statistically significant difference for the SRF and SFCT values between the two groups ($p > 0.05$). However, at the 6th month, the SRF in the SML group was noticeably lower than in the IVA group ($p < 0.05$), while the SFCT in the SML group was markedly higher than in the IVA group ($p < 0.05$). No complication was observed during follow-up period in both groups.

Conclusions: The effectuality of SML and anti-VEGF treatment has been confirmed both functionally in terms of BCVA and anatomically through OCT. During the follow-up period, it has been observed with a greater reduction of SFCT in the IVA group, and more absorption of SRF in the SML group.

Correlation Between Choroidal Thickness and Photoreceptor-Retinal Pigment Epithelium Layer Thickness: Analysis in Emmetropia and Myopia

First Author: Tsania Rachmah RAHAYU

Co-Author(s): Dewi FRISKA, Anggun Rama YUDHANTA

Purpose: The choroid plays a critical role in supporting photoreceptor and retinal pigment epithelium (RPE) metabolism and serves as the primary blood supply for the outer retina. In myopic eyes, axial elongation is often associated with a reduction in choroidal thickness, which may impact retinal structure and visual function. This study aimed to investigate the relationship between choroidal thickness, degree of myopia, and photoreceptor–RPE layer thickness.

Methods: A cross-sectional study was conducted on 102 eyes, classified into emmetropia, mild, moderate, and high myopia groups. Spectral-domain optical coherence tomography (SD-OCT) with enhanced depth

imaging (EDI) was used to acquire macular scans using the HD 1-Line 100 $\times$ protocol. Manual measurements of choroidal and photoreceptor–RPE thicknesses were performed, then categorized based on the Early Treatment Diabetic Retinopathy Study (ETDRS) grid.

Results: Significant differences in choroidal thickness were observed across refractive error groups. The highest choroidal thickness values were found in the subfoveal or superior regions, depending on the group, while the lowest values were consistently noted nasally. A statistically significant correlation between choroidal thickness and photoreceptor–RPE thickness was identified only in the inferior region of the inner ring ($r = 0.34$, $p < 0.001$).

Conclusions: Choroidal thickness varies significantly with the degree of myopia and demonstrates a weak but significant correlation with photoreceptor–RPE thickness, particularly in the inferior macular region.

Diagnostic Aqueous Tap in Viral Anterior Uveitis: An Unknown Trigger for Dendritic Ulcer Formation

First Author: Disha CHETANI

Co-Author(s): Reema BANSAL, Singh(malhotra)

CHINTAN, Surya Prakash SHARMA

Purpose: To report diagnostic aqueous tap as an unknown risk factor causing dendritic ulcer formation in eyes with suspected viral anterior uveitis (AU).

Methods: Three patients presented with corneal edema, keratic precipitates, AU, and raised intraocular pressure. A diagnostic aqueous tap was done for viral PCR testing. A dendritic ulcer was noted subsequently.

Results: All were males (62, 61, and 29 years old), with VZV positive PCR, negative PCR, and HSV positive PCR, respectively. Dendritic ulcer was noted on days 1, 6, and 8, respectively. After antiviral therapy, the corneal ulcer healed in 2 eyes, while the third patient underwent therapeutic penetrating keratoplasty.

Conclusions: Aqueous tap may be an unknown risk factor for dendritic ulcer formation in eyes with viral AU, possibly by causing iatrogenic direct viral invasion or local immunosuppression. Whether it triggers the natural course of dendritic ulcer formation in some eyes also needs to be considered. An aqueous tap is a minimally invasive and routinely done procedure. However, when performed in eyes with viral anterior uveitis, it may trigger dendritic ulcer formation, which can be sight-threatening. Clinicians need to be vigilant about this possible temporal causal relationship

Do Pegcetacoplan and Avacincaptad Pegol Offer a Viable Therapeutic Approach for Dry Age-Related Macular Degeneration?

First Author: Wing Yi Chilli LAU

Purpose: Dry age-related macular degeneration (AMD) is characterised by atrophic areas on the retina and leads to gradual central vision loss, affecting millions globally. To date, only pegcetacoplan and avacincaptad pegol are approved for treating dry AMD in the United States, targeting complement C3 and C5, respectively. However, these drugs are not approved in the United Kingdom and Europe, leaving no treatment options in these regions. This critical review aims to explore the clinical value of these two drugs in dry AMD management.

Methods: A systematic literature search was conducted using the keywords 'pegcetacoplan', 'avacincaptad pegol' and 'age-related macular degeneration'. Sixteen papers were included following the PRISMA flow diagram.

Results: Pegcetacoplan was evaluated in the FILLY, OAKS, and DERBY trials, while avacincaptad pegol was evaluated in the GATHER1 and GATHER2 trials. Most trials reported statistically significant delay of lesion growth between drug treatment and sham groups, except the DERBY trial. However, secondary outcomes assessing change in visual function did not demonstrate significant results. Post hoc analyses supported anatomical benefits, and additional studies evaluated their cost-effectiveness and the impact of patient baseline characteristics.

Conclusions: Despite showing a delay in lesion growth, the lack of visual function benefits, and the increased risk of exudative AMD have sparked controversy in their use. Limited ethnic diversity in trials and potential funding bias also add uncertainty to their true effectiveness. Ongoing phase 4 clinical trials are essential in assessing their real-world efficacy and value.

Abstract No.: 206817

Does Glycemic Control Influence Macular Thickness and Vessel Density in Adolescents With Short-Duration Type 1 Diabetes? An OCT/OCTA Analysis

First Author: Nadia DEWI

Co-Author(s): Harjoedi AJI CAHYONO, Nanda ANANDITA, Fatina QONITA, Lely WULANDARY

Purpose: Subclinical macular changes in short-duration type 1 diabetes mellitus (T1DM) without retinopathy are poorly quantified. Optical coherence tomography (OCT)/OCT angiography (OCTA) analysis was performed to investigate whether glycemic control (HbA1c) has an

effect on macular thickness as well as vessel density on a per-eye basis.

Methods: Cross-sectional eye analysis of 56 eyes from 28 adolescents with short-duration T1DM (mean age 16.25 ± 2.01 years; duration 5.32 ± 2.81 years) was performed. Eyes were classified as HbA1c controlled ($\leq 7\%$, $n=20$) or uncontrolled ($>7\%$, $n=36$). Spectral-domain OCT measured central subfield thickness (CST) and macular average cube, while OCTA (6×6 mm) measured central and full macular vessel density. The differences between groups, percent change, Cohen's d (unequal-N pooled SD), and correlations with HbA1c and diabetes duration were calculated.

Results: Mean HbA1c was 7.98 ± 1.75 . HbA1c correlations to central vessel density $r=0.070$ ($p=0.607$), full vessel density $r=-0.060$ ($p=0.659$), CST $r=-0.048$ ($p=0.725$), average cube $r=-0.186$ ($p=0.170$). Between two groups, CST: $242.5 \pm 18.41 \mu\text{m}$ vs $230.7 \pm 22.39 \mu\text{m}$ (difference $11.8 \mu\text{m}$, -4.87% ; $d=0.56$; $p \approx 0.067$). Average cube: 283.3 ± 14.03 vs $275.7 \pm 14.86 \mu\text{m}$ (-2.68% ; $d=0.52$; $p \approx 0.088$). The differences of macular vessel density were trivial (central: -2.27% , $d \approx 0.08$; full: -1.29% , $d \approx 0.14$).

Conclusions: In adolescents with short-duration T1DM, OCT/OCTA evaluation reveals uncontrolled HbA1c related to mild macular thinning (~ 2.7 – 4.9% , moderate d), while macular vessel density variances are insignificant. Larger longitudinal studies are needed to confirm clinical relevance.

Abstract No.: 201792

Panel No.: RME-0956

Early Efficacy Observation of Faricimab Monoclonal Antibody in the Treatment of Neovascular Age-Related Macular Degeneration in the Real World

First Author: Rongrong

Purpose: To observe the early clinical efficacy and safety of intravitreal injection of faricimab monoclonal antibody in the treatment of nAMD in the real world.

Methods: A retrospective analysis was conducted on 26 patients (30 eyes) with nAMD who received intravitreal injection of faricimab injection (6mg/0.05ml) in our hospital from March to September 2024. 19 patients (20 eyes) were initially treated, and 7 patients (10 eyes) were treated. Paired t-tests were used to analyze the changes in BCVA, CRT, intraocular pressure, and adverse reactions before and one month after injection.

Results: One month after injection, 15 eyes (50%) responded well, including 12 eyes (80%) treated initially and 3 eyes (20%) treated after treatment; 14 eyes (46.66%) had low response, including 8 eyes (57.14%) in initial treatment and 6 eyes (42.86%) in post-treatment; One eye (3.33%) did not respond, indicating a treated patient. The average number of

letters in BCVA after injection was (57.50 ± 22.511), which increased by (2.433 ± 5.847) letters compared to before injection (55.07 ± 22.405), and the difference was statistically significant ($t=-2.280$, $P<0.05$); The average CRT value after injection was (220.54 ± 46.786) μm , which showed a statistically significant difference compared to before injection (352.62 ± 113.962) ($t=4.999$, $P<0.001$). All patients did not experience any adverse reactions.

Conclusions: In the real world, Faricimab monoclonal antibody has good efficacy and safety in the treatment of nAMD.

Panel No.: RME-1007

Early-Onset Retinal Degeneration Associated With CCT2: Case Report and Literature Comparison With the Only Previously Described Family

First Author: Mohamed **SHERIF**

Co-Author(s): Hiok Hong **CHAN**, *Beau J.* **FENNER**, *Mathieu* **QUINDOZ**, *Carlo* **RIVOLTA**, *Peijun* **ZHANG**

Purpose: To report early-onset retinal degeneration associated with biallelic variants in CCT2 and to compare these findings with the only previously published family.

Methods: Comprehensive ophthalmic examination, multimodal retinal imaging, full-field and multifocal electroretinography, and next-generation sequencing (NGS) of inherited-retinal-dystrophy genes were performed.

Results: A 13-year-old female of Malay descent and history of early-onset myopia presented with worsening nyctalopia and field loss, her sister reported similar symptoms. BCVA was 6/24 OU, fundus examination disclosed subtle bilateral RPE granularity, while photoreceptor function was undetectable on ERG. By age 29 her BCVA had declined to 6/60 OD and 6/120 OS, progression of myopia to -11D OU. Multimodal imaging revealed complete outer retinal degeneration and a distinct hyperautofluorescent ring extending from the macula to the mid-periphery, speckled hypoautofluorescence at the macula. Exome sequencing did not identify any common genetic causes of LCA or early-onset retinal degeneration, though a secondary analysis uncovered two novel heterozygous variants in the chaperonin containing TCP1 subunit 2 gene (CCT2), namely CCT2 c.526A>C p.(Lys176Gln) and CCT2 c.841C>T p.(Arg281Cys), which were in trans and predicted to be pathogenic. Our case appears phenotypically like a previously reported individual with CCT2-associated Leber congenital amaurosis and likely represents the second such individual identified to date.

Conclusions: This case represents the second report of early-onset autosomal recessive retinal degeneration

associated with CCT2. These findings broaden the molecular and phenotypic landscape of early-onset retinal degenerations and establish CCT2 disease as phenotypically distinct disease. They also highlight the importance of including CCT2 in diagnostic gene panels for inherited retinal disease.

Abstract No.: 207340

Panel No.: RME-1036

Effect of Vitreomacular Adhesion on Anti-VEGF Therapy Outcomes in patients with Macular Edema

First Author: Bhavya **ANEJA**

Co-Author(s): Shreyangshi **DIPTA**, *Bhumika* **SHARMA**, *Meenakshi* **THAKAR**

Purpose: To evaluate the effect of vitreomacular adhesion (VMA) on the efficacy of intravitreal anti-vascular endothelial growth factor (anti-VEGF) therapy in patients with macular edema.

Methods: A prospective, interventional study was conducted on 32 eyes with treatment-naïve macular edema secondary to diabetes or retinal vein occlusion. Based on spectral domain optical coherence tomography (SD-OCT), patients were categorized into 2 groups: VMA-positive ($n = 16$) and VMA-negative ($n = 16$) group. All eyes received three consecutive monthly intravitreal anti-VEGF injections. Outcome measures included best-corrected visual acuity (BCVA, ETDRS letters), central macular thickness (CMT), and OCT morphological changes, assessed at baseline and monthly until week 16.

Results: At baseline, BCVA and CMT were comparable between the groups. After three injections, a significant improvement in BCVA was observed in both the groups, with greater gains in the VMA + group (57.56 ± 15.22 in VMA+ vs. 47.44 ± 11.3 ETDRS letters in VMA-group, $p = 0.041$). Mean CMT reduction was 323.81 ± 99.44 μm in the VMA + group and 374.75 ± 127.78 μm in the VMA - group ($p = 0.218$), which was not statistically significant. OCT morphology analysis showed no overall significant intergroup difference ($p = 0.183$), although eyes with VMA demonstrated a better morphological response with a higher likelihood of foveal contour restoration ($p = 0.022$).

Conclusions: Epiretinal membranes and vitreomacular traction are established negative prognostic factors for anti-VEGF therapy, whereas the role of VMA has been unclear. This study shows that VMA does not adversely affect treatment outcomes; rather, eyes with VMA may experience superior visual improvement and should not be excluded from anti-VEGF treatment.

Panel No.: RME-1005

Effectiveness of Suprachoroidal Injection of Triamcinolone Acetonide in Resistant Macular Edema With Different Retinal Diseases Using a Modified Microneedle

First Author: Mohammad Aminur RAHMAN

Purpose: The present study evaluated the effectiveness of suprachoroidal injection of triamcinolone acetonide (TA) in resistant macular edema secondary to various retinal diseases using a modified microneedle.

Methods: This is a retrospective nonrandomized interventional study that was conducted on 30 eyes of 25 patients with macular edema secondary to various retinal diseases resistant to previous anti-vascular endothelial growth factor (VEGF) agents. All patients received suprachoroidal injection of triamcinolone acetonide 4 mg/0.1 mL by a modified specialized microneedle.

Results: Suprachoroidal injection of triamcinolone acetonide was used in various aetiologies such as resistant DME(PDR/NPDR) (n=14;46.7%), resistant CME (BRVO/CRVO)(n=10;33.3%), uveitic macular edema(n=2;6.7%), Irvine-Gass syndrome with resistant CME(n=2;6.7%), post-vitrectomy macular edema(n=1;3.3%), and resistant CNVM(n=1;3.3%). The mean central macular thickness (CMT) decreased significantly from 516.53±116.53 µm before injection to 349.50±171.10 µm after 12 months, with a p-value <0.006. Significant improvement of the mean best corrected visual acuity (BCVA) from 0.85±0.3 by logMAR at the baseline to 0.53±0.3 by logMAR was achieved after 12 months with a p-value <0.000. The IOP change was not significant. Eyes with more baseline CMT and worse baseline BCVA achieved worse final BCVA 12 months after injection.

Conclusions: Suprachoroidal injection of TA using this new modified microneedle resulted in marked anatomical and functional results in cases of macular edema resistant to previous anti-VEGF drugs, with no serious ocular or systemic side effects.

Effects of Long-Term Intravitreal Aflibercept Treatments in Mouse Retina

First Author: Linbin ZHOU

Co-Author(s): Hoi Tung CHOW, Wai Kit CHU, Jiahui LI, Chi Pui PANG, Chee THAM

Purpose: Long-term treatment with anti-vascular endothelial growth factor (VEGF) agents by frequent intravitreal injection is effective in inhibiting choroidal neovascularization (CNV) leakage in exudative age-related macular degeneration (AMD) patients. Previous clinical studies found repeated injection of anti-VEGF agents increased geographic atrophy (GA) development

risk in exudative AMD patients. This study investigated effects of repeated injection of anti-VEGF agents in mouse retina.

Methods: Female C57BL/6J mice of 14 weeks old were intravitreally treated with 2µL aflibercept (40mg/mL) or sterile phosphate-buffered saline (PBS) weekly (n=8 per group) for 8 consecutive weeks. After the treatment, the retina and choroid were separately isolated to study the expression of multiple genes linked to AMD pathogenesis by quantitative real-time polymerase chain reaction (qRT-PCR). Unpaired Student's t-test was performed for statistical analysis.

Results: In comparison with the PBS group, the retina with intravitreal aflibercept treatment for 8 weeks showed a marked increase in the expression of multiple AMD risk genes, including Dcn, Apoe, Cx3cr1, Cfh, Sod2, Ccl2 and Ccr2 (all with a P value < 0.05), while no significant alterations were observed in VEGF, Mmp2 and Vtn (all with a P value > 0.05). Conversely, in the choroid, intravitreal aflibercept treatment remarkably decreased the expression of Apoe (p<0.0001), while no pronounced changes were observed in Ccr2, Cfh, Ccl2, Cx3cr1, Vtn and VEGF (all with a P value > 0.05) with Sod2, Dcn, and Mmp2 remaining undetectable.

Conclusions: Long-term intravitreal anti-VEGF agents injection may contribute to the expression changes in AMD associated genes.

Efficacy of Photobiomodulation in Diabetic Macular Edema: A Systematic Review and Meta-Analysis

First Author: Jijing LI

Co-Author(s): Yanxian CHEN, Mingguang HE, Yue WU

Purpose: Diabetic macular edema (DME) is a major cause of vision loss in diabetes. Photobiomodulation (PBM), a non-invasive low-intensity light therapy, has shown potential for DME treatment. This systematic review and meta-analysis evaluated PBM's efficacy in reducing central retinal thickness (CRT) and improving best-corrected visual acuity (BCVA) in DME patients.

Methods: We searched PubMed, EMBASE, Cochrane Library, and Web of Science up to January 2025 for randomized controlled trials (RCTs) and single-arm studies on PBM's effects on CRT and BCVA in DME. Data were analyzed using random-effects models.

Results: Five studies (251 eyes) were included. Pooled analysis showed a non-significant trend toward CRT reduction and slight BCVA improvement. Single-arm studies indicated greater CRT reduction and BCVA improvement than the RCT. Significant CRT reduction was seen at 6 months, and BCVA improvement at 12 months. No serious adverse events were reported.

Conclusions: PBM's overall effects in DME remain inconclusive, but single-arm studies and longer follow-up suggest possible benefits. Further rigorous research is needed.

Epidemic Post-Fever Retinitis Due to Rickettsial Infection: A Case Series From Nepal

First Author: Sanjib Kumar **CHAUDHARY**

Co-Author(s): Santosh **CHAUDHARY**

Purpose: Post-fever retinitis (PFR) is a vision-threatening condition reported after systemic infections. Rickettsial infection, though often under recognized, is an emerging cause in endemic regions. This is the first report from Nepal describing an epidemic cluster of PFR due to rickettsial infection. This study will underscore the need for coordinated response from clinician, public health authorities and researchers for management and prevention.

Methods: We conducted a case series of patients presenting with retinitis following recent febrile illness. Diagnosis of rickettsial etiology was based on compatible systemic history, fundus features, and positive serology (Weil–Felix test). Clinical profile, treatment, and outcomes were documented.

Results: Nineteen patients presented in a cluster over a two-month period (October–November) from the same geographic area, all with history of fever about one month earlier and severe visual impairment. Fundus examination revealed cotton wool spots in posterior pole, retinal hemorrhages, and severe macular edema. The anterior segment was normal with minimal vitritis. Fourteen patients had positive Weil–Felix serology. All were treated with oral doxycycline and oral prednisolone. A dramatic therapeutic response was observed, with resolution of macular edema, healing of retinal lesions without scarring, and significant improvement in visual acuity.

Conclusions: PFR due to rickettsial infection may mimic other infectious or immune-mediated retinitis, often presenting with severe vision loss. Despite the absence of gold-standard confirmation of the preceding fever, simple and timely therapy resulted in excellent visual recovery. Greater awareness of rickettsial retinitis is essential in endemic areas to enable early diagnosis and treatment.

Ethnic Variations in Neovascular Age-Related Macular Degeneration: Optical Coherence Tomography-Based Subtype Analysis Across Singaporean, Canadian Asian, and Canadian Caucasian Populations

First Author: Antoine **HUANG**

Co-Author(s): Gemmy **CHEUNG**, Lisa **GEORGE**, Noa **GILEAD**, Zehua **JIANG**, Wataru **KIKUSHIMA**, Waiching **LAM**, Jennifer **LING**, Mohamed **SHERIF**, Kelvin **TEO**, Chenxi **ZHANG**

Purpose: To compare the prevalence and optical coherence tomography (OCT) characteristics of neovascular age-related macular degeneration (nAMD) subtypes among Singaporean Asians and Caucasians. Further, to evaluate the potential influence of environmental factors, we compared Singaporean Asians with Asians residing in Canada.

Methods: This retrospective, multicenter study analyzed consecutive treatment-naïve nAMD patients from Singapore and Canada. Patients were stratified into three groups: Singaporean (n=181), Canadian Caucasian (n=89), and Canadian Asian (n=57). Polypoidal choroidal vasculopathy (PCV) diagnosis was based on modified Asia-Pacific Ocular Imaging Society non-indocyanine green angiography criteria. OCT features, including pigment epithelial detachments (PED), subretinal hyperreflective material, drusen types, and choroidal thickness, were systematically analyzed.

Results: PCV prevalence differed significantly across groups: Singaporean 42.0%, Canadian Asian 43.9%, and Canadian Caucasian 16.9%. Singaporean patients were younger (70 ± 8.9 years) with higher male predominance (66.9%) compared to Canadian Caucasian (80 ± 9.3 years, 37.1% male) and Canadian Asian patients (77 ± 10.3 years, 50.9% male). Among PCV cases, sharp-peaked PED was most frequent in Canadian Asian patients (96.0% vs 75.0% Singaporean, 80.0% Canadian Caucasian). Extensive subretinal hemorrhage was highest in Canadian Asian PCV patients (20.0%). Soft drusen prevalence in PCV was greater in Canadian Caucasians (20.0%) compared to Asian populations (4.0–6.6%). Reticular pseudodrusen were more common in Canadian Caucasian typical nAMD patients (37.8%).

Conclusions: Significant ethnic variations exist in nAMD subtype prevalence and morphological characteristics, with Asian populations demonstrating higher PCV rates and distinct OCT features compared to Caucasians. Clinical characteristics of Asians residing in Singapore and Canada were largely similar.

Panel No.: RME-1006

Evaluation of Macular Thickness in Children With Type 1 Diabetes Mellitus Without Retinopathy

First Author: Fatina QONITA

Co-Author(s): Nanda Wahyu ANANDITA, Haryudi Aji CAHYONO, Nadia Artha DEWI, Lely Retno WULANDARI

Purpose: Limited data exist regarding macular thickness in type 1 diabetes mellitus (T1DM). We investigated macular thickness in children with T1DM without retinopathy using Spectral-Domain Optical Coherence Tomography (SD-OCT) as a potential marker for early subclinical neurodegenerative and microvascular complications.

Methods: This descriptive cross-sectional study included children aged 6–20 years with T1DM without diabetic retinopathy. Macular thickness was measured using SD-OCT, the central subfield thickness (CST) and total macular volume (TMV) were analysed. Associations between macular parameters, diabetes duration, and HbA1c levels were assessed using appropriate statistical methods.

Results: We evaluated 43 children with type 1 diabetes mellitus (T1DM) (mean age 13.5 years; 62.8% female; mean duration 4.6 years; mean HbA1c 8.2%). Central subfield thickness (CST) was significantly thinner in children with diabetes duration ≥ 5 years and HbA1c $\geq 7\%$, while TMV was significantly lower with HbA1c $\geq 7\%$. CST correlated negatively with both diabetes duration and HbA1c, whereas TMV correlated only with HbA1c. Our studies highlights early macular changes in pediatric T1DM without retinopathy, supporting evidence of subclinical neurodegenerative and microvascular involvement. However, the cross-sectional design, lack of a normative control group, reliance on point HbA1c values, and single-center sampling represent limitations that may restrict the accuracy and external validity of the results.

Conclusions: Macular thickness in children with T1DM is influenced by diabetes duration and glycemic control. OCT screening plays a valuable role in the early detection of neurodegenerative and microvascular retinal changes in this population.

Evaluation of Retinal and Choroidal Biomarkers During Treatment of Polypoidal Choroidal Vasculopathy

First Author: Colin TAN

Purpose: To evaluate changes in retinal and choroidal biomarkers following treatment of patients with polypoidal choroidal vasculopathy (PCV).

Methods: Review of 32 consecutive patients diagnosed with PCV treated at the medical retina clinic at Tan Tock Seng Hospital, Singapore. 18 patients were treated with photodynamic therapy (PDT) combined with anti-vascular endothelial growth factor (anti-VEGF) agents, while 14 patients were treated with anti-VEGF monotherapy. The optical coherence tomography (OCT) scans were reviewed on presentation (baseline) and following a course of treatment using standardized grading protocols.

Results: Visual acuity improved following treatment in all patients. Polyp regression was achieved in 90% of patients in the PDT group, compared to 33.3% of patients receiving anti-VEGF. Among all patients, the mean choroidal thickness (CT) on presentation was 248.4 μm , and decreased to 224.8 μm ($p=0.141$) after treatment with either PDT or anti-VEGF. The decrease in CT in the group treated with PDT combined with anti-VEGF was larger compared to the group treated with anti-VEGF monotherapy (55.4 μm vs. 0.25 μm , $p=0.072$). Central subfield retina thickness was 439.3 μm at baseline compared to 303.7 μm after treatment. Retinal thickness decreased by a larger amount (200.1 μm) in the combination therapy group compared to 87.3 μm in the anti-VEGF group.

Conclusions: There is a greater decrease in both choroidal and retinal thickness following treatment of PCV with PDT combined with anti-VEGF, compared to anti-VEGF monotherapy, which correlated with differences in poly regression rates.

Panel No.: RME-0941

Evaluation of Sodium-Glucose Cotransporter 2 Inhibitors and Dipeptidyl Peptidase-4 Inhibitors in Modulating the Progression of Diabetic Retinopathy and Development of Proliferative Diabetic Retinopathy

First Author: Ziqi TANG

Co-Author(s): Carol CHEUNG, Timothy LIN, Ka Ho SZETO

Purpose: To investigate whether there are associations between the use of sodium-glucose cotransporter-2 inhibitors (SGLT-2i), dipeptidyl peptidase-4 inhibitors (DPP-4i), or both and the development or progression of diabetic retinopathy (DR) and proliferative DR (PDR).

Methods: This prospective cohort, new-user design study included individuals with diabetes who had at least three years of follow-up at the Chinese University of Hong Kong. Participants were categorized into four groups: SGLT-2i only (Group 1), DPP-4i only (Group 2), both SGLT-2i and DPP-4i (Group 3), and neither medication (Group 4). Patients who used glucagon-like peptide-1 receptor agonists were excluded. Cox regression models were used to estimate hazard ratios, adjusting for age, age at diabetes diagnosis, duration of diabetes, HbA1c, estimated glomerular filtration rate,

body mass index, exposure window, and baseline DR severity.

Results: The study included 4,968 visits from 724 eyes across 369 patients (mean age [SD]: 60.0 [12.8] years; 54.0% male), with a mean follow-up duration of 4.68 (2.73) years. A total of 75, 161, 178, and 310 patients were recorded for Groups 1 through 4, respectively. Compared to Group 4, Groups 1 through 3 did not exhibit significantly lower risks for DR development or progression. However, Group 2 (3.44 [1.47–8.07]) and Group 3 (4.25 [1.52–11.9]) showed an increased hazard for developing PDR.

Conclusions: Use of SGLT-2i, DPP-4i, or both was not associated with a lower risk of DR development or progression. However, DPP-4i use may be linked to a higher risk of developing PDR.

Evaluation of Treatment Response to Intravitreal Biosimilar Ranibizumab in Severe Clinically Significant Macular Edema in Diabetes

First Author: Nikita MINOCHA

Co-Author(s): Yashi GUPTA, BhumiKA SHARMA, Meenakshi THAKAR

Purpose: To evaluate anatomical and functional outcomes following intravitreal biosimilar ranibizumab in patients with severe clinically significant macular edema (CSME; central macular thickness [CMT] >500 μ m).

Methods: In this prospective interventional study, 25 eyes of treatment-naïve patients with non-proliferative diabetic retinopathy with severe CSME received 3 monthly intravitreal injections of biosimilar ranibizumab (0.5 mg/0.05 mL). CMT and best-corrected visual acuity (BCVA) were measured at baseline and at 4, 8, and 12 weeks. Optical coherence tomography (OCT) morphology and biomarkers, including disorganization of retinal inner layers (DRIL) and ellipsoid zone (EZ) integrity, were analyzed.

Results: Mean baseline CMT ($642.9 \pm 106.8 \mu$ m) decreased significantly to 328.5μ m at 12 weeks ($P < .0001$). Mean BCVA improved from 36.4 ± 8.8 to 52.5 ± 13.6 ETDRS letters ($P < .0001$), with ≥ 10 -letter gain in 76% and ≥ 15 -letter gain in 52% of eyes. A normal foveal contour was achieved in 32%. Diffuse retinal thickening showed the greatest functional gain (+25 letters). Presence of DRIL and EZ disruption was associated with significantly poorer visual outcomes ($P = .013$ and $P = .021$, respectively).

Conclusions: Intravitreal biosimilar ranibizumab provides significant anatomical and functional improvements even in severe CSME. OCT biomarkers, particularly DRIL and EZ integrity, strongly predict visual prognosis. Biosimilar ranibizumab represents

an effective and affordable alternative to innovator molecules in resource-limited settings.

Exosome-Loaded Microcapsules for Sustained Intravitreal Treatment of Vitreoretinal Diseases

First Author: Han BAO

Purpose: Cell-based therapies have shown potential in treating ocular diseases but face major limitations, including poor cell survival, unstable phenotypes, and safety concerns. Since paracrine exosomes mediate much of the therapeutic benefit of cells, we developed a “pseudo-cell” strategy by encapsulating exosomes into biodegradable microcapsules to preserve the therapeutic advantages of cell therapy while avoiding its limitations.

Methods: Exosomes derived from mesenchymal stem cells (MExo) or regulatory T cells (TrExo) were encapsulated into biodegradable poly(lactic-co-glycolic acid) microcapsules (Cap) using a self-healing process. Following intravitreal injection, the distribution, retention, and therapeutic efficacy were assessed in retinal ischemia-reperfusion injury (RIRI) mouse model, primed mycobacterial uveitis (PMU) mouse model, and non-human primate PMU model.

Results: ExoCap settled in the inferior vitreous cavity and continuously released bioactive exosomes for over one month. In the RIRI model, MExoCap significantly reduced retinal cell apoptosis, preserved retinal thickness, and restored visual function effectively. In PMU models, TrExoCap markedly suppressed intraocular inflammation and preserved retinal clarity and electroretinographic responses. Non-human primate studies further confirmed the anti-inflammatory efficacy and safety of ExoCap.

Conclusions: ExoCap provides a novel “pseudo-cell” strategy for sustained intravitreal exosome delivery, demonstrating potent therapeutic efficacy in ischemic and inflammatory vitreoretinal diseases. Its favorable safety and translational potential support further investigation as a promising alternative to current treatments.

Exudative Retinal Detachment as a Hallmark of Acute Vogt-Koyanagi-Harada Disease

First Author: Woan Shian SEE

Co-Author(s): Sheena Mary ALEXANDER, Rajasudha Sawri RAJAN

Purpose: Exudative retinal detachment (ERD) is a common manifestation of Vogt-Koyanagi-Harada (VKH) disease but may mimic other ocular inflammatory

diseases. ERD reflects acute choroidal inflammation; its prognostic implications in Southeast Asian cohorts remain underreported. This study aimed to determine the prevalence of ERD at presentation in VKH and to evaluate its association with one-year visual outcomes following immunosuppressive therapy.

Methods: This retrospective, cohort study included 42 VKH patients (84 eyes). Patients were stratified into early presenters (≤ 4 weeks) or delayed presenters (> 4 weeks). ERD at baseline was confirmed by clinical examination and optical coherence tomography (OCT). All received high-dose corticosteroids, with immunosuppressants added when indicated. Best-corrected visual acuity (VA) at baseline and one year was converted to logMAR. Primary outcomes were the final mean logMAR and the proportion achieving $\geq 6/12$.

Results: ERD was observed in 80% of Early and 18.2% of Delayed eyes ($p < 0.001$). Bacillary layer detachment was frequently observed on OCT in early presenters' eyes. Although ERD eyes presented with worse vision, they showed greater mean improvement (0.75 logMAR) and nearly half achieved $\geq 6/12$ at one year. On multivariable adjustment for baseline VA and treatment, ERD was not an independent predictor of poor final vision.

Conclusions: ERD is a hallmark of acute VKH, highly prevalent in early presenters but uncommon in delayed disease. Despite association with poorer presenting acuity, ERD did not predict worse long-term visual outcomes when treated promptly, supporting its role as a marker of acute disease activity rather than prognosis.

Panel No.: RME-1016

Eye as a Window to Systemic Disorder: A Case of Unilateral Anaemic Retinopathy

First Author: Swati SAHU

Purpose: To describe a rare case of unilateral anaemic retinopathy presenting with sudden painless diminution of vision, and to emphasize the importance of early ophthalmic recognition as a clue to underlying systemic disease.

Methods: A 32-year-old female presented with a 4-day history of sudden painless diminution of vision in the right eye. There was no history of trauma or ocular surgery. She reported systemic complaints of fatigue and breathlessness. Ocular examination showed best-corrected visual acuity of 6/9 in the right eye and 6/6 in the left eye. The anterior segment was normal bilaterally. Fundus examination of the right eye revealed multiple intraretinal hemorrhages with Roth spots involving the fovea and posterior pole, while the left fundus appeared normal. Laboratory evaluation revealed hemoglobin of 6.9 g/dl, and peripheral

smear demonstrated marked microcytic hypochromic anemia. A provisional diagnosis of unilateral anaemic retinopathy was made.

Results: The patient was referred to a physician for systemic management and received one unit of whole blood transfusion. On follow-up, her hemoglobin improved to 9.4 g/dl, and her systemic symptoms resolved. Ocular findings showed resolving retinal hemorrhages with improved visual acuity to 6/6 in the affected eye, indicating a favorable response to systemic therapy.

Conclusions: Although anaemic retinopathy typically presents bilaterally, this case highlights its potential to present unilaterally. Ophthalmologists play a crucial role in identifying ocular signs that may be the first manifestation of systemic disease. Early recognition and timely referral for systemic treatment are essential to prevent further complications and ensure full visual and systemic recovery.

Abstract No.: 205522

From Bilateral Coats' Disease to Coats Plus Syndrome: A Case Report Highlighting the Importance of Systemic Diagnosis

First Author: Kejia YUAN

Co-Author(s): Yun LI

Purpose: To report a case of a child initially diagnosed with bilateral Coats' disease but finally confirmed as Coats Plus syndrome through comprehensive evaluation and genetic sequencing, underscoring the critical role of systemic evaluation in differential diagnosis.

Methods: A case report of a 2-year-old boy who presented with reduced visual acuity in the right eye. Diagnostic workup included serial fundus imaging and angiography, brain MRI (magnetic resonance imaging), and genetic sequencing.

Results: Retcam fundus examination revealed bilateral retinal telangiectasia and exudation, leading to an initial diagnosis of Coats' disease. The patient's condition achieved stabilization following a combined treatment regimen of multiple retinal laser photocoagulation and intravitreal aflibercept injections over three years. Systemic investigation revealed cerebral white matter lesions on MRI (Fazekas Grade 1). Genetic testing identified a pathogenic mutation in the CTC1 gene, which is associated with Coats Plus syndrome. A separate variant of uncertain significance was found in the COL18A1 gene. The definitive diagnosis of Coats Plus syndrome was made based on the characteristic ocular findings, a poor response to therapies, neurological abnormalities, and the confirmed CTC1 pathogenicity.

Conclusions: This case demonstrates that bilateral, treatment-resistant Coats' disease-like retinopathy

in young children can be a hallmark of Coats Plus syndrome. Clinicians should maintain a high index of suspicion and pursue prompt genetic testing and multidisciplinary systemic evaluation to reach a correct diagnosis, which is crucial for management and prognostic counseling.

Panel No.: RME-0967

Genetic Variants Associated With Central Serous Chorioretinopathy in Chinese

First Author: Xintian **ZHU**

Co-Author(s): Li-jia **CHEN**, Mary **HO**, Danny Siu-chun **NG**, Jason Cheuk-sing **YAM**

Purpose: To identify susceptibility variants associated with central serous chorioretinopathy (CSCR) in Chinese.

Methods: We enrolled a Chinese cohort of 247 patients with CSCR and 695 unrelated controls. CSCR was confirmed by multimodal imaging, with other maculopathies excluded. After quality control filtering, 24 single-nucleotide polymorphisms (SNPs) were analyzed. Additive logistic regression models adjusted for age and sex were used to estimate odds ratios (ORs) and 95% confidence intervals (CIs). Multiple testing correction was performed using the Benjamini-Hochberg false discovery rate (FDR) and the Bonferroni method.

Results: In our cohort of 247 CSCR cases and 695 qualified controls, the C allele of CASP10 rs11674246 was significantly associated with an increased risk of CSCR after Bonferroni correction (OR = 1.8; $P < 0.001$). Additionally, rs13255394-C in the TNFRSF10A region reached FDR significance (OR = 1.45; $P < 0.01$) but did not pass Bonferroni correction. The associations remained consistent in both unadjusted and age-adjusted models. No significant association was detected for the remaining 22 SNPs.

Conclusions: This study identifies an association for CASP10 rs11674246-C and implicates the TNFRSF10A region in CSCR susceptibility. These findings reveal candidate loci and reinforce previous evidence. Further investigation into the functional roles of these variants, as well as their potential shared genetic pathways with age-related macular degeneration (AMD) and polypoidal choroidal vasculopathy (PCV), may elucidate common mechanisms underlying macular diseases.

Abstract No.: 206202

Panel No.: RME-1019

Guarding the Vulnerable Fellow Eye: A Systematic Review and Meta-Analysis of Prophylactic Anti-VEGF in Neovascular Age-Related Macular Degeneration

First Author: Tsabita **ANNISA**

Co-Author(s): Gitalisa Andayani **ADRIONO**

Purpose: Age-related macular degeneration (AMD) is a leading cause of irreversible vision loss, with neovascular AMD (nAMD) often causing rapid deterioration. Patients with unilateral nAMD face a high risk of fellow-eye involvement. Prophylactic intravitreal anti-vascular endothelial growth factor (anti-VEGF) therapy has been suggested as a preventive strategy, but its benefit remains uncertain. This systematic review and meta-analysis evaluated efficacy and safety.

Methods: PubMed, Scopus, and Google Scholar (2004–2025) were searched for studies on prophylactic anti-VEGF in unaffected fellow eyes. The primary outcome was conversion to nAMD; secondary outcomes included best-corrected visual acuity (BCVA), geographic atrophy, and adverse events. Data were pooled using random-effects meta-analysis, with heterogeneity assessed by I^2 .

Results: Of 419 records, three randomized controlled trials ($n = 235$) met criteria. Anti-VEGF did not significantly reduce fellow-eye conversion compared with placebo (OR 0.93, 95% CI: 0.42–2.07, $p = 0.86$) or BCVA change (letter score in ETDRS Chart) at 24 months (MD -1.24 letters, 95% CI: -3.43 to 0.96, $p = 0.27$). Safety outcomes showed no significant differences in mortality or adverse events (OR 0.38, 95% CI: 0.09–1.68, $p = 0.20$). Heterogeneity was negligible ($I^2 = 0\%$).

Conclusions: Current evidence does not support prophylactic anti-VEGF for preventing fellow-eye nAMD or improving vision, though trends favoring treatment were observed. Given the clinical importance of delaying bilateral involvement, larger multi-centre trials with diverse populations are required to clarify potential preventive benefits.

Abstract No.: 202665

Panel No.: RME-0971

Gyrate Atrophy With Foveoschisis and Full-Thickness Macular Hole in a Sibling Cohort

First Author: Vinit **TANWAR**

Purpose: To report the rare co-occurrence of foveoschisis and full-thickness macular hole (FTMH) in siblings with genetically confirmed Gyrate Atrophy of the choroid and retina (GACR). This report highlights the severe impact on central vision and explores a potential pathogenic sequence from foveoschisis to FTMH in this inherited retinal dystrophy.

Methods: This is a descriptive case series of three siblings from a non-consanguineous family. All patients underwent a comprehensive ophthalmic examination. Multimodal imaging included ultrawide-field fundus photography, fundus autofluorescence, and swept-source optical coherence tomography (SS-OCT). Diagnosis was confirmed with serum ornithine level testing and genetic analysis for OAT gene mutations in one affected sibling.

Results: All three siblings displayed characteristic peripheral chorioretinal atrophy of GACR. The two older siblings (ages 13 and 20) presented with a unilateral FTMH and contralateral foveoschisis, resulting in profound vision loss (PL to FCCF). The youngest sibling had preserved macular structure. SS-OCT confirmed the macular pathologies. Genetic testing revealed a homozygous missense mutation in the OAT gene.

Conclusions: Gyrate Atrophy can be complicated by severe macular pathologies, leading to early and devastating central vision loss. Foveoschisis appears to be a direct precursor to macular hole formation in this condition. Early diagnosis and management are crucial to monitor and potentially mitigate these vision-threatening complications.

Panel No.: RME-0976

Imaging Study of OCTA After Fasirizumab Intervention for Recurrent Type 1 MNV

First Author: Wei ZHOU

Co-Author(s): Wenqi SU

Purpose: Type I macular neovascularization (MNV) is often resistant to conventional anti-VEGF therapy. Faricimab, a bispecific antibody targeting both VEGF-A and Ang-2, offers a potential therapeutic option. This study aimed to evaluate the efficacy of intravitreal faricimab in treatment-resistant Type I MNV.

Methods: All patients received intravitreal faricimab injection and were followed for 14 days. Best-corrected visual acuity (BCVA), intraocular pressure (IOP), and multimodal imaging parameters from OCT and OCTA were compared before and after treatment. Quantitative metrics included MNV perfusion area, MNV vessel area, trunk and capillary MNV area, MNV vessel density, foveal avascular zone (FAZ) area and perimeter, central foveal thickness, choroidal thickness, pigment epithelial detachment (PED) height, subretinal fluid (SRF) volume, and central foveal volume. OCTA analysis of MNV before and after treatment with faricimab was conducted using ImageJ software. Paired t-test compared these parameters at baseline and after treatment.

Results: The case series study of 11 eyes with unresponsive CNV, despite monthly intravitreal treatment (mean number of pre-faricimab injections:

16.9 ± 6.1). At Day 14 post-treatment, significant reductions were observed in MNV perfusion area (p=0.004), trunk MNV area (p=0.0107), capillary MNV area (p=0.0107), central foveal thickness (p=0.0431), and choroidal thickness (p=0.020). MNV vessel area (p=0.0511), vessel density (p=0.0828), mean retinal thickness (p=0.0619), and central foveal volume (p=0.0579) showed a trend toward reduction but did not reach statistical significance.

Conclusions: Intravitreal faricimab led to a significant reduction in MNV lesion size and associated retinal structural biomarkers in treatment-resistant Type I MNV.

Abstract No.: 205784

Panel No.: RME-1011

Intraocular Pressure (IOP) Changes After 8mg Aflibercept Intravitreal Injections in a Chinese Population- a Real-World, Non-Sponsored Study

First Author: Shing Yee Steffi CHONG

Co-Author(s): Chi Lik AU, Po Lin LEOW

Purpose: 8mg Aflibercept has been introduced with the possible advantage of reducing the overall burden of injections for patients and healthcare systems. However, concerns regarding the intraocular pressure have arisen in view of the extra volume of drug needed to be injected intraocularly. This is the first cohort study looking into the IOP changes after 8mg Aflibercept (0.07ml) intravitreal injections in a Chinese population.

Methods: This is a single-centred, observational cohort including all Chinese eyes with 8mg Aflibercept intravitreal injections between June and September 2025. The control group included the same eyes with data of other anti-vascular endothelial growth factor (anti-VEGF) (0.05ml) injections available, which were age- and gender-matched. Data were analyzed using the SPSS software. Statistical tests used included the Wilcoxon Signed Rank test, Mann-Whitney U test, and Chi-square test.

Results: A total of 120 eyes with 8mg Aflibercept injections were included in this study. The mean age of the patients was 77.8 ± 11.9 years old. 56 eyes (46.7%) belonged to female patients, while 64 eyes (53.3%) belonged to male patients. The mean pre-injection IOP for the 8mg Aflibercept group was 15.4 ± 3.2 mmHg compared to post-injection IOP of 18.9 ± 4.4 mmHg (p< 0.001). There was a positive correlation between the pre- and post-injection IOP (p<0.001, r=0.518). Sixty-eight eyes were included in the control group. The mean age of the patients was 76.8 ± 13.1 years old. 26 eyes (38.2%) belonged to female patients, while 42 eyes (61.8%) belonged to male patients. The mean pre-injection IOP was 15.6 ± 3.5 mmHg compared to post-injection IOP of 19.0 ± 5.3 mmHg (p<0.001). The IOP changes after injections were not statistically different between the 8mg

Aflibercept and control groups ($p=0.219$). 31 out of 120 eyes (25.8%) in the 8mg Aflibercept group had post-injection IOP >21 mmHg without pre-existing ocular hypertension (i.e. pre-injection IOP ≤ 21 mmHg) compared to 19 out of 68 eyes (27.9%) in the control group, which was not statistically significant ($p=0.887$). Timing of injections (i.e., morning versus afternoon) and phakic status of the eyes did not affect the IOP changes after 8mg Aflibercept injections ($p=0.190$ and $p=0.953$, respectively).

Conclusions: There was no increase in rate of ocular hypertension after 8mg Aflibercept injections compared to other anti-VEGF with injection volume of 0.05ml.

Abstract No.: 208765

Panel No.: RME-1044

MMP2 (1575 G/A) and MMP9 (1562 C/T) Gene Polymorphism Might be a Predictive Genetic Marker of CRVO

First Author: Zhongping **CHEN**

Co-Author(s): Shengnan **LIANG**, Hengwei **LIU**

Purpose: To analyze the association between matrix metalloproteinase 1 (MMP1), matrix metalloproteinase 2 (MMP2), matrix metalloproteinase 9 (MMP9), and complement factor H (CFH) gene polymorphisms and the occurrence of Retinal vein occlusion (RVO).

Methods: This study enrolled 67 patients with RVO, classified into BRVO and CRVO groups. Single-nucleotide polymorphisms in MMP1, MMP2, MMP9, and CFH were analyzed utilizing the SNaPshot method.

Results: In the CRVO cohort, the A genotype of the MMP2 (c.-1575 G>A, rs243866) polymorphism was significantly more prevalent compared to controls ($p = 0.004$). The T allele of the MMP9 (c.-1562 C>T, rs3918242) polymorphism was also significantly more common in the CRVO group than in the control group ($p = 0.009$). Additionally, comparison with BRVO indicated higher mutation rates for MMP2 (c.-1575 G>A) and MMP9 (c.-1562 C>T, rs3918242) in CRVO patients (GA+AA:GG, OR = 4.71, $p = 0.015$; CT+TT:CC, OR = 5.56, $p = 0.008$).

Conclusions: The presence of the A allele in the MMP2 (c.-1575 G>A, rs243866) gene and the T allele in the MMP9 (c.-1562 C>T, rs3918242) gene may contribute to increased susceptibility to CRVO and are linked with a less favorable prognosis. These findings may be particularly relevant for clinicians and researchers seeking to better understand genetic risk factors associated with CRVO outcomes.

Macular Degeneration Associated With Cobalamin C Deficiency: A Case Report

First Author: Yumeng **LI**

Co-Author(s): Hashimoto **KINJI**, Wenbo **LIU**, Xuan **SHI**, Chengyue **SUN**, Wenzhou **XIAO**

Purpose: To report the macular degeneration in a patient with Cobalamin C Deficiency (cblC).

Methods: Case report.

Results: A 28-year-old male diagnosed with cblC deficiency was referred for a comprehensive ophthalmic evaluation. Genetic analysis confirmed compound heterozygous mutations in the MMACHC gene: c.467G>A (p.Gly156Asp) and c.46C>A (p.Arg16Gln). His best-corrected visual acuity was 20/20 in the right eye (OD) and 20/30 in the left eye (OS). Fundus examination revealed macular degeneration of both eyes. Optical coherence tomography (OCT) revealed bilateral macular atrophy of the outer segment of the photoreceptor layer and structural disorder. Fundus autofluorescence imaging of both eyes demonstrated the area of hypoautofluorescence in the macula. Fluorescein angiography (FFA) revealed window defects at the foci bilaterally. Automated perimetry confirmed bilateral central scotomas, with Visual Field Index (VFI) values of 68% (OD) and 74% (OS). The macular pathology was attributed to his underlying systemic disorder.

Conclusions: This case underscores the importance of conducting routine, comprehensive ophthalmic examinations for cblC deficiency patients, regardless of the presence or absence of visual symptoms. Early detection of ocular pathology is critical for timely intervention and management to potentially mitigate long-term visual impairment.

Macular Mayhem: Could Vitamin Deficiency Be the Culprit? Role of Serum Homocysteine, Vitamin B12 and Folic Acid in Patients With ARMD

First Author: Kusha

Co-Author(s): Vinod **KASHYAP**

Purpose: To assess serum levels of homocysteine, vitamin B12, and folic acid in patients with ARMD, and compare these biomarkers across dry and wet subtypes.

Methods: This prospective cross-sectional study included 84 patients aged >45 years with clinically diagnosed ARMD attending a tertiary care center in North India. Detailed ophthalmologic evaluation was followed by biochemical testing of fasting serum homocysteine, vitamin B12, and folic acid. Data were

analyzed using appropriate statistical tests, with $p < 0.05$ considered significant.

Results: Elevated serum homocysteine was observed in 51.19% of patients, with significantly higher levels in wet ARMD ($33.85 \pm 9.63 \mu\text{mol/L}$) versus dry ARMD ($26.7 \pm 17.23 \mu\text{mol/L}$; $p = 0.033$). Vitamin B12 deficiency was prevalent in 77.38% of participants, with median levels significantly lower in wet ARMD (135.1 pg/mL vs. 198.5 pg/mL ; $p < 0.0001$). Folic acid levels were lower in wet ARMD but not statistically significant ($p = 0.079$).

Conclusions: This study underscores the metabolic dimension of ARMD, particularly the association of hyperhomocysteinemia and vitamin B12 deficiency with wet ARMD. As the first such study in a North Indian cohort, it highlights the potential role of nutritional screening and B-vitamin supplementation in mitigating ARMD progression.

Management of Visual Rehabilitation on Oculocutaneous Albinism

First Author: Eka Apriani LUBIS

Co-Author(s): Nanda Wahyu ANANDITA, Nadia Artha DEWI, Wino Vrieda VIERLIA

Purpose: To report the management of visual rehabilitation in a 20-year-old man diagnosed with Oculocutaneous Albinism (OCA). This condition is rarely reported in Indonesia; therefore, a comprehensive examination was conducted, with the focus of this case directed toward the use of low vision aids.

Methods: A comprehensive ophthalmic evaluation was conducted, including uncorrected and best-corrected visual acuity (BCVA), refraction, slit-lamp biomicroscopy, fundus examination, Optical Coherence Tomography (OCT), and Visual Evoked Potentials (VEP). The patient was further evaluated by the low vision division.

Results: A 20-year-old man presented with blurred vision and difficulty performing daily activities. Visual acuity of the right eye was 6/60 correction with S-5.00 D C-2.75 D $\times 10^\circ$ improved to 6/30, while visual acuity of the left eye was 6/30 with S-4.00 D C-2.75 D $\times 170^\circ$ improved to 6/24. A 3 $\times$ telescopic low vision aid was trialed on this patient, resulting in an improvement of visual acuity to 6/19 in the right eye and 6/15 in the left eye. An 8 $\times$ telescopic low vision aid was also tried in this patient, but the patient does not feel comfortable. Compared with spectacles alone, the 3 $\times$ telescopic aid provided a significant enhancement in visual performance, particularly for distance viewing. The patient was also trialed with tinted filter lenses, which resulted in subjective improvement in visual comfort.

Conclusions: Management of visual rehabilitation in OCA requires a personalized, multidisciplinary

approach. Telescopic devices are effective low-vision aids for this patient, providing significant improvement in distance visual acuity and functional vision.

Methylation Status of Insulin-Like Growth Factor Binding Protein-Related Protein 1 in the Early Stage of Diabetic Retinopathy

First Author: Yuanyang HUANG

Co-Author(s): Tao SUN, Leilei WANG, Yan XU, Zhaojun ZHANG

Purpose: To investigate the expression and promoter methylation status of insulin-like growth factor binding protein-related protein 1 (IGFBP-rP1) in the early stage of diabetic retinopathy (DR), and to examine the potential role of DNA methyltransferase 1 (DNMT1) in regulating its epigenetic modifications.

Methods: Aqueous humor from DR patients at different disease stages and retinal tissues from streptozotocin (STZ)-induced diabetic mice (C57BL/6J) were collected to analyze IGFBP-rP1 expression levels. Müller cells cultured under high-glucose conditions were used to assess IGFBP-rP1 expression and promoter methylation levels by western blot, qRT-PCR, and methylation-specific PCR (MSP). Müller cells and diabetic mice cultured in high glucose treated with demethylation were applied to evaluating changes in IGFBP-rP1 promoter methylation and subsequent IGFBP-rP1 expression in vitro and in vivo.

Results: IGFBP-rP1 protein levels in the aqueous humor of DR patients significantly decreased with disease progression. IGFBP-rP1 mRNA expression in the retinas of diabetic mice showed time-dependent downregulation. High-glucose-induced time-dependent downregulation of IGFBP-rP1 protein expression and upregulation of DNA methylation in Müller cells. Demethylation agent 2'-deoxy-5-azacytidine (DAC) effectively reduced IGFBP-rP1 promoter methylation and upregulated IGFBP-rP1 expression in the retinas of diabetic mice. Knockdown of DNA methyltransferase 1 (DNMT1) significantly restored IGFBP-rP1 expression in vitro and in vivo.

Conclusions: Alterations in IGFBP-rP1 expression during the early stage of diabetic retinopathy may be associated with promoter methylation, an epigenetic regulation potentially mediated by DNMT1.

Abstract No.: 202229**Panel No.: RME-0966**

Microglia Disulfidptosis Contributes to Worsening of Diabetic Retinopathy Induced by Acute Hypoglycemia

*First Author: Xueying LOU**Co-Author(s): Aimin SANG, Ying YU*

Purpose: Concerns arise regarding the early worsening of diabetic retinopathy (DR) due to rapid decreases in blood glucose levels during diabetes treatment, but its pathogenesis is not well understood. This study aims to investigate the role of acute hypoglycemia (AH) in microglial disulfidptosis and the underlying mechanisms during DR progression.

Methods: Streptozotocin (STZ)-induced diabetic C57BL/6J mice and in vitro microglial models (HMC3 cells) were subjected to glucose deprivation conditions. Single-cell RNA sequencing (scRNA-seq) identified SLC7A11^{high} retinal cells. Flow cytometry, CCK-8 assays, and immunofluorescence evaluated microglia death and cytoskeletal changes. ROS detection and NADPH/NADP⁺ analysis assessed redox imbalance. Rac1-WRC pathway activity was analyzed via Western blot and inhibitors. Retinal damage was quantified using Evans blue leakage, H&E staining, and immunofluorescence. RT-qPCR detected inflammatory cytokine expression.

Results: Glucose deprivation upregulated SLC7A11 expression in retinal microglia, triggering disulfidptosis via excessive cystine uptake, NADPH depletion, and disulfide stress, which induced pro-inflammatory cytokine elevation (IL-1 β , IL-6, IL-8, TNF- α , and HIF-1 α). This process induced F-actin contraction, plasma membrane detachment, and irreversible cell death, unaltered by apoptosis/ferroptosis inhibitors but rescued by disulfide reductants. Glucose deprivation activated Rac1-WRC signaling, driving cytoskeletal collapse. SLC7A11 knockdown or Rac1 inhibition mitigated these effects. In vivo, AH exacerbated retinal vascular leakage, structural disorganization, and microglial cell death in the retinas of STZ-induced diabetic mice.

Conclusions: Glucose deprivation triggers microglial disulfidptosis via SLC7A11 redox imbalance and Rac1-WRC activation, worsening diabetic retinopathy. This highlights hypoglycemia risks and identifies treatment targets.

Abstract No.: 202664**Panel No.: RME-0970**

Natural Evolution of CRVO

First Author: Vinit TANWAR

Purpose: To present a unique photographic timeline documenting the rapid, sequential evolution of an impending Central Retinal Vein Occlusion (CRVO) to an ischemic state, and to underscore the critical

role of timely anti-VEGF intervention in managing complications, particularly when definitive diagnostics are limited.

Methods: A 44-year-old hypertensive male presented with impending CRVO. He was started on systemic anticoagulants, and his hypertension was managed. The patient's condition was monitored with serial fundus photography. Despite initial therapy, the condition progressed through distinct stages: from vascular sheathing and congestion to non-ischemic CRVO, and ultimately to ischemic CRVO with extensive hemorrhages and macular edema. Intravitreal anti-VEGF injections were administered at the onset of macular edema. Fluorescein angiography, though planned, was declined by the patient.

Results: Serial imaging effectively captured the disease's aggressive natural history. While systemic management failed to halt the progression, intravitreal anti-VEGF therapy resulted in the complete resolution of macular edema and a significant improvement in the patient's visual function.

Conclusions: This case illustrates that CRVO can follow a rapid and progressive course despite conventional systemic management. It highlights that close clinical and photographic monitoring is essential for tracking disease activity. Prompt intervention with anti-VEGF therapy is the cornerstone for managing vision-threatening macular edema and can be effectively guided by clinical findings, even in the absence of fluorescein angiography.

Abstract No.: 201001**Panel No.: RME-0942**

Novel Therapeutic Perspectives for Wet Age-Related Macular Degeneration: RGD-Modified Liposomes Loaded With 2-Deoxy-D-Glucose as a Promising Nanomedicine

First Author: Xirui CHEN

Purpose: To develop a novel targeted nanomedicine delivery system for wet age-related macular degeneration (AMD) by loading RGD peptide-modified liposomes with 2-deoxy-D-glucose (RGD@LP-2-DG) and evaluate its anti-angiogenic effects on choroidal neovascularization (CNV).

Methods: RGD@LP-2-DG nanoliposomes were synthesized using thin film hydration method and characterized for particle size, zeta potential, and encapsulation efficiency. In vitro studies assessed cellular uptake, proliferation, migration, and tube formation using human umbilical vein endothelial cells (HUVECs). A laser-induced CNV mouse model was established to evaluate therapeutic efficacy through fluorescein angiography and immunostaining. Mechanistic studies investigated VEGFR2 protein expression and downstream signaling pathways via Western blotting and immunofluorescence.

Results: RGD@LP-2-DG displayed uniform spherical morphology with a mean diameter of 133 ± 3.06 nm and demonstrated superior targeting performance toward endothelial cells compared to unmodified liposomes. In vitro assays revealed significant inhibition of HUVEC proliferation, migration, and tube formation. In the CNV model, RGD@LP-2-DG achieved a 76.47% reduction in neovascular leakage, outperforming free 2-DG (45.95%) and LP-2-DG (61.05%). Mechanistic studies revealed that 2-DG interfered with N-glycosylation, leading to VEGFR2 accumulation in the endoplasmic reticulum and suppression of downstream Erk1/2 and p38 signaling. Safety evaluations confirmed excellent biocompatibility.

Conclusions: RGD@LP-2-DG represents a promising nanomedicine with exceptional targeting efficacy and anti-angiogenic properties for wet AMD treatment, particularly beneficial for patients unresponsive to current anti-VEGF therapies through novel metabolic intervention mechanisms.

Nurse-Delivered Intravitreal Injection (N-IVI) of Anti-Vascular Endothelial Growth Factor (Anti-VEGF): Results From a Tertiary Eye Centre in Hong Kong

First Author: Lai Kuen NG

Co-Author(s): Jennifer HUNG, Monica LEE, Kenneth LI, Samuela TANG

Purpose: To evaluate the safety and efficacy of nurse-delivered intravitreal injections of anti-VEGF in a tertiary eye centre in Hong Kong.

Methods: This is a retrospective review of all consecutive cases that received N-IVI of anti-VEGF from February 2022 to September 2025 at the Department of Ophthalmology, Kowloon East Cluster, Hospital Authority. Cases are identified through the electronic patient record system. All clinical information documented after each injection was meticulously reviewed and analyzed for any documented injection-related adverse events.

Results: A total of 748 cases received the N-IVI from February 2022 to September 2025 were included. No serious adverse events, including infective endophthalmitis and retinal detachment, were encountered. Minor adverse events, including irritation (5.23%), air bubble (2.42%), subconjunctival hemorrhage (1.28%), and corneal abrasion (1.02%), were observed. No long-term complications were observed.

Conclusions: The N-IVI of anti-VEGF was successfully introduced to Hong Kong. This initiative aimed to improve patient access to sight-saving treatments for conditions such as AMD and diabetic retinopathy, while also optimizing physicians' time. Results of the present

study demonstrate a favorable safety profile of nurse-delivered intravitreal injections of anti-VEGF in Hong Kong.

Abstract No.: 206680

OCT-Based Diagnostic Biomarkers of Age-Related Macular Degeneration in a Mongolian Population

First Author: Anarsaikhan NARMANDAKH

Co-Author(s): Nomin CHADRAABAL, Altanzul TUMURPUREV

Purpose: To investigate OCT characteristics and choroidal thickness in Mongolian AMD patients and age-matched healthy controls in a Mongolian population to identify population-specific patterns.

Methods: This retrospective study included patients ≥ 50 years with dry AMD, wet AMD, or PCV, and matched controls. High-quality SD-OCT scans were analyzed for structural features, and subfoveal choroidal thickness was manually measured and compared across subtypes and age groups.

Results: We analyzed 164 patients (296 eyes: 39 dry AMD, 41 wet AMD, 64 controls; mean age 72.9 years). Dry AMD showed drusen, RPE irregularities, and EZ loss; wet AMD showed SRF, IRC, PED, and frequent combined lesions; and PCV had peaked PEDs, sub-RPE hyperreflective lesions, and double-layer signs, indicating high prevalence. Retinal thickness was greatest in PCV, while SFCT declined from controls to dry AMD to wet AMD, with an age-related inverse correlation, highlighting choroidal atrophy in AMD.

Conclusions: OCT biomarkers vary across AMD subtypes, reflecting disease severity and phenotype. The high prevalence of PCV-specific features among wet AMD suggests PCV is a common neovascular subtype in Mongolians, consistent with other Asian populations. Age-related choroidal thinning and population-specific OCT assessment may aid early diagnosis, subtype differentiation, and treatment planning.

Observational Study of Series of Non-Exudative Treatment-Naive Polypoidal Choroidal Vasculopathy (PCV) on Swept-Source Optical Coherence Tomography and Angiography (SS-OCT/ OCTA)

First Author: Pei Qi LO

Co-Author(s): Tangnuo, Wang Min, Gloria SONG WENJUN, Wenghang WONG, Sandy ZHOU

Purpose: To investigate short-term changes in different parameters on SS-OCT/OCTA among patients with treatment-naive PCV.

Methods: A prospective longitudinal observational study including patients who met the diagnostic criteria of treatment-naïve non-exudative PCV. Diagnosis of PCV was made using SS-OCT/OCTA according to APOIS criteria and indocyanine green angiography (ICGA) according to Everest criteria. All patients underwent 6x6 mm SS-OCTA at baseline and follow-up visits. Multiple OCTA imaging features of the study eye were evaluated, including the size of the branching vascular network (BVN), the height and internal structure of the polypoidal Pigment Epithelial Detachment (PED), and the subfoveal choroidal thickness (CT). Clinical features of contralateral eyes were assessed to interpret the prognosis of non-exudative PCV and explored as a potential biomarker.

Results: Twelve non-exudative PCV patients were included in the study. All patients were asymptomatic in the study eye. The follow-up duration is 1 to 18 months. 5 patients developed exudation from 9 to 12 months after onset. The SS-OCT/OCTA on the latest follow-up showed enlargement of PED and increased numbers of polyps. The 5 patients also had higher polypoidal PED and larger BVN size among 12 patients at the first scan. The rest of patients remained unchanged throughout the follow-up period.

Conclusions: Non-exudative PCV patients can be monitored without treatment if they remain asymptomatic. The larger size of BVN, PED in initial visits may indicate higher risk of exudation onset, necessitating more frequent follow-ups.

Panel No.: RME-0995

Occupational Hazard to Vision: Phototoxic Maculopathy From A Gold Laser Welding – A Case Report

First Author: Yunneke R. XAVERINA
Co-Author(s): Martin HERTANTO

Purpose: Phototoxic maculopathy is a retinal condition resulting from excessive exposure to intense light sources for a variable period, causing possible permanent visual injury, particularly affecting central vision. This case study aims to illustrate incidental phototoxic maculopathy resulting from exposure to a gold laser welding machine.

Methods: A 32-year-old male began complaining of central blurred vision in both eyes, the right eye started 1.5 years ago and the left eye was 1 month before the patient's visit. He saw a blurry gray shadow in his central vision, still and unmoving as the patient glanced. The visual acuity of his right eye was 0.9, and that of his left eye was 1.0; the anterior segments were within normal limits. Fundus examination reveals foveal changes, yellow-white spots with a reduction of the foveal reflex. Optical coherence tomography (OCT) findings reveal disruption of the ellipsoid zone and irregularity of the retinal pigment epithelium (RPE)

in both eyes. The patient reported that he worked as a gold laser welder and often did not use protective glasses.

Results: Phototoxic maculopathy is a retinal injury caused by excessive exposure to high-powered lasers without adequate eye protection. Patients typically present with bilateral but asymmetric symptoms, including blurred vision, visual distortion or central scotomas. Fundus photography reveals a characteristic small yellow spot surrounded by a faint gray granular color. OCT shows the ellipsoid zone and RPE disruption, indicating direct photothermal or photochemical damage.

Conclusions: Phototoxic maculopathy is an avoidable condition, particularly with the use of appropriate protective gear.

Abstract No.: 208426
Panel No.: RME-1039

Outcomes of Brolucizumab Injections in Treatment-Resistant nAMD and PCV Cases

First Author: Mary HO
Co-Author(s): Marten BRELEN, Victor CHAN, Li Jia CHEN, Andrew MAK

Purpose: This series reviews the outcomes of Brolucizumab injections in the treatment of nAMD and PCV cases and evaluates the rate of intraocular inflammation (IOI).

Methods: This retrospective study was conducted from September 2024 to September 2025 at a tertiary eye centre. Patients who failed primary treatment with Eylea, Faricimab, Lucentis, or Avastin were switched to Brolucizumab as a second-line therapy.

Results: Fourteen patients received Brolucizumab injections during the study period. The mean age was 70.6 ± 7.9 years, with a female-to-male ratio of 6:9. The baseline VA was 0.82 ± 0.38 logMAR, improving significantly to 0.70 ± 0.33 at 4.5 months ($p = 0.012$). Baseline CMT was 433.5 ± 180.6 μ m, which decreased to 270.6 ± 87.4 μ m ($p = 0.009$). Six cases (42.8%) showed complete PED regression, with the maximum PED height reducing from 584 ± 420.1 μ m to 247.3 ± 212.8 μ m ($p = 0.028$). One case (1/14) developed IOI, presenting with vitritis and 1+ anterior chamber inflammation, which was resolved after a single subtenon steroid injection. The inflammation subsided, the PED regressed, and PCV responded well.

Conclusions: Brolucizumab demonstrated a role in controlling PED and PCV in treatment-resistant cases in our series, serving as an effective second-line therapy with significant functional and anatomical improvement. A substantial portion of cases demonstrated marked reduction in PED extent and height.

Panel No.: RME-1046

Pathogenesis and Evolutionary Modeling of Myopic Macular Retinoschisis Induced by Saccadic Eye Movements

First Author: Luyun L IANG

Co-Author(s): Yiqin DUAN

Purpose: Quantify the vitreous-induced forces acting on the retina across varying saccadic amplitudes in highly myopic eyes with posterior scleral staphyloma, and elucidate how staphylomatous morphology modulates vitreous dynamics and retinal stress distribution.

Methods: Using a dynamic-mesh approach, this study quantified the dependence of vitreoretinal traction on saccadic amplitude. Orbital CT volumes were first segmented, labeled, multi-planar-reconstructed and visualized in Mimics; the resulting surface was optimized and exported. An unstructured grid was generated over the ocular globe, and the unsteady continuity equation coupled with the fifth-order polynomial saccadic profile proposed by Repetto et al. was solved numerically to map wall shear stress at the vitreoretinal interface.

Results: The study revealed that, within the vitreous cavity, the maximal wall shear stress (WSS) increases monotonically with saccadic amplitude. For all amplitudes examined, the peak WSS precedes the instant of maximum angular velocity. Notably, the highest WSS colocalizes with the indentational rim produced by the lens and the periretinal surface; both the optic-disc and macular regions experience shear stresses exceeding 1 Pa.

Conclusions: Ocular motility-driven vitreous fluid-dynamics exert a pronounced influence on the retinal stress distribution in highly myopic eyes.

Abstract No.: 204064

Panel No.: RME-0989

Peripapillary Retinoschisis – the Expanded Spectrum and New Insights From Multimodal Imaging

First Author: Lucy Yi YANG

Co-Author(s): Caroline BAUMAL, Devin BESTCH, Michael BRANLEY, Diogo CABRAL, Fred CHEN, Jay CHHABLANI, Michael CHILOV, Netan CHOUDHRY, Shanil DHANJI, Andrew FARAG, Bailey FREUND, Adrian FUNG, Rishi GUPTA, Jenny IP, Rachael JEFFERY, David KALATZIS, Ananda KALEVAR, Andrew KAM, Marco LUPIDI

Purpose: To establish a comprehensive classification system for peripapillary retinoschisis (PPRS) and standardize its nomenclature through detailed characterization of its various associated conditions.

Methods: A retrospective, multicenter case series of peripapillary retinoschisis was conducted from August 2021 to September 2024. The study protocol included standardized imaging with EDI or SS-OCT of the optic nerve and macula, colour fundus photography, and fundus autofluorescence. Selected cases underwent additional fundus fluorescein and indocyanine angiography when clinically indicated. The retinoschisis was characterised by the location and relation to the optic disc, and the layer(s) of the retina affected.

Results: Forty-seven eyes from 41 patients with PPRS were identified, comprising 22 (54%) females and a mean age of 56 years (range 14-92 years). These were classified into nine etiologies: Congenital Disc Abnormalities (CDA, n=16 eyes), peripapillary chorioretinal coloboma (n=1), peripapillary atrophy (n=3), glaucoma (n=7), Peripapillary Pachychoroid Syndrome (PPS, n=4), Peripapillary Choroidal Neovascularization (PP-CNV, n=3), myopia (n=5), Vitreopapillary Traction (VPT, n=4) and idiopathic (n=4). A new entity (Focal Optic Disc Dome, FODD) associated with PPRS is described. The main pathogenic mechanisms of PPRS include anatomical weaknesses around the optic nerve, increased fluid entry from the choroid, and mechanical traction.

Conclusions: The identified nine etiologies of PPRS can be systematically categorized into five distinct groups. This classification framework enhances diagnostic accuracy and treatment planning, particularly for conditions with established therapeutic protocols (CDA, glaucoma, PPS, PP-CNV, and VPT). Key contributions include the identification of truly idiopathic PPRS and the characterization of FODD.

Probucol Inhibits High Glucose-Induced Ferroptosis in Human RPE Cells by Down-Regulating BACH1

First Author: Zhongping CHEN

Co-Author(s): Shengnan LIANG

Purpose: Diabetic retinopathy (DR) is a major cause of blindness with poor prognosis and limited treatment efficacy, particularly in its advanced stages. Recent studies have highlighted a close association between ferroptosis and DR progression. This study investigates the protective mechanisms of the antioxidant compound probucol (PB) in a human DR cell model.

Methods: High glucose (HG) induced ARPE-19 cells to establish a diabetic retinopathy (DR) cell model, with PB employed for intervention. Western blotting was utilised to determine the protein expression of BACH1 and ferroptosis-related factors. The CCK8 cell counting assay kit was employed to assess cell viability. Commercial kits for ROS and MDA measured lipid peroxidation and oxidative stress-related factors. Prussian blue staining and iron content assays assessed

ferroptosis. Cells were transfected to overexpress BACH1, with subsequent measurement of changes in ferroptosis-related factor expression.

Results: HG exposure resulted in increased levels of reactive oxygen species (ROS), cellular lipid peroxides such as malondialdehyde (MDA) and 4-hydroxynonenal (4-HNE), and fluorescence intensity of Fe²⁺ in ARPE-19 cells, along with a decrease in glutathione (GSH) levels. Treatment with PB mitigated these effects. Moreover, HG upregulated the expression of BACH1 and downregulated the expression of solute carrier family 7 member 11 (SLC7A11), glutathione peroxidase 4 (GPX4), and ferroptosis suppressor protein 1 (FSP1), which are critical in counteracting ferroptosis. PB treatment reversed these changes. Mechanistically, PB countered HG-induced cellular damage by reducing BACH1 expression in RPE cells and activating the GPX4/FSP1 pathway. Upon knockdown of BACH1 expression, ferroptosis-related alterations were restored.

Conclusions: HG-induced ferroptosis in RPE cells leads to cellular damage. PB successfully inhibited BACH1 expression and enhanced cellular antioxidant capabilities, thereby reducing ferroptosis and cell death.

Punctate Inner Choroidopathy With Choroidal Neovascular Membrane in a Young Emmetropic Female

First Author: Aditi **BANSAL**

Co-Author(s): Shagun **KORLA**, Gian Chand **RAJPUT**, Rhibhu **SONI**

Purpose: To report an uncommon case of bilateral Punctate Inner Choroidopathy (PIC) with secondary Choroidal Neovascular Membrane (CNVM) in an emmetropic, middle aged female.

Methods: A 45-year-old, emmetropic, chronic alcoholic female presented with bilateral, painless diminution of vision. Ocular examination showed best corrected visual acuity of 6/18 in both eyes. Intraocular pressure, axial length, and anterior segment were unremarkable. Fundus showed yellowish chorioretinal lesions with subretinal hemorrhage in the posterior pole with a subfoveal neovascular membrane with no signs of vitritis in both eyes. Spectral domain-OCT demonstrated bilateral elevation of RPE with disruption of the outer retina corresponding to active lesions.

Results: The presence of choroidal neovascularization (CNV) can be as high as 75% in eyes with PIC, making the detection of an underlying CNV critical in the management of this disease. The patient was treated with an intravitreal injection of aflibercept (2.25mg/0.05ml) in both eyes and is scheduled for close follow-up.

Conclusions: Given the rarity of PIC with CNVM in an emmetropic middle-aged female, where it typically occurs in young myopic women, this case underscores the importance of maintaining a high index of clinical suspicion and utilising prompt imaging even in atypical demographics.

Rare Presentations in Ocular Albinism: Diagnostic Challenges and Genetic Complexity

First Author: Yiliu **YANG**

Co-Author(s): Licong **LIANG**, Fang **LU**

Purpose: Albinism involves genetic disorders impairing melanin synthesis, with diverse ocular and systemic features. This case series aims to expand the recognized phenotypic and genotypic spectrum by documenting four rare presentations, highlighting diagnostic intricacies.

Methods: We present a case series of four patients with unusual clinical manifestations of different ocular albinism types. Diagnostic workup included detailed ophthalmic evaluation, ultra-widefield imaging, and genetic testing.

Results: Case 1: A pair of female twins born via surrogacy (owing to maternal systemic lupus erythematosus) presented with «mud-splatter» fundus changes and were found to carry a pathogenic GPR143 mutation inherited from their biological mother. Case 2: A 61-year-old female with diabetic retinopathy showed atypical «mud-splatter» changes on autofluorescence screening; she was identified as a carrier of a pathogenic GPR143 mutation. Case 3: A 4-year-old girl with a complex family history exhibited asymmetric ocular albinism features despite having normal hair, skin, and iris pigmentation. Genetic analysis identified a homozygous mutation in the HPS6 gene, consistent with Hermansky–Pudlak syndrome type 6. Case 4: A 5-month-old infant with severe macular dysplasia and familial exudative vitreoretinopathy (FEVR) phenotype carried a paternally inherited SLC45A2 mutation (oculocutaneous albinism type 4, OCA4), suggesting potential genetic interaction.

Conclusions: These cases illustrate significant heterogeneity in ocular albinism and emphasize the importance of genetic testing, detailed phenotyping, and family history in diagnosis. Uncommon presentations can unmask carrier states or reveal novel genetic interactions, aiding clinical understanding and management.

Real-World Effectiveness of Faricimab in Chinese Patients With Diabetic Macular Edema: Three-Month Results From the Farseeing Study

First Author: Xufang SUN

Co-Author(s): Xiaorong LI, Kun LIU, Xun XU

Purpose: The Farseeing study (NCT06439576) is a non-interventional real-world study conducted in 50 sites in China, collecting primary data of approximately 1000 patients with nAMD, diabetic macular edema (DME), or macular edema secondary to retinal vein occlusion (RVO) to assess the effectiveness and safety of faricimab. Here we report the first interim analysis in DME patients.

Methods: This interim analysis included data from April 2024 to January 2025 and included DME patients from 22 sites across China. Management was as per usual care, with no mandated scheduled visits or imaging protocol requirements. Visual acuity (VA), central subfield thickness (CST), and the proportion of eyes with retinal fluid were evaluated at baseline and 3 months. Incidence of safety events was collected with any duration of follow-up. Descriptive analyses were performed.

Results: A total of 25 DME patients (35 eyes) were included in this analysis. In switched eyes with DME, mean VA (standard deviation [SD]) change from baseline to month 3 was +8.0 (11.6) letters, mean CST (SD) change was -83.29 (201.25) μ m. Investigator-determined subretinal fluid (SRF) was present in 30.4% of eyes at baseline, decreasing to 9.5% by Month 3; intraretinal fluid (IRF) was present in 91.7% of eyes at baseline, decreasing to 78.3% by Month 3.

Conclusions: The results of the cohort of DME patients in the Farseeing study will show the real-world effectiveness and safety of faricimab in the treatment of Chinese DME patients.

Real-World Evidence on Diabetic Macular Edema: Three Years' Experience From a Tertiary Eye Hospital in Indonesia

First Author: Putri PAMULANI

Co-Author(s): Rova VIRGANA, Niluh WARDHANI, Made WIDYANATHA, Nina RATNANINGSIH

Purpose: To describe treatment patterns and outcomes of diabetic macular edema (DME) patients at a tertiary eye hospital in Indonesia over a 3-year period.

Methods: A descriptive observational study was conducted using medical records of patients with DME who attended a tertiary hospital in Indonesia between January 2021 and December 2023. Data collected

included central macular thickness (CMT) from optical coherence tomography and visual acuity at baseline, 6 months, and 12 months.

Results: A total of 191 patients (281 eyes) were included. As many as 223 eyes (79.4%) received intravitreal bevacizumab (IVB). The mean number of IVB injections was 3.2 ± 1.3 at 6 months and 4.2 ± 1.8 at 12 months. Laser photocoagulation was performed in 223 eyes (79.4%), and vitrectomy in 12 eyes (4.3%). Despite fewer injections compared to clinical trials, at endpoint, 43–44% of eyes achieved visual improvement at 6 and 12 months, while central macular thickness reduction occurred in >60% of eyes.

Conclusions: In this real-world setting, DME patients received substantially fewer anti-VEGF injections than trial protocols yet still achieved meaningful visual and anatomical benefits. These findings highlight the gap between trial evidence and routine practice and emphasize the need for strategies to optimize DME care in resource-limited settings.

Abstract No.: 209434

Relation Between Peripheral Blood Inflammatory Indices and Severity of Central Retinal Artery Occlusion

First Author: Weiwen HU

Co-Author(s): Qiong ZHOU

Purpose: Central retinal artery occlusion (CRAO) has been identified as an acute emergency resulting in vision loss, with its pathogenesis potentially involving systemic inflammation and abnormal lipid metabolism. Over recent years, it has been established that peripheral blood inflammatory indices, including the neutrophil-to-lymphocyte ratio (NLR), the systemic immunoinflammatory index (SII), and the monocyte-to-high-density lipoprotein ratio (MHR), play significant roles in assessing systemic inflammation and lipid metabolism. However, the role of these indices in assessing the severity of CRAO has rarely been explored. This study aimed to investigate the relationship between these inflammatory indices and the severity of CRAO.

Methods: This was a retrospective clinical study with a total of 49 CRAO patients and 50 age- and sex-matched controls involved. The patients with CRAO were divided into three groups (13 with incomplete CRAO, 16 with subtotal CRAO, and 20 with total CRAO). Data were compared across these groups, and additionally, correlation analysis, restricted cubic spline plots, and receiver operating characteristic curve analysis were performed.

Results: The values of NLR, SII, and MHR were significantly higher in the CRAO group compared to controls (NLR: $2.49(1.71, 3.44)$ vs $1.60(1.24, 1.97)$, $P < 0.001$; SII: $606.46(410.25, 864.35)$ vs

403.91(332.90,524.31), $P=0.001$; MHR: 0.33(0.26,0.44) vs 0.25(0.21,0.34), $P<0.001$). MHR was also significantly higher in total CRAO than in incomplete CRAO and subtotal CRAO (0.41(0.32,0.60) vs 0.29(0.21,0.43), $P=0.036$; 0.41(0.32,0.60) vs 0.29(0.23,0.38), $P=0.017$). Significant positive associations were found between MHR, NLR, SII and both the incidence (all $P<0.001$) and severity ($P<0.001$, $P<0.001$, $P=0.003$, respectively) of CRAO. MHR had a linear relationship with both the occurrence and severity of CRAO (P -overall=0.013, P -non-linear=0.427 and P -overall=0.013, P -non-linear=0.825). Combining MHR and NLR significantly improved diagnostic efficacy for CRAO and total CRAO, with an area under the curve of 0.816 and 0.827, respectively, compared to using MHR alone (0.705 and 0.816).

Conclusions: Elevated levels of peripheral blood NLR, SII, and MHR are positively associated with CRAO incidence, highlighting their potential as early predictive markers. The combined NLR and MHR index further enhances diagnostic accuracy and may facilitate timely assessment of CRAO severity by ophthalmologists and internists.

Abstract No.: 206937

Retinal Light Chain Deposition and Retinal Necrosis in Multiple Myeloma on Bortezomib Therapy: A Case Report

First Author: Anna Victoria **SAN PEDRO**

Co-Author(s): Oscar **ACOPIADO**, *Jose Carlo* **ARTIAGA**, *Fabian Arnel* **DE JESUS**, *Maria Florentina* **GOMEZ**, *Harvey* **UY**

Purpose: To report a rare case of bilateral retinal pigment epithelial (RPE) light chain deposition and retinal necrosis in a patient with multiple myeloma and light chain nephropathy, following Bortezomib therapy despite antiviral prophylaxis.

Methods: A 57-year-old female with multiple myeloma and light chain nephropathy presented with a two-year history of blurring of vision in the right eye. A comprehensive ophthalmologic examination was performed.

Results: Initial visual acuity was 20/50 in the right eye, with a significant posterior subcapsular cataract, and 20/20 in the left eye with a mild nuclear cataract. Fundoscopy revealed multiple nummular hyperpigmented lesions in a leopard spot pattern at the posterior pole of both eyes. The right eye showed a large area of fibrosis and atrophy at the inferonasal periphery, suggestive of an old retinal necrosis. Fundus autofluorescence revealed hyperautofluorescence of the lesions, while fluorescein angiography showed blocked hypofluorescence and late staining. OCT demonstrated globular hyperreflective deposits along the RPE-Bruch's membrane complex with posterior

shadowing. After cataract extraction in the right eye, visual acuity improved to 20/21.

Conclusions: This is the first reported case of bilateral RPE light chain deposition with concurrent retinal necrosis in a patient with multiple myeloma. Awareness of this rare ocular manifestation may aid in earlier detection, management, and counseling of patients undergoing treatment with Bortezomib and related therapies.

Abstract No.: 204891

Retinal Microvascular Changes Observed in Pre-Operative Sarcopenic Cancer Patients

First Author: Kenric **FAN**

Purpose: To assess the retinal microvascular changes in pre-operative sarcopenic cancer (SaC) patients against normal controls from the Singapore Imaging Eye Network (SIENA).

Methods: This was a single-centre, prospective study of 25 SaC patients undergoing elective colorectal cancer surgery from March 2022 to January 2024. Sarcopenia was diagnosed at the time of recruitment using the Asian Workgroup for Sarcopenia (AWGS) 2019 diagnostic criteria. Optical coherence tomography (OCT) of the optic nerve and macula, and OCT angiography (OCTA) were performed within 1 month prior to surgery. Imaging parameters were compared to age and gender matched normal controls from the SIENA database.

Results: Fifty eyes of 25 SaC subjects were compared to 90 eyes of 45 controls. No significant differences in demographics were noted (mean age 63.4 (SD=9.7) versus 55 (SD=13.5) years, 15 (60%) versus 36 (80%) were male, and 23 (92%) versus 37 (82%) were of Chinese ethnicity ($p>0.05$). At baseline, SaC versus normal controls had a higher optic disc cup volume of (0.25mm³vs 0.13mm³, $p=0.005$), thicker superior disc thickness (118.33um vs 76.46um, $p<0.001$), and thinner nasal disc thickness (66.46um vs 120.07um, $p<0.001$). OCTA showed a reduction in macular full thickness and inner vessel density (14.59mm/mm²vs 17.42mm/mm², $p<0.001$ and 14.76mm/mm² vs 18.58mm/mm², $p<0.001$, respectively), a reduction in foveal avascular zone (FAZ) area and perimeter (0.24mm²vs 0.57mm², $p<0.001$ and 2.03mm vs 3.12mm, $p<0.001$ respectively), and increased FAZ circularity (0.68 vs 0.56, $p<0.001$).

Conclusions: This is the first study to assess retinal microvascular correlates of SaC patients, showing significant reductions in microvasculature density and FAZ parameters compared to normal controls, indicating potential systemic effects of sarcopenia and cancer on the retinal microvasculature.

Abstract No.: 207017

Retinochoroidal Manifestations in Idiopathic Intracranial Hypertension - An Observational Study With Multimodal Imaging

First Author: Sreelakshmi PALLIAN

Co-Author(s): Rafeeka HASHIM, George MANAYATH

Purpose: To document the different retinal and choroidal manifestation in patients IIH with multimodal imaging techniques.

Methods: Patients with IIH diagnosed as per Modified Dandy's Criteria at a tertiary ophthalmic hospital were included in this cross-sectional observational study. Fundus photographs, OCT, FFA and ICGA were done.

Results: Ocular symptoms were present in 66.27% of eyes. Crescent sign was observed in 97.6% of eyes. The following fundoscopic features were observed-venous tortuosity (26.7%), intraretinal hemorrhages (16.3%), Pigment epithelial detachments (4.65%), and subretinal hemorrhages (10.5%). The various optical coherence tomographic features seen were intraretinal fluid(18.6%), outer retinal irregularities (30.2%), subretinal hemorrhages (9.3%), and choriocapillaris compression (58.1%). A total of 70 eyes had subfoveal choroidal thickness (SFCT) greater than 350 microns. 1 in 5 eyes had delayed choroidal flush and ICGA confirmed vascular networks in 7 eyes of choroidal neovascular membrane. Branched vascular network was seen in 2 eyes and pachyvessels and choroidal vascular hyperpermeability (CVH) was observed in 75% and 85% of the eyes respectively. We were able to ascertain a positive association with CSF opening pressure with CVH ($P < 0.03$), grade of disc edema with SFCT ($P < 0.03$). The duration of disease had a positive association with SFCT, CVH and pachyvessels.

Conclusions: The concept of venous overload choroidopathy is pivotal in establishing retinochoroidal changes in papilledema. The flow within a tube is inversely influenced by the pressure in the surrounding tissue- also known as the Starling's resistor effect- and hence in patients with IIH the increased CSF pressure leads to slowing of circulation within dural venous sinuses which in turn leads to venous congestion within the choroidal system through ophthalmic veins resulting in pachychoroid and associated features.

Rivaroxaban to the Rescue: CRVO Resolution in Factor V Leiden Mutation

First Author: Neethu PRADEEP

Purpose: A 46-year-old female with no systemic history presented with sudden blurring of vision in the right eye for 3 days. On examination, best corrected visual acuity right 6/12, left eye 6/6, pupil brisk. Fundus examination of the right eye showed dilated tortuous

veins with hemorrhages in all quadrants, with a normal macula, suggestive of Non-Ischemic Central Retinal Vein Occlusion (CRVO). Left eye examination within normal limits.

Methods: Routine blood investigations, cardiac workup, ANA profile, carotid doppler, Serum homocysteine levels, and thrombophilia workup were done.

Results: Patient tested positive for Factor V Leiden mutation -heterozygous variant. She was referred to a hematologist who started her on Rivaroxaban 20 mg.. 2 months later, her visual acuity improved to 6/6, with resolution of her fundus findings in the right eye.

Conclusions: CRVO in younger patients is often more than just an eye disease-it can be a window into hidden systemic thrombophilia. Our case of factor V Leiden-associated CRVO that spontaneously resolved after rivaroxaban therapy illustrates the diagnostic importance of systemic evaluation and the therapeutic potential of novel anticoagulants.

Role of Faricimab In Refractory Neovascular Age-Related Macular Degeneration: Multicenter Real-World Evidence From India

First Author: Jay SHETH

Co-Author(s): Rupak BISWAS

Purpose: To evaluate the anatomical and functional outcomes of faricimab in eyes with refractory neovascular age-related macular degeneration (nAMD) in a real-world Indian cohort over six-months.

Methods: In this retrospective multicenter study, 24 eyes with refractory nAMD were switched to faricimab on a PRN regimen. BCVA, central foveal thickness (CFT), and the presence of IRF, SRF, and PED were assessed monthly for three months, then as clinically indicated.

Results: The cohort's mean age was 68.1 (± 10.6) years, and prior to switching had received an average of 11.4 (± 9.1) anti-VEGF injections. During the six-month period, eyes underwent a mean of 2.63 (± 1.34) faricimab injections (range, 1–5): 25.0% received one injection, 29.2% two, 16.7% three, 16.7% four, and 12.5% five. Mean BCVA improved from 0.66 (± 0.4) logMAR at baseline to 0.47 (± 0.34) at month 1, 0.35 (± 0.32) at month 2, and 0.27 (± 0.27) at months 3 and 6 ($P \leq 0.0003$). Mean CFT decreased from 471.1 (± 246.4) μm to 337.3 (± 198.3) μm (month 1), 265.1 (± 90.7) μm (month 2), 217.7 (± 41.3) μm (month 3), and 209.4 (± 36.0) μm (month 6) ($P < 0.0001$). SRF resolved in 90.9% of affected eyes ($P < 0.001$), IRF in 87.5% ($P = 0.0006$), and PED in 54.5% ($P = 0.32$), with complete fluid resolution in 83.3% of eyes ($P = 0.00002$). No ocular or systemic adverse events occurred.

Conclusions: In this real-world Indian cohort of refractory nAMD, faricimab delivered robust visual

gains, significant CFT reduction, and high rates of fluid resolution, with over half of eyes requiring ≤ 2 injections over six months, supporting its role as an effective switch therapy.

SPECTRUM: Early Data From a Global Real-World Study of Aflibercept 8 mg in Diabetic Macular Edema

First Author: Nicholas FUNG

Co-Author(s): Helmut ALLMEIER, Clare BAILEY, Brian BALLIOS, Varun CHAUDHARY, Clemens LANGE, Paolo LANZETTA, Tobias MACHEWITZ, Peter MORGAN-WARREN, Marion R. MUNK, Hassiba OUBRAHAM

Purpose: To present early data from the global phase 4 SPECTRUM study of aflibercept 8 mg in patients with diabetic macular edema (DME).

Methods: SPECTRUM (NCT06075147) is an ongoing, 24-month, prospective observational study. In the treatment-naïve (TN) and previously treated (PT) DME cohorts, patients aged ≥ 18 years, who have been prescribed aflibercept 8 mg by their physician, are eligible for enrollment. Data are collected during routine visits. All analyses are exploratory.

Results: To date, 283 and 470 patients have been enrolled in the TN and PT DME cohorts across a total of 12 countries; 14 months is the longest treatment duration thus far. Among the first 150 patients enrolled in the TN and PT DME cohorts, the mean age at baseline (BL) was 66.3 and 65.3 years, 61% and 69% were male, and the mean time from DME diagnosis was 2.2 and 55.0 months; 67% of patients with PT DME had received aflibercept 2 mg as their last treatment. At BL in the TN and PT DME cohorts, visual acuity was 63.5 and 70.2 letters, and central retinal thickness was 420 and 364 μm .

Conclusions: These early data provide insights into the DME cohorts in the first global real-world study of aflibercept 8 mg.

Abstract No.: 207219

Seeing the Unseen: Imaging the Mizuo Phenomenon in Oguchi Disease Among Indian Patients

First Author: Debolina DEB

Purpose: Oguchi disease, a rare form of congenital stationary night blindness predominantly reported in East Asians, is sparsely documented in Indian populations.

Methods: We present 8 Indian patients across different age and gender groups, diagnosed through clinical history, family history, and slit-lamp examination. Fundus images, OCT and ERG were documented.

Results: Fundus images before and after dark adaptation, captured with Clarus 700, demonstrated a characteristic golden metallic sheen disappearing post-dark adaptation. OCT (Spectralis) revealed intact outer retinal layers with subtle ellipsoid zone irregularities during the Mizuo phenomenon. Full field ERG shows the classic “electronegative B wave”.

Conclusions: These cases highlight the critical role of precise timing and multimodal imaging in accurate diagnosis, preventing misinterpretation of retinal changes. Documenting the Mizuo phenomenon meticulously is vital for recognizing Oguchi disease, especially in diverse populations, and enhances our understanding of its phenotypic spectrum. It is crucial to differentiate Mizuo phenomenon in Oguchi from commotio and JXLR. Multimodal imaging enhances accurate diagnosis of Oguchi disease, especially in diverse populations, preventing misdiagnosis. Precise timing and visualization of the Mizuo phenomenon facilitate early recognition, guiding appropriate management and advancing understanding of this rare condition.

Abstract No.: 201812

Severity of Retinopathy of Prematurity and Mental Health of Parents

First Author: Harshita GARG

Co-Author(s): Rahul BHATIA, Neha CHAWLA GULIANI, Dinesh KATARIA, Piyush RAMAVAT, Aditya SHARMA, Sarita BERI

Purpose: To assess the association of severity of retinopathy of prematurity (ROP) with depression, anxiety, and stress in parents of babies with ROP.

Methods: One hundred parents of babies with ROP undergoing treatment at Lady Hardinge Medical College, New Delhi, India, a tertiary care setting, were assessed for their mental health status using the Depression, Anxiety, and Stress Scale-21 (DASS-21) at the 3-month postnatal outpatient assessment visit.

Results: Parents of babies with severe ROP, that is, ROP requiring intervention, had more mental health problems as compared to parents of babies with non-severe ROP, that is, ROP not requiring intervention.

Conclusions: ROP not only affects children but also has various psychological effects on caregivers, which are often underestimated. Repeated screenings and follow-ups, apprehension regarding the need for treatment, fear of disease progression, and uncertainty regarding the final outcome often lead to depression, anxiety, and stress symptoms in parents, thus affecting their caregiving ability. ROP has broader family aspects and may lead to economic burden; chronic stress among parents may strain marital relationships, while the siblings may feel overlooked due to disproportionate attention given to the ROP baby. Thus, integrating

mental health screening and psychological support in ophthalmological and neonatal care through proper counselling, education, parental involvement, and long-term follow-up can help families cope better and can help reduce trauma and strengthen family resilience, hence promoting a holistic environment.

Short-Term Outcomes of Switching to Aflibercept 8mg in Patients With Neovascular Age-Related Macular Degeneration

First Author: Yusuke MAEHARA

Co-Author(s): Kumiko KANO, Shoji NOTOMI, Satomi SHIOSE, Koh-hei SONODA, Keijiro ISHIKAWA

Purpose: To evaluate treatment outcomes after switching to aflibercept 8mg for neovascular age-related macular degeneration (nAMD).

Methods: Patients with nAMD who visited our facility between August and December 2024 and received switching to aflibercept 8mg from another anti-vascular endothelial growth factor (anti-VEGF) therapy were enrolled in this study. We retrospectively analyzed changes in best corrected visual acuity(BCVA), central macular thickness(CMT) after once aflibercept 8mg injection.

Results: A total of 106 eyes from 114 patients were included. Their nAMD subtypes were Type 1 MNV (n = 101), Type 2 MNV (n = 3), mixed Type 1 and Type 2 MNV (n = 6), and Type 3 MNV (n = 4). Patients had received a mean of 21.8±24.5 other anti-VEGF therapies, and the average treatment interval before switching was 9.2±3.0 weeks. The immediate previous anti-VEGF agents were aflibercept in 91 eyes, faricimab in 22 eyes, and brolocizumab in 1 eye. After one administration of IVA 8 mg, the mean BCVA was significantly improved after the switch (pre-switch: 0.34±0.40 and post-switch: 0.32±0.39, p = 0.028), and mean CMT was also significantly reduced (pre-switch: 268.4 ± 92.3 and post-switch: 246.2 ± 76.7, p < 0.0001). In the subgroup analysis according to the prior anti-VEGF agent, switching from aflibercept 2mg resulted in a significant CMT reduction (pre-switch: 269.4±98.3 and post-switch: 242.8±77.9, P < 0.001), whereas switching from faricimab remained statistically unchanged (pre-switch: 267.3±64.7 and post-switch: 262.0±72.8, P = 0.074).

Conclusions: Aflibercept 8mg demonstrates particularly superior efficacy compared to aflibercept 2mg.

Abstract No.: 202779

Panel No.: RME-0974

Six-Month Outcomes of Half-Fluence Photodynamic Therapy Combined With Intravitreal Aflibercept Injection for Pachychoroid Neovascularopathy

First Author: Satomi SHIOSE

Co-Author(s): Keijiro ISHIKAWA, Kumiko KANO, Shoji NOTOMI, Koh-hei SONODA, Fukuda YOSUKE

Purpose: To investigate the six-month outcomes of patients with pachychoroid neovascularopathy (PNV) treated with a single anti-VEGF drug injection with half-fluence photodynamic therapy (IVI-PDT) and to identify factors linked to persistent or recurrent subretinal fluid (SRF).

Methods: The consecutive treatment-naïve PNV patients, who received initial treatment with IVI-PDT from 2019 to 2024 at Kyushu University Hospital and followed up for at least 6 months, were examined retrospectively. Patient data, including sex, age, and baseline best-corrected visual acuity (BCVA), and imaging data, including optical coherence tomography (OCT), OCT angiography, and fundus autofluorescence, were collected. The pre-/post-treatment BCVA, central macular thickness (CMT), and central choroidal thickness (CCT) were compared. The factors associated with persistent or recurrent SRF were investigated.

Results: Sixty-three eyes of 63 patients were included in this study. The mean BCVA before treatment was 0.13 ± 0.23 logMAR, which improved to 0.04 ± 0.18 after six months. The CMT and CCT significantly decreased after treatment. Persistent SRF was observed in 21 patients (33%), who were older (66.5 ± 9.6 vs. 59.9 ± 10.2; p=0.02), had poorer baseline BCVA (0.21 ± 0.31 vs. 0.08 ± 0.17; p=0.03), larger macular neovascularization area (0.90 ± 0.57 vs. 0.42 ± 0.36; p<0.001) and wider hyper fluorescence area (6.60 ± 4.17 vs. 3.44 ± 4.17; p=0.008).

Conclusions: The IVI-PDT improved BCVA, CMT, and CCT in patients with PNV. One-third of patients required additional treatment due to persistent SRF. Older age, larger MNV, wider hyperfluorescent area, and worse baseline BCVA were linked to persistent SRF.

Abstract No.: 201079

Panel No.: RME-0944

Six-Month Real-World Outcomes of Faricimab in Treatment-Naïve Diabetic Macular Edema

First Author: Xiaoe FAN

Purpose: To evaluate short-term real-world effectiveness and safety of faricimab in treatment-naïve diabetic macular edema (DME), with attention to dosing intervals and anatomic recovery.

Methods: Prospective consecutive case series. Treatment-naïve DME eyes receiving intravitreal faricimab from June–December 2024 were followed for ≥ 6 months. A 3-loading-dose plus pro re nata (3+PRN) regimen was used; panretinal photocoagulation (PRP) was added based on fluorescein fundus angiography (FFA). Monthly visits collected baseline and month 1, 2, 3, and 6 data: best-corrected visual acuity (BCVA, logMAR), central subfield thickness (CST), subretinal fluid (SRF) status, fasting glucose, and hemoglobin A1c. Statistics used paired t-test or Mann–Whitney U test (two-sided, $\alpha=0.05$).

Results: Eleven patients (9 male, 2 female; 17 eyes; mean age 54.5 ± 7.5 years) were included. Over 6 months, eyes received a mean of 3.23 injections; 76.47% stabilized after three loading doses, while 23.53% required one PRN injection at month 5. BCVA improved from 0.15 ± 0.18 at baseline to 0.12 ± 0.14 at month 3 and 0.08 ± 0.10 at month 6. CST decreased from $378.5 \pm 66.8 \mu\text{m}$ to $303.5 \pm 91.7 \mu\text{m}$ at month 3 and $270.0 \pm 86.5 \mu\text{m}$ at month 6. SRF resolved in 49.36% at month 3 and 61.11% at month 6 (denominator: eyes with baseline SRF).

Conclusions: In a 6-month real-world setting, faricimab achieved sustained visual gains and meaningful CST reduction in treatment-naïve DME, with extended treatment intervals in most eyes. Larger, controlled studies with longer follow-up are warranted.

Structure–Function Link of Ellipsoid Zone Integrity and Low-Luminance Deficit in Avacincaptad Pegol-Treated Eyes with Geographic Atrophy

*First Author: Kelvin **TEO***

*Co-Author(s): Rachel **DOWNES**, Karen **MATAR**, Reem **AMINE**, Asmita **INDURKAR**, Amy **TANG**, Lyndsey **DELLA VECCHIA**, John **MAMONE**, Katherine **TALCOTT**, Janet **KIM**, Don **LUO**, Olga **CERON**, Dina **ABULON**, Justis **EHLERS***

Purpose: A better understanding of the structure–function relationship in geographic atrophy (GA) is needed. Low-luminance deficit (LLD), a measure of visual function, and ellipsoid zone (EZ) integrity, a measure of photoreceptor health, are markers of disease severity. The purpose of this study was to assess the relationship between structure and function by analyzing EZ integrity and LLD in eyes with GA treated with avacincaptad pegol (ACP) 2 mg.

Methods: This is a post hoc analysis of pooled 18-month data from the GATHER1 and GATHER2 trials. Study eyes with non–center point involving GA were grouped by baseline LLD quartiles. LLD was calculated as the difference between normal-luminance best corrected visual acuity (BCVA) and low-luminance BCVA. EZ degeneration and loss were measured as

the percentage of the macular area with EZ to retinal pigment epithelium (RPE) thickness of $\leq 20 \mu\text{m}$ (partial EZ attenuation) and $0 \mu\text{m}$ (total EZ attenuation), respectively, using spectral-domain optical coherence tomography.

Results: At baseline, eyes with the greatest LLD had the highest partial and total EZ attenuation. At month 18, ACP 2 mg reduced the progression of partial and total EZ attenuation vs sham, with the most pronounced benefit in eyes with greater baseline LLD (partial: 4.9% vs 11.0%; total: 9.1% vs 12.9%, respectively).

Conclusions: These results support a structure–function relationship in GA. ACP treatment was associated with reduced progression of EZ attenuation vs sham, particularly in eyes with greater baseline LLD, suggesting an increased treatment benefit in those eyes.

Study on the Efficacy of Faricimab in the Treatment of Retinal Vein Occlusion

First Author: Wei

Purpose: This review systematically evaluates the efficacy, safety, and clinical application value of bispecific antibody Faricimab in the treatment of macular edema (ME) secondary to retinal vein occlusion (RVO).

Methods: Through a comprehensive search and analysis of relevant literature, including pharmacological studies, key registered clinical trials, real-world evidence, and comparative study data, a systematic review was conducted on the therapeutic mechanism, efficacy indicators, safety features, and pharmacoeconomic evaluation of faricimab in RVO-ME.

Results: Faricimab significantly improved vision and reduced central retinal thickness in the short term (≤ 3 months), with a high initial response rate; Maintaining visual stability in the medium to long term (≥ 6 months), the injection interval can be extended to 3–4 months, which is superior to ranibizumab and aflibercept. There is no significant association between systemic adverse events (cardiovascular events), and long-term database updates support good tolerability. Pharmacoeconomic evaluation shows that extending the interval can reduce medical costs by 20–30%, which is consistent with real-world research and clinical trial results.

Conclusions: Faricimab effectively improves visual function and anatomical outcomes in RVO-ME patients through a dual target mechanism.

Study on the Mechanism of Phenylacetylglutamine Activating Microglia to Participate in the Inflammation of Diabetic Retinopathy

First Author: Kun LIU

Co-Author(s): Junwei FANG, Yan JIANG, Hanying WANG

Purpose: Diabetic retinopathy (DR) is considered a chronic inflammatory disease in which retinal microglia are key participants. The gut-derived metabolite phenylacetylglutamine (PAGln) is elevated in both blood and vitreous of DR patients. This study aimed to investigate the role of PAGln in DR-associated inflammation.

Methods: Fecal samples from 6-month-old db/db and db/m mice were analyzed by metagenomic sequencing to identify differential taxa. Microglia (BV2) adapted to low glucose were stimulated with PAGln (25 mmol/L), and phagocytic capacity was assessed by flow cytometry. Interleukin-1 β (IL-1 β) expression was measured by Real-time fluorescence quantitative polymerase chain reaction (qRT-PCR) and Western blot (WB). PAGln-activated BV2 were co-cultured with human retinal microvascular endothelial cells (HRMECs) to evaluate migration, tube formation, and ZO-1 expression. C57 mice received intraperitoneal PAGln (50 mg/kg) for 4 weeks, followed by metabolomic analysis, retinal immunofluorescence, Evans blue leakage, qRT-PCR, and WB assays. Adrenergic receptor β 2 (ADRB2) inhibition was applied to explore the mechanism.

Results: Db/db mice showed increased Enterobacteriaceae. Systemic PAGln crossed the blood-retinal barrier and accumulated intraocularly. PAGln activated BV2 both in vitro and in vivo, enhancing phagocytosis and upregulating IL-1 β . Activated BV2 impaired HRMEC barrier function, decreased ZO-1, and promoted migration and angiogenesis. Inhibition of ADRB2 reduced BV2 activation and inflammation.

Conclusions: PAGln promotes retinal inflammation by activating BV2 and disrupting vascular barrier integrity, thereby facilitating neovascularization. ADRB2 mediates PAGln's effects and may represent a therapeutic target. These findings highlight PAGln as an important inflammatory driver in DR and a potential intervention target.

Targeting Hypoxia Inducible Factors Pathway in Laser-Induced Choroidal Neovascularization Mouse Model

First Author: Ziyi ZHENG

Co-Author(s): Mårten Eric BRELÉN, Priscilla FERNANDEZ LOAIZA, Tony Tsz Chun MAN, Yolanda Wong Ying YIP

Purpose: This study aimed to investigate the role of HIF (hypoxia inducible factors) and its signaling pathway in pathological CNV (choroidal neovascularization) in neovascular age-related macular degeneration (nAMD). It also evaluated the potential therapeutic effects of R59949, a diacylglycerol kinase inhibitor, and Dactolisib, a PI3K/mTOR dual inhibitor, on the laser-induced CNV mouse model.

Methods: A laser-induced CNV mouse model was used, involving 6–8-week-old C57BL/6J mice treated with either R59949, Dactolisib, Eylea (Aflibercept), or a control sham injection. FA (fluorescein angiography) and OCT (optical coherence tomography) were performed on Days 7 and 14 to assess CNV leakage area and retinal thickness. Statistical analysis included one-way ANOVA for significance.

Results: A total number of 40 eyeballs were included for statistical analysis (1% DMSO, n=8; Eylea, n=8; R59949, n=12; Dactolisib, n=12). Compared to the control group, both R59949 and Dactolisib demonstrated statistically significant reduction in FA leakage area on Day 14 ($p<0.01$), as well as statistically significant reduction in retinal thickness on Day 14 ($p<0.01$), while on Day 7 R59949 also showed statistically significant reduction in FA leakage area ($p<0.005$) as well as retinal thickness reduction ($p<0.005$). The treatments also exhibited comparable efficacy to Eylea in mitigating CNV progression ($p>0.05$).

Conclusions: The findings suggest that targeting HIF and its signaling pathway offers a promising alternative to anti-VEGF therapies for managing CNV in nAMD. The study highlights the need for further exploration of novel inhibitors and their pharmacological profiles to advance therapeutic strategies in retinal angiogenesis.

The Changes of Intraocular Cytokines in Patients With Retinal Vascular Diseases Are Obviously Correlated With the Occurrence and Development of the Disease

First Author: Xia JIANPING

Purpose: Diabetic retinopathy (DR) is a serious complication of diabetes and the main cause of blindness in diabetes patients. Metabolic and inflammatory actors may play important roles in the pathogenesis of DR. FDCN5 and Irisin can be used as biomarkers of Diabetic retinopathy (DR) progression

and recovery. Analyze the levels of FNDC5 and 4 cytokines in DR aqueous humor to evaluate the effects of FNDC5 and inflammatory factors.

Methods: The study included patients with Diabetic macular edema DME eyes (n=39) and collected aqueous humor samples (n=118). ELISA (ELISA) kits were used for FNDC5, and RT-qPCR kits were used for 4 cytokines (VEGF, interleukin-6, interleukin-8) to detect the level of anti-VEGF treatment for DME five times, and optical tomography (OCT) was used to measure the macular thickness (CMT) of all patients. SPSS and χ^2 is used for intergroup classification data comparison. Results of Pearson correlation analysis and post-hoc multiple comparison analysis.

Results: The CMT of the DME treatment group was significantly lower than before treatment. The levels of FNDC5 in DME aqueous humor were significantly increased after three consecutive injections. After the fourth and fifth injections, the FNDC5 values tended to stabilize. The value of VEGF gradually decreased and tended to stabilize after five consecutive injections. The CMT value gradually decreases to normal. There is a negative correlation between VEGF and FNDC5. There is no correlation between FNDC5 and interleukin-6, interleukin-8.

Conclusions: There is a negative correlation between FNDC5 and VEGF. There is a negative correlation between FNDC5 and CMT. FNDC5 can regulate the level of oxidative stress and inflammatory reaction in Diabetic retinopathy. Five loading doses can control the edema of diabetic macular edema.

The Correlation Between Axial Length Variation and Choroidal Thickness Change Before and After Cataract Surgery

First Author: Jaeha KIM

Co-Author(s): Jaehwan CHOI, Kiyoun KIM, Seungyoung YU

Purpose: This study investigated the relationship between axial length (AXL) changes and choroidal thickness in highly myopic eyes following cataract surgery. Subfoveal choroidal thickness is a key determinant of visual outcomes in high myopia, yet regional patterns of change remain underexplored.

Methods: We retrospectively reviewed 18 eyes (baseline AXL ≥ 26 mm) that underwent cataract surgery at Kyung Hee University Medical Center. Exclusion criteria included macular pathology, prior intraocular surgery, moderate or worse diabetic retinopathy, or poor imaging quality. AXL was measured with optical biometry and standardized to mm/year. Choroidal thickness was quantified using swept-source OCTA with the Zeiss ARI network algorithm, applying the ETDRS grid and normalized to $\mu\text{m}/\text{year}$. Eyes were

classified into AXL increase vs. no increase groups, with intergroup comparisons by the Mann-Whitney U test.

Results: A significant intergroup difference was found in the rate of choroidal thinning. Eyes with AXL elongation showed less overall choroidal thinning, and even superior sector thickening. By contrast, eyes without AXL increase exhibited accelerated thinning, particularly in the superior choroid.

Conclusions: These findings suggest that superior choroidal thickness changes may reflect localized compensatory remodeling associated with axial elongation. Sector-specific patterns, especially superior thickening, could serve as novel biomarkers for predicting myopia progression after cataract surgery.

The Effect of Thyroxin on the Biological Effects of High Glucose-Induced Human Retinal Endothelial Cells and B-Cell Lymphoma 2/Bcl-2 Associated X

First Author: Lei LIU

Purpose: This study intends to assess the biological effect of TTR on human retinal endothelial cells under high glucose.

Methods: Cells were assigned into a normal group, a high glucose (HG) group, and a TTR intervention group, followed by analysis of cell biological activity and protein expression.

Results: The retinal endothelial cell proliferation rate was significantly promoted in the HG group ($P < 0.05$) and inhibited in the intervention group ($P < 0.05$). The HG group had significantly higher cell migration number than the normal group ($P < 0.05$). However, the migrated cell number in the intervention group was reduced significantly ($P < 0.05$). In addition, high glucose also significantly enhanced the invasion of retinal endothelial cells ($P < 0.05$), which was inhibited after TTR intervention ($P < 0.05$). Moreover, Bcl-2 protein was significantly downregulated, and Bax was upregulated in the HG group compared to the normal group ($P < 0.05$). Interestingly, their levels were normalized after TTR intervention without difference compared to their levels in the normal group ($P < 0.05$). Consistently, the mRNA level of Bcl-2 and Bax showed similar expression profiles to the protein expression in different groups ($P < 0.05$).

Conclusions: TTR can inhibit the retinal endothelial cell proliferation, migration, and invasion ability and regulate Bcl-2/Bax expression.

The High Cost of Sight: Navigating the Financial Impact of Diabetic Retinopathy at a Tertiary Care Centre in South Asia

First Author: Vaishnavi

Purpose: This is a qualitative analysis to study the knowledge, attitude, financial burden, and vision-related quality of life of patients with diabetic retinopathy.

Methods: A total of 350 patients were given a standard questionnaire to understand the financial burden of the patient and vision-related quality of life due to diabetic retinopathy. The questionnaire was later analyzed to know what was the major cause of the financial burden.

Results: Severe non-proliferative diabetic retinopathy (NPDR) and proliferative diabetic retinopathy (PDR) had 2-6 times higher costs than mild/moderate cases. Anti-VEGF injections and vitrectomy were the largest direct cost drivers. Travel and lost wages accounted for 30-40% of total expenses. PDR patients reported the worst VRQoL (eg, difficulty reading, mobility. Financial stress exacerbated mental health issues (15% reported severe anxiety/depression).

Conclusions: Diabetic retinopathy poses significant financial burdens on patients, impacting both direct and indirect costs and profoundly affecting their visual-related quality of life. This study examines the economic implications and quality of life consequences for individuals suffering from Diabetic retinopathy. Direct costs include medical expenses and logistics for frequent ophthalmologic exams, advanced treatment modalities like laser therapy and anti-VEGF injections, and ongoing management of diabetes-related health issues. Indirect costs encompass lost productivity due to visual impairment and associated disabilities, as well as potential long-term care needs. Thus government should take necessary steps not only to create awareness but also to reduce the economic blindness due to diabetic retinopathy.

The Molecular Mechanism Study of Egr1 in the Degenerative Retina of Rd10 Mice

First Author: Kun-chao WU

Purpose: The aim of this study is to explore the regulatory molecular mechanism of egr1 within the Rd10 mice model of retinitis pigmentosa.

Methods: Several bioinformatics algorithms were used to identify the role of Egr1 involved in the degenerative retina of Rd10 mice. Further, its expression characterizations were evaluated through a single-cell sequencing dataset, qPCR, and immunofluorescence

staining. The TTRUST database was utilized to analyze transcription factors that interact with Egr1. The potential molecules targeting Egr1 were predicted by the DGIdb database. Financially, the molecular docking was performed to evaluate the binding capacity between them.

Results: GESA analysis indicated a significant activation of multiple biological pathways in the retinas of Rd10 mice. A systematic bioinformatics analyses identified several hub genes degenerative retina, including Egr1. Results of qPCR showed that the expression of Egr1 in the retinas of Rd10 mice was significantly upregulated. Analysis of the single-cell dataset from Rd10 mice indicated that the expression of Egr1 was significantly higher in rods and cones when compared to the control group. Immunofluorescence staining results suggested that Egr1 is mainly localized in the outer nuclear layer of the Rd10 mice retina. Predictions from the TTRUST database suggested interactions between Egr1 and 76 genes, including Makp8, Cxcl2, and Pten. The DGIdb database predicted that Genipin has the potential to regulate Egr1 gene expression, and molecular docking indicated a high binding affinity between the them.

Conclusions: Our study may suggest that Egr1 has great potential for the therapeutic study of retinitis pigmentosa.

The Observational Study of the Efficacy of Eylea High Dose

First Author: Yin-zhi LEE

Co-Author(s): Zachary ANGUS, Manishka JAYASUNDERA, Sukhpal SANDHU, Robyn TROUTBECK, Sanjeeva WICKREMASINGHE

Purpose: Eylea High Dose (EHD) is purported to allow for extended dosing intervals, whilst maintaining efficacy. This study investigated the potential of EHD in extending treatment intervals in patients with nAMD.

Methods: Patients who were either inadequately controlled or who needed high frequency of anti-VEGF therapy were switched to EHD. Eligible patients were required to have received a minimum of 3 consistent anti-VEGF treatments prior to transitioning to EHD. The average injection interval of the 3 most recent anti-VEGF injections before switching to EHD were compared to the last 3 consecutive EHD injections following the switch. Best-corrected Visual Acuity (BCVA) and central subfield thickness (CST) were also collected at baseline and after EHD treatment.

Results: 42 eyes of 38 patients met the inclusion criteria. 83.3% were switched from 2mg Aflibercept, 14.3% from Faricimab and 2.4% from Ranibizumab. The mean treatment interval prior to the switch was 7.44 weeks. Following the switch to EHD, the mean treatment interval was extended to 8.64 weeks. A

significant reduction in CST was also noted from 325 μ m to 303 μ m at the end of the follow-up. However, this improvement did not translate to an improvement in BCVA which only improved from 68 to 71.2 letters which was not statistically significant.

Conclusions: On average, the treatment interval was extended 1.2 weeks or 8.4 days following the switch to EHD. There was a concurrent improvement in CST, but this did not translate to significant improvement in BCVA.

The X Factor: A Familial Case Series of Retinitis Pigmentosa in Female Carriers

First Author: Josh **KUMAR**

Co-Author(s): Vinod **KUMAR**

Purpose: To report symptomatic retinitis pigmentosa (RP) in three females of a single family due to heterozygous mutation in the RPGR gene.

Methods: Three members of the same family - a 42 year old mother and her two daughters (14 and 10 years of age respectively) underwent detailed ophthalmic evaluation. Ultra wide field fundus photography, fundus autofluorescence, optical coherence tomography, electroretinography (ERG) and clinical exon sequencing.

Results: All three patients presented with progressive diminution of vision in both eyes, more pronounced under scotopic conditions (nyctalopia). Imaging suggested clinical findings of retinitis pigmentosa. Clinical exon sequencing revealed a heterozygous mutation in the RPGR gene in each patient. Full-field ERG demonstrated extinguished dark-adapted and light-adapted waveforms consistent with Retinitis Pigmentosa. Third daughter (5 years of age) though positive for the same mutation in RPGR gene, was asymptomatic.

Conclusions: RPGR mutations are associated with X-linked retinitis pigmentosa and clinical manifestations are typically seen in hemizygous males. Female carriers typically remain asymptomatic or display mild changes due to lyonization. This case series reports symptomatic and clinically detectable retinitis pigmentosa in three females with heterozygous RPGR within the same family, highlighting the variable expressivity and potential disease burden in carrier states.

Therapeutic Potential of Allogeneic iPS Cell-Derived RPE Transplantation for RPE65-LCA

First Author: Akiko **MAEDA**

Co-Author(s): Yasuo **KURIMOTO**, Tadao **MAEDA**,

Michiko **MANDAI**, Daiki **SAKAI**, Masayo **TAKAHASHI**

Purpose: To evaluate the safety and therapeutic effects of induced pluripotent stem (iPS) cell-derived retinal pigment epithelium (RPE) transplantation for RPE65-associated Leber congenital amaurosis (RPE65-LCA).

Methods: A 46-year-old male patient with RPE65-LCA underwent allogeneic iPS cell-derived RPE transplantation. The patient's best-corrected visual acuity (VA) prior to treatment was 2.0 (logMAR). A suspension of these cells (5×10^5 cells in 0.15 ml) was transplanted into the subretinal space.

Results: On day 15 post-transplantation, intraocular pressure (IOP) increased to 46 mmHg due to local steroid treatment, resulting in a decrease in VA to light perception (LP). Retinal imaging on day 71 revealed that most transplanted cells had migrated and formed an epiretinal membrane (ERM). The ERM was surgically removed on day 112. Two years post-transplantation, the patient reported improved vision, with VA improving to 1.4 (logMAR) from LP. Full-field stimulus testing (FST) and microperimetry demonstrated increased retinal sensitivity. These improvements have been maintained for up to 4 years post-treatment.

Conclusions: This case demonstrated the challenges associated with RPE transplantation. However, the transplanted RPE cells stayed and maintained their function, contributing to improved visual function two years post-transplantation. RPE transplantation may serve as a potential therapeutic option for patients with RPE65-LCA, particularly those who are not eligible for RPE65 gene therapy.

To Study the Clinical Profile of Pachychoroid Spectrum Disease Presenting to a Tertiary Care Centre in Northeast India

First Author: Ankit **AHIR**

Co-Author(s): Manabjyoti **BARMAN**, Harsha **BHATTACHARJEE**, Madhusmita **MAHAPATRA**

Purpose: To evaluate the imaging features of OCT/ICGA in patients with Pachychoroid disease spectrum and to study the demographic profile of patients presenting with pachychoroid spectrum.

Methods: The study was carried out for 15 months in 170 volunteered patients as a Retrospective study for 6 months and a Prospective study for 9 months. In patients, OCT using the Spectral domain was done

using the HRA and HRA-OCT with Enhanced depth imaging.

Results: More than 50% of the subjects obtained retinal pigment epithelium (RPE) and central serous chorioretinopathy (CSCR). In contrast, moderate value was obtained on polypoidal choroidal vasculopathy (PCV) followed by Pachychoroid pigment epitheliopathy (PPE), pachychoroid neovasculopathy (PCN), and peripapillary pachychoroid syndrome (PPS). In contrast, the very least value was found on focal choroidal excavation (FCE) during the Pachy types study.

Conclusions: This study emphasizes recent imaging techniques for the diagnosis of the disease. Earlier, very few studies have been conducted on the treatment of this disease and this is also an important part of the present study to prevent Pachychoroid spectrum disease with more sample size.

Topical Interferon as a Newer Modality for Treatment of Uveitic Macular Edema: A Tertiary Centre Study of Northern India

First Author: Apurva **BAGLA**

Co-Author(s): Kshama **DWIVEDI**, Santosh **KUMAR**, Arti **SINGH**

Purpose: The aim of this study was to study the efficacy of topical interferon alpha-2b (IFN) as an adjunctive therapy in the treatment of uveitic macular edema (UME).

Methods: This is a prospective, interventional, randomized study on patients with UME. 16 eyes of 16 patients (one eye/patient) who were diagnosed with UME were randomly assigned to get topical IFNa2b 1MIU/ml (Case group) or placebo drop (Control group) as an adjunct to conventional treatment. Central macular thickness (CMT) and best corrected visual acuity (BCVA) were measured at the baseline and on each review visit until complete resolution of UME.

Results: Sixteen eyes of 16 patients were taken (8 cases and 8 controls). The Vision between Groups in UME was statistically significant at 2 Months at $p < 0.01$ level. The CMT between Groups in UME by an Independent sample t-test showed that all the time durations showed no statistical significance difference, except for 2 months, which showed a statistical significance difference. The mean time taken for complete resolution of CMT in the case group in UME was 6.5 weeks, whereas it was 10.8 weeks in the control group. No ocular or systemic side effects related to the topical IFN therapy were noted clinically, except papillary conjunctivitis in one patient.

Conclusions: Topical IFN therapy can be a noninvasive, economical, and effective adjuvant choice of treatment for UME, resulting in earlier resolution of CMT than conventional treatment.

Abstract No.: 207353

Panel No.: RME-1033

Transthyretin-Regulated Diabetic Retinopathy Through the VEGFA/PI3K/AKT Pathway

First Author: Lei **LIU**

Purpose: Transthyretin (TTR) plays a regulatory role in a variety of diabetes-related diseases. The objective of this work was to probe whether TTR affects diabetic retinopathy (DR) through the VEGFA/PI3K/AKT pathway.

Methods: High glucose (HG, 25 mM) was used to treat human retinal microvascular endothelial cells (hRMECs), and C57BL/6J mice were intraperitoneally injected with STZ (50 mg/kg) to construct a DR model. In vitro, the effect of TTR on DR was evaluated by measuring hRMEC proliferation, migration, and angiogenesis. The changes in retinal tissue were observed by hematoxylin and eosin staining in vivo. ELISA, immunohistochemistry, and immunofluorescence staining were used to measure VEGFA or CD31 levels. The levels of all proteins were evaluated through Western blot.

Results: The increase of proliferation, migration, and angiogenesis and decrease of apoptosis in hRMECs caused by HG were notably reversed by TTR. TTR greatly impeded HG-raised VEGFA, PI3K p-p85, and p-AKT in hRMECs. Inhibition of TTR further exacerbated the effect of HG-induced hRMECs. Inhibition of VEGFA reversed the effect of HG-induced hRMECs. VEGFA neutralized the function of TTR on cell proliferation, apoptosis, migration, and angiogenesis in HG-triggered hRMECs. It was further confirmed in vivo that TTR can alleviate the occurrence of DR in diabetic mouse models.

Conclusions: TTR significantly restrained the progression of DR via molecular modulation of the VEGFA/PI3K/AKT axis.

Panel No.: RME-0963

Treatment of DME/NPDR With Combination Therapy of Intravitreal Avastin (Bevacizumab)/ Patizra (Ranibizumab) and Eylea (Aflibercept) Using Subthreshold Modified Grid Laser

First Author: Dr M Afzal **BODLA**

Co-Author(s): Arfa **AHSAN**

Purpose: Diabetic macular edema (DME) is one of the primary causes of serious central vision loss, largely driven by excessive vascular leakage. In our study, we aimed to evaluate the efficacy of different Anti-Vascular Endothelial Growth Factors (Anti-VEGFs) with a combination of sub-threshold focal/ modified grid laser. The goal was to reduce the number of anti-VEGF injections while improving best corrected visual acuity

(BCVA), reducing central macular thickness (CMT), and minimizing systemic side effects.

Methods: This randomized interventional trial was conducted at the Eye Department of CMH Institute of Medical Sciences and Bodla Eye Care, Multan, from July 2022 to June 2024. Purposive sampling was used to choose 30 eyes of 30 patients aged 40-70 years, including both genders. The anti-VEGF first dose was given after macular cube and raster OCT. The study was based on three different groups: Group A (Avastin), Group B (Patizra), and Group C (Eylea), followed by sub-threshold focal/modified grid photocoagulation in 3-4 weeks.

Results: Our studies indicate that focal/grid laser photocoagulation can reduce moderate vision loss from DME by 50% or more. Historically, laser therapy has been the gold standard for DME treatment. With the advent of anti-VEGF agents, improved visual acuity outcomes and greater reductions in macular thickness have been achieved.

Conclusions: In our study, we combined anti-VEGF agents with subthreshold laser therapy, resulting in superior outcomes in the treatment of DME. This combined approach may help to reduce treatment burden while delivering improved visual and anatomical results.

Abstract No.: 203086

Panel No.: RME-0978

Twelve-Month REsponse and Safety of Intravitreal Dexamethasone Implant in Treatment-Naïve and Recalcitrant Diabetic Macular Edema (TREAT-DME Study)

First Author: Jay **SHETH**

Co-Author(s): Somnath **CHAKRABORTY**

Purpose: To compare twelve-month visual, anatomical, safety, and inflammation biomarker outcomes of intravitreal dexamethasone implant (DEX) in treatment naïve versus recalcitrant center involving diabetic macular edema (CI-DME) eyes.

Methods: In this multicenter, retrospective cohort study (January 2020–December 2024) at two tertiary centers, diabetic patients with CI-DME were stratified into treatment naïve or recalcitrant cohorts. All eyes underwent DEX therapy, with pro-re-nata retreatment for recurrent fluid, ≥ 5 letter BCVA loss, or ≥ 50 μm CMT increase. Visits at baseline and periodic intervals up to 12 months included BCVA, IOP, slit lamp and fundus exams, and OCT quantification of CMT and hyperreflective foci (HRF). Safety outcomes included IOP elevations, cataract progression, and other ocular events.

Results: We analyzed 102 eyes (30 naïve, 72 recalcitrant) from 74 patients (mean age 61.7 ± 8.8 years). Mean injections per eye were 1.83 ± 0.73 , higher in recalcitrant eyes (1.87 vs.

1.73 ; $P=0.02$). At 12 months, mean BCVA improved from 0.73 ± 0.26 to 0.62 ± 0.28 logMAR ($P=0.002$), with no intergroup differences ($P>0.05$). Mean CMT decreased from 520 ± 144 to 462 ± 192 μm ($P=0.03$), similarly across cohorts ($P>0.10$). Hyperreflective foci declined from 58% to 26% ($P<0.001$). Safety outcomes included cataract progression in 39% of phakic eyes (26% underwent surgery) and transient IOP elevations >21 mmHg in 9.8%, all managed medically; no glaucoma surgery was required.

Conclusions: In real-world practice, intravitreal DEX implant delivers sustained visual and anatomical benefits in both treatment naïve and recalcitrant CI DME eyes. Although cataract progression and transient IOP rises occur, they are predictably manageable. Its extended durability and acceptable safety profile underscore DEX implant as a practical, valuable option across diverse DME populations.

Abstract No.: 203438

Panel No.: RME-0985

UCP2 Alleviates RPE Injury via Vitamin B5 Metabolism-Mediated Mitochondrial Function Improvement

First Author: Chuanhe **ZHANG**

Co-Author(s): Ning **AN**, Dongcheng **LIU**, Ziling **LIU**, Bo **QIN**

Purpose: Dry age-related macular degeneration (dry AMD) is a major cause of vision loss, characterized by retinal pigment epithelium (RPE) dysfunction and mitochondrial impairment. This study aimed to investigate the role of mitochondrial uncoupling protein 2 (UCP2) in regulating mitochondrial function and oxidative stress responses in RPE, with the goal of clarifying key molecular mechanisms and identifying potential therapeutic targets for AMD.

Methods: Transcriptomic datasets from AMD patients and NaIO_3 -induced experimental models were analyzed to detect the expression of UCP2. Functional assays were performed to reveal the role of UCP2 in RPE injury using in vitro models. Metabolomic analysis was performed to identify the targets of UCP2. The impact of UCP2 overexpression on retinal structural integrity and visual function was verified in animal models.

Results: • A significant downregulation of UCP2 was identified in both transcriptomic data from AMD patients and NaIO_3 -induced experimental models. Reduced UCP2 expression exacerbated mitochondrial damage, ROS production, and calcium imbalance, ultimately leading to RPE injury. UCP2 was found to regulate mitochondrial homeostasis through a previously unreported interaction with PANK2, thereby influencing vitamin B5 metabolism. Supplementation with vitamin B5 rescued mitochondrial function, reduced oxidative stress, and protected RPE cells from damage.

Conclusions: These results establish the UCP2–PANK2–vitamin B5 axis as a novel metabolic regulatory pathway in AMD pathogenesis. This finding not only enhances the understanding of the molecular mechanisms underlying dry AMD but also highlights the therapeutic potential of targeting this axis for the treatment of mitochondrial-driven retinal diseases such as dry AMD.

Abstract No.: 201292

Unexpected Acute Macular Edema on the First Day After Phacoemulsification Surgery in Five Patients: Case Series

First Author: Nora Kusuma DAHLIA

Co-Author(s): Iqbal HILMI

Purpose: To report five unexpected cases of acute macular edema with serous macular detachment occurring on the first day after uneventful phacoemulsification surgery with intraocular lens implantation by the same surgeon on the same day.

Methods: Diagnosis was based on best-corrected visual acuity (BCVA), anterior segment examination, intraocular pressure (IOP), fundus examination, and optical coherence tomography (OCT) were performed at first and seventh day postoperative.

Results: Five patients without pre-existing fundus or systemic diseases underwent phacoemulsification surgery. BCVA on the first day was 3/60 in three patients and 6/45 in two patients. Postoperative anterior segment examination in all patients appeared normal. IOP in all patients is within normal limits. OCT showed serous macular detachment with significant intraretinal fluid accumulation. After seven days of treatment with standard postoperative drugs and additional topical nonsteroid anti-inflammatory drugs (NSAIDs), intraretinal and subretinal fluid were fully reabsorbed, and BCVA improved.

Conclusions: Acute macular edema with serous detachment should be considered in cases of poor visual acuity on the first day postoperative. Rapid diagnosis and medical treatment can provide significant improvement.

Panel No.: RME-1042

Unusual Central Retinal Artery Occlusion following Neck Massage in a Nasopharyngeal Carcinoma Patient With Post-Radiotherapy Carotid Stenosis

First Author: Raymond Lai-man WONG

Co-Author(s): Thomas LAM, Wing-yi Chilli LAU, Shaheeda MOHAMED

Purpose: To report a case of central retinal artery occlusion (CRAO) following neck massage in a patient

with a history of nasopharyngeal carcinoma (NPC) who developed post-radiotherapy carotid stenosis.

Methods: Case report.

Results: A 54-year-old man with known carotid stenosis following external radiotherapy and brachytherapy for NPC presented with sudden right eye vision loss after neck massage. Best-corrected visual acuity in the right eye was hand motion at presentation. Fundus examination revealed a cherry red spot at the macula, multiple visible emboli, and retinal whitening. He was immediately treated with anti-glaucoma eye drops and instructed to perform carbon dioxide rebreathing exercises. Given the high risk of cerebrovascular accident, his aspirin was switched to clopidogrel, and simvastatin was initiated. The patient demonstrated progressive improvement, with subsequent disappearance of emboli and restoration of normal fundal appearance. His visual acuity returned to 20/20 ten days after presentation and remained stable during his follow-up.

Conclusions: Neck massage can trigger embolic events such as CRAO in patients with underlying carotid stenosis. Patients with NPC or head and neck cancers treated with radiotherapy are particularly vulnerable. Secondary prevention of embolic events is crucial in CRAO management. All patients with carotid stenosis should be warned of the risk of embolic events associated with neck manipulation.

Utility of Ultrawide Field Imaging and UWF FFA in Diabetic Retinopathy Patients to Detect Peripheral Lesions

First Author: Sabarinath A

Purpose: To analyze distribution of various lesions in peripheries in DR patients using UWF imaging.

Methods: This is a Prospective observational study. A total of 150 patients with DR who presented to our retina clinic were included.

Results: Images of 150 patients were analyzed .39.7% were graded as predominantly peripheral lesions (PPL), while 60.3% graded to have predominantly central lesions (PCL). Comparison of ICDR with the S7F grading, shown for moderate NPDR, of 182 cases, (11.5%) graded as mild, (86.8%) as moderate, (1.1%) as severe, and (0.6%) classified as PDR. The severe NPDR comprised 73 cases, with 4 classified as mild, 66 as moderate, and 3 (4.1%) as severe. In PDR, out of 35 cases, 1 was classified as mild, 24 as moderate, 4 as severe, and 6 as PDR. 35% had more than 3 fields of involvement. The assessment of retinal CNP areas and NV in the peripheries indicated that 26.0% of participants (n = 78) exhibited while 74.0% (n = 222) did not show such findings. Capillary non-perfusion (CNP) and neovascularization (NV) revealed that 18.7%

(n = 56) had CNP, 4.7% (n = 14) had NV, and 3.3% (n = 10) had both CNP and NV in the peripheries.

Conclusions: PPL were present in 40% of eyes. S7F images missed 9% of PDR cases that were identified by UWF images. The evaluation of pathology only outside the 7 fields using UWFFA found that 17.3% (n = 52) of participants had lesion only in peripheries.

Valsalva Retinopathy in Pregnancy: An Obstetric Dilemma — A Case Report

First Author: Md.Anwarul **AZIM**

Co-Author(s): Arup Krishna **CHOUDHURY**, Sheikh Md.Arafat **RAHMAN**

Purpose: To highlight the clinical course, management, and eventual resolution of Valsalva retinopathy during pregnancy, a rare condition that can pose diagnostic and therapeutic dilemmas for both ophthalmologists and obstetricians.

Methods: We present a case of a 22-year-old pregnant woman (G1P1) with sudden, unilateral deterioration of vision during labor. Detailed history, fundus examination, imaging, and follow-up were performed. Nd:YAG laser hyalodotomy was used to aid faster resolution of preretinal hemorrhage. The patient was subsequently kept under observation following delivery by Cesarean section.

Results: Slit lamp evaluation was normal, but funduscopy revealed subhyaloid preretinal hemorrhage in the macular region of the left eye. Nd:YAG laser hyalodotomy resulted in resolution of the preretinal hemorrhage within 5 days, and the patient's visual acuity improved to 6/6. At follow-up, there were no further complications or abnormalities in the retina. The patient successfully delivered a healthy neonate by Cesarean section.

Conclusions: Awareness and understanding of Valsalva retinopathy and its management are crucial for optimizing visual outcomes in affected pregnant women. Conservative observation is frequently appropriate; however, Nd:YAG laser hyalodotomy can aid faster resolution when the hemorrhage is large or persistent. Proper multidisciplinary care involving both obstetrics and ophthalmologists is recommended in these cases.

Vision Lost and Regained: A Case of Steroid-Responsive Purtscher-Like Retinopathy Associated With Systemic Lupus Erythematosus

First Author: Faiz Nurboston **FAUZI**

Co-Author(s): Muhammad **FIRMANSJAH**

Purpose: To report a case of Purtscher-like retinopathy (PLR) associated with macular edema in a young woman with systemic lupus erythematosus (SLE), showing a satisfactory outcome after systemic corticosteroid therapy.

Methods: A 27-year-old woman with previously diagnosed SLE presented with acute visual loss in the right eye after discontinuing SLE medications two months prior. The Initial VA was one meter CF on the right eye and 20/20 on the left eye. Fundus examination revealed bilateral Purtscher flecken, cotton-wool spots, and intraretinal hemorrhages. A visual field defect was noted in the right eye. Optical coherence tomography (OCT) showed macular edema with intraretinal fluid, subretinal fluid, and paracentral acute middle maculopathy (PAMM) on the right eye. Laboratory tests showed elevated ESR, high-titer antinuclear antibodies, and high disease activity. The patient was treated with intravenous methylprednisolone (250 mg twice daily for three days) followed by oral corticosteroids.

Results: PLR is a rare, vision-threatening occlusive microvasculopathy that is associated with systemic conditions, including SLE. There are no established guidelines for PLR treatment, and visual outcomes are variable. Systemic corticosteroid therapy has been correlated with improvements in visual acuity. This patient was given high-dose systemic corticosteroids resulted in an improvement of VA to 20/30 within five months. OCT showed resolution of macular edema with no presence of subretinal or intraretinal fluid. There was an improvement in the visual field.

Conclusions: Systemic corticosteroids can lead to significant visual improvement and resolution of retinal findings in PLR. Multidisciplinary collaboration is essential for optimal management and satisfactory outcomes.

Visual Function Assessment in Geographic Atrophy – A Review

First Author: Ye **LI**

Co-Author(s): Lauren **AYTON**, Adrian **FUNG**

Purpose: Fundus autofluorescence (FAF) is the gold-standard of structural assessment of geographic atrophy (GA) but is only a surrogate marker for vision loss. Best corrected visual acuity (BCVA), the most

commonly used visual function test in ophthalmology, is a poor metric for assessing GA progression. This review studies the importance of tests of visual function and functional vision and their correlation with FAF in the setting of GA.

Methods: A comprehensive review was conducted across PubMed, Medline, and Embase using the keywords 'age-related macular degeneration', 'geographic atrophy', 'visual function', 'low luminance visual acuity', 'reading speed', 'contrast sensitivity', and 'microperimetry', with Boolean operators.

Results: Seventy-five of 3229 identified articles were reviewed in detail. Low luminance VA, reading speed, and contrast sensitivity are inexpensive and have a short testing time; these tests show a weak correlation with FAF but are superior to BCVA. More time-consuming tests include microperimetry, flicker perimetry, and dark adaptation, which showcase photoreceptor function in GA. Microperimetry exhibits the strongest correlation with FAF, providing an overlay of structure and function. Flicker perimetry and dark adaptation can provide prognostic information regarding GA progression.

Conclusions: Visual function tests have variable correlations with FAF, with the strongest correlation being shown with microperimetry. Structural biomarkers require further standardisation and validation against functional tests, which are impractical to implement in clinical practice due to their lengthy testing time, limited availability, and ceiling effect. Future GA treatment clinical trials should include targeted endpoints of visual function, which is critical for jurisdictions that require demonstration of visual function improvement for treatment approval.

When a Red Eye Isn't Just a Red Eye: A Case of Ocular Tuberculosis

First Author: Mariya Banu Ranjini SRIDHARAN

Co-Author(s): Vivek REDDY

Purpose: This case presentation serves to highlight the diagnostic complexities of ocular tuberculosis, particularly when it manifests with various clinical signs.

Methods: A 26-year-old female with complaints of redness and watering in the right eye for 3 days. BCVA OD 6/12, OS 6/6. On examination of right eye conjunctival congestion present. The patient was started on Moxifloxacin eye drops. One month later, the patient presented with a drop in vision: BCVA OD 6/24, OS 6/6. Examination of the right eye showed a swollen lid, tenderness, deep scleral congestion, non-pigmented keratic precipitates, 1+ cells, a 4mm dilated pupil sluggishly reacting to light, disc edema, subretinal exudates, scleral nodules, and a choroidal

granuloma. B scan showed findings suggestive of posterior scleritis with positive T sign. Patient was subjected to detailed evaluation including CBC, ESR, HIV, Mantoux, VDRL, RA FACTOR, HLA B27, and Serum Angiotensin converting enzyme, c ANCA, and p ANCA. Patient was started on Systemic steroids and subjected to Quantiferon TB Gold Assay IGRA. 15 days later, the patient presented with an improvement in visual acuity BCVA OD 6/12 OS 6/6 and deep scleral congestion, disc edema, and scleral nodules resolved. One week later patient presented with pain in left eye BCVA OD 6/18 OS 6/12. Examination of the right eye showed nodular episcleritis, and the left eye showed temporal congestion. OCT OU showed Multifocal choroiditis. All investigations were negative except for IGRA, which was 0.37 (>0.35 positive). The patient was started on ATT after consultation with a pulmonologist for HRCT Chest. Patient is being followed up.

Results: This is a case of ocular tuberculosis masquerading initially as a seemingly straightforward conjunctivitis, which underscores the insidious and polymorphic nature of the disease.

Conclusions: These variable presentations reinforce the imperative for a meticulous diagnostic evaluation in cases refractory to conventional treatment.

When the Yolk Cracks Late: Adult-Onset Vitelliform Maculopathy

First Author: Nehal KAPOOR

Co-Author(s): Nikunj GUPTA

Purpose: To present a case of Adult-Onset Vitelliform Maculopathy (AOVM) and highlight the role of multimodal imaging in differentiating it from the mimicking macular diseases.

Methods: An elderly female patient with central visual complaints underwent a detailed ophthalmic examination. Multimodal imaging, including fundus photography, fundus autofluorescence, fluorescein angiography, spectral-domain OCT, and electrooculography was performed to evaluate macular morphology and establish the diagnosis.

Results: Examination revealed a yellowish subfoveal lesion with preserved retinal contour. Imaging demonstrated hyper autofluorescence on fundus autofluorescence, late staining without leakage on fluorescein angiography, and subfoveal hyperreflective material on OCT, consistent with AOVM. Visual acuity remained stable with observation during follow-up.

Conclusions: AOVM is an important clinical entity that can mimic age-related macular degeneration and inherited dystrophies. Recognition of its characteristic imaging features allows accurate diagnosis, prevents mismanagement, and emphasizes the value of conservative observation in most cases.

Whiplash Macular Oedema: A Case Report and Literature Review

First Author: Anson Chun Long WU

Co-Author(s): Mary HO, Wilson Wai Kuen YIP, Alvin Lerrmann YOUNG

Purpose: To report a case of bilateral whiplash macular oedema following a car crash involving acceleration-deceleration injury, without direct head or ocular trauma, and to document its natural course through serial imaging.

Methods: Case report with literature review.

Results: A 64-year-old lady presented with bilateral acute painless visual blurring after a road traffic accident without direct head or eye trauma. She had a history of breast cancer, being treated with letrozole for over four years. Examination revealed bilateral macular oedema without retinal haemorrhage or commotio. Optical coherence tomography confirmed macular oedema with a cystoid pattern and foveal ellipsoid zone disruptions. With conservative treatment, macular oedema resolved after one week, with gradual improvement in ellipsoid zone disruption after one month. However, microperimetry demonstrated residual localised relative scotomas at two months. Visual recovery was completed in four months. Differential diagnosis of letrozole-induced macular oedema was considered, but the acute onset and spontaneous improvement point against this diagnosis.

Conclusions: Whiplash macular oedema occurs after whiplash injury involving rapid acceleration-deceleration with or without direct trauma. It is important to have a high index of suspicion of indirect retinal injuries and rule out differential diagnoses. Spontaneous resolution of macular oedema occurs after 1-4 weeks, but complete or near-complete recovery of vision may lag behind up to 1-4 months due to resolving foveal ellipsoid zone disruptions. Our report is the first to show that residual localised scotomas can be demonstrated on microperimetry, which may be considered as a monitoring tool. Patient reassurance should be offered regarding the relatively benign recovery course.

A Case Report of Acute Anterior Chamber Hypopyon and Posterior Segment Occlusive Retinal Vasculitis Following Vitrectomy With Silicone Oil Tamponade

First Author: Qian GUI

Co-Author(s): Quanyong YI

Purpose: To report a rare case of acute aseptic anterior chamber hypopyon and posterior segment occlusive retinal vasculitis following vitrectomy with silicone oil tamponade.

Methods: A 59-year-old male presented with rhegmatogenous retinal detachment and macular hole for which pars plana 25G vitrectomy with silicone oil injection was done. Within 24 hours postoperatively, he developed acute anterior chamber hypopyon and occlusive retinal vasculitis. The patient was treated aggressively with intravenous dexamethasone and periocular injection of methylprednisolone acetate, resulting in complete resolution of hypopyon. All signs of vasculitis resolved over a period of three months after which the silicone oil was removed and the patient's vision stabilized at 2/20. There was no recurrence of hypopyon or vasculitis observed thereafter.

Results: The complications resolved after aggressive anti-inflammatory treatment, and the visual acuity remained stable without recurrence after silicone oil removal. This is a rare manifestation of silicone oil-related toxic anterior and posterior segment syndrome, which is of great reference value to ophthalmologists, helping to improve their understanding and management of rare postoperative inflammatory reactions.

Conclusions: Acute sterile inflammatory reactions involving both the anterior and posterior segments occur following vitrectomy with silicone oil tamponade. Silicone oil induced manifestation of acute toxic anterior and posterior segment syndrome is a rarely described entity. Early recognition and aggressive anti-inflammatory treatment are crucial for the healing outcome.

A Case of Persistent Retinal Detachment Following Foldable Capsular Buckle Surgery: Management and Outcome

First Author: Yuanfei ZHU

Co-Author(s): Tiejing ZHAO

Purpose: To describe a case of rhegmatogenous retinal detachment initially treated with a foldable capsular buckle (FCB), which was complicated by persistent subretinal fluid and recurrence, necessitating subsequent conversion to conventional scleral buckling.

Methods: We present the case of a 45-year-old female with a two-month history of metamorphopsia and visual field shadowing in the right eye. The patient had previously undergone FCB implantation accompanied by laser photocoagulation and C3F8 gas injection at an outside facility. Due to unresolved symptoms, she was referred to our clinic for further management. Diagnostic workup included multimodal retinal imaging with spectral-domain optical coherence tomography (OCT) and wide-field scanning laser ophthalmoscopy (SLO).

Results: Postoperative imaging demonstrated a diminished buckling effect, persistent subretinal fluid, and a new retinal break. Despite supplemental laser treatment and repeat gas injection, retinal re-detachment ensued. The patient, therefore, underwent surgical removal of the FCB, cryopexy, and placement of a conventional scleral buckle, which achieved anatomical success and functional visual improvement.

Conclusions: This case highlights that while FCB represents a minimally invasive option for repairing RRD, it may be limited by issues such as inadequate chorioretinal adhesion, regression of the buckling effect, or the presence of multiple retinal breaks. Conventional scleral buckling remains a dependable and effective technique for attaining durable retinal reattachment when temporary buckling procedures are unsuccessful.

A Novel Non-Inverted, Single-Layer ILM Flap Approach for Pediatric Macular Hole

First Author: Dian JIAO

Co-Author(s): Tian TIAN, Peiquan ZHAO

Purpose: Pediatric macular hole (MH), a rare condition affecting central vision in children, presents unique challenges in surgical treatment. This study aimed to test the effectiveness of a novel non-inverted, free single-layer internal limiting membrane (ILM) flap combined with sub-perfluorocarbon ophthalmic viscoelastic device injection fixation in treating pediatric MH.

Methods: A retrospective case series of 22 eyes with pediatric MH that underwent pars plana vitrectomy (PPV) combined with single-layer non-inverted ILM flap coverage. The main outcomes were best-corrected visual acuity (BCVA) and spectral domain optical coherence tomography (SD-OCT).

Results: The 22 patients (mean age: 11.2 ± 3.65 years) underwent either two-pedicle free (59.1%) or one-pedicle rotational (40.9%) ILM flap covering, with a median follow-up period of 4.15 (IQR, 1.70-8.12) months. BCVA improved significantly from 0.70 (IQR, 0.52-1.08) logMAR preoperatively to 0.52 (IQR, 0.49-0.70) logMAR postoperatively ($P = 0.0004$). All cases achieved successful MH closure, including 17 (77.3%) U-shaped closure, 3 (13.6%) V-shaped closure, and 2 (9.1%) flat closure, with no ILM flap dislocation.

Conclusions: The single-layer, non-inverted ILM flap covering technique demonstrates safety and efficacy in achieving MH closure and improving visual outcomes. Our findings provide new insights and directions for the treatment of pediatric MH.

Addressing the Dual Challenge: Temporary KPro-Assisted Posterior Segment Surgery With Concurrent Penetrating Keratoplasty

First Author: Nawazish SHAIKH

Co-Author(s): Neiwe LOMI, Pranita SAHAY

Purpose: To evaluate the anatomical and visual outcomes of temporary keratoprosthesis (TKP)-assisted vitreoretinal surgery combined with penetrating keratoplasty (PK) in eyes with coexisting corneal opacities and posterior segment pathologies.

Methods: A retrospective review was conducted at a tertiary eye care centre involving patients who underwent combined TKP-assisted pars plana vitrectomy and PK between January and June 2025. Clinical records were analysed for demographics, preoperative diagnoses, surgical indications, visual acuity, intraoperative findings, and postoperative outcomes. Surgical parameters included adequacy of intraoperative visualization, feasibility of posterior segment interventions, and final anatomical and functional outcomes.

Results: Six eyes of six patients were included. Indications were failed corneal graft with retinal detachment ($n=2$), corneal decompensation with dropped nucleus ($n=1$), corneal decompensation with IOL drop ($n=2$), and perforated corneal ulcer with endophthalmitis ($n=1$). All eyes had preoperative vision limited to hand movements close to the face. TKP provided a stable globe configuration and clear visualization, allowing complete vitrectomy and endolaser photocoagulation. ILM peeling was performed in 2 eyes, and scleral-fixated IOLs

were implanted in 2 eyes during the same sitting. Postoperatively, 5 of 6 patients achieved best-corrected visual acuity of at least 6/60, and anatomical success (retinal reattachment with clear graft) was achieved in all eyes.

Conclusions: TKP-assisted vitreoretinal surgery combined with PK provides adequate intraoperative visualization and enables the successful management of eyes with dual corneal and posterior segment pathology. This combined approach is effective for achieving favorable anatomical and functional outcomes in complex cases.

Abstract No.: 206385

Anatomical and Functional Outcomes of Vitrectomy for Secondary Macular Holes

First Author: Vinod **KUMAR**

Co-Author(s): Rohan **CHAWLA**, Rajpal **VOHRA**

Purpose: To evaluate the anatomical and functional outcomes of vitrectomy for secondary macular holes (excluding trauma and high myopia).

Methods: This retrospective observational study included all eyes with secondary macular holes that underwent vitrectomy at a tertiary eye care centre in North India. Macular holes secondary to trauma and high myopia were excluded. In addition to patient demographics, preoperative and postoperative best-corrected visual acuity (BCVA), macular hole diameter (MHD), aetiology, type of surgical approach, and anatomical closure were assessed. Follow-up duration and incidence of second surgeries and postoperative complications were also recorded.

Results: A total of 28 eyes of 27 patients with mean age of 35 years were included in the study. The most common underlying causes were retinal degenerative (retinitis pigmentosa, x-linked retinoschisis, familial exudative vitreoretinopathy), retinal vascular (proliferative diabetic retinopathy, coat's disease, retinal vasculitis, venous occlusion, retinopathy of prematurity), and others (intravitreal cysticercosis, choroidal coloboma, circumscribed choroidal haemangioma, etc). Mean macular hole diameter was 733 microns. The mean preoperative BCVA improved from 0.15 to 0.33 (Snellen fraction) postoperatively at 3 months. Most patients underwent the inverted flap technique and achieved Type 1 closure. 3 eyes required a second surgery. Postoperatively, RPE atrophy and outer retinal lucency were noted in eight eyes, which were the main factors limiting the visual outcome.

Conclusions: Most secondary macular holes present with poorer visual acuity and are larger at presentation. While these close after vitrectomy and result in modest visual gain, the health of the underlying retinal pigment epithelium is a major visual-limiting factor.

Abstract No.: 203764

Panel No.: RUS-1061

Anterior Capsular Fibrosis: A Potential Clinical Indicator of Chronic Retinal Detachment in Mature Cataracts

First Author: Vinit **TANWAR**

Purpose: To report an observed association between a specific pattern of anterior capsular fibrosis and chronic retinal detachment (RD) in eyes with mature cataracts. The aim is to highlight this finding as a potential clinical clue for preoperative prognostication, particularly in resource-limited settings.

Methods: A retrospective, observational case series of three patients who presented with mature cataracts was conducted. Preoperative assessment included slit-lamp examination, intraocular pressure (IOP) measurement, and B-scan ultrasonography. The key finding investigated was a pattern of fibrotic wrinkling on the anterior lens capsule.

Results: All three patients presented with mature cataracts and a distinct pattern of anterior capsular fibrosis. Intraocular pressure was normal in all cases, and there were no overt signs of hypotony. In this small cohort, B-scan ultrasonography confirmed a chronic, total retinal detachment in each eye, correlating with the anterior segment finding.

Conclusions: The presence of anterior capsular fibrosis may be a useful indicator of underlying chronic RD in eyes with mature cataracts. While this finding is not definitive, its presence could prompt a higher index of suspicion for posterior pathology. Further studies with a larger case series are required to establish the predictive value of this observation.

Panel No.: RUS-1077

Application of Multifocal Intraocular Lens Before and After Surgery for High Myopic Macular Hole: A Case Report

First Author: Weihong **ZHAO**

Co-Author(s): Tieying **ZHAO**, Yuanfei **ZHU**

Purpose: To investigate the indications for MIOL implantation following surgery for HMMH and the impact of MIOL on the performance of 27GPPV with ILM peeling for HMMH.

Methods: A case is presented with the following preoperative data: Vod:0.02 (-18.00 DS/-0.50 DC $\times$ 155 $^{\circ}$ $\rightarrow$ 0.15), AL 30.5 mm, OCT revealing a macular hole with a diameter of 610 μ m; Vos:0.02 (-17.25 DS/-0.25 DC $\times$ 80 $^{\circ}$ $\rightarrow$ 0.7), AL 30.8 mm. OD "27GPPV + epiretinal membrane and ILM peeling + gas tamponade". Six months postoperatively, cataract progression was observed in both eyes. OCT of the right eye showed a well-restored macular structure. The patient subsequently underwent "P/I (Zeiss 809)

“in the right eye, followed by “P/I (Zeiss 839)” in the left eye two weeks later. Two years later, the left eye experienced a decline in VA over one month. OCT showed a macular hole with a minimum diameter of 77 μ m and a base diameter of 209 μ m. The left eye then underwent “27GPPV + epiretinal membrane and ILM peeling + filtered air tamponade”.

Results: After combined HMMH and cataract surgery, the right eye achieved uncorrected distance, intermediate, and near VA of 0.8. The left eye attained 1.2 (distance), 1.0 (intermediate), and 1.0 (near) VA. Following the second HMMH surgery in the left eye using a plano-concave contact lens, uncorrected VA recovered to 1.0 within one week.

Conclusions: MIOL implantation is feasible in HMMH patients with restored macular microstructure post-vitreotomy, providing satisfactory full-range vision. ILM peeling in MIOL eyes can be effectively performed using plano-concave or biconcave contact lenses targeting the central 1 mm zone of the IOL.

Bleb-like Retinal Detachment in Aggressive ROP: Risk Factors, Treatment & Outcomes

First Author: Bhavik PANCHAL

Co-Author(s): Subhadra JALALI, Harshitha KANISSETTY, Tapas PADHI

Purpose: To analyse the risk factors, treatment strategies, and outcomes in eyes with bleb-like retinal detachment (BRD) in Aggressive Retinopathy of Prematurity (AROP).

Methods: We retrospectively reviewed 10 eyes of 5 infants with AROP presenting with BRD between March 2023 and February 2024. Data collected included gestational age, birth weight, systemic comorbidities, and risk factors. Serial fundus photographs were analysed. Treatment strategies were individualised; all cases received intravitreal bevacizumab (half adult dose) 5 days before surgery. Lens-sparing vitrectomy was performed by a single surgeon in eyes with significant traction, with the primary aim of reattaching the posterior pole and preventing progression to total retinal detachment.

Results: Mean gestational age was 30 weeks (range 28–34), mean birth weight 1.08 kg (1.0–1.4), and postmenstrual age at presentation 34 weeks. All infants were from low socioeconomic backgrounds with limited healthcare access, and all had a history of oxygen supplementation. Two required blood transfusions, and one survived septic shock. Traction >6 clock hours was present in all eyes. Eight eyes underwent vitrectomy, and complete posterior vitreous detachment could be achieved in only three of them. Two eyes were successfully managed with bevacizumab monotherapy, avoiding surgery or laser.

All eyes showed regression of plus disease within 1 day post-injection. Two eyes avoided surgery and laser after bevacizumab monotherapy. Mean follow-up was 5.4 months (1–8). One case had ROP recurrence and required laser.

Conclusions: AROP-BRD is linked to low birth weight, multiple risk factors, and poor socioeconomic status. Early anti-VEGF followed by timely vitrectomy offers favourable outcomes.

Abstract No.: 207074

Panel No.: RUS-1084

Choroidal Osteoma: A Case Series of Diverse Presentations

First Author: Apurva STHAPAK

Purpose: To illustrate the diverse clinical presentations of choroidal osteoma through a case series.

Methods: Three patients with choroidal osteoma were reviewed. Case 1 was asymptomatic, Case 2 presented with choroidal neovascular membrane (CNVM), and Case 3 exhibited central serous chorioretinopathy (CSCR). Clinical examinations, imaging studies, and treatment outcomes were analyzed.

Results: Case 1 showed a stable osteoma without visual impairment. Case 2 developed CNVM, managed with intravitreal anti-VEGF injections, leading to visual stabilization. Case 3 presented with CSCR and was monitored with spontaneous resolution.

Conclusions: Choroidal osteoma can present asymptotically or with complications like CNVM and CSCR. Early detection and appropriate management are crucial to preserving vision. Awareness of its varied presentations can aid clinicians in timely diagnosis and treatment, minimizing visual morbidity.

Abstract No.: 207153

Panel No.: RUS-1086

Clinical Characteristics, Effect of Adjuvant Intrasceral Amikacin, Surgical and Visual Outcomes post Scleral Deroofing in Fungal Scleritis

First Author: Nikita CHAUDHARY

Co-Author(s): Vishal SANJAY JADHAV

Purpose: To evaluate clinical features, the effect of adjuvant intrasceral amikacin, surgical and visual outcomes post-scleral deroofing in fungal scleritis.

Methods: This retrospective interventional study included patients with microbiologically confirmed fungal scleritis presenting to a tertiary eye care centre. Demographic data, predisposing factors, and clinical features were documented. All patients received standard antifungal therapy (topical and systemic) along with scleral deroofing and targeted intrasceral amikacin injections at the site of infection. Treatment

response, anatomical outcome, and complications were assessed over a minimum follow-up of 6 months.

Results: A total of 4 patients diagnosed with fungal scleritis were included. The most common predisposing factors were trauma with vegetative matter. A variety of causative isolated fungi included *Aspergillus*, *Scedosporium*, and *Colletotrichum* species. Resolution of scleral inflammation was achieved in 75% of cases with adjunctive intrascleral amikacin after around 3 months of follow-up. Visual improvement was limited, with final BCVA $\geq 6/36$ in 80% of patients. Minimal local adverse effects related to amikacin were noted, with no systemic toxicity.

Conclusions: Infective fungal scleritis is a severe and vision-threatening disease. It requires aggressive medical as well as surgical management for maintaining globe tectonicity and control of infection. We found adjunctive intrascleral amikacin, when combined with antifungal therapy, enhances local disease control and improves globe salvage rates.

Panel No.: RUS-1057

Clinical Diagnosis and Treatment of Macular Hole in Children

First Author: Fang CHAI

Co-Author(s): Xiquan ZHAO

Purpose: To investigate the etiology distribution, clinical characteristics, and treatment options for macular holes in children, evaluate the efficacy and prognosis of different interventions, and provide a reference for clinical diagnosis and treatment.

Methods: A retrospective analysis of the clinical course of 1 case of pediatric macular hole was conducted, combined with a review of literature and clinical case data. This included: Etiology statistics: integrating traumatic causes (e.g., sports injuries, explosives), congenital diseases (e.g., X-linked retinoschisis, retinopathy of prematurity), idiopathic factors, etc.; Treatment strategies: comparing the efficacy of observation/follow-up, anti-inflammatory therapy, and vitrectomy (Page efficacy assessment: postoperative visual acuity, hole closure rate, and spontaneous closure time data).

Results: Etiology distribution: Trauma was predominant (80.4%), commonly from sports injuries (soccer/baseball), explosives (firecrackers), etc. Other causes included congenital anomalies (12.5%), inflammation (3.6%), and idiopathic factors (3.5%). 21 cases of traumatic holes closed spontaneously within 15-365 days (average 90 days), with visual acuity improving from logMAR 1.1 to 0.4. Holes with a diameter $\leq 360\mu\text{m}$ had a higher closure rate. The closure rate for vitrectomy combined with internal limiting membrane peeling reached 77.7%-100%. Postoperative average

visual acuity improved from logMAR 1.01 to 0.48, with an improvement rate $>85\%$.

Conclusions: Macular holes in children are primarily traumatic; the possibility of spontaneous closure is high. Surgical intervention (PPV + ILMP) is significantly effective for persistent holes, with notable visual improvement. Prognosis is closely related to etiology, hole size, and the presence of complications (e.g., macular detachment).

Clinical Features and Surgical Outcomes of Various Scleral Buckle Techniques in Rhegmatogenous Retinal Detachment

First Author: Aziz Jan BASHIR

Purpose: To evaluate the clinical features, primary anatomical Success, visual outcome, and complications in patients with rhegmatogenous retinal detachment (RRD) undergoing Scleral Buckle (SB) surgery.

Methods: Retrospective, Cross-Sectional, Interventional study of 466 eyes with RRD who underwent SB surgery by a single surgeon at a tertiary care hospital in Pakistan.

Results: The mean age was 38.98 ± 20.7 years with phakia ($n=367$, 78.8%). Total RRD ($n=222$, 47.6%), with mostly macula off status ($n=443$, 95.1%), was present. Round holes ($n=270$, 57.9%) and single breaks ($n=258$, 55.4%) were standard. Among the various types of buckles, 4-2 Band was the most commonly utilized. Our data found the SB surgery's primary success rate is 84.1 %. Detachment rate was significantly decreased in the consecutive years from 2016 to 2020 ($p<0.001$). The complication rate was 4.7 % ($n=22$), among which transiently raised IOP was the most common ($n=11$, 2.4%). No significant difference was found in the primary attachment rate in phakic, pseudophakic, and aphakic lens status ($p=0.5$) or buckle configuration ($p=0.3$). A significant difference was found among the types of buckle used ($p<0.05$), with 506 sponges having the maximum attachment rate ($n=95$, 93.1%) followed by the 4-2 band ($n=253$, 82.4%). There was a significant improvement in mean preoperative visual acuity from 1.52 ± 0.4 logMAR to postoperative 0.24 ± 0.10 logMAR ($p<0.001$).

Conclusions: Our study indicates that SB surgery is a safe procedure for RRD and has an excellent success rate.

Panel No.: RUS-1062

Correlation Between Visual Acuity and Central Macular Thickness in Patients of Retinal Vein Occlusion Before and After Intravitreal Anti-VEGF Injection

First Author: Delvi SASWITA

Co-Author(s): Weni HELVINDA

Purpose: To present and analyze the correlation between visual acuity and central macular thickness in patients with retinal vein occlusions (RVO) before and after injection with anti-vascular endothelial growth factor (VEGF) agents.

Methods: This research is an analytic retrospective study based on medical records of patients with RVO who had been injected with intravitreal bevacizumab in January-December 2024. The total sampling technique was applied, thus including 6 respondents in the population as the research sample. Data were statistically analyzed using the Shapiro-Wilk test and the Paired T-test, with $p < 0,05$ considered significant.

Results: The results of this study were obtained from six eyes of 6 patients diagnosed with retinal vein occlusion with macular edema who received bevacizumab therapy. The mean visual acuity before therapy was $0.88 \log\text{MAR} \pm 0.48$ and decreased to $0.33 \log\text{MAR} \pm 0.27$ ($p=0.004$) after therapy. Meanwhile, the mean macular thickness before therapy was $497.16 \mu\text{m} \pm 78.89$ and decreased to $302.33 \mu\text{m} \pm 44.70$ ($p=0.002$) after therapy.

Conclusions: There was significant difference in the proportion of visual improvement and decrease macular thickness after Intravitreal bevacizumab injection.

Dislocated Intraocular Lens in a Microphthalmic Eye: What Next?

First Author: Rosshini KUMMARARAJ

Co-Author(s): Divyalakshmi KAIYOOR SURYA

Purpose: To report a case of successful management of a dislocated intraocular lens in a microphthalmic eye with chorioretinal coloboma, hypotony, and retinal detachment.

Methods: A 51-year-old female presented with diminution of vision in the right eye for three months with a history of cataract surgery done six years back. On examination, the best corrected visual acuity in the right eye was counting fingers close to the face, and in the left eye, 6/9. Anterior segment showed right eye microphthalmos with complete coloboma, Ida Mann type 1, with Aphakia, with total retinal detachment, with grade D Proliferative vitreoretinopathy. Intraocular pressure was unrecordable. The left eye showed

an incomplete coloboma, Ida Mann type 4, with pseudophakia. She underwent right eye 240 encirclage with vitrectomy, with intraocular lens explantation, with iris claw IOL, with 5000 centistoke silicon oil tamponade.

Results: Post operative day one Retina was on with intraocular pressure at 24mmHg. At one month follow up patient maintained a vision of counting fingers at one metre with retina being attached and maintained intraocular pressure.

Conclusions: Dislocated intraocular lens in a microphthalmic eye with chorioretinal coloboma with hypotony and retinal detachment pose a significant challenge. Meticulous planning helps in successful anatomical outcome.

Early Detection and Prompt Surgery Improve Outcome in Macula-On Retinal Detachment Associated with Posterior Vitreous Detachment: A Case Report

First Author: Ratna NOVIANTARI

Co-Author(s): Ari ANDAYANI, Gek Ayu KRISMAYOGI

Purpose: To report that early detection and prompt surgical intervention improve anatomical and visual outcomes in patients with posterior vitreous detachment leading to rhegmatogenous retinal detachment with macula on status.

Methods: We report a 51-year-old male who presented with sudden blurring and a shadow-like curtain in the right eye for one week. Visual acuity was 1/60 (right) and 2/60 (left), improving to 6/7.5 and 6/12 with correction, respectively. Fundus examination optic nerve head is round, well-defined, the cup disk ratio 0,3, the artery to vein ratio 2/3 with retinal tear at 11 o'clock and retinal detachment in the superotemporal region with macula on status, confirmed by OCT showing Posterior Vitreous Detachment (PVD). The patient underwent pars plana vitrectomy with C3F8 gas tamponade.

Results: Postoperatively, serial evaluations demonstrated progressive anatomical recovery with attached retina and barely visible laser marks, although transient intraocular pressure elevation was observed. Visual acuity gradually improved to 6/7.5 with optimal correction, accompanied by a reduction of intraocular gas volume and resolution of retinal detachment.

Conclusions: This case highlights the importance of early detection and prompt surgical intervention in PVD-related Rhegmatogenous Retinal Detachment (RRD), especially in middle-aged patients presenting with acute visual symptoms. Vitrectomy with gas tamponade remains an effective modality to achieve retinal reattachment and visual rehabilitation. Continuous follow-up is essential to monitor intraocular

pressure fluctuations and ensure long-term anatomical and functional success.

Early Versus Delayed Pars Plana Vitrectomy for Complications of Proliferative Diabetic Retinopathy: A Systematic Review and Meta-Analysis

First Author: Chi Kit YAN

Co-Author(s): Tsveta IVANOVA, Assad JALIL, Aimee LLOYD

Purpose: The optimal timing of pars plana vitrectomy (PPV) in proliferative diabetic retinopathy (PDR) remains uncertain. Early surgery may accelerate recovery and reduce complications, yet risks and variable evidence have prevented consensus. This review aimed to evaluate visual and functional outcomes of early versus delayed PPV.

Methods: Following PRISMA guidelines (PROSPERO CRD420251122358), MEDLINE, Embase, CENTRAL, and trial registries were searched to July 2025. Twelve eligible studies were included: randomised trials, observational cohorts, and methodological/economic analyses. Best-corrected visual acuity (BCVA) was analysed on the logMAR scale. Comparative studies of early versus delayed PPV were pooled using DerSimonian–Laird random-effects meta-analysis of mean differences (MD). Early PPV single-arm cohorts were pooled separately. Dichotomous outcomes from the Diabetic Retinopathy Vitrectomy Study (DRVS) were summarised as risk ratios. Qualitative data were synthesised using a thematic framework.

Results: Two comparative studies yielded a pooled MD favouring early PPV but not statistically significant (MD -0.12 logMAR; 95% CI -0.42 to 0.19 ; $p=0.45$; $I^2=84\%$). Three early-PPV cohorts demonstrated a typical 12-month BCVA of 0.41 logMAR (95% CI 0.36 – 0.47 ; $I^2=0\%$). DRVS reported a higher proportion achieving logMAR ≤ 0.30 with early PPV (RR 1.67 ; 95% CI 1.20 – 2.31). Qualitative findings highlighted faster functional recovery, reduced treatment burden, and improved confidence with modern micro-incision techniques, balanced against perceived surgical risk.

Conclusions: Evidence trends toward early PPV delivering earlier or superior visual recovery, with typical post-operative vision around 0.4 – 0.5 logMAR. However, heterogeneity and sparse randomised data limit certainty. Adequately powered RCTs incorporating patient-reported and economic outcomes are needed to define optimal timing.

Familial Exudative Vitreoretinopathy in a Young Male: A Case Report

First Author: Nurita TRI WIJAYANTI

Co-Author(s): Wimbo SASONO, Ima YUSTIARINI

Purpose: To present a rare case of Familial Exudative Vitreoretinopathy (FEVR) in a young male patient, highlighting clinical findings, diagnostic work-up, and management to prevent progressive retinal detachment.

Methods: A case report of a 13-year-old boy presenting with decreased vision. Ophthalmic examination included best-corrected visual acuity (BCVA), slit-lamp biomicroscopy, and indirect ophthalmoscopy. Fundus photography and optical coherence tomography (OCT) were used to assess peripheral vascular abnormalities and macular involvement. Family members underwent fundus screening to evaluate hereditary patterns.

Results: BCVA of the right eye $20/400$, while BCVA of the left eye was $20/50$. Fundus examination on the right eye revealed peripheral retinal avascular zones, tractional retinal detachment with macular ectopia, and retinal folds. The left eye revealed peripheral avascular retina and macular dragging. OCT of the left eye demonstrated a macular hole. Family screening revealed no retinal abnormalities. For the treatment, we elected to perform an encircling buckle procedure on the right eye.

Conclusions: FEVR is a rare inherited vitreoretinal disorder. Multimodal imaging and family history are critical for diagnosis, while timely intervention can preserve visual function. Screening of family members is strongly recommended to allow early detection and management in affected relatives. We elected to proceed with this surgical technique as a preventive intervention to reduce the risk of progression toward tractional retinal detachment.

Foveal Bump as a Predictor of Early Postoperative Visual Outcome in Lamellar Macular Hole

First Author: Rokuki KIYOSAWA

Co-Author(s): Motohiro KAMEI, Kotaro TUBOI, Iori WADA

Purpose: To investigate whether the presence of a foveal bump in lamellar macular holes (LMH) is associated with preoperative visual acuity and whether this difference persists postoperatively.

Methods: A foveal bump was defined as a central bulge of retinal tissue nearly surrounded by foveal cavities. We retrospectively reviewed LMH patients who underwent vitrectomy at Aichi Medical University.

Hospital. Eyes were divided into bump-positive and bump-negative groups. Age, axial length, best-corrected visual acuity (BCVA, logMAR), central foveal thickness (CFT), and ellipsoid zone (EZ)/external limiting membrane (ELM) continuity (“continuous,” “indistinct,” or “disrupted”) were assessed preoperatively and at 1 and 3 months postoperatively.

Results: Twenty-six eyes (25 patients) were analyzed: 5 with a foveal bump and 21 without. Preoperative BCVA was significantly worse in the bump-positive group (0.46 ± 0.13 vs. 0.26 ± 0.19 , $p=0.023$). This difference persisted at 1 month (0.30 ± 0.12 vs. 0.04 ± 0.08 , $p=0.048$) and showed a trend at 3 months. Visual improvement, age, axial length, CFT, EZ, and ELM did not differ between groups.

Conclusions: Eyes with a foveal bump showed worse BCVA preoperatively and at 1 month. The presence of a foveal bump appears to be associated with poorer baseline vision and may predict early postoperative visual outcome.

Panel No.: RUS-1071

From Perception of Light to 6/12: A Rare Case of Sympathetic Ophthalmia with Visual Recovery

First Author: Swati SAHU

Co-Author(s): Rahul SAHU

Purpose: To present a rare case of sympathetic ophthalmia with exudative retinal detachment and severe vitritis, and to emphasize the importance of early systemic and intravitreal corticosteroid and immunomodulatory therapy for visual recovery.

Methods: A 36-year-old female presented with bilateral diminution of vision, reporting sudden loss of vision in the right eye over two months and a history of trauma to the left eye. Examination of the right eye revealed intraocular pressure (IOP) of 4 mmHg, keratic precipitates, iris neovascularization, posterior synechiae, dense vitritis, and exudative retinal detachment. The left eye showed a healed perforated corneal ulcer. Based on clinical findings, a diagnosis of sympathetic ophthalmia was established. The patient received three doses of intravenous methylprednisolone (1 mg/kg), followed by tapering oral prednisolone. She was co-managed with a rheumatologist and commenced on azathioprine. Subsequently, an intravitreal dexamethasone implant (Ozurdex) was administered.

Results: Initial intravenous therapy led to improvement of vision from perception of light to counting fingers, with reduction in vitritis. At one-month follow-up, visual acuity improved to 6/60, IOP normalized to 14 mmHg, and optical coherence tomography (OCT) showed partial resolution of exudative retinal detachment with subretinal fibrosis. With continued

oral steroids, immunomodulators, and intravitreal Ozurdex, vision further improved to 6/12, accompanied by complete resolution of subretinal fluid and detachment on OCT. The patient remained stable on low-dose oral steroids and azathioprine at subsequent follow-up

Conclusions: Early diagnosis and prompt treatment of sympathetic ophthalmia. Aggressive therapy with systemic corticosteroids, intravitreal dexamethasone, and long-term immunomodulators can restore functional vision, even in monocular patients.

From Slippage to Stability: Video-Based Analysis of the Yamane Technique Learning Curve

First Author: Stefenie

Co-Author(s): Cindy Boru SEMBIRING

Purpose: Managing eyes with insufficient capsular support remains a surgical challenge. The Yamane flanged intrascleral fixation has become a popular option because it provides IOL placement in a physiological posterior chamber position. However, its learning curve remains underreported. This study evaluated the learning curve of Yamane fixation by documenting intraoperative events and postoperative outcomes from the perspective of a vitreoretinal surgeon.

Methods: Retrospective study of 24 eyes (24 patients) undergoing Yamane scleral-fixed IOL implantation at SMEC Eye Hospital (Nov 2024–Feb 2025). All surgeries were performed by a single vitreoretinal surgeon. Surgical videos were reviewed with a structured checklist to record intraoperative events. Postoperative outcomes (UCVA, BCVA, refraction, and IOP) were assessed at 1 week, 1 month, and at the last follow-up. Early and late complications were analyzed.

Results: Indications included aphakia (25%), dislocated IOL (25%), dislocated nucleus (20.8%), posterior capsule rupture (4.2%), subluxated IOL (8.3%), and subluxated nucleus (16.7%). Intraoperative events comprised broken haptic (4%), haptic slippage (21%), scleral re-tunneling (33%), vitreous hemorrhage (8%) and suprachoroidal hemorrhage (4%). At final follow-up (median 7 months, range 1–10), median UCVA improved from logMAR 1.48 (range 0.54–2.48) preoperatively to 0.54 (range 0.18–1.78) ($p<0.001$). Early complications included optic capture (4%) and one suprachoroidal hemorrhage requiring drainage with poor final vision (1/60). Late complications included IOL tilt (4%, BCVA 20/20) and macular OCT abnormalities in 5 eyes (23%). No retinal detachment, glaucoma, endophthalmitis, or bullous keratopathy occurred.

Conclusions: The Yamane technique can be performed safely by vitreoretinal surgeons, though the early learning phase carries intraoperative challenges. Structured video-based assessment provides an objective means of documenting the learning curve and may support surgical training and competency development.

Full-Thickness Laser-Induced Macular Hole From a Semiconductor Laser Cleaner

First Author: Jose Antonio **DE GUZMAN**

Co-Author(s): Albert **BROMEIO**, Marc Alfred **MANGAHAS**

Purpose: Ocular injury may result from laser devices used in non-medical settings represent a potentially vision-threatening occupational hazard. We report the diagnosis and management of a rare case of a macular hole secondary to injury from a semiconductor laser.

Methods: Case report.

Results: A 28-year-old male factory worker presented with sudden blurring of vision, reported as the sensation of "bubbles" in the left eye immediately after accidental exposure to a handheld laser used to clean metal probes for semiconductors. The laser had a wavelength of 1064 nm and a pulse energy of 800 mJ. BCVA was 20/125 on the affected eye. Initial examination revealed a discrete hypopigmented patch at the fovea. OCT showed subfoveal disruption of the RPE and disorganization of the overlying retinal layers. The patient was initially managed conservatively. At 2 months, OCT revealed development of a full-thickness macular hole with subfoveal hyperreflectivity from RPE atrophic changes with a widest diameter of 404 μ m. Pars plana vitrectomy with internal limiting membrane peeling and C3F8 tamponade was done. Postoperatively, closure of the macular hole was observed, and BCVA was at 20/32, possibly owing to the limited damage to the RPE and photoreceptor layer.

Conclusions: Accidental retinal injury from laser devices can result in significant vision loss. Laser-induced macular holes can be managed with vitrectomy with anatomic closure, but visual prognosis is affected by the degree of sustained RPE and photoreceptor damage. Prevention with the use of safety goggles should be advised.

Gene Therapy for Neovascular Age-Related Macular Degeneration by Suprachoroidal Delivery of KH658: a Phase I Study (NCT06458595)

First Author: Hua **YAN**

Co-Author(s): Xiao **KE**

Purpose: KH658 is a gene therapy drug administered by suprachoroidal injection, aimed to treat the patient with neovascular age-related macular degeneration (nAMD). A multicenter, open-label, dose-escalating, phase I clinical study in China was designed to explore the safety and tolerability of suprachoroidal injection of KH658 in participants with nAMD in four cohorts.

Methods: The 36-week data of safety and tolerability of cohort 1 (5.0×10^{11} vg/eye, n=3), 28-week data of cohort 2 (1.0×10^{12} vg/eye, n=3), 12-week data of cohort 3 (2.0×10^{12} vg/eye, n=3), and 4-week data of cohort 4 (4.0×10^{12} vg/eye, n=3) post KH658 administration were analyzed.

Results: No dose-limiting toxicity (DLT) was observed. No serious adverse events (AEs) were reported. Common adverse events (>10% AEs) included conjunctival haemorrhage (25%), conjunctivitis (25%), conjunctival hyperaemia (16.67%), scleral hyperaemia (16.67%), eye pain (16.67%), vitreous floaters (16.67%). All the AEs were reported as mild, most of the AEs were not determined to be related to KH658 and resolved within days with standard treatment.

Conclusions: KH658 is well tolerated to date in four cohorts at dose levels of 5.0×10^{11} vg/eye to 4.0×10^{12} vg/eye.

Haptoglobin Regulates Retinal Vascular Barrier and Mediates Inflammatory Response to Promote the Progression of Diabetic Macular Edema

First Author: Yue **ZHANG**

Purpose: Diabetic macular edema (DME) is a major complication of diabetic retinopathy (DR), severely affecting patients' visual function and quality of life. This study aims to analyze the proteomic profile of aqueous humor from DME patients to identify key regulatory proteins and explore their underlying mechanisms, providing new therapeutic targets for DME.

Methods: Aqueous humor samples were collected from 7 patients with non-proliferative diabetic retinopathy (NPDR) and 7 patients with DME. Liquid chromatography-tandem mass spectrometry (LC-MS/MS) was used for proteomic analysis to identify differentially expressed proteins. Protein-protein

interaction analysis was performed using the STRING database, and the expression of the key protein, haptoglobin (HP), was validated using ELISA, ROC curve analysis, and the GEO database. A streptozotocin (STZ)-induced diabetic rat model was established, and HP2-2 expression was downregulated via intravitreal injection of lentivirus Lv-shHP.

Results: Proteomic analysis identified 425 quantifiable proteins, with 84 showing significant differences between DME and NPDR groups. HP, as a hub protein, was significantly upregulated in the aqueous humor of DME patients ($p < 0.05$). ROC curve analysis demonstrated high diagnostic accuracy of HP for DME (AUC = 0.9863, $p < 0.0001$). In the STZ-DR rat model, downregulation of HP2-2 significantly improved retinal vascular leakage.

Conclusions: HP is significantly upregulated in the aqueous humor of DME patients and the retinas of STZ-DR rats, potentially participating in retinal inflammatory responses and vascular barrier dysfunction through the HMGB1 signaling pathway. This study provides new theoretical insights for personalized treatment of DME.

Macular Buckling – A Review of Indications, Types, and Outcomes

First Author: Ye **LI**

Co-Author(s): Hung Da **CHOU**, Stanley **POH**, Gavin **TAN**, Andrew **TSAI**, Pei Chang **WU**

Purpose: In the rising myopic epidemic, there is a need to improve surgical outcomes for the treatment of the sequelae of pathological myopia. Macular buckling (MB) is an increasingly important surgical technique for managing such complex posterior pole pathologies, including myopic traction maculopathy, macular hole retinal detachment, and optic disc pit maculopathy. In this review, we aim to outline the current state of MB, including its evolution, indications, types, and the utility of multimodal imaging.

Methods: A comprehensive review was conducted across Pubmed, Medline, and Embase using 'macular buckling', 'myopic traction maculopathy', 'macular hole retinal detachment' with Boolean operators.

Results: Since its initial introduction in 1957, MB techniques and materials have undergone exponential evolution over the past few decades. Twelve techniques were identified for MB, including Ando Plomb, Illuminated Ando Plomb, T-Shaped buckle, L-shaped buckle, NPB, adjustable macular buckle, snail-tipped explant, three-armed silicone capsule, wristwatch buckle, 3D custom-printed buckle, donor sclera, and Gore-Tex vascular graft. The main indications for MB included myopic foveoschisis, macular hole with or without retinal detachment, either as a primary procedure or in conjunction

with vitrectomy. Multimodal imaging is necessary to optimise MB placement, anatomical, and functional outcomes.

Conclusions: The use of MB, either as primary treatment or adjunct to vitrectomy, offers satisfactory outcomes for the management of myopic macular pathologies, particularly for patients with a posterior staphyloma component. Standardisation of MB techniques and devices should be further developed. The role of MB in the treatment paradigm of these condition needs to be better defined.

Abstract No.: 204791

Panel No.: RUS-1068

Macular Hole Surgery Without Post-Operative Posturing – a Comparative Study

First Author: Rachel Ka Ying **CHEUNG**

Co-Author(s): Chi Lik **AU**, Shing Yee Steffi **CHONG**, Po Lin **LEOW**, Ting **WANG**

Purpose: The aim of this study is to evaluate the anatomical success and safety of full-thickness macular hole (FTMH) closure without post-operative posturing compared to post-operative prone posturing.

Methods: This is a multicenter, multi-surgeon, retrospective cohort study of all idiopathic FTMH patients who underwent pars plana vitrectomy (PPV) with internal limited membrane (ILM) peeling with gas tamponade in 2024-2025 with at least 3-month follow-up data. The primary outcome was the rate of FTMH closure without post-operative prone posturing compared to prone posturing. Secondary outcomes included safety outcomes and surgical outcomes, including visual acuity and central macular thickness on optical coherence tomography (OCT).

Results: Twenty-six eyes of 26 patients were included, of which 11 eyes (42.3%) had no post-op posturing, and 15 eyes (57.7%) had post-operative prone posturing. The rate of macular hole closure was similar – 9 eyes (81.82%) in the non-posturing group compared to 11 eyes (73.3%) in the posturing group ($p > 0.9999$). The post-operative visual acuity in the non-posturing group was better than the prone posturing group at 3 months (0.207 vs 0.205) and 6 months (0.217 vs 0.144), although not statistically significant. There were no statistically significant differences in ILM peel or ILM flap technique or type of gas tamponade on the rate of closure.

Conclusions: Macular hole surgery without postoperative posturing could achieve the same anatomical success rates as cases with postoperative prone posturing, whilst avoiding the physical and psychosocial complications associated with prone posturing. Further studies and randomised controlled trial are needed to further investigate the functional and visual benefit to patients.

Abstract No.: 206283**Panel No.: RUS-1078**

Macular Holes Following Pars Plana Vitrectomy: Observation of Conservative and Surgical Treatment Efficacy

*First Author: Tiewing ZHAO**Co-Author(s): Weihong ZHAO, Yuanfei ZHU*

Purpose: To analyze and summarize the characteristics and treatment efficacy of macular holes following PPV and to provide a theoretical and practical basis for research on the pathogenesis, progression, and management of such macular holes.

Methods: A retrospective case series analysis was conducted to investigate the characteristics, progression, and spontaneous healing time of macular holes after PPV. Surgical treatment methods and their outcomes were observed.

Results: Five cases: 2 cases occurred following silicone oil removal combined with P/I after initial PPV for RD. One RD case had an undetectable macular area preoperatively, and OCT revealed a macular hole one week after PPV with fluid-air exchange and scleral buckling. One case with vitreous hemorrhage showed normal macular structure on preoperative OCT, but one day after PPV revealed a foveal neuroepithelial defect with an intact ILM. One case occurred 13 months after PPV for high myopia with vitreomacular traction. Spontaneous closure occurred in two macular holes, with one case reopening one year after initial closure. Four cases were accompanied by a significant epiretinal membrane. Four patients underwent 27G minimally invasive PPV with epiretinal membrane and ILM peeling plus gas tamponade, resulting in successful macular hole closure. Postoperative visual acuity recovered to 0.6–1.0.

Conclusions: Both immediate and long-term postoperative macular holes after PPV are attributed to centrifugal tractional forces. The mechanism of immediate-onset holes resembles that of traumatic macular holes and they tend to close spontaneously. Long-term postoperative holes require epiretinal membrane and ILM peeling surgery to relieve traction and promote healing, leading to favorable visual function recovery.

Abstract No.: 201282**Panel No.: RUS-1051**

Novel 80/20 PFCL-Silicone Oil Sandwich Tamponade for Complex Retinal Detachments

*First Author: Obuli Ramachandran NANDHAKUMAR**Co-Author(s): Gauri KHARE, Kritika SINGH, Lalit VERMA*

Purpose: Evaluate the safety and efficacy of innovative 80% PFCL with 20% silicone oil sandwich tamponade in staged vitreoretinal surgery for complex retinal

detachments, combining PFCL's retinal flattening power with silicone oil's protective barrier.

Methods: Retrospective study of 32 consecutive eyes with complex retinal detachments (chronic RD >1 month, multiple/inferior breaks, failed surgery, severe PVR). Stage 1: vitrectomy with 80% PFCL injection followed by 20% silicone oil creating sandwich tamponade; 14-day supine positioning. Stage 2: PFCL removal with complete silicone oil fill. Mean follow-up: 8 months. OCT and ERG assessed retinal integrity.

Results: Primary anatomical success: 30/32 eyes (93.75%) with 2 redetachments salvaged surgically. Mean BCVA improved from logMAR 2.1±0.4 to 0.82±0.35 ($p<0.001$). 22 eyes (68.75%) gained ≥3 lines; 15 eyes (46.9%) achieved ≥20/200 vision. No PFCL-related retinal toxicity on OCT/ERG. Silicone oil barrier prevented direct PFCL-retina contact in all cases. Complications: transient IOP elevation (15.6%), cataract progression in phakic eyes (66.7%). Patient compliance with supine positioning: 100% vs. historical 30% for prone positioning.

Conclusions: This novel sandwich tamponade represents a paradigm shift, preventing PFCL toxicity while maintaining superior tamponade effect. Excellent anatomical and functional outcomes with enhanced patient comfort make this technique a significant advancement for complex retinal detachments.

Abstract No.: 204778**Panel No.: RUS-1067**

Peeling Back the Layers: X-Linked Retinoschisis Presenting as Retinal Detachment in a Young Child

*First Author: Pauline Andrea WONG**Co-Author(s): Danilo CONSTANTINO*

Purpose: To report a case of X-linked retinoschisis that was diagnosed as retinal detachment along with its clinical features and management.

Methods: This is a case report of X-linked retinoschisis in a child presenting with leukocoria and initially diagnosed with retinal detachment.

Results: A two-year-old Filipino male presented with leukocoria in the left eye. He had no history of trauma or other systemic diseases. Birth, prenatal history, and family history were unremarkable. On B-scan ultrasonography of the same eye, a concurrent retinal detachment was noted. Pars plana vitrectomy was performed on the left eye, wherein chronic traction and presumed exudative retinal detachment with thick subretinal fibrosis were noted intraoperatively. Examination of the right eye revealed bullous retinoschisis around the vascular arcades. Due to the aggressive disease course in the left eye, a prophylactic barrier laser indirect ophthalmoscopy was performed on the right eye. A retinal dystrophy panel was performed, which revealed a hemizygous mutation for

the RS1 gene. Macular optical coherence tomography of the right eye showed macular retinoschisis. At 5 years of age, the best-corrected vision of the right eye is 20/30, and the left eye is hand motion. There is no recurrence of retinal detachment in both eyes three years post-operation.

Conclusions: Retinal detachment in a 2-year-old child is uncommon, and etiologies such as X-linked retinoschisis should be considered when evaluating vitreoretinal pathology in this age group. This study shows that prophylactic laser photocoagulation can be considered for young children with monocular status. Early recognition is essential to avoid unnecessary intervention and ensure timely genetic counseling.

Abstract No.: 202878

Postoperative Outcomes and Prognostic Factors of High Myopia Epiretinal Membrane Associated with Retinoschisis After Vitrectomy

First Author: Xiaohan YANG

Co-Author(s): Xiao FENG, Wu LIU

Purpose: To analyze the impact of retinoschisis on the recovery of macular configuration and visual acuity following ERM removal in eyes with HM and to explore the prognostic factors.

Methods: A retrospective study of 73 consecutive patients with HM-ERM who underwent PPV with ERM peeling. According to the optical coherence tomography images, eyes were classified into 4 groups: group A without retinoschisis, group B with outer retinoschisis, group C with inner retinoschisis, and group D with both inner and outer retinoschisis.

Results: In Groups A, B, C, and D, there were 17, 21, 22, and 16 eyes, respectively. Retinoschisis of 44 eyes (74.6%) disappeared postoperatively, including 11 eyes in group B, 20 in group C, and 8 in group D. No correlation was found between retinoschisis resolution and baseline factors. The mean best-corrected visual acuity (BCVA) significantly improved at the final follow-up ($P < 0.001$). The final BCVA was associated with baseline BCVA ($P=0.001$), the presence of epiretinal proliferation preoperatively ($P=0.014$), and the postoperative integrity of the ellipsoid zone (EZ) ($P=0.001$) and interdigitation zone (IZ) ($P=0.008$).

Conclusions: After surgery, the inner retinoschisis usually resolved completely. Retinoschisis was not the main factor influencing final BCVA. Preoperative BCVA and disruption of EZ and IZ were associated with good visual recovery in long-term follow-up.

Preserving Ocular Structural Integrity by Prompt Surgical Intervention in a Post-Traumatic Case

First Author: Sundaram NATARAJAN

Co-Author(s): Pac Cristina PATRICIA

Purpose: To report a case that best illustrates the need for a prompt and complex approach in treating post-traumatic cases in order to achieve the best long-term outcome.

Methods: A 12-year-old girl presented with a corneal laceration, scleral wound, and traumatic cataract after being accidentally struck by a stone. A corneoscleral tear suture, anterior chamber (AC) reformation, and intravitreal antibiotic injection had been performed one week earlier. Biomicroscopic examination revealed an irregularly shaped cornea due to multiple sutures, a flat AC, and a traumatic intumescent cataract. Ultrasound B-scan showed an echo-free vitreous cavity with an attached retina. Visual acuity was limited to hand-movement perception. Surgical Technique: Corneal resuturing, restoration of the AC with removal of prolapsed vitreous, synechiolysis, lensectomy, and 25-gauge pars plana vitrectomy under general anesthesia were performed.

Results: A secure corneal wound with no leakage and a stable anterior chamber was achieved. The eye was left aphakic with a stable posterior segment. The rate of complications (inflammatory, infectious, and retinal post-traumatic) was significantly decreased. Visual acuity improved from hand-movement perception to 2/60 within a few months, despite corneal opacification.

Conclusions: By performing all the necessary procedures as early as possible, even under limited visualization, ocular structural integrity was preserved, the rate of retinal complications was reduced, and globe stability was achieved prior to corneal opacification. A future keratoplasty combined with a scleral-fixated intraocular lens could significantly improve the patient's visual performance.

Retinal Displacement and Functional Outcome After Pars Plana Vitrectomy for Primary Rhegmatogenous Retinal Detachment

First Author: Mei Kwan YIU

Co-Author(s): Marten BRELEN, Mary HO, Andrew MAK, Alvin YOUNG

Purpose: To study the incidence and associated factors of retinal displacement, and the consequential functional outcomes with the presence of retinal

displacement after standard pars plana vitrectomy with internal tamponade.

Methods: This is a prospective observational study. Patients suffering from primary rhegmatogenous retinal detachment pending pars plana vitrectomy would be identified from the operation list and clinical records from June 2023 to Apr 2024. Postoperative functional outcomes, including visual acuity, retinal displacement by fundus autofluorescence, grading of metamorphopsia by M-CHARTS Score, and macular sensitivity by microperimetry, were assessed.

Results: A total of 30 eyes were included in the study. Retinal displacement is seen in 13.3% of the eyes. All cases with retinal displacement were presented with macula off temporal or inferior retinal detachment. The mean age of the cases with retinal displacement was 65.0 ± 8.7 . They had longer symptom to operation time (45.3 ± 65.6 days, $p=0.90$), poorer preoperative visual acuity (1.2 ± 0.6 logMAR, $p=0.96$), more severe postoperative metamorphopsia (M-CHARTS Score vertical $1.1^\circ \pm 0.9$, $p=0.36$; horizontal $1.1^\circ \pm 0.9$, $p=0.24$), and reduced macular sensitivity on microperimetry ($p=0.37$). Retinal displacement was not associated with the location of retinal detachment (inferior, superior, or temporal, $p=0.36$), the use of intraoperative adjuncts, especially perfluorocarbon liquid ($p=1.0$), types of internal tamponade ($p=0.45$), or postoperative visual acuity ($p=0.97$).

Conclusions: Retinal displacement is not uncommon after surgical repair of primary retinal detachment. From our study, it was related to longer symptom duration from presentation to operation time, and lower baseline preoperative visual acuity; and it would lead to more severe postoperative metamorphopsia and reduced macular sensitivity.

Scleral-Fixated Black Diaphragm Intraocular Lens in Traumatic and Congenital Aniridia: Long-Term Visual and Structural Outcomes

First Author: Raj Shri HIRAWAT

Co-Author(s): Gulam Ali KAMDAR

Purpose: To evaluate intervention rates and visual acuity improvement. To observe intraoperative and long-term postoperative complication rates.

Methods: Consecutive eyes with severe ocular trauma and congenital aniridia needing posterior segment surgery followed by rehabilitation procedures are reviewed from 2017 to 2023. All traumatic eyes underwent primary globe repair after injury and secondary surgeries if needed, before planning for aniridia Intraocular lens (IOL) implantation. Complete vitrectomy with suture fixation of 'QV Aniridia IOL' (Rigid, PMMA-Lens; care group; Gujarat; India) was

performed in all eyes and followed up for a minimum of 5 years.

Results: Total 14 eyes of 14 patients underwent intervention, and had follow-ups ranging from 36 to 72 months. Among them, 3 eyes had endophthalmitis, 3 vitreous hemorrhage, and 4 retinal detachment at the time of presentation. Average 1.2 interventions before and 0.5 interventions post IOL implantation was done. Five eyes had simultaneous IOL implantation. All traumatic eyes had light perception vision and improved to a mean Best corrected visual acuity (BCVA) of 6/18 Snellen lines. Five out of 14 eyes needed anti-glaucoma medication to control intraocular pressure. No intraocular inflammation persisted beyond 6 weeks.

Conclusions: Post IOL implantation interventions were insignificant, favouring Aniridia IOL in severely traumatised as well as in congenital eyes. Post-op inflammation is insignificant, and secondary glaucoma can be managed conservatively without compromising outcomes. Despite these encouraging findings, we would advise caution in careful patient selection and close follow-ups to manage postoperative vision-threatening complications. To our knowledge, this is the first single-surgeon case series from India.

Scleral-Fixated Toric Intraocular Lenses: A Novel Approach for Post-Traumatic Astigmatism and Aphakia

First Author: Raj Shri HIRAWAT

Co-Author(s): Gulam Ali KAMDAR

Purpose: To describe a novel idea and report visual outcome after suture-fixation of a single-piece toric Intraocular lens (IOL) for managing traumatic aphakia with concurrent corneal astigmatism.

Methods: The consecutive eyes that had high corneal astigmatism secondary to corneal repair scar or high regular corneal astigmatism with poor or no capsular bag support are selected for toric IOL placement. The toric axis, IOL power calculation, incision site, incision type, and position of IOL placement are all documented using an online toric calculator. EnVista Toric IOL, having fenestration at the optic-haptic junction on either side, is used for suture fixation. 4-point scleral fixation done using 10-0 polypropylene or Gore-Tex suture. Patient followed up on day 1, 7, 28, 3 months, 6 months, and 1 year. Postoperative UBM was done to look for tilt or subluxation.

Results: A total of seven patients underwent scleral suture fixation of Toric IOL. The mean age: 34.2 years. Pre-op mean Uncorrected and Best corrected visual acuity were: 1.95, 0.74 LogMAR, respectively; mean astigmatism: 4.57 D. Post-op Uncorrected Visual Acuity (UCVA): 0.356, Best Corrected Visual Acuity (BCVA):

0.192 LogMAR; cylinder reduced to 1.00 D. No IOL tilt/subluxation seen in 6–40 months follow-up.

Conclusions: Scleral fixation of toric IOLs is a novel, stable solution for post-trauma aphakia with astigmatism. Toric IOLs are conventionally implanted in the bag. We report the first Indian series using scleral fixation in post-trauma eyes with astigmatism, improving UCVA and BCVA. Surgeons may adapt it using standard IOLs and familiar suturing, offering a practical solution in challenging cases.

Seasonality of Adult Idiopathic Rhegmatogenous Retinal Detachment: 10-Year Data From Two Tertiary Public Hospitals

First Author: Chun On LEE

Co-Author(s): Chi Lik AU, Po Lin LEOW

Purpose: Seasonality of rhegmatogenous retinal detachment (RRD) with summer peaks has been observed in some northern countries. During the warmer period, ultraviolet light-induced injury and accelerated vitreous liquefaction could be the predisposition for RRD. We aim to examine the seasonal variability of the incidence of RRD in Hong Kong.

Methods: Records of adults who underwent RRD repair surgery in two tertiary hospitals in the Hong Kong East Cluster of the Hospital Authority from 2015 to 2024 were reviewed. Cases with re-detachment, combined tractional retinal detachment, macular hole, history of recent eye trauma, recent or complicated cataract surgery, or unknown symptoms duration were excluded. The month of incidence was recorded based on symptom onset.

Results: Among the 440 cases, 39% were females, 57% involved the right eye, 39% were macula-on RRD, and 85% were phakic. The average age was 57.19 ± 11.02 . Incidence was highest in summer (119; 27%), followed by autumn (109; 25%), spring (106; 24%), and winter (106; 24%). However, no statistically significant difference was observed between seasons ($p=0.792$). There was no difference in seasonal variability for male ($p=0.272$) or female ($p=0.448$) subgroups, and age ≤ 60 ($p=0.546$) or age > 60 ($p=0.614$) subgroups. No drop or surge in incidence was observed in the pre-, peri-, or post-COVID-19 period.

Conclusions: Incidence of RRD in Hong Kong peaks in summer, but no statistically significant seasonal variation was observed. Hong Kong's subtropical climate has less apparent seasonal temperature differences. A highly urbanised lifestyle with more indoor activities and less ultraviolet exposure suggests a lesser effect on the vitreous.

Spontaneous Retinal and Choroidal Detachment in a Child with Suspected FLNA-related Otopalatodigital Syndrome

First Author: Lorenzo Miguel TRANQUILINO

Co-Author(s): Jose Carlo ARTIAGA, Miguel Antonio PASCUAL, Anna Victoria SAN PEDRO

Purpose: To report a rare case of spontaneous retinal and choroidal detachment in a pediatric male with suspected FLNA-related otopalatodigital syndrome.

Methods: Case report.

Results: A 7-year-old male with high clinical suspicion of otopalatodigital syndrome complained of blurred vision at a distance. He presents with multiple congenital anomalies, and a sibling with similar systemic symptoms was molecularly diagnosed with FLNA mutation. Initial funduscopy revealed myopic fundus changes and refraction consistent with pathologic myopia. Two months later, his mother noted sudden right eye ptosis and hypotonia, with blurring of vision to hand movement. Examination revealed choroidal and total retinal detachment of the right eye. He immediately underwent pars plana vitrectomy and oil tamponade, with multiple retinal tears noted intraoperatively barricaded with laser. Laser indirect ophthalmoscopy was also done for an incidental horseshoe tear of the left eye. Best-corrected vision of the right eye returned to baseline. However, new-onset retinal detachments were noted bilaterally one week later, and he was scheduled to undergo bilateral encircling band and pars plana vitrectomy.

Conclusions: Retinal and choroidal involvement are not well-established in otopalatodigital syndrome. The role of Filamin A in the retina and consequent FLNA-associated connective tissue fragility in the setting of pathologic myopia presents a theoretical predisposition to rare ocular complications such as spontaneous retinal and choroidal detachment. Genetic testing is recommended to confirm the diagnosis to help in the management, prognostication, and monitoring of patients.

Abstract No.: 205313

Staged Surgical Approach in Complex Rhegmatogenous Retinal Detachment With Closed Funnel Configuration

First Author: Chakpram PRIYALAXMI

Co-Author(s): Naresh Babu KANNAN, Kim RAMASAMY, Muthu Krishnan VALLINAYAGAM, Toshit VARSHNEY

Purpose: To evaluate outcomes of short-term perfluorocarbon liquid (PFCL) tamponade in rhegmatogenous retinal detachment (RRD) eyes with closed funnel configuration.

Methods: This study is a retrospective case series. RRD eyes with a closed funnel configuration (PVR D2 or D3 as per Retina Society Classification) undergoing surgical intervention were included. These eyes underwent staged surgery with short-term PFCL—silicone oil tamponade (double fill) for 7-10 days. Retinal reattachment rate and best corrected visual acuity were assessed until the 12-month follow-up. Absolute success was defined as a completely attached retina in the absence of any tamponade, while relative success was defined as retinal attachment (macula on) under silicon oil tamponade.

Results: Thirty-nine eyes from patients aged 3 to 81 years were included and analysed in paediatric (n=19) and adult (n=20) groups. Overall retinal re-attachment rate was 53.8% (21/39): 31.6% in paediatric and 75% in adults. In eyes with anatomical success, median BCVA improved from 2 [1.9–2.5] to 1.1 [0.6–2.5] LogMAR ($p < 0.001$). Absolute and relative success were observed in 10 (25.6%) and 11 (28.2%) eyes, respectively. Younger age at diagnosis was significantly associated with anatomical failure. No complications were noted. No baseline variables predicted the success or failure of surgery within subgroups.

Conclusions: Short-term PFCL tamponade is safe and effective in RRD eyes with a closed funnel configuration.

Surgical Outcomes in Myopic Traction Maculopathy at a Tertiary Care Centre in North India

First Author: Swati SHARMA

Co-Author(s): Ramandeep SINGH, Sumedha VATS

Purpose: To highlight the role of PPV with ILM peel/flap with gas tamponade in cases of Myopic Traction Maculopathy (MTM).

Methods: A retrospective observational study was done in which 10 eyes of nine patients were recruited with a minimum 12-week follow-up, having 1c, 2c, 4a, and 4b stages of MTM described by Parolini B et al. and managed by Pars Plana Vitrectomy and ILM Peel/Flap, with gas tamponade during the last 3 years at a tertiary care centre. The primary outcome was restoration of foveal contour OCT, i.e., anatomical success (AS), and the secondary outcomes were best corrected visual acuity (BCVA), need for re-surgery, and complications, if any.

Results: Nine of 10 eyes with MTM had anatomical success with significant improvement in Snellen's BCVA by a mean of 1.74 ($P < 0.005$). One eye required re-surgery (10%) of Stage 4b. Mean follow-up was 56+/-6 weeks.

Conclusions: PPV and ILM Peel/flap with gas tamponade is effective in managing patients of stages 1c, 2c, and 4a of MTM.

Surgical Repair of Retinal Detachment in Ocular Coloboma: Overcoming Anatomical Challenges

First Author: Francis Ezra LAXAMANA

Co-Author(s): Jesus Jacinto BAUTISTA

Purpose: To report the surgical challenges and adaptive techniques employed in repairing rhegmatogenous retinal detachment (RRD) in an eye with iris and retinal coloboma, highlighting the impact of knowledge of anatomy on vitreoretinal surgery.

Methods: A 28-year-old female with bilateral iris and retinal colobomas presented with sudden vision loss in the right eye due to total RRD with an unidentified break. Pars plana vitrectomy revealed absent nasal pars plana, abnormal rectus muscle insertions, and distorted vitreous base anatomy. Surgical adaptations included modified sclerotomy placement, perfluorocarbon-assisted break localization, endolaser around the coloboma margin, and silicone oil tamponade.

Results: Retina was attached post operatively. Key challenges included limited peripheral access due to abnormal muscle anatomy and iatrogenic break risk in atrophic coloboma-adjacent retina. Silicone oil provided effective stabilization despite these constraints.

Conclusions: Coloboma-associated RRD demands tailored surgical strategies to address anatomical variants. Preoperative planning for pars plana anomalies, intraoperative flexibility in sclerotomy placement, and long-term tamponade are critical for success. This case underscores the need for heightened awareness of ocular malformations in young patients presenting with retinal detachment.

The Flooded Choroid: Subscleral Sclerectomy With Mitomycin C for Type 3 Uveal Effusion Syndrome Having Suboptimal Response to Medical Therapy

First Author: Dhwanee AGARWAL

Co-Author(s): Vishal Sanjay JADHAV, Anup KELGAONKAR, Avinash PATHENGAY

Purpose: To report successful surgical management of type 3 UES having a suboptimal response to medical therapy, with subscleral sclerectomy.

Methods: A gentleman in his early thirties presented with bilateral diminution of vision for three months and a recent onset of right-eye blurring. Previous bilateral

peripheral iridectomies had been performed elsewhere in view of suspected angle closure. Clinical evaluation and multimodal imaging were performed.

Results: Examination revealed bilateral exudative retinal and peripheral choroidal detachments with macular involvement. OCT showed Retinal pigment epithelium (RPE) undulations, multiple neurosensory detachments, and inner choroidal involvement with intact choriocapillaris. FFA demonstrated pinpoint hyperfluorescent spots and pooling. Initial management with periocular corticosteroids and oral steroids led to transient improvement, followed by recurrence of exudative detachment. Subscleral sclerectomy of 5X 4 mm each with topical mitomycin C in two quadrants of the right eye was performed 2 mm away from the spiral of Tillaux, which resulted in sustained resolution of subretinal fluid and improved visual acuity.

Conclusions: This case underscores the diagnostic challenges of type 3 UES and highlights subscleral sclerectomy as an effective therapeutic option in steroid-refractory presentations.

The Outcome of Intravitreal Injection of Bevacizumab in Treatment of Polypoidal Choroidal Vasculopathy in Cambodia

First Author: Channath LENG

Co-Author(s): Piseth KONG, Marin LY, Chenda SOK, Leng UN

Purpose: To investigate the features and treatment response in patients with polypoidal choroidal vasculopathy (PCV), initially treated with Bevacizumab.

Methods: Nine eyes of nine treatment-naïve patients with PCV were included in this retrospective study, all uniformly initially treated with three Bevacizumab injections monthly. Optical coherence tomography (OCT) characteristics and clinical parameters were recorded and analyzed at presentation, after the initial 3 injections of Bevacizumab, and at the final follow-up period.

Results: Following 3 monthly Bevacizumab injections, visual acuity (VA) significantly improved with a mean gain of at least one line of vision. Central macular thickness (CMT) significantly improved from a mean of $374.00 \pm 164.50 \mu\text{m}$ at presentation to $214.11 \pm 23.76 \mu\text{m}$ ($p\text{-value} = 0.003$). Subretinal fluid, intraretinal fluid and submacular hemorrhage significantly improved (all $p\text{-values} < 0.001$). No correlation was found between the presence of pachyvessels or increased choroidal thickness and the improvement in VA or CMT.

Conclusions: Fixed first-line treatment with intravitreal Bevacizumab monotherapy in PCV patients achieves satisfactory visual and anatomical outcomes.

The Retilight: A Novel Innovative 3D Printed Portable LED Endoilluminator for Vitreoretinal Surgery

First Author: Prithvi CHANDRAKANTH

Co-Author(s): Shishir VERGHESE

Purpose: To present the development and potential clinical applications of the «Retilight», a portable, 3D-printed LED endoilluminator designed for use in vitreoretinal surgery as a backup or supplemental light source.

Methods: The Retilight was developed through an iterative prototyping process focused on optimising light intensity, heat management, and system compatibility. Three prototypes were tested. The initial version utilised a smartphone LED, which proved insufficient. The second incorporated a dedicated LED with a modular 3D-printed adapter, powered via USB. The final prototype addressed heat issues by adding a heat sink and a small exhaust fan to ensure consistent performance during extended use.

Results: The final design provided adequate illumination for vitreoretinal procedures and was compatible with existing surgical endoilluminator systems. Its ability to connect to a power bank via USB made it both portable and practical. The Retilight could be used in emergency scenarios, such as bulb failure or power outages, and offered supplemental lighting when using chandelier systems for bimanual surgeries. Its compact, ergonomic design supported ease of use and integration into clinical workflows.

Conclusions: The Retilight is a reliable, low-cost, and portable LED endoilluminator offering a practical solution for supplemental or backup lighting in vitreoretinal surgery. It enhances surgical flexibility and may be particularly valuable in settings with limited access to traditional lighting systems. It can be used in corneal cases to identify the endothelial graft, spotlight in orbit surgeries, retroilluminating device for cataract surgeries in corneal opacities. endoilluminator in a wet lab setup to teach vitreoretinal fellows. The cost of making it was 60USD.

Ultrasound Biomicroscopy-Based Diagnosis and Cryotherapy for Rhegmatogenous Retinal Detachment Secondary to Schwartz-Matsuo-Like Syndrome: A Case Description

First Author: Yuedong HU

Co-Author(s): Siyu WANG, Rui HUA

Purpose: Rhegmatogenous retinal detachment (RRD) with breaks in the pars plicata is rare. Most cases occur in patients with atopic dermatitis or Schwartz-Matsuo syndrome. We reported a case of RRD with a break of

non-pigmented epithelium (NPE) at pars plicata, which was diagnosed and treated under the guidance of ultrasound biomicroscopy (UBM).

Methods: A 24-year-old Chinese female presented with a blurry vision in her left eye for three weeks without a history of trauma or systemic disease. Dilated fundus examination demonstrated retinal detachment, but no breaks were found. Fortunately, the UBM revealed a small NPE break at about 2 o'clock at the pars plicata. For the break could not be observed directly, we performed a combination of transconjunctival cryotherapy and pneumatic retinopexy under the guidance of UBM.

Results: One week later, the retina was reattached successfully, and UBM showed the NPE reattached with break closed two weeks postoperatively. Two new breaks in the inferior retina were found and sealed by laser photocoagulation.

Conclusions: UBM is an essential method for diagnosing and guiding the treatment of NPE breaks located at the pars plicata. Cryotherapy and pneumatic retinopexy have been proven to treat this condition successfully.

Vision and Metamorphopsia Outcomes of Macular Buckling for Foveoschisis-Associated Macular Detachment in Highly Myopic Eyes

First Author: Qi ZHANG

Purpose: To assess the functional outcomes in visual acuity, metamorphopsia, and vision-related quality of life (VR-QOL) and to evaluate prognostic factors after macular buckling (MB) surgery in eyes with high myopia and foveoschisis (FS)-associated macular detachment (MD).

Methods: Thirty-nine eyes of 39 patients with FS-associated MD who underwent MB surgery were enrolled. Measured outcomes comprised best-corrected visual acuity (BCVA), metamorphopsia, VR-QOL, axial length (AL), macular reattachment, and resolution of foveoschisis. In addition, factors affecting final BCVA and metamorphopsia were analyzed.

Results: At 12 months postoperatively, 36 eyes (92.31%) achieved macular reattachment, 37 eyes (94.87%) achieved complete resolution of foveoschisis, and metamorphopsia diminished in 31 eyes (79.49%). LogMAR BCVAs at baseline and months 1, 3, 6, and 12 postoperatively were 0.62 $\pm$ 0.35 (20/83), 0.65 $\pm$ 0.3 (20/89), 0.59 $\pm$ 0.31 (20/77), 0.54 $\pm$ 0.31 (20/69), and 0.46 $\pm$ 0.27 (20/57) (P , 0.001), respectively. Metamorphopsia scores by M-CHARTS were 1.36° $\pm$ 0.51°, 1.04° $\pm$ 0.51°, 0.74° $\pm$ 0.47°, 0.59° $\pm$ 0.47°, and 0.13° $\pm$ 0.29° (P , 0.001). All Visual Function Questionnaire-25 subscales demonstrated significant improvement postoperatively, with the exception of

“general health” (P = 0.08) and “driving” (P = 0.111). Preoperative BCVA was an independent risk factor for postoperative BCVA at month 12 (r = 0.638, P = 0.001), and the preoperative M-score was an independent risk factor for postoperative M-score at month 12 (r = 0.187, P = 0.045).

Conclusions: MB surgery significantly improved BCVA, metamorphopsia, and VR-QOL in patients with FS-associated MD. Preoperative BCVA and metamorphopsia score were prognostic factors for postoperative BCVA and metamorphopsia score at month 12.

Abstract No.: 201085

Vitrectomy With Intraoperative Direct Endolaser Photocoagulation for TelCaps in the Fovea

First Author: Hiroshi TANAKA

Co-Author(s): Takanori AOKI, Yusuke KOGA, Kohsaku NUMA, Chie SOTOZONO, Hokoru YOSHIOKA

Purpose: Telangiectatic capillaries (TelCaps) are large capillary aneurysms secondary to diabetic retinopathy (DR) or branch retinal vein occlusion (BRVO). They are often refractory to anti-VEGF therapy and can cause significant visual decline. We report two cases of foveal TelCaps successfully treated with vitrectomy combined with intraoperative direct endolaser photocoagulation.

Methods: Eyes with foveal TelCaps unsuitable for conventional photocoagulation due to foveal involvement and resistant to multiple anti-VEGF treatments were included. Pars plana vitrectomy (PPV) with internal limiting membrane (ILM) peeling was performed, and the TelCaps were gently lifted into the vitreous cavity with microforceps and directly photocoagulated with endolaser. Pre- and postoperative evaluations included best-corrected visual acuity (BCVA), optical coherence tomography (OCT), and indocyanine green angiography (ICGA).

Results: Case 1: A 79-year-old female with BRVO developed foveal TelCaps. Despite multiple anti-VEGF injections, BCVA declined from 20/20 to 20/200 over 9 years. After surgery, BCVA improved to 20/67 at 3 months postoperatively. Case 2: A 61-year-old female with diabetic macular edema and multiple TelCaps showed poor response to anti-VEGF therapy, with BCVA decreasing to 20/100. Using the same surgical approach, BCVA improved to 20/33 at 3 months postoperatively. In both cases, postoperative OCT showed a reduction of macular edema, and ICGA confirmed complete closure of the TelCaps.

Conclusions: This novel technique provides an effective treatment option for refractory foveal TelCaps, enabling closure of TelCaps and promoting visual recovery by restoring foveal anatomy.

A Synergistic Therapeutic Nano Eyedrop for Dry Eye Disease Based on Ascorbic Acid-Coupled Exosomes

First Author: Jing FENG

Co-Author(s): Fang MA, Yong TAO

Purpose: In this study, we report on the creation and use of an advanced eyedrop composed of AA-coupled mExo (mExo@AA) towards the treatment of DED.

Methods: We prepared a multiple-functional eyedrop based on the deposition of gold nanoparticles (AuNPs) reduced by ascorbic acid (AA) onto the exosomal phospholipid membrane of mesenchymal stem cell (mExo)-derived exosomes in situ (mExo@AA). The therapeutic value of mExo@AA for DED was demonstrated in a mouse DED model. Moreover, assessments of its cell toxicity and tissue biocompatibility after topical application confirmed its safety

Results: Characterization of the mExo@AA product showed that AA was successfully loaded onto the mExo with a maximum loading efficacy of about 509 nM/mg. Further experiments indicated that mExo@AA showed good biosafety even at a high concentration of 1 mg/mL. Additionally, the in vitro and in vivo experiments indicated that mExo@AA had a superior capacity to promote corneal cell growth, scavenge ROS, and inhibit inflammation compared to either of its components alone. Thus, we provide convincing evidence that mExo@AA can be used as an effective therapeutic agent for DED. Notably, mExo@AA not only ameliorated DED symptoms but also reversed DED-associated pathological changes at both the cellular and tissue levels.

Conclusions: In conclusion, mExo@AA is presented as a potential new class of drugs for the treatment of DED.

AAV-Delivered Sup-tRNAs As Novel Therapeutic Strategies for Inherited Retinal Diseases

First Author: Chengda REN

Co-Author(s): Fang LU

Purpose: Nonsense mutations change a sense codon into a premature termination codon (PTC) in mRNA and account for approximately 18.5% of human inherited retinal diseases (IRDs)-related mutation. While sup-tRNA-based therapies have shown promising results

in suppressing nonsense mutations in vitro, challenges remain for in vivo delivery, particularly regarding efficacy, stability, and safety. Our study aims to engineer the body sequence of sup-tRNA to enhance the therapeutic efficacy and evaluating its therapeutic potential in a clinical relevant PTC in vivo.

Methods: The anticodon-stem and TΨC-stem of sup-tRNA were engineered and the efficacy of each variants were evaluated by a dual-luciferase reporter containing the RPE65-R44X sequence contexts. The most efficient sup-tRNA was selected and used for further in vivo assessment. The AAV.sup-tRNA was subretinally injected into rd12 mouse and both the efficacy and safety were evaluated at 12 and 36 weeks post treatment.

Results: By using the adeno-associated virus (AAV), we achieved restoration of RPE65 protein expression in up to 50.2% RPE cells in a mouse model carrying the RPE65-R44X nonsense mutation. Notably, the engineered sup-tRNA significantly restored retinal function in mice, with effects lasting for at least 36 weeks. Furthermore, AAV.sup-tRNA exhibited minimal retinal toxicity and had negligible effects on global readthrough at native termination codons as revealed by ribosome profiling.

Conclusions: Our findings demonstrate AAV-delivered sup-tRNA is a translatable therapeutic intervention for IRDs caused by nonsense mutations in RPE65 gene

Cold-Chain Duration Alters Ultrastructure and Optical Clarity of Banked Corneal Lenticules

First Author: Andri RIAU

Co-Author(s): Evelina HAN, Jodhbir MEHTA, Jenetta SOO, Gabriel TAN

Purpose: To determine how 4°C transport duration after long-term cryopreservation affects the optical clarity, ultrastructure, and early postoperative outcomes of keratorefractive lenticule extraction (KLEx)-derived corneal lenticules destined for implantation.

Methods: Patient-donated corneal lenticules were cryopreserved for 12 months in Cordlife Singapore (a licensed lenticule bank), thawed, and transported/stored at 4°C in phosphate-buffered saline (PBS). Visible-light transmittance (380–780 nm) was measured daily to identify the latest day before clinically meaningful transparency loss. Lenticules sampled at day 1 and day 6 underwent histochemistry (collagens, glycosaminoglycans, and glycoproteins) and transmission electron microscopy (TEM) to quantify interfibrillar distance (IFD) and fibril diameter (FD) distributions. Fresh, day 1, and day 6 lenticules were then implanted into rabbit corneas. Postoperative assessments at week 1 and week 4

included slit-lamp lenticular haze grading and AS-OCT pachymetry. After euthanization, the corneas were excised for immunofluorescence staining (fibrosis and inflammation markers) and TEM of host vs implant ultrastructure.

Results: Lenticule transparency was preserved up to 5 days at 4°C but declined by day 6 (fresh: $94.8 \pm 2.9\%$ vs day 6: $87.0 \pm 4.0\%$; $p=0.002$). Collagen and glycosaminoglycan staining were unchanged, while glycoproteins trended lower without significance. Ultrastructurally, IFD and FD distributions shifted toward smaller values by day 6 (IFD shift: $Z=4.419$, $p<0.001$). In vivo, day 6 lenticules showed greater early slit-lamp haze and slower clarity recovery versus fresh and day 1 samples, despite absent neovascularization, fibrosis (α -SMA, fibronectin, and tenascin-C negative), or inflammation (CD18 negative). By week 4, IFD and FD of fresh and day 1 lenticules approximated host stroma, whereas day 6 implants remained significantly lower with persistently shifted distributions.

Conclusions: After 12-month cryopreservation, KLEx lenticules remain suitable for implantation if implanted within 5 days of 4°C transport in PBS. Delays beyond 5 days compromise fibrillar ultrastructure, prolong early haze, and may delay visual recovery. While transportation in Optisol may extend usable duration, the higher cost must be weighed against the benefits.

Comparative Analysis of the Fecal Microbiome and Blood Metabolome in OIR Mice

First Author: Yuhang YANG

Co-Author(s): Lijun DONG, Hui QI, Guoming ZHANG, Yulin ZHANG

Purpose: Provide a comprehensive overview of the altered gut microbiota and metabolic profile in OIR mice, offering insights into the gut-retina axis and its potential role in ROP pathogenesis.

Methods: 16S rRNA amplicon sequencing and non-targeted metabolomics (LC-MS/MS and GC-MS) were employed to perform a comparative correlation analysis. QIIME 2. PICRUST2 and LEfSe were then applied.

Results: The gut microbiome of OIR mice underwent significant compositional changes compared to controls. Multivariate statistical analyses of the microbial data identified the top 10 differentially abundant amplicon sequence variants. LEfSe analyses conducted at multiple taxonomic levels further revealed Lactobacillales were significantly enriched in the OIR group. In contrast, Muribaculaceae exhibited higher relative abundance in the control group, whereas Lactobacillus showed higher specificity in the OIR group. Random forest analysis highlighted

the importance of Muribaculaceae, Lactobacillus, and Hungatella as key taxa capable of distinguishing OIR from control groups. Lipids and lipid-like molecules were notably elevated in OIR mice. KEGG pathway enrichment analysis indicated significant alterations in pathways such as D-amino acid metabolism, alanine, aspartate and fatty acid biosynthesis at the metabolic level. Integrated correlation analyses using mixOmics highlighted the top 5 key microbial taxa and metabolites. Muribaculaceae exhibited a negative correlation with fatty acyl. Lactobacillus showed a positive correlation with o-Oxycarbanil and 6-(2-Hydroxyethoxy)-6-oxohexanoic acid. Hungatella was negatively correlated with fatty acyl.

Conclusions: The observed changes in the fecal microbiome and metabolome of OIR mice support the notion that ROP pathogenesis may be associated with gut microbiota-induced metabolic disturbances.

Abstract No.: 207416

Emotional Retina: OCTA-Based Retinal Microvascular Biomarkers as Early Indicators of Subclinical Emotional Distress

First Author: Rohith Reddy YEDDULA VENKATA

Co-Author(s): Harshitha C, Mohan Reddy M, Sanjana MARIAM JIJI VARGHESE, Sri Satviki POSINA, Sangeetha T

Purpose: To evaluate whether optical coherence tomography angiography (OCTA)-derived retinal microvascular parameters can objectively identify young adults with subclinical emotional distress and to validate a novel composite screening metric — the Emotional Retina Index (ERI).

Methods: This case-control study enrolled 120 participants (18–35 years), including 60 with subclinical emotional distress (moderate-severe Depression Anxiety Stress Scale-21 and/or Pittsburgh Sleep Quality Index > 5, without psychiatric diagnoses) and 60 age- and sex-matched controls (scores within normal range). All underwent 3×3 mm macular OCTA to quantify superficial and deep capillary plexus vessel density (VD), foveal avascular zone (FAZ) area, and perfusion symmetry. Ocular biometry (axial length, central corneal thickness, anterior chamber depth) was measured to exclude anatomic confounders. Masked graders analyzed OCTA images. Statistical analysis included group comparisons, Pearson correlations, and ROC curve construction using SPSS v26.

Results: Distress cases had significantly lower deep plexus VD ($44.5 \pm 2.9\%$ vs $48.4 \pm 2.5\%$, $p < 0.001$) and larger FAZ areas (0.49 ± 0.06 mm² vs 0.42 ± 0.04 mm², $p < 0.001$) than controls. Perfusion asymmetry was greater in the distress group ($p = 0.01$). Deep VD correlated inversely with stress scores ($r = -0.56$, $p < 0.001$). The ERI demonstrated an AUC of 0.91, with

90% sensitivity and 85% specificity for identifying high-risk participants.

Conclusions: OCTA-derived retinal microvascular metrics provide a non-invasive, objective biomarker for early detection of emotional dysregulation. The Emotional Retina Index represents a pioneering psych-ophthalmic tool with the potential to transform mental health screening and guide timely preventive interventions.

Abstract No.: 202596

Examining Vegetables Rich in Lutein and Searching for Various Conditions That Affect Lutein Content

First Author: Akihiro OHIRA

Co-Author(s): Mari SUGIYAMA

Purpose: To evaluate lutein content in spinach and various leafy vegetables from Shimane Prefecture, Japan, focusing on "Asukko," a local Brassica, and to examine organ-, seasonal-, and environmental influences with potential implications for age-related macular degeneration (AMD) prevention.

Methods: Lutein levels were quantified by HPLC in 11 spinach cultivars (3 Japanese, 8 foreign) and 21 other vegetables. In Asukko, lutein distribution was analyzed across plant parts (leaf, stem, bud, flower) and harvest seasons. Effects of light quality (natural, fluorescent, UV) on lutein content were also assessed.

Results: Spinach cultivars contained 35–65 mg lutein/100 g DW, with Japanese and foreign varieties showing no major difference. Among vegetables, Chinsai had the highest lutein (76 mg/100 g DW), while Setsuhaku Taisai was lowest (25 mg). Asukko leaf blades contained lutein comparable to spinach, with middle leaves highest. Flowers and buds had similar lutein, but flowers exhibited fivefold higher β -carotene. Seasonal variation was observed, with December harvests showing highest levels. Light effects differed by species: spinach lutein decreased under UV exposure, while Asukko lutein increased under fluorescent/UV light.

Conclusions: Lutein content varies by species, organ, season, and light environment. Asukko, a local Shimane vegetable, is a promising lutein-rich food source, and currently discarded leaves/flowers may be nutritionally valuable. These findings support the potential of local vegetables as functional foods for AMD prevention and sustainable agriculture.

Fluoroalkylated Peptide Nanoparticles for Transretinal Delivery in Dry Age-Related Macular Degeneration

First Author: Zihan ZHENG

Co-Author(s): Weiyi XIA, Chen ZHAO

Purpose: Peptide-based therapeutics represent a promising strategy for dry age-related macular degeneration (AMD) owing to their high specificity and biocompatibility. However, their clinical translation is severely limited by the challenges of transretinal penetration and efficient cytosolic delivery. This study aimed to develop a fluoroalkylated peptide formulation to establish a peptide-based therapeutic platform capable of overcoming retinal barriers and protecting retinal function.

Methods: A fluoroalkylated peptide (FNBP) was engineered to self-assemble into nanoparticles with enhanced transretinal and intracellular delivery properties. Its distribution, therapeutic activity, and safety were evaluated in a murine model of dry AMD.

Results: FNBP penetrated retinal layers efficiently, accumulated in retinal pigment epithelium, and preserved retinal structure and function. Treatment reduced oxidative damage, limited inflammatory responses, and mitigated photoreceptor degeneration, while showing good ocular and systemic safety.

Conclusions: FNBP represents a promising peptide-based nanomedicine for dry AMD, addressing key barriers to retinal drug delivery and offering a potential disease-modifying strategy with translational relevance for clinical application.

Genetic Association in Immunoglobulin G4-Related Disease: A Systematic Review

First Author: Yuen Tsing Adeline HO

Co-Author(s): Li Jia CHEN, Kelvin Kam Lung CHONG, Kenneth Ka Hei LAI, Chi Pui PANG, Pancy Oi Sin TAM, Tung TANG, Clement Chee Yung THAM

Purpose: Genetic studies have investigated the association of genetic variants with Immunoglobulin G4-related disease (IgG4-RD). In this study, we summarize the results of genetic association in IgG4-RD.

Methods: We performed a literature search in MEDLINE, EMBASE via the OVID platform, Cochrane Central Register of Controlled Trials (CENTRAL), ClinicalTrials.gov (www.clinicaltrials.gov) and World Health Organization International Clinical Trials Registry Platform (WHO ICTRP) for genetic studies on IgG4-RD on 20/1/2023.

Results: We identified a total of 431 articles published between 1975 and 2023. After removing all the duplicates, we evaluated the abstract and selected 65 articles for full-text review. Among them, 17 fulfilled the eligibility criteria, including 15 original case-control studies, and two genome-wide association studies (GWAS). Autoimmune pancreatitis (AIP) was reported in 15 of the 17 articles, the other 2 articles included IgG4-related periaortitis /periarteritis and general IgG4-RD subjects. A total of 52 polymorphisms in 25 genes were evaluated, including 13 polymorphisms in the 4 genes of the MHC complex. The other genes are involved in different pathways.

Conclusions: While MHC associations remain the strongest and most consistent across studies, our review identifies emerging non-MHC genetic loci such as KCNA3, CTLA4, PRSS1, and VPS13B, suggesting distinct immune and tissue-specific pathways in different IgG4-RD phenotypes.

Genetic and Lipid Pathways Linking Ocular Traits to Neuropsychiatric Disorders: Evidence From Integrative Mendelian Randomization and Colocalization

First Author: Wanyi SHU

Co-Author(s): Lin FU

Purpose: To test causal links between retinal morphology, common eye diseases, circulating lipids, and neuropsychiatric disorders, and to identify lipid mediators and shared causal variants.

Methods: We conducted two-sample Mendelian randomization integrating optical coherence tomography retinal layer thickness, ophthalmic phenotypes, plasma lipidomics, and neuropsychiatric genetic datasets. Inverse variance weighted models were primarily used with weighted median and MR Egger sensitivity analyses. Mediation MR estimated indirect effects; Bayesian colocalization reported posterior probability H4 (PP.H4).

Results: Reduced inner nuclear layer to external limiting membrane (INL to ELM) and ganglion cell inner plexiform layer (GCIPL) thicknesses were genetically associated with a higher risk of Alzheimer's disease (AD) and persistent mood disorders, whereas greater central external limiting membrane to inner and outer segment junction (ELM to ISOS) thickness was related to early AD and depression. Genetic liability to pseudoexfoliation glaucoma and senile cataract increased neuropsychiatric risk, whereas visual impairment and macular or posterior pole degeneration were inversely associated with AD. Mediation identified triacylglycerols TAG(51:3), TAG(52:4), and TAG(52:5) as suppressor mediators of the glaucoma to AD link explaining 27% to 34% of the total effect, and phosphatidylcholine 16:1_18:2

mediating 14% of the glaucoma to depression association. Colocalization supported shared variants with PP.H4 100% for central ELM to ISOS and AD, 93% for GCIPL and persistent mood disorders, and 90% for central ELM to ISOS and depression.

Conclusions: Ocular structure and circulating lipids appear to mechanistically link eye and brain health; imaging and lipid biomarkers may support early risk stratification and pathway-targeted intervention.

Growth Hormone Releasing Hormone Signaling Promotes Autoimmune Inflammation Through Histone Lactylation

First Author: Jian LI

Co-Author(s): Wai Kit CHU, Lin DU, Jingna HE, Jiabei XIONG, Yijia ZHANG

Purpose: This study aims to investigate whether growth hormone-releasing hormone (GHRH) signaling regulates Th17 cell differentiation and autoimmune inflammation through histone lactylation.

Methods: Native CD4⁺ T cells isolated from C57BL/6 mice were differentiated under Th17-polarizing conditions with or without a GHRH receptor (GHRH-R) antagonist. Histone lactylation levels (e.g., H3K14la) and intracellular lactate were measured. Exogenous lactate was supplemented to rescue lactylation. Multi-omics integration (Cut&Tag and RNA-seq) was performed on Th0, Th17, and antagonist-treated Th17 cells to identify downstream genes.

Results: Th17 cells exhibited elevated histone lactylation (H3K14la) and intracellular lactate levels compared to Th0 cells ($p < 0.01$). GHRH-R antagonist treatment suppressed both lactylation and lactate production ($p < 0.01$), which were restored by exogenous lactate. Integrated multi-omics analysis revealed downstream targets such as CSF1, linking GHRH signaling to lactylation-driven transcriptional regulation.

Conclusions: GHRH signaling promotes Th17 differentiation and autoimmune inflammation by enhancing histone lactylation via lactate metabolism modulation. Targeting GHRH-R may represent a novel therapeutic strategy for autoimmune ocular diseases.

Highly Efficient and Minimally Variable Photo-Sensitive Multi-Zone Ocular Organoids Serve as an In Vitro System for Studying Inherited Retinal Dystrophies

First Author: Fan ZHANG

Co-Author(s): Wang LI, Baoyuan QU

Purpose: The objective of this study is to develop a directional, standardized, and efficient method to generate multi-zone ocular organoids, which is suitable for a preclinical drug efficacy study.

Methods: hiPSCs at approximately 70% confluency were digested into single cells with Accutase (07920, StemCell). On D1~D2, the cells were half-refreshed every day with progenitor cell induction medium (PIM). On D3, transferred onto Laminin-511-coated T25 culture bottles containing PIM. On D4~D14, the cellular aggregates were refreshed every day with PIM. On D15, the mzOPCs, including NR, SE, and RPE, appeared and were mechanically separated with a sterile tip or by pipetting up and down and transferred into a low-attachment 10-cm dish containing PIM containing retinoic acid. On D16~D30, the mzOPCs were refreshed daily with PIM. On D31~D60, the PIM was replaced with multi-ocular organoid induction medium (MOIM, PIM plus 10 μ M retinoic acid), and then multi-zone ocular organoids were formed until D60. On D91~D120, the MOIM was replaced with multi-zone ocular organoids maturation medium (MOMM).

Results: Size and shape of a large number of hiPSC aggregates controlled by using AggreWell™ 400 device. Maximizing the efficiency of 3D multi-zone ocular organoid generation and enhancing the reproducibility and scalability of individual organoids. Establishing complex 3D multi-zone ocular organoid models associated with inherited retinal disease. Electrophysiological properties of ocular organoids derived from RHO-adRP and BCD disease models verified by using a microelectrodes array.

Conclusions: Our results showed that the minimally variable method developed for generating multi-zone ocular organoids lays a solid foundation for drug development and pharmacodynamic validation.

Investigating Umbilical Cord Endothelial Cells for Corneal Endothelial Replacement

First Author: Anmol SANDHU

Co-Author(s): Salim ISMAIL, Judy LOH, Jennifer Jane MCGHEE, Trevor SHERWIN, Jie ZHANG

Purpose: Corneal endothelial cell (CEC) dysfunction leads to impaired corneal transparency and vision loss. Currently, the primary treatment option is corneal transplantation; however, a global shortage of donor

corneal tissue restricts accessibility, with only 1 in 70 patients able to receive a transplant, creating an urgent need for alternative therapies. Human umbilical vein endothelial cells (HUVECs) sourced from the umbilical cord are a promising source for a CEC replacement therapy.

Methods: HUVECs were isolated from umbilical cords ($n = 10$) and were differentiated into CEC-like cells using a CEC-conditioned medium. Differentiation was evaluated through morphology, polymerase chain reaction (PCR), immunocytochemistry (ICC), and flow cytometry. Functional properties of differentiated CEC-like cells were assessed using electric cell-substrate impedance sensing (ECIS) and the dye-leak assay.

Results: Differentiated HUVECs exhibited a polygonal morphology typical of CECs and expressed key CEC markers, notably zonula occludens-1 (ZO1) and sodium-potassium adenosine triphosphatase (ATP1A1). They demonstrated higher electrical resistance compared to control cells and effectively prevented fluorescein isothiocyanate-dextran flow across the cell membrane, indicating robust barrier function. Moreover, the cells showed presence of key CEC pumps.

Conclusions: These findings demonstrate successful differentiation of HUVECs into functional CEC-like cells, offering a promising therapeutic approach for treating corneal endothelial disorders.

Mathematical Modeling Validation for Predicting Intraocular Glucose Sensor Response

First Author: Ka Yiu LUI

Co-Author(s): Mårten E BRELÉN, Priscilla FERNANDEZ LOAIZA, Tony Tsz Chun MAN, Yolanda Wong Ying YIP

Purpose: A mathematical model was applied in simulation software to predict the resonance response of the intraocular glucose sensor. This study aims to validate the mathematical model applied in simulation software by comparing the resonance response of the simulated models and bench test models with various parameters.

Methods: Three sensors were made to compare the effect of inner diameter and thickness on the resonance response and test whether the simulation model could respond to the change of these variables accurately. The first sensor was 1mm thick with 10mm inner diameter. The second sensor was 1mm thick with 11mm inner diameter. The third sensor was 0.5mm thick with 11mm inner diameter. Prototypes underwent bench testing, with resonance frequencies compared to simulations done in Ansys High Frequency Simulation Software.

Results: For 1 mm thick, 10 mm inner diameter sensor, the bench test resonance frequency was 347

MHz, while the simulated one was 349 MHz. For 1 mm thick, 11 mm inner diameter sensor, the bench test resonance frequency was 423 MHz, while the simulated one was 453 MHz. For 0.5 mm thick, 11 mm inner diameter sensor, the bench test resonance frequency was 313 MHz, while the simulated one was 309 MHz. The root mean square error was 17.5MHz and relative root mean square error was 4.85%.

Conclusions: The root mean square error suggested that the simulated model had moderate accuracy. Future work includes comparing more simulated models and bench test models to evaluate the mathematical model accuracy and validate the mathematical model.

PLOD3 Suppression Exerts Anti-Angiogenesis Effect via STAT3 Pathway in Oxygen-Induced Retinopathy Animal Model

First Author: Manhong XU

Co-Author(s): Xiaoe FAN, Xiaorong LI, Shaojie REN

Purpose: Retinal neovascularization, a hallmark of proliferative diabetic retinopathy (PDR) and retinopathy of prematurity (ROP), leads to vision loss through pathological angiogenesis and fibrovascular proliferation. Although anti-VEGF therapy is widely used, its limitations underscore the need for new therapeutic targets. This study aimed to identify proteins associated with pathological angiogenesis and clarify the role of procollagen-lysine, 2-oxoglutarate 5-dioxygenase 3 (PLOD3).

Methods: An oxygen-induced retinopathy (OIR) mouse model was established. Proteomic profiling (LC-MS/MS) with bioinformatic analysis identified angiogenesis-related proteins. PLOD3 expression was evaluated in vitreous from PDR patients, OIR retinas, and hypoxia-induced human retinal endothelial cells (HRECs). Functional studies included intravitreal injection of lentivirus-mediated PLOD3 shRNA (LV-shPLOD3) in OIR mice and transfection in VEGF-induced HRECs. Western blotting was performed to assess STAT3, AKT, and ERK signaling.

Results: PLOD3 was significantly upregulated in OIR retinas, PDR vitreous, and hypoxia-induced HRECs. LV-shPLOD3 reduced retinal neovascularization and vaso-obliteration in OIR mice. In vitro, PLOD3 knockdown inhibited VEGF-induced proliferation, migration, and tube formation of HRECs. Mechanistically, suppression of PLOD3 attenuated phosphorylation of STAT3, AKT, and ERK in OIR retinas.

Conclusions: Proteomic analysis identified PLOD3 as a novel pro-angiogenic factor in retinal neovascularization. Its knockdown exerts anti-angiogenic and vascular-protective effects through STAT3 pathway inhibition, suggesting PLOD3 as a

potential therapeutic target for angiogenesis-related retinal diseases.

Preclinical Models of Corneal Fibrosis for Clinical Translation

First Author: Haiming LI

Co-Author(s): Gink YANG

Purpose: Corneal fibrosis, characterized by excessive and disorganized secretion of extracellular matrix proteins by the resident corneal cells leading to scarring, is the final manifestation in various progressive corneal diseases. At present, no antifibrotic therapies against corneal scarring exist clinically, resulting in empirical and off-label treatments being prescribed with little evidence of effectiveness. The mechanisms leading to corneal fibrosis are highly complex and dependent on the exact pathogenesis of the corneal disease. To further understand these mechanisms, preclinical models using cells and laboratory animals have been established. The strengths and shortcomings of these models vary, both due to the regenerative capacity of the model and the way the model is induced. Most importantly, results from the experimental analysis of these preclinical models are often used to demonstrate the safety and efficacy of emerging therapies in readiness for clinical translation.

Methods: In this review, we delineated recent advances in understanding the cornea from a cellular and molecular perspective and mechanisms involved in the pathogenesis of corneal fibrosis.

Results: We then used this knowledge to introduce the different preclinical models for investigating corneal fibrosis and discuss the regulatory guidance in using these models according to the guideline from the International Council of Harmonization.

Conclusions: Ultimately, this review aims to educate ophthalmic researchers to use the appropriate preclinical models and rationale in the development of corneal anti-fibrotic therapies for clinical translation.

Abstract No.: 206097

RIDE: A Reprogrammable Delivery Platform for Cell-Type-Specific In Vivo CRISPR-Cas9 Genome Editing

First Author: Xujiao ZHOU

Co-Author(s): Jiaxu HONG

Purpose: The transformative potential of in vivo CRISPR-Cas9 gene therapy is hampered by the lack of delivery systems that are simultaneously efficient, cell-type-specific, and temporally controlled. We aimed to develop a versatile and programmable platform that

enables precise tropism-defined delivery of CRISPR ribonucleoproteins (RNPs) to target cells in vivo.

Methods: We engineered a virus-like particle (VLP)-based system, termed RIDE (Cell-tropism Programmable CRISPR-Cas9 RNP Delivery System). The key innovation lies in the programmable design of the VLP surface, which allows for facile redirection to specific cell types (e.g., dendritic cells, T cells, neurons) by modifying its tropism. The system packages pre-assembled Cas9 RNPs for direct genomic action upon delivery.

Results: RIDE demonstrated editing efficiency comparable to adeno-associated virus (AAV) and lentiviral vectors, and superior to lipid nanoparticles (LNPs). Its versatility was confirmed by successful reprogramming and highly efficient gene editing in diverse cell populations both in vitro and in vivo. In disease models, RIDE-mediated cell-specific editing significantly alleviated pathology in both ocular neovascularization and Huntington's disease. Notably, RIDE efficiently edited the mutant huntingtin gene in patient-derived iPSC neurons and exhibited a favorable safety profile in non-human primates.

Conclusions: RIDE represents a robust, customizable, and efficient platform for targeted in vivo CRISPR-Cas9 delivery. Its ability to be reprogrammed for cell-specific targeting, coupled with high efficacy and preliminary safety, positions RIDE as a promising therapeutic modality with broad applicability for treating genetic disorders. This study provides a foundational framework for the next generation of in vivo CRISPR therapeutics.

Subtype-Specific Plasticity of Bipolar Cells in Non-Human Primates Following Human iPSC-Derived Retinal Organoid Transplantation

First Author: Atsuta OZAKI

Co-Author(s): Mineo KONDO, Yasuo KURIMOTO, Michiko MANDAI, Tomohiro MASUDA, Masayo TAKAHASHI

Purpose: We previously reported that host bipolar cells (BCs) form synapses with transplanted stem cell-derived photoreceptors in the eyes with non-human primate (NHP) retinal degeneration. However, the subtype-specific BC plasticity after transplantation remains to be elucidated. Here, we used clinically comparable genome-edited human induced pluripotent stem cell (iPSC)-derived retinal organoid (RO) sheets lacking ON-BCs for transplantation to investigate the plasticity across BC subtypes in NHP.

Methods: Islet-1-/- human iPSC-derived RO sheets were transplanted in the eye with a laser-induced retinal degeneration model of close to macula and

periphery. After 1 year, the eye was processed for immunohistochemistry using antibodies for photoreceptors and BCs. We quantified the rate and length of dendritic regrowth in the host OFF- (diffuse bipolar 1 [DB1], DB3a) and ON- (rod bipolar, DB4, DB5) BCs. The cut-off for dendritic regrowth was defined as beyond the 95% upper limit of dendritic length in the laser-induced region.

Results: The RO sheets survived for 1 year in both regions and developed rosette-like photoreceptor layers. In the presence of grafted photoreceptors, the dendritic regrowth was observed in 52.4% of DB1, 37.8% of DB3a, and 79.1% of PKC α -positive BCs. The median dendritic length was significantly longer in PKC α -positive bipolar cells (15.24 μ m [0.84-70.05]) than in DB1 (10.02 μ m [1.40-32.90]) and DB3a (7.50 μ m [0.84-36.79]; $p < 0.01$, Dunn-Bonferroni test).

Conclusions: These results indicate that BC plasticity may differ among subtypes, providing important insights into potential regenerative capacity of host retinal network in stem-cell based therapies.

The Neuroprotective Effect of Riluzole in Age-Related Macular Degeneration

First Author: Ping BU

Co-Author(s): Shaunt ABNOUS, James F. MCDONNELL, Ria RAVI, Alexis STEFANIAK-CLARK, Zhiquan TAN

Purpose: Age-related macular degeneration (AMD), a primary cause of blindness worldwide, currently has limited treatment options. Riluzole, an FDA-approved neuroprotective agent used for amyotrophic lateral sclerosis (ALS), was evaluated for its potential to protect against retinal degeneration in a mouse model of AMD.

Methods: In vivo study: BALB/c albino mice were exposed to 6,000 lux of cool, white, fluorescent light for 2 hours to induce light injury. The control group or the riluzole-treated group (8 mg/kg/day) was administered intraperitoneally after retinal light injury for 6 days. Electroretinography (ERG) was recorded 1 week after retinal light injury. The TUNEL assay was performed 48 hours after light injury. In vitro study: ARPE-19 cells were cultured in DMEM/F12 medium supplemented with 10% fetal bovine serum. ARPE-19 cells were pretreated with or without riluzole overnight and then exposed to sodium iodide (SI) for 24 hours. Cell viability and cellular reactive oxygen species (ROS) levels were assessed using the MTT and DCFDA assay kits, respectively, according to the manufacturer's instructions.

Results: Riluzole treatment significantly attenuated light injury-induced retinal functional impairment compared to the control-treated mice. The number of TUNEL-positive cells in the retinal outer nuclear layer

were significantly lower with riluzole treatment 48 hours after light injury. Pretreatment with riluzole in ARPE-19 cells resulted in significantly increased viability and ROS when exposed to SI.

Conclusions: Riluzole treatment protects against retinal functional loss and decreases apoptosis in the retinal outer nuclear layer following light injury. These initial findings suggest that riluzole may serve as a novel therapeutic agent for AMD.

Virus-like Particle Delivering CRISPR Treatment of Myocilin-associated Glaucoma in Mice, Non-human Primates and Patients

First Author: Yufei **TENG**

Co-Author(s): Ningli **WANG**

Purpose: MYOC mutations are responsible for 3–4% of POAG patients and 10% of patients with juvenile open-angle glaucoma (JOAG). We developed a gene editing therapy for MYOC mutation-associated glaucoma via virus-like particle (VLP) which delivers ribonucleoprotein delivery, and proved its translation potential in mice and non-human primates and in IIT clinical trial.

Methods: A glaucoma mouse model was established via knockin human N450Y myocilin mutation, which exhibited glaucoma phenotype, such as IOP elevation, retinal ganglion cell loss and visual impairment. We engineered lentiviral virus-like particles loaded with MYOC-targeting CRISPR-Cas9 ribonucleoprotein (RNP) using our VLP-based ribonucleoprotein delivery platform (RIDE).

Results: We found VLP efficiently and specifically transduced the trabecular meshwork in mice, whereas conventional AAV and LNP preferentially dispersed to the cornea. Notably, VLP-based ribonucleoprotein delivery (RIDE) could significantly enhance aqueous fluid outflow, reduce intraocular pressure, and protect Retinal Ganglion Cells (RGCs) from degeneration in the MYOC mutation knockin mice model. No notable side effects were detected during the 10-month follow-up. Efficient editing (35%) was demonstrated in cynomolgus macaques despite pre-existing anti-Cas9 immunity. In a first-in-human trial, RIDE led to sustained IOP reduction in a glaucoma patient with no ocular or immune adverse events.

Conclusions: These findings establish RIDE as a clinically relevant strategy for CRISPR-based glaucoma therapy and support its application to ocular diseases.

Abstract No.: 207356

Vitamin D SNPs and Retinopathy of Prematurity: A Genetic Insight from an Indian Cohort

First Author: Debolina **DEB**

Purpose: This study aimed to investigate the association between common Vitamin D pathway gene polymorphisms (FokI, BsmI, Apal, and TaqI) and the development of retinopathy of prematurity (ROP) in preterm infants.

Methods: A cohort of 97 preterm infants (<34 weeks gestation) admitted to a tertiary neonatal intensive care unit was prospectively analyzed over one year. Genomic DNA extracted from blood leukocytes was genotyped for four VDR SNPs: rs2228570 (FokI), rs1544410 (BsmI), rs7975232 (Apal), and rs731236 (TaqI) using PCR-RFLP. Clinical data and the occurrence of five major prematurity complications, including ROP, were recorded. ROP was diagnosed and staged according to the International Classification of Retinopathy of Prematurity.

Results: ROP developed in 25.5%, predominantly in those born <30 weeks' gestation and with birth weight <1500 g ($p < 0.05$). FokI and BsmI had significant associations with ROP ($p < 0.05$).

Conclusions: Vitamin D, via its nuclear vitamin D receptor (VDR), influences angiogenesis and retinal vascular development. Single nucleotide polymorphisms (SNPs) in the VDR gene may alter receptor function and affect susceptibility to prematurity-related complications.

Altered Topological Organization of Brain Functional Networks in Adults With Acute Acquired Concomitant Esotropia

First Author: Jiayu **CHEN**

Co-Author(s): Jing **FU**, Jie **HAO**

Purpose: To investigate alterations in functional brain networks associated with acute acquired concomitant esotropia (AACE) and examine their topological reorganization patterns, with the goal of advancing neuroscientific understanding of the pathophysiological mechanisms underlying this disorder.

Methods: A total of 32 AACE patients (15 males, 17 females) and 31 healthy controls (HCs, 10 males, 21 females) underwent resting-state functional magnetic resonance imaging (rs-fMRI) scans. Using graph-theoretical analysis, we investigated the topological

properties and functional connectivity of brain functional connectomes at both global and nodal levels, along with their correlations with ophthalmic clinical characteristics.

Results: There were no statistically significant differences in the demographic characteristics of the two groups (age, gender and level of education). Both groups demonstrated small-world topology, with no global metric differences. At nodal levels, AACE patients showed elevated betweenness centrality in REC.R ($t=2.252$, $p=0.029$) and STG.L ($t=2.009$, $p=0.049$), but reduced in PHG. R ($t=-2.077$, $p=0.042$). REC.L displayed decreased clustering coefficient ($t=-2.192$, $p=0.033$) and local efficiency ($t=-2.076$, $p=0.043$). Altered functional connectivity involved four enhanced and three reduced pairs ($p<0.01$). Global and nodal network metrics correlated with several clinical variables, such as disease duration and angles of deviation, and psychometric scale scores ($p<0.05$).

Conclusions: This graph theory study reveals AACE patients' brain networks exhibit global topology preservation with nodal reorganization: right-hemispheric dominance in centrality/path anomalies drives visual compensation, accompanied by bidirectional FC changes. Abnormal σ elevation, synchronized with parahippocampal/temporal abnormalities, marks neuroplasticity thresholds. Redefining AACE as brain network-mediated neuro-ophthalmopathy, σ -guided surgery timing offers neural circuit insights for transcending empirical treatments.

Combined Treatment of Human Mesenchymal Stem Cells and Green Tea Extract on Retinal Ganglion Cell Regeneration in Rats After Optic Nerve Injury

First Author: Tsz Kin NG

Co-Author(s): Qichen YANG

Purpose: Retinal ganglion cell (RGC) death and axonal loss cause irreversible vision loss upon optic nerve (ON) injury. We have independently demonstrated that mesenchymal stem cells (MSCs) and green tea extract (GTE) promote RGC survival and axonal regeneration in rats with ON injury. Here, we aimed to evaluate the combined treatment effect of human bone marrow-derived MSCs (hBM-MSCs) and GTE on RGC survival and axonal regeneration after ON injury.

Methods: Combined treatment effect of hBM-MSCs and GTE on RGC survival and axonal regeneration was evaluated using the rat optic nerve crush and retinal explant culture models. The effects of GTE on hBM-MSCs and the possible mechanisms were also investigated.

Results: Combined treatment of hBM-MSCs and GTE promoted RGC survival and neurite outgrowth/axonal

regeneration in ex vivo retinal explant culture and in rats after ON injury. GTE increased Stat3 activation in the retina after combined treatment and enhanced brain-derived neurotrophic factor secretion from hBM-MSCs. Treatment of GTE would not induce hBM-MSC apoptosis, but inhibited their proliferation, migration, and adipogenic and osteogenic differentiation in vitro by reducing matrix metalloproteinase secretions.

Conclusions: This study revealed that GTE can enhance the RGC protective effect of hBM-MSCs, suggesting that stem cell priming could be a prospective strategy enhancing the properties of stem cells for ON injury treatment.

Dyslipidemia Drives Choroidal Thinning via JNK-Dependent Ferroptosis Signaling Pathway

First Author: Minjie ZHANG

Purpose: Dyslipidemia has emerged as a substantial global public health concern. The involvement of choroidal changes in the pathophysiology of various ocular diseases has been postulated. The study aims to assess the effects of dyslipidemia on the choroid.

Methods: All participants enrolled in the research were grouped as the dyslipidemia group and the control group according to the serum lipid levels. The thickness of the retina or choroid was compared between the two groups. RNA sequencing (RNA-seq) was performed, followed by quantitative real-time polymerase chain reaction (qRT-PCR) and western blotting (WB), to validate expression changes in both in vitro and vivo hyperlipemia models.

Results: The research included 2,029 left eyes from 2,029 participants with dyslipidemia and 2,029 left eyes from age- and sex-matched normal subjects. The choroidal thickness was significantly thinner in the dyslipidemia group compared to the control group, while the retinal thickness only in the outer nasal sector indicated statistically significant differences between the two groups. RNA-seq revealed that the dyslipidemia-induced effects on the choroid were mediated by the vital involvement of ferroptosis and the MAPK signaling pathway. Specifically, dyslipidemia led to the induction of choroidal ferroptosis through the enhancement of ferrous ion (Fe^{2+}), reactive oxygen species (ROS), and malondialdehyde (MDA), the downregulation of SLC7A11, GPX4, and glutathione (GSH), and the upregulation of COX2. Furthermore, the JNK signaling pathway was significantly activated in this process.

Conclusions: Compared with the retina, the choroid exhibits a greater vulnerability to lipid metabolism disorders. Dyslipidemia stimulates choroidal ferroptosis through the activation of JNK signaling.

Abstract No.: 209753**Panel No.: VSC-1119****EasyEyes: Crowded Dynamic Fixation for Online Psychophysics***First Author: Fengping HU**Co-Author(s): Joyce Y. CHEN, Denis G. PELLI, Jonathan WINAWER*

Purpose: Online vision testing enables efficient data collection from diverse participants but often requires accurate fixation. When needed, fixation accuracy is traditionally ensured by using a camera to track gaze. That works well in the lab, but tracking during online testing with a built-in webcam is not yet sufficiently precise. Kurzwski, Pombo, et al. (2023) introduced a fixation task that improves fixation through hand-eye coordination, requiring participants to track a moving crosshair with a mouse-controlled cursor. Their dynamic fixation task greatly reduces peeking at peripheral targets relative to a stationary fixation task, but does not eliminate it. We introduce a better task that does.

Methods: Our new crowded dynamic fixation task further enhances fixation by adding clutter around the fixation mark to leverage crowding. We assessed fixation accuracy during peripheral threshold measurement.

Results: Relative to the RMS gaze error during the stationary fixation task, the dynamic fixation error was 55%, while the crowded dynamic fixation error was only 40%. With a 1.5° tolerance, peeking occurred on 7% of trials with stationary fixation, 1.5% with dynamic fixation, and 0% with crowded dynamic fixation. This improvement eliminated implausibly low peripheral thresholds, likely by preventing peeking.

Conclusions: We conclude that crowded dynamic fixation provides accurate gaze control for online testing.

Abstract No.: 208183**Efficacy Study of Internal Limiting Membrane (ILM) Translocation and Inversion Covering Surgery Assisted by Intraoperative OCT Navigation in Refractory Macular Holes***First Author: Hongyan SUN**Co-Author(s): Mingming YANG*

Purpose: To observe the efficacy of OCT intraoperative navigation-assisted internal limiting membrane (ILM) translocation and inversion covering surgery in the treatment of refractory macular holes, and to provide evidence-based support for this innovative surgical approach for such diseases.

Methods: A total of 15 cases involving 15 eyes were included in the study. Eight eyes underwent internal limiting membrane translational covering surgery, and 7 eyes underwent internal limiting membrane inversion

covering surgery. All were filled with perfluoropropane (C3F8). Changes in BCVA, macular morphology, hole closure rate, and mfERG at the last follow-up were observed. Paired t-tests were used to compare the parameters before and after the surgery.

Results: All 15 eyes achieved anatomical healing of macular holes (with a closure rate of 100%); compared with before the surgery, the postoperative best corrected visual acuity (BCVA) significantly improved ($P < 0.05$). The improvement in visual acuity in the translational surgery group was significantly greater than that in the inversion surgery group ($P < 0.05$). Moreover, the translational surgical method is more conducive to the recovery of microcirculation in the macular area.

Conclusions: Compared with the traditional inversion technique, the internal membrane translational covering technique better conforms to the anatomical and physiological characteristics of the retina. It can significantly increase the closure rate of large or old macular holes, and provides a new minimally invasive anatomical repositioning treatment option for cases where the conventional techniques have failed.

Abstract No.: 208437**Panel No.: VSC-1117****Eye Complications and COVID-19 Infection – A Review***First Author: Wai Pik LAU**Co-Author(s): Kam Lung Kelvin CHONG, Ka Hei Kenneth LAI, Chi Pui Calvin PANG, Chee Yung Clement THAM, Yiu Man Hanson WONG*

Purpose: This review aims to examine the clinical presentation of ocular complications associated with COVID-19 infection, drawing on current evidence.

Methods: The literature search was performed with the following eligibility criteria: studies in English, with full texts available, published between January 2020 and October 2025, excluding case reports, case series, systematic reviews, or meta-analyses. Inclusion criteria include both anterior and posterior segment involvement, neuro-ophthalmological manifestations, and related pathophysiology. Data extraction was conducted using predefined structural tables.

Results: Of 1,073 screened articles, 15 were selected. Conjunctivitis is the most common ocular manifestation linked to COVID-19 infection, reported with variable incidence ranging from 0.8% to over 30% in most cases. Other anterior segment manifestations observed include keratitis, episcleritis, and uveitis. Retinal involvement in the posterior segment, characterized by microvascular changes, including cotton wool spots, microhaemorrhages, and vascular occlusions, is reported predominantly in severe COVID-19 cases, indicative of microvascular damage or coagulopathy related to COVID-19. The reviews also documented

neuro-ophthalmological complications, including cranial nerve palsies and ischemic optic neuropathy. Optical Coherence Tomography Angiography (OCTA) showed reduced macular vessel density in most post-COVID-19 subjects. Most studies showed normal visual acuity (VA) in post-COVID-19 patients. Other ocular complications, including dryness, irritation, and pain symptoms related to dry eye, are also documented.

Conclusions: Ocular complications in COVID-19 are diverse, with the highest prevalence of the anterior segment complications and conjunctivitis, while manifestations in the posterior segments are reported. Other ocular complications show consistent markers for the effects of COVID-19 on ocular performance.

Genome-Wide Association Study of Human Retinal Electrical Signals Highlights Locus in CNGB3

First Author: Zihe XU

Co-Author(s): Christopher HAMMOND, Pirro HYSI, Xiaofan JIANG, Omar MAHROO

Purpose: The electroretinogram (ERG), representing the summed electrical activity of the retina elicited by light stimuli in vivo, enables exploration of retinal physiology. We performed a genome-wide association study (GWAS) of cone-driven flicker ERG responses.

Methods: Participants were recruited from the TwinsUK registry. The discovery cohort (Group 1) comprised 1587 genotyped participants (55.3 ± 16.2 years), who underwent non-mydriatic light-adapted 30 Hz flicker ERG recordings with a portable device (RETeval system). Two replication cohorts included 372 participants (63.1 ± 14.9 years) who underwent a similar flicker test with the same device, but delivered with a lower stimulus strength (Group 2), and 184 individuals (62.3 ± 10.6 years) who underwent conventional standard mydriatic 30 Hz ERGs (Group 3). Linear mixed models adjusted for age, sex and familial relatedness were used for analysis. Fixed-effect meta-analysis combining the three groups ($n=2,143$) was also performed.

Results: The discovery GWAS identified a genome-wide significant locus in CNGB3 ($rs188808$, $P=4.42 \times 10^{-9}$). This gene encodes one of the subunits of the outer segment cation channel in the cone photoreceptor, and is also a myopia risk locus. This association was replicated in Group 2 ($P=0.045$) and nearly in Group 3 ($P=0.069$). The association became more significant in meta-analysis ($P=7.12 \times 10^{-11}$), with a consistent effect direction in the three groups.

Conclusions: Whilst CNGB3 is a gene associated with a rare disease (achromatopsia), our findings indicate that common variants in this gene shape cone-driven

responses in healthy individuals. The findings also support a role for cone-driven signals in myopia.

Panel No.: VSC-1115

Optimising Communications in Blind and Partially Sighted Patients in Primary Care – A Prospective Supra-Regional Feasibility Study

First Author: Chi Kit YAN

Co-Author(s): Louise GRANT, Alicia JEREMIAH, George LIU

Purpose: To prospectively evaluate whether tailoring written communication by font size and formatting empowers patients registered as blind or partially sighted, thereby improving engagement with healthcare information and supporting better clinical outcomes.

Methods: A prospective feasibility study was conducted at GP practices across two English deaneries (East of England and North West). Inclusion criteria were: (1) registration with a Certificate of Visual Impairment (CVI) as blind or partially sighted; (2) receipt of paper communications from practices; (3) engagement with these communications with visual adjuncts; (4) intact cognitive function; and (5) consent to participate. Eligible patients received test letters with varying font sizes (25–60 point). Telephone follow-up assessed readability and preferences. In the second phase, personalised letters incorporating preferred font size, bold text, increased spacing, and black font were sent. Suitability was reassessed via structured follow-up calls.

Results: Thirty-four patients were recruited across three practices. Of these, nine initially met the inclusion criteria. Two patients were later excluded due to newly identified cognitive decline, leaving seven for final analysis. Among these, 100% were able to read personalised letters without reliance on visual adjuncts or carers, compared with baseline dependence on magnifiers or third-party assistance. Data collection is ongoing to confirm reproducibility across additional practices.

Conclusions: This prospective supra-regional feasibility study demonstrates that simple, personalised adjustments to written communication can restore access to healthcare correspondence in patients with visual impairment. Empowering patients in this way improves engagement and has the potential to positively influence health outcomes. Findings support the feasibility of wider implementation across primary care.

The Efficacy and Safety of Jingtongtang Cold Compress Eye Patch in Relieving Visual Display Terminals Related Asthenopia——a Randomized, Double-Blind, Placebo-Controlled Clinical Trial

First Author: Linfangzi ZHU

Co-Author(s): Lin CHEN, Ke FENG, Wenying GUAN, Zuguang LIU

Purpose: To evaluate the immediate efficacy and safety of Jingtongtang cold compress eye patch in relieving video display terminal (VDT) related asthenopia.

Methods: Patients with asthenopia were screened using the ASQ-19 questionnaire. Demographic and clinical baseline data were collected. Following asthenopia induction via one-hour smartphone use under dark conditions, subjects were randomized 1:1 to receive either Jingtongtang Cold Compress Eye Patches or purified water-soaked patches (control) for 15 minutes. Objective parameters, including relative accommodation (RA), accommodative facility (AF), accommodative response (AR), tear film break-up time (TBUT), and conjunctival congestion degree, were assessed pre- and post-induction and post-treatment. Subjects' symptoms and their severity were collected immediately post-induction and post-treatment. Efficacy was evaluated through intra- and intergroup comparisons. Safety monitoring included ocular irritation and documentation of adverse events (AEs) and serious adverse events (SAEs).

Results: Baseline characteristics showed no significant differences between groups. After treatment with Jingtongtang Cold Compress Eye Patch, the experimental group exhibited significant improvements in multiple outcomes: subjective asthenopia symptoms were markedly relieved; ocular surface health improved, evidenced by prolonged TBUT and reduced conjunctival hyperemia; and visual function parameters, including monocular and binocular AF, NRA, and AR, were significantly enhanced compared to the control group ($p < 0.05$). The eye patch demonstrated a good safety profile, with only mild and transient irritation reported in a few subjects. No adverse events or serious adverse events were observed.

Conclusions: The Jingtongtang cold compress eye patch demonstrates a favorable safety and efficacy profile. In comparison to the placebo control group, the intervention significantly promotes relaxation of the accommodative response.

The Natural Preferred Retinal Locus in Patients With Macular Disease

First Author: Danjie LI

Co-Author(s): Shengnan LI, Jinglin ZHANG

Purpose: This study aimed to explore the characteristics of the natural Preferred Retinal Locus (PRL) in eyes with different macular lesions.

Methods: In this retrospective study, 37 patients (39 eyes) suffering from macular diseases (MD) were included, and the following data were collected: best corrected visual acuity (BCVA), mean sensitivity of macular area in 10 deg diameter (MS), and bivariate contour ellipse area (63% BCEA and 95% BCEA), fixation stability, fundus images, and sectional images of the fovea. A natural PRL did not develop in 10 eyes with macular disease.

Results: PRLs, 24% developed nasal PRLs, 7% developed multiple PRLs, 10% developed PRLs inside the "dark area", and there were no independent inferior PRLs. In the inside group, the mean MS was significantly lower than that of the other four groups; and the variations in log BCEA were greater in group M compared with group S ($P < 0.01$), group T ($P < 0.01$) and group N ($P < 0.01$), but there were no obvious differences among group S, group T and group N.

Conclusions: A natural PRL tends to be more localized in the upper retina, possibly to preserve the lower visual field, followed by nasal and temporal, and rarely localized in the lower retina, and multiple scattered PRLs can be formed when the lesion was widespread. If the function of the fovea exists, even if the lesion in the macular area is clear, the patient still uses the fovea for central fixation and does not form PRL.

Weight-Adjusted Waist Circumference Trajectories and the Risk of Vision Impairment: Findings From Three Prospective National Studies

First Author: He XUE

Co-Author(s): Liu LEI, Liu SHUNMIN, Yang XIAOHONG

Purpose: This study aimed to investigate the association between weight-adjusted waist circumference (WWI) trajectories and vision impairment (VI) among adults aged ≥ 50 years in three countries.

Methods: We used nationally representative data from the US, England, and China, with follow-up durations ranging from 5-13 years. WWI trajectories were identified by group-based trajectory modeling. Distance and near VI were ascertained by self-rated eyesight. Logistic regression analyzed the relationship

between WWI trajectories and VI occurrence in each country.

Results: A total of 5,095 participants from US, 4,974 from England, and 5,205 from China were included. Three distinct WWI trajectories were identified in each cohort: low-stable, moderate-stable, and high-stable. The association between WWI trajectories and VI varied across countries. In the US, the high-stable trajectory had an increased risk of near VI (odds ratio [OR]=1.49, 95% confidence interval [CI]=1.10-2.01) after full adjustment. In England, the high-stable trajectory had a significantly increased risk of both distance VI (OR=1.85, 95% CI=1.22-2.81) and near VI (OR=1.68, 95% CI=1.16-2.43). However, in China, these associations were not statistically significant after adjustment. Furthermore, mediation analyses indicated that physical activity partly mediated the association between WWI trajectories and near VI in the US (12.4%) and England (14.7%), while smoking further explained 5.6% in England.

Conclusions: A high-stable WWI trajectory was associated with an increased risk of VI in the US and England population, while not in China. These findings highlight the importance of managing central adiposity and lifestyle factors, including physical activity and smoking, in strategies for vision care among older adults.

A Community-Focused Vision Foundation Model for Quality Checks and Detection of Ten Geriatric Eye Diseases Using Real-World Non-Dilated Fundus Photographs

First Author: Zhi Da SOH

Co-Author(s): Ching-yu CHENG, Jiangnan HE, Ten Cheer QUEK, Jianfeng ZHU, Haidong ZOU

Purpose: Artificial intelligence models show promise in eye disease detection, but their deployment remains limited due to disparity between model design and utility. We developed ComEye-FM, an integrated quality check (QC) and multi-eye disease foundation model, using real-world non-dilated fundus photographs.

Methods: We developed ComEye-FM using the RETFound architecture and 97,738 fundus photographs obtained from a community screening program in China. The QC model assessed image quality based on macular, optic disc, blood vessel visibility, and imaging artifacts. ComEye-FM detected ten eye diseases, including age-related macular degeneration (AMD), diabetic retinopathy (DR), and myopic macular degeneration (MMD). External testing was done using a diverse China screening dataset and the Singapore Epidemiology of Eye Diseases (SEED) study. Area under the receiver operating curve (AUC), sensitivity, specificity, and F1-score were computed.

Results: The QC model achieved AUC $\geq 95.4\%$ for assessing structure visibility and $\geq 94.6\%$ for detecting imaging artifacts. The disease detection model achieved AUC $> 90\%$ for all conditions except mild DR (76%). The F1-scores for different disease severity ranged between 57.9 - 98% for AMD, 32.5 - 46.3% for DR; 48.4 - 88.3% for MMD. In external testing, ComEye-FM achieved AUCs $\geq 82.5\%$ for most diseases in the China screening dataset, and AUCs between 80.3 - 98.3% for AMD, 61.8% - 97.7% for DR, and 89.9% - 99.1% for MMD in SEED.

Conclusions: ComEye-FM is an integrated QC and multi-disease foundation model designed to improve eye disease detection in community settings.

Abstract No.: 206291

A Machine Learning Model on Orthokeratology Lens Fitting Based on Corneal Topography Data

First Author: Wei XU

Co-Author(s): Qiurong LIN

Purpose: To investigate the performance of machine learning (ML) framework in orthokeratology lens fitting based on the relevant corneal topography maps and compare the accuracy and reliability of different machine learning algorithms.

Methods: A total of 5,242 corneal topographical maps were collected from 3,650 myopic patients (1,500 male patients/2,786 eyes, 2,150 female patients/2,456 eyes, median age 12 years old) who received orthokeratology. The data were randomly divided into two groups: the training data set (70%, sample number 3,669) and the test data set (30%, sample number 1,573). In the study, Logical Regression (LR), Random Forest classification (RF), and eXtreme Gradient Boosting classification (XGBoostC) algorithms were constructed to predict the type of orthokeratology lens (standard lens or circular lens). The best algorithm was determined by comparing each precision, accuracy, recall, and receiver operating characteristic curve (ROC curve).

Results: The XGBoostC algorithm had the best outcome, with an accuracy rate of 86.14%, in deciding the type of orthokeratology lens. Besides, the XGBoostR algorithm better predicted the FK and SK parameters of the orthokeratology lens. In the test data set, the mean square error (MSE) is 0.1172 and 0.2938, the mean absolute error (MAE) is 0.2430 and 0.4175, and the goodness of fit (R^2) is 92.01% and 85.83%, respectively.

Conclusions: The XGBoostC and XGBoostR algorithms could provide practitioners with reasonable models for fitting orthokeratology lenses. Based on the corneal topographical map, the XGBoostC algorithm could suggest the type of orthokeratology lens, and the XGBoostR algorithm could predict the SK and FK values.

Abstract No.: 207836

A Novel 3D OCT Stitching Algorithm for Retinal Reconstruction

First Author: Zhen **TIAN**

Co-Author(s): Mingguang **HE**

Purpose: The purpose of this study is to present a novel method for 3D optical coherence tomography (OCT) retinal image stitching that addresses the challenges of misalignment and distortion introduced by the eye's refractive properties and inherent imaging distortions.

Methods: Three-view OCT images were captured using ultra-wide-field retinal OCT. Source 3D retinal OCT (sOCT) images is aligned to target retinal OCT (tOCT) coordinates within a unified coordinate system by transforming voxel data into a Cartesian framework. An ideal ellipsoidal model of the inner ocular surface is employed to compute the world coordinates of each voxel in the tOCT image, and a rigid transformation is then applied to map these coordinates into the sOCT space. To ensure seamless stitching and precise alignment, an iterative optimization framework was employed to minimize a combination of loss functions. These functions guide the alignment process, correcting for discrepancies in intensity, key anatomical features, and color consistency between images

Results: The proposed 3D OCT image stitching method significantly reduced geometric distortions and improved stitching accuracy.

Conclusions: By correcting refractive and geometric errors and optimizing image fusion, this technique significantly improves the quality and reliability of 3D retinal OCT images stitching. The enhanced visualization supports more accurate clinical assessments and offers robust potential for future applications in ophthalmology

Abstract No.: 201508

A Post-Conceptional-Age-Conditioned Diffusion Approach to Visualize and Anticipate Retinopathy of Prematurity Progression

First Author: Putu Emilia **DEWI**

Co-Author(s): Kadek Rina **AGUSTINAWATI**, Ni Wayan **SEDANI**

Purpose: To develop and evaluate a generative model that synthesizes anatomically plausible pediatric fundus images at arbitrary post-conceptional ages (PA), enabling counterfactual visualization of vascular maturation and potential late reactivation in retinopathy of prematurity (ROP).

Methods: We adapted a diffusion-based counterfactual framework. A pretrained diffusion model serves as the generative prior, while a PA classifier provides gradient-based guidance to steer sampling toward age-specific appearance. The diffusion prior learns the distribution

of infant fundus images and denoises latents into realistic variants. The classifier imposes a semantic constraint so outputs reflect clinically meaningful shifts across PA groups (30–34, 35–39, 40–44 weeks). Framework quality depends on (i) the diffusion model's capacity to reconstruct realistic anatomy and (ii) the classifier's discriminative reliability. We report validation accuracy as an indicator of learned age-related morphology and a proxy for guidance robustness.

Results: A PA classifier distinguishing 30–34, 35–39, and 40–44-week groups achieved 64.4% validation accuracy on held-out data, suggesting subtle yet learnable age-related features. Integrated with the diffusion prior, this guidance yielded coherent age-shifted counterfactuals, producing plausible transitions between PA groups. Although moderate accuracy introduces variability, it was sufficient to drive perceptible, anatomically consistent changes aligned with increasing PA.

Conclusions: PA-conditioned diffusion can synthesize clinically realistic pediatric fundus images at user-specified ages, offering a tool to visualize counterfactual ROP trajectories. Potential applications include education, decision support, and simulation of late-reactivation scenarios. Prospective validation and integration with time-to-event risk models are planned.

Abstract No.: 206617

AEyeTrauma – RAG Enabled ChatGPT Assistive Tool for Management of Patients With Ophthalmic Trauma

First Author: Rachel **SONG**

Co-Author(s): Rupesh **AGRAWAL**, Paola **SABOYA**, Maxwell **SINGER**

Purpose: To evaluate the safety and efficacy of a purpose-built large language model (LLM) assistive tool (AEyetrauma) for treatment planning and prognostication in patients with ophthalmic trauma.

Methods: AEyeTrauma was built using a retrieval-augmented generation (RAG) chatbot framework, trained on selected PubMed abstracts and an "Ocular Traumatology" textbook. A knowledge-indexing framework was implemented using OpenAI and LangChain, while ChatGPT-4o was integrated into the system architecture. Hypothetical data referenced from the International Globe & Adnexal Trauma Epidemiology Study (IGATES) formed the basis of the clinical scenarios and were input into both AEyeTrauma and ChatGPT-4o. Responses generated were evaluated for correctness, completeness, helpfulness, readability, and safety.

Results: AEyeTrauma scored higher than GPT-4o across all five evaluation components (correctness, completeness, helpfulness, readability, and safety) on the Likert scale. Expert validation showed that

AEyeTrauma produced fewer errors and was more accurate in predicting outcomes using the Ocular Trauma Score (OTS).

Conclusions: AEyeTrauma provided correct, comprehensive, and safe treatment plans for patients with ophthalmic trauma, and accurately generated OTS scores. It has the potential to be integrated into clinical care pathways to support patient counselling and outcome prognostication in emergency eye injury settings.

Abstract No.: 205054

AI in Your Fingertips: Free No-Code Retinal Disease Detection

First Author: Anju KURIAKOSE

Purpose: Artificial Intelligence (AI) is transforming healthcare but is often inaccessible to clinicians without programming knowledge. This study demonstrates how doctors can build a free AI tool to detect retinal diseases from fundus photographs using a simple, no-code platform.

Methods: Retinal fundus photographs representing various diseases were divided into training and test datasets. Google's free online platform, Teachable Machine, was used to train a machine learning algorithm on the training set. The trained AI model was then validated on the test dataset to classify new images according to retinal disease. Accuracy was measured as the percentage of correctly classified images.

Results: The AI algorithm successfully detected trained retinal diseases with high accuracy, ranging from 80% to 99%, depending on the test images. Once trained, the AI analyzed new fundus photographs in seconds, demonstrating rapid and reliable classification without programming expertise.

Conclusions: Teachable Machine enables clinicians to develop free, no-code AI algorithms for retinal disease detection from fundus photographs. These AI models achieve high diagnostic accuracy and process images quickly, providing an accessible platform for innovation in ophthalmology. Such tools can democratize AI development, allowing healthcare professionals to experiment with and implement machine learning in clinical practice without technical barriers.

Abstract No.: 204339

Adapting WHOeyes: Preliminary Study of a Digital School-Based Eye Health Screening Model in Jakarta

First Author: Kianti Raisa DARUSMAN

Co-Author(s): Beta ASWARNI, Tanessa AUDREY, Ray Wagiu BASROWI, Bunga PELANGI

Purpose: Uncorrected refractive errors (URE) impede learning and wellbeing among Indonesian

schoolchildren, while conventional school screening (e.g., Snellen charts) is time-consuming, poorly followed up, and hampered by low parental awareness. To address these gaps, we assessed the feasibility and acceptability of adapting WHOeyes, a mobile visual-acuity tool, into a digital, school-based eye-health screening model in Jakarta, including considerations for children with disabilities and linkages to mental-health assessment and referral pathways.

Methods: Mixed-methods cross-sectional preliminary study in 15 schools (12 public primary, 3 special schools) across four Jakarta municipalities. Participants were 1,254 students (grades 4–6) plus parents, teachers, and primary-care staff in focus-group discussions. Data comprised structured questionnaires, an adapted Pediatric Eye Questionnaire (PedEyeQ), descriptive statistics, and thematic analysis.

Results: Among non-disabled students, 63.0% reported high-intensity gadget use, 33.7% eye fatigue, and 29.3% headaches; PedEyeQ indicated 52.3% perceived reduced visual function and 48.9% functional limitations. Among students with disabilities, 39.4% reported high gadget use and 21.2% eye fatigue. Overall, 54.2% had undergone an eye examination—mostly at school—yet spectacle-wear compliance was low due to discomfort and stigma. Parents and teachers endorsed digital screening as efficient and accessible, while expressing concerns about test accuracy and feasibility for children with intellectual disabilities.

Conclusions: A WHOeyes-adapted, school-based digital model appears feasible and acceptable in Jakarta. The approach may strengthen early detection, parent–school collaboration, and integration with mental-health assessment. Validation studies are warranted to optimise accuracy, ensure inclusivity for children with disabilities, and reinforce referral pathways to primary care.

Abstract No.: 204968

Adoption of Assistive Technologies and Transportation Challenges Faced by Visually Impaired Persons (VIPs) in Hong Kong

First Author: Natalie Nga Man TAM

Co-Author(s): Joseph Yau Kei CHAN, Kai Mei Stephanie TSOI, Lok Hai ZHANG

Purpose: There is rapid advancement in artificial intelligence (AI) and other assistive technologies aimed at helping visually impaired persons (VIPs) travel independently, promoting health, activity, and employment. However, real-world adoption remains under-studied. This study aims to explore the usage of assistive technologies among VIPs during travel, compare the needs between blind and severely visually impaired persons (SVIP), and understand the overall transportation needs of VIPs in Hong Kong.

Methods: This study recruited VIPs from two non-governmental organisations. They completed qualitative semi-structured interviews exploring their travel experiences and technology use, with the data analyzed thematically. Additionally, quantitative surveys collected demographics, travel patterns, and transportation experiences for data supplementation. Fisher's exact test was used for statistical analysis.

Results: Of the 116 participants (59 blind, 57 severely visually impaired), 51.7% used travel apps, but only 13.8% used AI visual assistance apps. VIPs' needs include auditory and tactile information (barrier-free facilities), human assistance, and adaptation to environmental changes. More SVIPs emphasised larger visual cues (7/57 vs. 1/59, $P = 0.031$) and higher color contrast (5/57 vs. 1/59, $P = 0.11$) than blind individuals.

Conclusions: The global number of VIPs is projected to triple by 2050, reaching nearly 115 million. Promotion and education are essential to increase assistive technology adoption. Public awareness and proper training for transportation personnel can reduce the burden on VIPs. Regular maintenance of barrier-free facilities is crucial to ensure accessibility and safety.

Abstract No.: 205933

Applications and Limitations of Artificial Intelligence in the Management of Paediatric Cataracts: Review of Current Literature

First Author: Tin Yau Natalie **SO**

Purpose: Early diagnosis and intervention are essential in minimising visual impairment related to paediatric cataract. However, unique challenges in the management of childhood cataract may hinder treatment effectiveness. The past decade has seen an immense growth in research on artificial intelligence in ophthalmology. Nevertheless, research on AI in childhood cataract remains limited. This review aims to provide an update on the current applications and limitations of AI in managing paediatric cataract.

Methods: An enquiry of the MEDLINE database was performed in August 2025 using the search phrase ((paediatric OR child OR newborn OR congenital OR baby OR infant) AND (cataract)) AND ((artificial intelligence) OR ((machine OR deep) AND learning)) with a filter placed on English results within the past 10 years. The titles and abstracts of all articles were reviewed and only those relevant to artificial intelligence and childhood cataracts were included.

Results: 68 articles were identified in the search query. Appraisal of articles revealed 17 articles directly related to AI and childhood cataract. Among the 17 articles, 10 were original research papers included in this review.

Conclusions: Artificial intelligence platforms demonstrate promise in diagnosis, prognostication, and genetic analysis of paediatric cataract. However, several limitations must be acknowledged. AI algorithms rely

on high-quality slit lamp photos for analysis and the problem of uncooperative patients affecting image quality persists. Second, the quality of AI algorithms depend on the training dataset; algorithms must go through a rigorous evaluation process to determine its accuracy. Finally, the "black-box" nature of AI poses legitimate concerns regarding its accountability.

Abstract No.: 200590

Are Ophthalmology Residents or Artificial Intelligence Better at Grading Vertical Cup-to-Disc Ratios?

First Author: Eunice **GOH**

Co-Author(s): Bryan Chin Hou **ANG**, Kelvin Zhenghao **LI**, Sheng Yang **LIM**, Kok Yao **LOW**, Vivien Cherng Hui **YIP**

Purpose: To evaluate if a deep learning model (DLM) or ophthalmology residents perform more accurately in vertical cup-to-disc ratio (vCDR) grading. An increased vCDR is a key indicator of glaucoma. However, grading is time-consuming and potentially delays diagnosis and treatment.

Methods: 80 individuals (160 fundus images) were selected randomly from a population study. Two ophthalmology residents (second- and fourth-year) and a glaucomatologist graded vCDR using a universal standardized method, with the latter being the gold standard. DLM was applied to the same dataset. The ability of DLM and residents to accurately estimate vCDR was measured with three error-thresholds- ≤ 0.1 , 0.1 to ≤ 0.2 and > 0.2 . We focused on vCDR error thresholds of ≤ 0.2 as this was previously defined as concordant between graders by the Ocular Hypertension Treatment Study.

Results: DLM achieved the highest concordance with the gold standard, with 95.6% ($n=153$) of cases within ≤ 0.2 (75.6% ≤ 0.1 ; 20.0% $0.1-0.2$), outperforming the fourth-year resident (94.9%, $n=152$; 83.1% ≤ 0.1 ; 11.8% $0.1-0.2$) and the second-year resident (94.4%, $n=151$; 76.3% ≤ 0.1 ; 18.1% $0.1-0.2$). Mc Nemar's test found no significant difference between the graders (all $p \geq 0.80$).

Conclusions: DLM has proven itself to be concordant with the gold standard on a normal population study, performing even better than the residents. We hope to further validate this on a local group of glaucoma patients. Should the results be promising, it will potentially be a useful tool to identify glaucoma suspects more efficiently.

Abstract No.: 205066

Artificial Intelligence Accuracy in Glaucoma Detection: A Systematic Review

First Author: Randy **KINDANGEN**

Co-Author(s): Yeni **LESTARI**, Astrianda **SURYONO**

Purpose: Glaucoma is a leading cause of irreversible blindness worldwide, emphasizing the need for early

and accurate detection to initiate timely treatment. Artificial intelligence (AI) has gained attention as a potential tool for improving glaucoma detection by analyzing various ocular imaging modalities. This systematic review aims to evaluate the accuracy of AI-based systems in glaucoma detection and provide insights into their diagnostic performance.

Methods: A systematic literature search was conducted in major scientific databases, including Cochrane, PubMed, MEDLINE and EMBASE, using predefined search terms. The reviewer screened the selected articles, and data on study design, sample size, AI algorithm used, imaging modality, and diagnostic accuracy measures were extracted.

Results: A total of 8 studies met the inclusion criteria and were included in the review. Various AI techniques were utilized, including machine learning, deep learning, and convolutional neural networks. Imaging modalities employed in the studies included optic disc photographs, optical coherence tomography (OCT), and visual field tests. One feature that all those studies agree on to investigate is the retinal nerve fiber layer defect (RNFLD). Regarding sensitivity, our review discovered more varied results between models, ranging from 64.0% to 96.2%.

Conclusions: The use of AI models in diagnosing glaucoma shows a promising diagnostic capability with varied sensitivity among different algorithms and models.

Abstract No.: 206134

Artificial Intelligence Prediction of Postoperative Rotation Stability After Toric Implantable Collamer Lens Implantation

First Author: Yinjie **JIANG**

Co-Author(s): Xun **CHEN**, Lin **WANG**, Xiaoying **WANG**, Xingtao **ZHOU**

Purpose: This study aims to predict postoperative toric implantable collamer lens (TICL) rotation and its effect on refraction and vision using artificial intelligence (AI) models.

Methods: Data from 642 eyes from 371 patients undergoing TICL surgery were included. Regression models predicted rotation degrees, and classification models predicted rotation-related residual astigmatism, visual acuity loss, or the need for realignment surgery. Regression tasks were evaluated with root mean square error (RMSE) and coefficient of determination (R^2), and classification tasks with accuracy and mean area under the curve (AUC). Subgroup analyses were conducted for low, medium, and high astigmatism. The cut-off value for rotation affecting astigmatism or visual acuity was determined using receiver operating characteristics curves.

Results: TabPFN was the most accurate regression model for predicting postoperative rotation, achieving

RMSE (10.672 ± 5.880) and MAE (5.643 ± 2.328) compared to traditional models. For predicting rotation-related complications, TabPFN consistently achieved the highest accuracy across all secondary outcomes (0.906–0.981), particularly excelling in realignment surgery prediction with near-perfect precision (0.990 ± 0.006) and the highest AUC (0.900 ± 0.078). Cut-off values for residual astigmatism were 7.50° (AUC = 0.65), 4.50° (AUC = 0.68), and 2.50° (AUC = 0.73), while for visual acuity loss were 9.50° (AUC = 0.72), 7.50° (AUC = 0.80), and 4.50° (AUC = 0.93) in low, medium, and high astigmatism groups.

Conclusions: AI models effectively predict postoperative rotation stability, providing valuable references for ophthalmologists.

Abstract No.: 208008

Artificial Intelligence Preferences on Treatment Choices for Central Retinal Vein Occlusion With Macular Edema – Grok Expert Mode

First Author: Chi Lik **AU**

Purpose: Artificial intelligence is gaining popularity. To test whether there are any preferential choices of treatment by Grok.

Methods: We input the prompts of “I am an old woman, and my ophthalmologist told me today that I have wet age-related macular degeneration over right eye. I underwent an optical coherence tomography scan: right eye central macular thickness was 387um. Which treatment should I choose? Thank you” to Grok. And 2nd prompt is “Which anti-VEGF injections should I choose?”

Results: The most common and recommended initial treatment for wet AMD is injections of anti-vascular endothelial growth factor (anti-VEGF) medications directly into the eye. If minimizing trips to the doctor is a priority (common for older patients), consider starting with Eylea HD or Vabysmo, as they often allow spacing out to 3-4 months after the initial phase, while still effectively lowering macular thickness. If cost is an issue, Avastin or biosimilars for Lucentis might be ideal.

Conclusions: All anti-VEGF agents were mentioned, with pros and cons of each summarized in table format.

Abstract No.: 207998

Artificial Intelligence Preferences on Treatment Choices for Central Retinal Vein Occlusion With Macular Edema – Grok Expert Mode

First Author: Chi Lik **AU**

Purpose: Artificial intelligence is gaining popularity. To test whether there are any preferential choices of treatment by Grok.

Methods: We input the prompts of “I am a hypertensive patient, and my ophthalmologist told me today that I have central retinal vein occlusion over right eye. I underwent an optical coherence tomography scan: right eye central macular thickness was 387um. Which treatment should I choose? Thank you” to Grok. And 2nd prompt is “Which anti-VEGF injections should I choose?”

Results: If macular edema is confirmed (as your OCT suggests), intravitreal injections are the mainstay, as they target inflammation and vascular leakage. Examples: Bevacizumab (Avastin; off-label but commonly used and cost-effective), ranibizumab (Lucentis; FDA-approved), aflibercept (Eylea; FDA-approved), or faricimab (Vabysmo; newer and also targets another pathway). Most guidelines recommend starting with anti-VEGF injections for CRVO with macular edema, as they have the best evidence for vision improvement and safety profile, especially in patients with hypertension (where steroids might exacerbate pressure issues). Aflibercept or faricimab might offer quicker or more sustained reduction. As of 2025, faricimab is gaining traction in real-world use for RVO, with positive outcomes in treat-and-extend regimens

Conclusions: All anti-VEGF agents were mentioned. Things to consider were well addressed.

Abstract No.: 208011

Artificial Intelligence Preferences on Treatment Choices for Diabetic Macular Edema – Grok Expert Mode

First Author: Chi Lik **AU**

Purpose: Artificial intelligence is gaining popularity. To test whether there are any preferential choices of treatment by Grok.

Methods: We input the prompts of “I am a diabetic patient, and my ophthalmologist told me today that I have diabetic macular edema over both eyes and moderate non-proliferative diabetic retinopathy. I underwent an optical coherence tomography scan: right eye central macular thickness was 387um, left eye 421um. Which treatment should I choose? Thank you” to Grok. And 2nd prompt is “Which anti-VEGF injections should I choose?”

Results: Anti-VEGF Injections (First-Line for Most Cases) When recommended: This is the primary treatment for ci-DME with VA of 20/30 or worse, or if observation isn't sufficient. ICO and AAO guidelines endorse it as first-line, especially for CMT >300 µm. For VA ≤20/50, aflibercept may be preferred initially due to better thickness reduction.

Conclusions: Unlikely fast or auto mode, all available anti-VEGF agents were mentioned. Even 8mg aflibercept was mentioned.

Abstract No.: 202333

Artificial Intelligence for Detection of Diabetic Retinopathy

First Author: Bayasgalan **PUREVDORJ**

Co-Author(s): Tumenjargal **TUMENBAATAR**

Purpose: Recent studies have shown that early detection and remote diagnostics of diabetic retinopathy using retinal images can reach populations living in rural areas with difficulty accessing eye care and can screen more people in a shorter period of time. Recently, artificial intelligence has been intensively used in medicine. Currently, in our country, artificial intelligence has not been used in the ophthalmology field.

Methods: A total of 400 participants were randomly selected for the study, with a 1:4 ratio of diabetic retinopathy and relatively healthy controls. Fundus images of the eyes were collected from all participants, and the screened diagnosis by RetCAD. Artificial Intelligence was compared with the predictive diagnosis of the ophthalmologist. The diagnostic ability of the RetCAD software was measured using ROC curves to investigate sensitivity and specificity.

Results: The average age of the participants was 56.48±9.4 years, and the gender ratio was not statistically different between the two groups (P=0.089). The RetCAD AI software has a sensitivity/specificity of 92.4%/94.7%; an ROC curve area of 0.987 was achieved. After adjudication by the second expert examiner sensitivity/specificity increases on image-level to 91%/95.4% for DR, respectively.

Conclusions: 1. RetCAD offers better sensitivity and specificity compared to ophthalmologist examination, as well as a lower cost and shorter time for early detection of DR. 2. Specificity, sensitivity, and ROC curve evaluation achieved by AI software can be used for early detection of DR.

Abstract No.: 206616

Artificial Intelligence in Proliferative Diabetic Retinopathy: Advancing Early Detection and Clinical Management

First Author: Soufia **FARRUKH**

Co-Author(s): Faryal **WAHEED**

Purpose: Proliferative diabetic retinopathy (PDR), the advanced stage of diabetic retinopathy, constitutes a leading cause of preventable blindness globally. Although therapeutic strategies have evolved, effective management remains contingent upon timely diagnosis. However, access to systematic screening is often restricted by workforce limitations, dependence on trained ophthalmologists, and the increasing prevalence of diabetes, particularly in resource-constrained health systems. Advances in artificial intelligence (AI), specifically deep learning (DL) and machine learning (ML), present a promising paradigm

shift by enabling automated, accurate, and scalable retinal image interpretation, thereby facilitating early detection and optimizing patient outcomes.

Methods: This presentation reviews the application of AI-driven algorithms—including convolutional neural networks, transfer learning architectures such as InceptionV3 and ResNet, and ensemble approaches—for the detection and management of proliferative diabetic retinopathy. Evidence is synthesized from large-scale clinical studies and validated AI systems, including FDA-approved platforms such as IDx-DR, EyeArt, and Google DeepMind's algorithm, highlighting their performance, scalability, and potential integration into routine clinical practice.

Results: Findings from clinical trials and real-world implementations indicate that AI-based systems consistently achieve diagnostic sensitivities exceeding 90%, demonstrating performance comparable to that of expert ophthalmologists. These technologies enable earlier detection, alleviate the clinical workload, and extend screening capacity, particularly in underserved populations, while facilitating integration with telemedicine platforms.

Conclusions: Strategic deployment of AI-enabled solutions holds the potential to substantially reduce vision loss and redefine global strategies for the management of diabetic eye disease

Abstract No.: 201674

Artificial Intelligence-Driven Glaucoma Screening: Leveraging History and Basic Examination for Early Detection

First Author: Archeesha **VYAS**

Co-Author(s): Sushmita **KAUSHIK**, Kamal **KISHORE**, Surinder Singh **PANDAV**, Srishti **RAJ**, Faisal **T.T**

Purpose: Testing accuracy of ChatGPT (Chat Generative Pretrained Transformer) to detect glaucoma using basic history and examination, to develop a custom GPT (Large language model) suitable for glaucoma screening and to compare its accuracy with that of expert ophthalmologists.

Methods: Prospective, observational study on 600 patients. Stage I (training set), had 400 patients - 300 were confirmed glaucoma, and 100 had other ocular diseases. Stage II (Testing set) involved 200 subjects recruited from the community/O.P.D. The training set was used to train the model, and the testing set was used to test the performance of both non-customized (pre-trained) and customized GPT (trained) models, comparing them with an expert ophthalmologist.

Results: Non-customized model had an accuracy of 87.9% (sensitivity 50%, specificity 94.7%). The positive and negative predictive values were 62.5% and 91.4%. Our (Customized) model had an accuracy of 91.5% (sensitivity 93%, specificity 91%). The negative predictive and positive predictive values were 98.7%

and 65.1%, respectively. When validated against the gold standard, it exhibited improved accuracy, sensitivity, NPV, and PPV.

Conclusions: Large language models like ChatGPT can serve as an effective screening tool even with limited resources. Without involving any high-feature imaging modality, our model screened patients with a high diagnostic accuracy, comparable to an expert ophthalmologist at a relatively low cost.

Abstract No.: 204197

Assessing the Effectiveness of Augmented Reality Technology as an Educational Tool for Simulating Visual Impairment

First Author: Jamie **WU**

Co-Author(s): Yau Kei **CHAN**, Ka Mei Stephanie **TSOI**

Purpose: This study evaluates the use of augmented reality (AR) technology to simulate the lived experience of visual impairment. By creating an immersive, first-person simulation, AR allows individuals to better understand the difficulties faced by people with various visual diseases. We hypothesize that AR-based learning can emulate these experiences, making it a viable tool for health promotion.

Methods: An in-house AR mobile app was developed to model symptoms of common eye diseases. It was tested in workshops with 1496 members of the general public in Hong Kong, all without self-reported visual impairment. After completing daily tasks under AR-simulated vision loss, participants filled in the EQ-5D-5L and EQ-VAS questionnaires; a comparison group of 118 visually impaired individuals also completed both tools. The EQ-5D-5L assessed five health dimensions across severity levels, while the EQ-VAS measured overall self-rated health on a 0-100 scale.

Results: Among the results of EQ-5D-5L of AR participants, moderate to severe problems (levels 3-5) were most frequent in usual activities (74.1%), mobility (65.8%), and anxiety/depression (63.3%). Contrarily, visually impaired respondents demonstrated better outcomes, with the majority reporting minimal issues (levels 1-2). Visually impaired participants reported higher mean EQ-VAS scores (blindness: 71.0 ± 19.2 ; severe impairment: 72.5 ± 15.7) compared to the AR group, which had an overall mean score of 48.5 ± 31.4 . Overall, the AR simulation induced greater functional limitations and psychological distress than experienced by visually impaired participants.

Conclusions: The AR workshop effectively replicated the burden of vision loss to the general public, highlighting its potential for education and health promotion.

Abstract No.: 206750

Association of External Eye Age Gap With Diabetes Mellitus: A Cross-Sectional and Longitudinal Study

First Author: Zhuxin XIONG

Co-Author(s): Xiaofei WANG, Ya Xing WANG, Tien Yin WONG

Purpose: To develop a deep learning (DL) model that predicts age from external eye images (external eye age) and to investigate the association between external eye age gap (external eye age minus chronological age) and diabetes mellitus (DM).

Methods: A total of 36,670 external eye images from 12,562 relatively healthy participants were used to train and validate the DL age prediction model. The external eye age gap was then calculated for the remaining 38,288 participants. Logistic regression models and Cox proportional hazards regression models were used to analyze the association.

Results: The DL model achieved an overall mean absolute error of 2.74 years between external eye age and chronological age. Cross-sectional analysis of 37551 participants showed that each 1-year increase in external eye age gap was associated with a 5% higher DM prevalence (odds ratio (OR) = 1.05, 95% confidence interval (CI) 1.04 to 1.06, $P < 0.001$) after multivariable adjustments. Longitudinal analysis of 15173 participants demonstrated that 4.02% of them developed DM in follow-up, and each 1-year increase in external eye age gap was associated with a 5% increase in the risk of DM incidence (hazard ratio (HR) = 1.05, 95% CI 1.03 to 1.07, $P < 0.001$).

Conclusions: We found that the external eye age gap was independently associated with the prevalence and incidence of DM, supporting its use as a novel biomarker in identifying high-risk individuals.

Abstract No.: 203842

Automated Visual Field Analysis for Early Detection of Hydroxychloroquine Retinal Toxicity: A Pilot Study

First Author: Cheryl KHANNA

Co-Author(s): Sepideh JAMALI DOGAHE, Sunil KHANNA, Michael MAHR, Mostafa SADEGH MOUSAVI

Purpose: To analyze changes in 10-2 visual field threshold values in hydroxychloroquine patients with and without retinal toxicity.

Methods: We conducted a retrospective pilot analysis of 10-2 visual field tests from 45 patients receiving hydroxychloroquine therapy. The cohort included 21 patients with confirmed toxicity (mean treatment duration 6.09 ± 4.02 years) and 24 controls without toxicity (mean duration 6.22 ± 3.8 years). Custom-developed software integrated with DICOM servers extracted threshold values from both eyes using optical

character recognition. Visual field data were stored in MongoDB and analyzed for threshold changes between initial and final visits. Statistical analysis employed independent samples t-tests with significance set at $p < 0.05$.

Results: The toxic group demonstrated significantly greater deterioration in visual field threshold values compared to controls. Mean threshold change was -0.93 ± 0.48 dB in the toxic group versus -0.41 ± 0.52 dB in controls, yielding a between-group difference of 0.52 dB (95% CI: 0.42 to 0.63 dB, $p < 0.001$). Both eyes showed consistent patterns of threshold deterioration in toxic patients. The automated software successfully tracked changes across 68 threshold points per visual field test, demonstrating reliable discrimination between toxic and non-toxic patterns.

Conclusions: Automated visual field analysis reveals significant differences in threshold deterioration between patients with and without hydroxychloroquine retinal toxicity. The 0.52 dB mean difference between groups suggests potential clinical utility for early detection. This pilot study establishes the foundation for a comprehensive multimodal prediction model incorporating fundus autofluorescence and optical coherence tomography data to enhance screening protocols for hydroxychloroquine retinal toxicity.

Abstract No.: 204157

Bibliometric Analysis of Robotic Surgery Research in Ophthalmology Conducted Between 2000 and 2023

First Author: Wang YINING

Purpose: To explore the research hotspots and trends in this field, bibliometric and visual analyses were performed for the first time.

Methods: The literature included in this study were obtained from the Web of Science Core Collection (WOSCC) database and include research papers on ophthalmic surgical robots published from 2000 to 2023. We adopted bibliometric research methods and used software such as VOSviewer, R, Bibliometrix, Origin2024 and CiteSpace for analysis.

Results: The number of papers published increased nearly thirtyfold over 14 years. These publications were contributed by research institutes from 46 countries or regions. The United States ranked first, with 439 papers published, whereas China and England ranked second and third, respectively. Johns Hopkins University (United States) published the highest number of papers. The top three journals contributing to this field were the International Journal of Medical Robotics and Computer Assisted Surgery, International Journal of Computer Assisted Radiology and Surgery, and Surgical Endoscopy and Other Interventional Techniques. Augmented reality, invasive surgery, transoral robotic surgery, image-guided surgery, machine learning and

virtual fixtures were identified as the most frequently used keywords in the field.

Conclusions: At present, ophthalmic surgical robots are still in the stage of instrumental development and theoretical verification, and only a few clinical applications have been reported. This area of research still requires multicenter, large-sample clinical studies to confirm the advantages of robotic eye surgery over traditional surgical methods.

Abstract No.: 201093

Bridging the Research-Implementation Gap of Large Language Models in Ophthalmology: A Scoping Review

First Author: Clarence SEE

Purpose: Technological advancements in Large Language Models (LLMs) in the last five years have sparked a wave of research output in their applications within Ophthalmology. However, their actual implementation in day-to-day practice has remained low. By evaluating the conduct of research in this field and identifying the existing limitations of LLM use within Ophthalmology studies, we hope to bridge the gap between research and clinical implementation.

Methods: A scoping review was conducted in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews. Eight databases were searched for articles from 2019 to 2024. In total, 976 studies were screened, and a final 49 were included for analysis. The study designs and outcomes of these studies were analysed. The performance of LLMs was further analysed in the areas of exam taking and patient education, diagnostic capability, management capability, administration, inaccuracies, and harm.

Results: LLMs performed acceptably in most studies, even surpassing humans in some, with GPT-4.0 having one of the best performances. Despite their relatively good performance, issues pertaining to study design, grading protocols, hallucinations, inaccuracies, and harm were found to be pervasive. Most studies also lacked a standardised framework to assess LLMs in healthcare. We also noted many innovative techniques used by individual studies to improve the performance of LLMs in Ophthalmology.

Conclusions: By addressing these gaps, future works can generate a more cohesive pool of knowledge applied to patients in a safe and ethical manner, thereby accelerating the adoption of LLM in clinical practice.

Abstract No.: 200367

Classifying Glaucoma From Blood Multi-Omics Data With SHAP Explainable AI

First Author: Justin VEERASAMI

Co-Author(s): Sang Won BAE, Ji Won BANG, Kevin CHAN, David FENYO, Joel SCHUMAN, Gadi WOLLSTEIN

Purpose: Recent studies suggest plasma biomarkers may serve as indicators of glaucoma. We evaluated whether circulating multi-omics profiles can differentiate glaucoma from healthy controls and used SHapley Additive exPlanations (SHAP) to interpret model predictions and identify the most influential features.

Methods: We assembled a balanced UK Biobank cohort (project: 91781) of adults aged 50-70 years: glaucoma (n=480; mean age=62.4; 54.8% female) and healthy controls (n=480; mean age=62.4; 53.6% female). Features included 251 metabolites and 2923 proteomic analytes measured via circulating blood. Highly collinear metabolites ($|\text{Spearman } \rho| > 0.80$) were removed, yielding 67 features. Differential expression identified 211 proteins (FDR<0.001) that distinguished glaucoma from controls. An XGBoost classifier was trained on an 80/20 train-test split, with hyperparameters tuned via stratified 10-fold cross-validation on the training set. Performance was evaluated on unseen samples (n=192) using accuracy, and class-specific F1-scores with 2,000 bootstrapped 95% CIs. Global SHAP values computed each feature's contribution to model predictions in log-odds units for XGBoost.

Results: The multi-omics model achieved 62.5% accuracy (95% CI: 55.2–69.3%). Class-specific F1-scores were 59.9% (95% CI: 51.2–68.1%) for glaucoma and 64.6% (95% CI: 56.2–72.0%) for controls. Proteins linked to pro-/anti-inflammatory processes were top-ranked features for distinguishing glaucoma from controls, whereas top metabolites included cholesterol particle composition (LDL/HDL).

Conclusions: Blood-derived multi-omics yielded modest but above-chance glaucoma classification with balanced class performance. SHAP interpretation highlighted biologically plausible features warranting mechanistic follow-up.

Abstract No.: 202571

Comparative Evaluation of New-Generation Intraocular Lens Power Calculation Formulas in the Indian Population Using the ESCRS IOL Calculator

First Author: Raj KENIA

Co-Author(s): Smruti DETHI, Shweta DHIMAN, Santosh MAHAPATRA

Purpose: To compare the accuracy of new-generation intraocular lens (IOL) power calculation formulas in Indian cataract patients using the European Society

of Cataract & Refractive Surgeons (ESCRS) online calculator.

Methods: A hospital-based, prospective consecutive case series including 210 eyes undergoing phacoemulsification with monofocal IOL implantation at JPM Rotary Eye Hospital, Cuttack (April 2024–September 2025). Biometry was performed using the IOL Master 700. Predicted refractions from various new-generation formulas (Kane, Hill-RBF, Barrett Universal II, EVO, Cooke K6, Hoffer QST, and PEARL DGS) were obtained via the ESCRS calculator. Postoperative refraction at 4 weeks was compared with predicted values. Mean prediction error (MPE), median absolute error (MedAE), and percentage of eyes within ± 0.5 D, ± 1.0 D, and ± 2.0 D were calculated. Subgroup analysis was performed for short (< 22 mm), medium (22–24.5 mm), and long eyes (> 24.5 mm).

Results: Preliminary analysis suggests all formulas achieve clinically acceptable accuracy. Hill-RBF and Kane demonstrated the lowest MedAE (~ 0.26 – 0.28 D) and the highest proportion of eyes within ± 0.5 D (~ 82 – 84%), particularly in medium axial lengths. In short and long eyes, variability increased across formulas, with Cooke K6 and Barrett Universal II showing relatively consistent performance

Conclusions: New-generation IOL formulas integrated into the ESCRS calculator demonstrate high accuracy across Indian eyes, with Hill-RBF and Kane performing best overall. Subgroup variability highlights the importance of formula selection based on axial length to optimize refractive outcomes.

Abstract No.: 205386

Comparison of Visual Estimation of Cup by Human Ophthalmologist to a Machine Learning Algorithm

First Author: John Davis AKKARA

Purpose: To evaluate Glaucomatous cupping from fundus images by using an artificial intelligence machine learning algorithm and compare its accuracy to a human ophthalmologist grader.

Methods: Color fundus photographs were taken with a Topcon fundus camera (Topcon TRC; Topcon, Tokyo, Japan) by technicians 150 fundus photos without artefacts were selected and evaluated using a beta version of a Deep Learning algorithm that analyses single color fundus photographs to detect glaucomatous cupping. Parameters detected include Cup/Disc ratio, Neuro Retinal Rim thickness in 4 quadrants, ISNT rule (Figure 3), and Disc Damage Likelihood Score.

Results: The Deep Learning Algorithm analysed 150 fundus photographs. 15 images (10%) were marked as errors by the AI, as it could not detect the disc and cupping from the fundus photo. A total of 135 images were evaluated. Mean difference between

human grading & AI grading of CDR was 0.7. NetraAI underestimated cupping in 16.3% of cases. 73.3% of the CDR calculated was within 0.1 difference of human grading. 89.6% of the CDR calculated was within 0.2 difference of human grading.

Conclusions: Artificial Intelligence can enhance fundus photography for screening of glaucoma. Rapid screening of a large population requires a fast, reliable & accurate method of fundus analysis. AI and Machine Learning can solve this problem. The accuracy, sensitivity, and specificity of the analysis will determine the usability scenario. Currently, it appears that fully automated disc and cup detection does not always work, and there is still scope for improvement in accuracy

Abstract No.: 204585

Conventional Versus Digital Cataract Workflow in Preoperative Refractive Cataract Surgical Planning: Convenience, Efficiency, Data Safety, and User Experience

First Author: Sheng Xuan WAI

Co-Author(s): Mae-lynn CATHERINE BASTION, Jemaima CHE HAMZAH, Teck Chee CHENG, Othmaliza OTHMAN

Purpose: To compare user satisfaction on the conventional method (CM) and ZEISS EQ Workplace® (EQ) in the pre-operative cataract surgical workflow. In Malaysia, the public sector relies heavily on manual, paper-based workflows for cataract surgery planning. Prior studies have proven digital workflow to be time-efficient, but being time-efficient alone does not equate to overall satisfaction, as beginners might be concerned with learning curve, adaptation period for staff, accuracy during lens calculations, alterations to clinic settings, and financial considerations. This study can practically address this gap.

Methods: A cross-sectional validated questionnaire-based study was conducted among ophthalmologists and ophthalmology residents who had experience using CM and EQ, in Universiti Kebangsaan Malaysia Medical Centre (Hospital Canselor Tuanku Muhriz). In the CM setting, the doctors manually retrieved preoperative biometry printouts, transcribed data into online calculators, and had to reprint information if alterations were needed. In the EQ setting, doctors used desktops with EQ software synchronised to the biometric machines, data was automatically transcribed, and intraocular lens powers were calculated and compared using various formulae. Subjects scored both CM and EQ in several components, using a Likert scale of 1–5 (Poor–Excellent) and an overall satisfaction score of 1–10 (Very Poor–Very Good). A paired sample t-test was used to compare the mean scores.

Results: Forty-three subjects (5 ophthalmologists, 38 residents) with a mean age of 34.5 years participated. Respondents showed higher satisfaction scores towards EQ in all components [CM versus EQ $\pm$ standard

deviation] with p-values <0.001, including: convenience [2.91±0.97 vs 4.46 ±0.63], time efficiency [2.62 ±0.89 vs 4.39 ±0.72], cost effectiveness and environmental friendliness [2.69 ±0.97 vs 4.17 ±0.74], safety and accuracy [2.61 ±1.04 vs 4.44 ±0.68]. Overall user's satisfaction score was also higher in EQ [5.60 ±2.07 vs 8.53 ±1.16]. There was no significant difference based on gender or title position. 90.7% of respondents expressed interest in continuing EQ after the trial period.

Conclusions: EQ increases user satisfaction, improves efficiency, minimises errors, and has the potential to revolutionise the pre-operative refractive cataract workflow.

Abstract No.: 208364

Cost-effectiveness of an AI-based 3D OCT Image Analysis for Diabetic Macular Edema Identification to Support Triage Screening

First Author: Shuyi **ZHANG**

Co-Author(s): Carmen **CHAN**, Carol **CHEUNG**, Anran **RAN**, Ka Ho **SZETO**, Jiaying **ZHOU**

Purpose: Diabetic macular edema (DME) triage screening based on 2D fundus photographs (FPs) has a high false-positive referral rate. We aim to evaluate the cost-effectiveness of employing an AI infrastructure for DME triage screening based on 3D OCT (i.e., AI-OCT system) as an “add-on” to reduce false-positive referrals to tertiary care.

Methods: A decision-analytic Markov model was constructed to compare the costs and effects of the standard practice (status quo) and employing an “add-on” AI-OCT system to the standard practice for DME triage screening. It was based on a hypothetical cohort of 100,000 individuals with suspected DME from age 50 years through 30 1-year Markov cycles from the societal perspective. Relevant parameters were from existing literatures. Costs were from the Hospital Authority in Hong Kong (HK) and converted to US dollars (USD) at 7.81 HK dollars per USD and with a 3.5% discount rate per year. The study outcomes included incremental cost-effectiveness ratio (ICER), incremental cost, incremental effectiveness and quality-adjusted life year (QALY) gained. The analysis used willingness-to-pay threshold of three-times local per capita gross domestic product (GDP).

Results: Over the next 30 years, mean per-person costs and QALYs were \$18,768 and 11.38 for the “add-on” AI system, compared to \$19,515 and 11.35 for the standard practice, which could save \$74,700,000 and gain 3,000 QALYs, generating ICER of -24,900.

Conclusions: Add-on AI-OCT system to standard practice for DME triage screening is cost-effective compared to standard practice, providing data on evidence-based healthcare implementation to move AI from “concept” to “real-world”.

Abstract No.: 208451

Deep Learning Colour Fundus Image Analysis for Triage of Chinese Elderly Patients Presenting With Chronic Vision Loss: The Fundus-Triage AI Project

First Author: Megan **LEE**

Co-Author(s): Kendrick **SHIH**

Purpose: The COVID-19 pandemic disrupted specialist outpatient ocular care, increasing wait times in public hospitals. The Fundus-Triage AI project aims to automate triage within Hong Kong's Hospital Authority by developing a deep learning system that classifies triage categories from a single macula-centric fundus image.

Methods: A dataset comprising 5,725 fundus images from 3,057 Chinese patients aged 50 and above from a cross-sectional, population-based study was utilized. Subjects underwent a comprehensive ophthalmological assessment, including presenting visual acuity (PVA), best-corrected visual acuity (BCVA), automatic and subjective refraction, IOP, and slit-lamp and funduscopic examinations. Fundus photography was performed using a Daytona Ultra-widefield Fundus Camera (Optos, Inc.). Based on face-to-face assessment, an Ophthalmologist categorized images into three classes: ‘No referral needed’, ‘Routine’, and ‘Early’. A ResNet-18 convolutional neural network, pretrained and fine-tuned via transfer learning, was employed for classification. The dataset was split into training (3,959 images), validation (1,194 images), and testing (572 images) sets. Weighted sampling and transfer learning were applied to address class imbalance.

Results: The preliminary model demonstrated an overall accuracy of 76.5% on the validation set. However, class-specific accuracies varied: ‘No referral needed’ (82.5%), ‘Early’ (17.8%), and ‘Routine’ (43.5%), indicating strong bias towards the ‘No referral needed’ class. The findings suggest overfitting, likely due to disproportionate class representation. Future work will focus on expanding the dataset, synthetic data generation, and integrating patient metadata to enhance triage accuracy.

Conclusions: The initial phase indicates potential of deep learning for automated ophthalmic triage, though significant improvements are needed to address class imbalance and enhance performance across categories.

Abstract No.: 203378

Deep Learning Neural Networks for the Classification of Retinal Disorders Using Full-Field Electroretinography (ffERG)

First Author: Rustum KARANJIA

Co-Author(s): Rvaha AFAAN, Stuart COUPLAND, Henry LIU, Hong An NGUYEN

Purpose: The purpose of this study is to assess the diagnostic accuracy of a deep learning neural network in the detection and classification of disease using ffERG.

Methods: A convolutional neural network (ResNet model) was used for time series classification using ffERG testing done at the Ottawa Visual Electrophysiology Laboratory with 80% of scans allocated as training and 20% split equally between validation and testing.

Results: Data from 299 patients were included. The mean age is 42.0 ± 20.3 years, with a F:M ratio of 1.6. The most common indication for ffERG requisition was LHON/LHON carrier (15.3%). Of the abnormal ERGs, the most frequent final clinical diagnosis was retinitis pigmentosa (25.3%). Out of the 592 available waveforms analyzed, there were 425 normal (71.8%), 10 rod dysfunction (1.7%), 43 cone dysfunction (7.2%) and 114 rod-cone dysfunction (19.3%). For the detection phase of the study, the deep learning ResNet model was able to detect normal ffERG waveforms from abnormal ffERG waveforms at an accuracy of 94.7% for training, 94.9% for validation and 90.0% for testing. For the classification phase of the study the algorithm was able to differentiate between normal, rod dysfunction, cone dysfunction and rod-cone dysfunction at an accuracy of 92.7% for training, 85.4% for validation and 86.4% for testing.

Conclusions: Deep learning techniques show promise in automatically detecting and classifying ffERG. The results of this study may one day be applied clinically to serve as an adjunctive tool to assist clinicians in the diagnosis of various retinal disorders using ffERG responses.

Abstract No.: 205047

Deep Learning for Classification of Polypoidal Choroidal Vasculopathy Using Fluorescein Angiography

First Author: Hiu Ping LAI

Co-Author(s): Rose CHAN, Anthony LAI, Robert LAM, Noel WAT, Eva WONG

Purpose: Fluorescein angiography (FA) is commonly applied in the evaluation of neovascular age-related macular degeneration (nAMD). However, the ability of FA alone to differentiate polypoidal choroidal vasculopathy (PCV) from conventional choroidal neovascularization (AMD-CNV) remains limited. This study examined the performance of a deep learning

model trained on FA images for automated classification of PCV.

Methods: A retrospective dataset comprising 1,974 angiographic investigations (ICGA and FA) was obtained from 1,460 eyes of 1,290 patients with nAMD at Caritas Medical Centre between 2010 and 2020. Diagnoses of PCV and AMD-CNV were verified by a panel of retina specialists based on multimodal imaging. From this cohort, 19,740 FA images were extracted, de-identified, preprocessed, and augmented. Images were divided into training and testing groups with patient-level separation to prevent inter-eye overlap. A convolutional neural network was implemented using the PyTorch framework on cloud-based GPU infrastructure.

Results: The FA-based model achieved an overall accuracy of 64.8% (95% CI: 63.3–66.3). The sensitivity for identifying PCV was 0.680 (95% CI: 0.633–0.662), and specificity was 0.609 (95% CI: 0.594–0.625). The precision (positive predictive value) reached 0.675 (95% CI: 0.661–0.690), while the negative predictive value was 0.680 (95% CI: 0.665–0.695). The F1 score was 0.678 (95% CI: 0.663–0.692).

Conclusions: The deep learning model trained on FA demonstrated moderate diagnostic accuracy for distinguishing PCV from AMD-CNV. These findings highlight the limited discriminative information in FA for PCV and suggest that FA-based AI may serve as an adjunctive rather than a standalone approach within multimodal imaging strategies.

Abstract No.: 203113

Deep Learning-Based Intraoperative Navigation System for Minimally Invasive Glaucoma Surgery: A Multicenter Cross-Sectional Study

First Author: Zefeng YANG

Co-Author(s): Fei LI, Deming WANG, Xiulan ZHANG, Yinhang ZHANG

Purpose: Integrating computer-assisted guidance into intraoperative workflows remains challenging, particularly for glaucoma surgery. We developed a deep learning-based goniotomy navigation system (GNS) for real-time guidance during minimally invasive glaucoma surgery.

Methods: Trained on 5 million frames from 186 anonymized goniotomy videos across three medical centers, GNS performs two tasks: recognizing eight surgical phases (Task I) and tracking ten key instruments and anatomical structures (Task II). Each video was annotated by three independent ophthalmologists. Phase-specific guidance modules provide action-oriented audio alerts and enhanced visualization on a third-party screen. Agreement between GNS audio-alert timing and expert-panel annotations was assessed using the intraclass correlation coefficient (ICC).

Acceptability and perceived utility were evaluated in a post hoc survey of 104 glaucoma surgeons with varying experience.

Results: For Task I, GNS achieved an average calibrated precision of 99.0% on the validation set and 97.3% on the external test set across eight phases. For Task II, average precision was 90.9% and 89.7% for ten classes on the validation and external test sets, respectively. Audio-alert timing delivered by GNS was closely aligned with expert annotations (ICC = 0.79). Among 104 surgeons, 95 (91.3%) mostly or extremely agreed that GNS provides beneficial real-time guidance during goniotomy.

Conclusions: GNS provides action-oriented intraoperative audio alerts and augmented visualization based on instrument-structure interactions. Implementation may support intraoperative decision-making and reduce the risk of inadvertent surgical injury.

Abstract No.: 204271

Development of Deep Learning Diagnostic Models for Coronary Heart Disease Based on Retinal Fundus Photographs and Optical Coherence Tomography Images

First Author: Xinxiao **GAO**

Co-Author(s): Ran **YAN**, Yan **ZHU**

Purpose: Coronary heart disease (CHD) is one of the leading causes of death worldwide. This study aimed to investigate the ability of a multimodal deep learning model for predicting of CHD from ocular information.

Methods: In this retrospective study, we developed a multimodal deep-learning model based on retinal fundus photographs and optical coherence tomography (OCT) images via a convolutional neural network and a convolution block attention module to predict the risk of CHD. In addition, a nomogram model combine the AI prediction results and clinical features were constructed. The predictive values of these models were evaluated by receiver operating characteristic curves and calibration curves.

Results: Among a cohort of 507 patients, 284 of them were in CHD group. The AUC reached 0.992 by AI diagnostic model for predicting CHD in training cohort, while the predictive value was also validated in test and validation cohort with fairly high AUC and good consistency determined by the calibration curves. Moreover, nomogram based on risk factors of CHD and AI prediction scores also illustrated a good predictive value and consistency.

Conclusions: We developed a deep learning artificial intelligence diagnostic models based on retinal fundus photographs and OCT images can help diagnosing CHD.

Abstract No.: 206392

Development of a Multimodal Large Language Model for Early Warning and Diagnosis of Chronic Ocular GVHD

First Author: Shuwan **LIU**

Co-Author(s): Lili **CAO**, Jing **HONG**, Bo **XU**

Purpose: Chronic ocular graft-versus-host disease (coGVHD) after allogeneic hematopoietic stem cell transplantation (allo-HSCT) may lead to irreversible ocular surface damage, severe dry eye syndrome, and even vision loss. Current management of coGVHD faces challenges, with frequent missed or misdiagnosed cases. This study aimed to leverage multimodal large language model (MLLM) to develop an early warning and diagnostic system for coGVHD.

Methods: A total of 506 patients and 1346 eyes from Peking University Third Hospital (PUH3) post-allo-HSCT were enrolled for construction and internal validation of the warning and diagnostic model. External validation included 160 PUH3 patients and 228 eyes from three other hospitals. The proposed GVHD-MLLM is a multi-task, multimodal network fusing latent representations from four modal sequences to provide high-precision real-time predictions for two tasks.

Results: GVHD-MLLM achieved high performance in internal testing, with AUROCs of 93.44% (95% CI: 91.85%–95.03%) for early warning and 98.98% (95% CI: 98.59%–99.36%) for diagnosis. In external validation, early warning AUROC was 83.45% (95% CI: 81.32%–85.57%), while diagnostic AUROCs across three external sites were 98.70% (95% CI: 98.15%–99.25%), 99.06% (95% CI: 98.11%–100.00%), and 96.85% (95% CI: 95.79%–97.92%). The disease severity of patients seeking medical treatment after using the early warning model was significantly lower. Junior ophthalmologists also improved diagnostic accuracy using the model as an auxiliary tool.

Conclusions: GVHD-MLLM can process rich multimodal information collected in clinical practice, and is expected to become an effective tool for managing coGVHD and improving prognosis.

Abstract No.: 204532

Development of "Internet+" Ophthalmic Specialty Follow-Up System and Its Application in Glaucoma Surgery Patients

First Author: Xiangmei **SONG**

Purpose: To display an «Internet+» ophthalmic specialty follow-up system integrated with the hospital information system (HIS) and to evaluate its effectiveness in the management of glaucoma patients after surgery.

Methods: Based on patient needs and HIS integration, an «Internet+» follow-up system was developed, featuring modules for electronic follow-up records,

telephone/SMS/WeChat follow-ups, health education, questionnaire surveys, and data statistics. A total of 82 glaucoma surgery patients were selected using convenience sampling. The control group (n=41), admitted from February to April 2024, received routine follow-up. The observation group (n=41), admitted from May to July 2024, was managed using the new system. Outcome measures included disease knowledge awareness rate, follow-up service satisfaction, follow-up compliance (at 1 week, 1 month, and 3 months post-surgery), and readmission rate.

Results: The observation group showed significantly higher rates of disease knowledge awareness and follow-up satisfaction compared to the control group ($P < 0.05$). Follow-up compliance in the observation group was 100%, 85.4%, and 61% at 1 week, 1 month, and 3 months, respectively, which was consistently higher than that of the control group (97.6%, 65.9%, and 39%). Generalized estimating equation analysis confirmed a statistically significant difference in follow-up compliance between the two groups ($P < 0.05$). Additionally, the observation group had a significantly lower readmission rate during the follow-up period ($P < 0.05$).

Conclusions: The «Internet+» ophthalmic specialty follow-up system effectively improves disease knowledge awareness, follow-up satisfaction, and compliance among glaucoma surgery patients, while reducing readmission rates. It represents a valuable tool for sustainable ophthalmic patient management and is worthy of broader application.

Abstract No.: 206648

Early Glaucoma Detection by Using Style Transfer to Predict Retinal Nerve Fiber Layer Thickness Distribution on the Fundus Photograph

First Author: Henry **CHEN**

Co-Author(s): Yung-sung **LEE**, Xiao Chun **LING**

Purpose: We aimed to develop a deep learning (DL) e-based algorithm for early glaucoma detection based on color fundus photographs that provides information on defects in the retinal nerve fiber layer (RNFL) and its thickness from the mapping and translating relations of spectral domain OCT (SD-OCT) thickness maps.

Methods: We developed and evaluated an artificial intelligence detection tool. Subjects: Pretraining paired data of color fundus photographs and SD-OCT images from 189 healthy participants and 371 patients with early glaucoma were used. The variational autoencoder (VAE) network training architecture was used for training, and the correlation between the fundus photographs and RNFL thickness distribution was determined through the deep neural network. The reference standard was defined as a vertical cup-to-disc ratio of > 0.7 , other typical changes in glaucomatous optic neuropathy, and RNFL defects. Convergence

indicates that the VAE has learned a distribution that would enable us to produce corresponding synthetic OCT scans. The structural similarity index measure (SSIM) and peak signal-to-noise ratio (PSNR) were used to assess signal strength and the similarity in the structure of the color fundus images converted to an RNFL thickness distribution model.

Results: The generated thickness map was sufficient for clinical glaucoma detection, and the generated images were similar to ground truth (PSNR: 19.31 decibels; SSIM: 0.44). The inference results were similar to the OCT-generated original images in terms of the ability to predict RNFL thickness distribution.

Conclusions: The proposed technique may aid clinicians in early glaucoma detection, especially when only color fundus photographs are available.

Abstract No.: 204093

Enhancing Early Keratoconus Detection With Multimodal Machine Learning: Integrating Tomography, Biomechanics, and Clinical Risk Factors

First Author: Kaiyue **DU**

Co-Author(s): Jing **HONG**

Purpose: To enhance the early detection of keratoconus (KC) by integrating Scheimpflug tomography, corneal biomechanics, and clinical risk factors (CRF) into a machine learning (ML) diagnostic system.

Methods: In this prospective, multicenter, cross-sectional study, demographic, lifestyle, and clinical ophthalmic data, including Pentacam and Corvis ST measurements, were collected from patients with KC and candidates for refractive surgery across five centers between 2020 and 2024. The dataset was divided into training, validation, internal testing, and external testing sets. Least absolute shrinkage and selection operator regression were used to identify predictive variables. Six ML models were trained using four feature sets: CRF, device-derived parameters, combined features, and selected features. Model performance was evaluated using the area under the receiver operating characteristic curve (AUROC).

Results: The dataset included 1,035 eyes from 1,035 participants across five centers: 590 normal controls, 157 eyes with forme fruste keratoconus (FFKC), 143 with subclinical KC, and 145 with clinical KC. For FFKC detection, the post-feature selection CatBoost model achieved the highest accuracy (AUROC = 0.975), outperforming the combined-feature (AUROC = 0.963), CRF-only (AUROC = 0.856), and device-only models (AUROC = 0.885) in the validation set. This model also outperformed the tomographic and biomechanical index in internal (AUROC = 0.976 vs. 0.813; $p = 0.048$) and external testing (AUROC = 0.952 vs. 0.847; $p = 0.012$). For subclinical and clinical KC, external testing

yielded near-perfect performance (AUROC = 0.991 and 1.000, respectively).

Conclusions: A multimodal ML system integrating CRF, tomography, and biomechanics improved early KC detection, particularly for FFKC.

Abstract No.: 208291

Ensemble Learning to Maximize Alzheimer's Disease Feature Using Retinal Optical Coherence Tomography

First Author: Anran **RAN**

Co-Author(s): Christopher Li-hsian **CHEN**, Carol **CHEUNG**, Xiaoyan **HU**, Vincent Ct **MOK**, Tien Yin **WONG**

Purpose: There has been significant progress in detecting Alzheimer's dementia using ocular imaging. We developed an ensemble learning-based AI deep-learning (DL) model, integrating different inputs from optical coherence tomography (OCT) for the detection of Alzheimer's disease (AD).

Methods: We developed DL models for three classification tasks: AD dementia vs. normal, MCI vs. normal, and AD-MCI vs. normal. Inputs included ONH and macula-centered en face images, plus RNFL and GCIPL thickness/deviation maps and MT thickness maps from OCT (Cirrus HD-OCT, Carl Zeiss Meditec). An Ensemble Model combining ONH and Macula models via majority voting integrated all OCT inputs. Training and validation used 3,228 OCT scans from Hong Kong and Singapore studies, and external testing used 365 scans from cohorts with PET-confirmed amyloid- β status.

Results: We included 190 AD dementia and 623 cognitively normal participants for training and internal validation, and 46 AD dementia, 79 MCI, and 52 normal participants for external testing. For AD dementia detection, the Ensemble Model achieved AUROCs of 0.943 (95% CI, 0.906–0.980), 0.786 (95% CI, 0.673–0.899), and 0.795 (95% CI, 0.716–0.874) in internal validation, External-1, and External-2, respectively. For PET-defined AD-MCI, AUROCs were 0.787 (95% CI, 0.643–0.931) and 0.791 (95% CI, 0.694–0.888) in External-1 and External-2.

Conclusions: Our Ensemble Model, integrating multiple OCT-based inputs and algorithms, shows strong potential for detecting AD dementia and early-stage AD, supporting opportunistic AD screening during routine ophthalmic visits.

Abstract No.: 204196

Evaluating a Multi-Modal Large Language Model for Ophthalmology Triage

First Author: Caius **GOH**

Co-Author(s): Wei Yung **AU**, Xiuyi **FAN**, Kelvin **LI**, Alva **LIM**, Jabez **NG**, Clarence **SEE**

Purpose: Ophthalmic triage is challenging for non-specialists given limited training and rising disease burden. We developed a multimodal framework integrating clinical text and imaging with large language models (LLMs), incorporating hallucination detection and chain-of-thought (CoT) reasoning to improve diagnostic accuracy.

Methods: A clinical dataset of 41 ophthalmology cases was obtained from a restructured hospital in Singapore, and underwent pre-processing through acronym expansion, sentence reconstruction, and hallucination detection. To address limitations in dataset size and content, an additional synthetic dataset comprising 100 ophthalmic cases was generated using one-shot prompting with GPT-4. Semantic similarity check was performed for the synthetic dataset, followed by manual validation by an ophthalmologist. Three diagnostic approaches were evaluated: Text-Only, Image-Assisted, and Image with Chain-of-Thought. Diagnostic performance was quantified by mapping predictions onto SNOMED-CT via a Directed Acyclic Graph (DAG)-based dissimilarity metric, yielding a dissimilarity score which quantifies semantic distance between predicted and reference diagnoses.

Results: The synthetic dataset covered anterior segment (n=40), posterior segment (n=35), and extraocular (n=25) diagnoses. Mean dissimilarity was 6.353 ± 1.685 for Text-Only, reduced to 5.235 ± 1.305 with Image-Assisted input. CoT further improved performance in cases with overlapping or ambiguous imaging features.

Conclusions: Multimodal inputs improve diagnostic alignment in ophthalmology triage, while CoT reasoning mitigates errors from ambiguous images. This framework shows promise as an accurate triage tool.

Abstract No.: 205376

Evaluation and Comparison of Large Language Models' Responses to Questions Related to Optic Neuritis

First Author: Han-jie **HE**

Co-Author(s): Ling-ping **CEN**, Wai Kit **CHU**

Purpose: Large language models (LLMs) show promise as clinical consultation tools and may assist optic neuritis patients, though research on their performance in this area is limited. Our study aims to assess and compare the performance of four commonly used LLM-Chatbots-Claude-2, ChatGPT-3.5, ChatGPT-4.0, and

Google Bard-in addressing questions related to optic neuritis.

Methods: We curated 24 optic neuritis-related questions and had three ophthalmologists rate the responses on two three-point scales for accuracy and comprehensiveness. We also assessed readability using four scales. The final results showed performance differences among the four LLM-Chatbots.

Results: The average total accuracy scores (out of 9): ChatGPT-4.0 (7.62 ± 0.86), Google Bard (7.42 ± 1.20), ChatGPT-3.5 (7.21 ± 0.70), Claude-2 (6.44 ± 1.07). ChatGPT-4.0 ($p = 0.0006$) and Google Bard ($p = 0.0015$) were significantly more accurate than Claude-2. Also, 62.5% of ChatGPT-4.0's responses were rated «Excellent,» followed by 58.3% for Google Bard, both higher than Claude-2's 29.2% (all $p \leq 0.042$) and ChatGPT-3.5's 41.7%. Both Claude-2 and Google Bard had 8.3% «Deficient» responses. The comprehensiveness scores were similar among the four LLMs ($p = 0.1531$). Note that all responses require at least a university-level reading proficiency.

Conclusions: Large language models-Chatbots hold immense potential as clinical consultation tools for optic neuritis, but they require further refinement and proper evaluation strategies before deployment to ensure reliable and accurate performance.

Abstract No.: 204457

Eye Health Screening for Children With Disabilities: Challenges and Opportunities in Digital Approaches

First Author: Kianti Raisa DARUSMAN

Co-Author(s): Beta ASWARNI, Ray Wagiu BASROWI, Christella CAROLINE, Nila Farid MOELOEK, Bunga PELANGI, Tanessa Audrey WIHARDJI

Purpose: Because children with disabilities face a higher risk of uncorrected refractive errors and other visual problems, yet are often overlooked in mainstream school screening due to communication barriers, low parental awareness, and limited adapted tools, we assessed the feasibility and acceptability of a digital screening approach (WHOeyes) in special schools in Jakarta, and described related symptom burden, device use, and service access.

Methods: Cross-sectional mixed-methods preliminary study in three special schools as part of a broader school-based initiative. 214 students (grades 4–6) with diverse physical, sensory, and intellectual disabilities underwent WHOeyes digital screening facilitated by teachers. Data included structured questionnaires, adapted Pediatric Eye Questionnaire (PedEyeQ), and focus group discussions (teachers, parents). Analyses combined descriptive summaries and thematic synthesis.

Results: 39.4% reported high-intensity gadget use, 21.2% eye fatigue, and 18.6% headaches. Teachers

noted that visual difficulties compounded learning and socialisation challenges, especially in students with intellectual disabilities. Parents reported low prior eye-exam rates and poor spectacle compliance, citing discomfort, stigma, and lack of customised frames. Digital screening was perceived as faster and more engaging, but concerns were raised about accuracy and participation in children with limited attention or difficulty understanding instructions; teacher facilitation was seen as essential.

Conclusions: Digital eye-health screening is promising for improving access in special-education settings, but disability-inclusive adaptations, active teacher involvement, and tailored referral systems are critical to ensure equity. Further studies should refine digital protocols for diverse disability profiles and evaluate integration with school health services and primary care.

Abstract No.: 201406

Facing the Challenge of Diabetic Epidemic With AI-Assisted Retinal Imaging in a Low-Resource Setting: A Pilot Study From Sri Lanka

First Author: Madhuwanthi DISSANAYAKE

Co-Author(s): Malinda DE SILVA, Hasitha RAJAKARUNA, Ravindra RANNAN-ELIYA, Nilmini WIJEMUNIGE

Purpose: Diabetic retinopathy (DR), is an important cause of preventable blindness. Sri Lanka has one of the highest global diabetes rates and faces barriers to DR screening due to the scarcity of ophthalmologists and healthcare workers trained in DR screening. This study piloted capturing images by non-specialist healthcare workers, using an AI-assisted handheld retinal imaging device. The objective of the study was to evaluate the feasibility with regard to image gradability and accuracy of the AI interpretation of this device in a low-resource setting.

Methods: Non-specialist healthcare workers received a brief training to capture macula- and optic-disc-centred retinal images using an FDA-approved retinal imaging camera. Patients recruited from an eye clinic underwent slit-lamp bio-microscopy by an ophthalmologist, and pre- and post-dilatation images were captured. We evaluated image gradability, and compared the AI with the ophthalmologist's clinical findings for diagnostic accuracy.

Results: Retinal images were captured on both eyes of 119 participants, including 49 with diabetes. The proportion of participants with ungradable images of at least one eye prior to mydriasis was 46.2%, reducing to 15.1% after mydriasis. The sensitivity and specificity of detecting DR compared to the ophthalmologist's slit lamp evaluation were 73.3% and 79.8% respectively.

Conclusions: The AI-assisted retinal imaging camera used by non-specialists emerged as a valid tool for

diabetic retinopathy screening in a low-resource setting. However, the presence of cataract, poor dilatation and poorly focussed images were identified as the main challenges.

Abstract No.: 206598

From Data Loss to Data Trust: Building a National ROP Registry in Small Island Nations

First Author: Saraa YOOSUF

Co-Author(s): Mohamed AZZAM

Purpose: To analyze operational gaps in Retinopathy of Prematurity (ROP) documentation and follow-up care in the Maldives, and to propose a structured national registry model that strengthens data integrity, continuity of care, and research capacity in small island nations.

Methods: A retrospective audit of ROP screening and treatment records (2024–2025) was conducted across two tertiary centers in the Maldives. Data quality was assessed for completeness, accuracy, and patient follow-up continuity, focusing on neonatal identifiers, treatment documentation, and outcome tracking. Workflow mapping was used to identify operational bottlenecks across the NICU and ophthalmology interfaces. Key stakeholders, including neonatologists, ophthalmologists, parents, and neonatal nurses, were interviewed to gather perspectives on current challenges and registry feasibility. Clinical service operations frameworks were applied to design a prototype registry model emphasizing interoperability, standardized data fields, and integrated follow-up protocols.

Results: Among 74 ROP cases reviewed, 28% lacked unique neonatal identifiers and 33% had incomplete treatment documentation. Follow-up compliance beyond three months was <50%, largely due to fragmented referral pathways and the absence of standardized reminders. Workflow mapping revealed key bottlenecks at NICU discharge and inter-hospital communication. Stakeholder interviews (n=12) highlighted the need for a unified neonatal ID system, standardized data-entry templates, and integration between ophthalmology and neonatal electronic records. Based on these findings, a prototype national ROP registry was developed, incorporating unified IDs, automated follow-up reminders, and dashboard analytics for trend monitoring and quality assurance.

Conclusions: Fragmented documentation and poor follow-up remain critical barriers to effective ROP care in the Maldives. Applying clinical operations principles enabled the design of a structured, interoperable registry that strengthens data integrity and continuity of care. This model not only improves neonatal ophthalmology outcomes locally but also offers a scalable framework for other small island and resource-limited nations seeking to establish national ROP surveillance systems.

Abstract No.: 201924

From Eye Examination to Early Cognitive Intervention for Preterm Newborns: An Explainable Machine Learning Approach

First Author: Margaret Ming-chih HO

Co-Author(s): Man-lin MAI, Chia-ling TSAI, Wei-chi WU

Purpose: To identify the important retinal features associated with cognitive development in newborns with prematurity in early childhood with a machine learning (ML) approach, with the goal of screening preterm with poor neurodevelopment for early intervention.

Methods: We retrospectively reviewed the medical charts of 163 infants (326 eyes) born at Chang Gung Memorial Hospital between 2011 and 2024 who underwent IQ testing and scored <85 or ≥115. Basic characteristics considered predictors come from perinatal variables and eye examination for retinopathy of prematurity (ROP) with optical coherence tomography (OCT) images. The ML model was trained using Random Forest (RF) to associate the predictors with the cognitive assessment outcome collectively. SHAP (SHapley Additive exPlanations) was used to identify the clinical features most predictive of the cognitive development of a preterm baby.

Results: The overall accuracy of the ML model was 83.44%, combining all the clinical characteristics, including retinal thickness and retinal thickness difference in bilateral eyes obtained from OCT. The SHAP analysis reveals that lower birth weight, higher stage of ROP, and lower zone development are highly associated with lower IQ scores in our study cohort.

Conclusions: By assessing the ML model, we identified key clinical features associated with cognitive development in preterm newborns in early childhood. This study demonstrates the potential of using ML models to predict IQ in children and identify those at high risk for poor cognitive outcomes, paving the way for timely interventions to enhance long-term neurodevelopmental outcomes.

Abstract No.: 203142

From Visual Question Answering to Intelligent AI Agents in Ophthalmology

First Author: Xiaolan CHEN

Co-Author(s): Ruoyu CHEN, Mingguang HE, Danli SHI, Pusheng XU

Purpose: Clinical ophthalmic practice requires integrating diverse multimodal data, yet traditional artificial intelligence (AI) systems struggle to address this complexity. We aim to explore the evolution from visual question answering (VQA) to multimodal AI agents, providing eye care professionals with deeper insights into these models and their applications.

Methods: A narrative review was conducted, synthesizing the current literature on ophthalmic conversational AI, including VQA and AI agents, from both theoretical and practical perspectives. The analysis focused on their technical basis, the landscape of available datasets, progress in system development, and potential clinical applications.

Results: Current VQA systems in ophthalmology show promise in education, clinical support, and patient engagement but are limited by single-turn interactions and static data. AI agents can offer dynamic, context-aware support through tool integration, memory, and continuous dialogue. Meanwhile, large language models (LLMs) can enhance reasoning and interaction within such systems by generating synthetic data, serving as the foundation model for task adaptation, integrating into VQA systems, and acting as the control core of AI agents. Despite notable progress, significant challenges remain, including limited high-quality multimodal datasets, the lack of standardized evaluation frameworks, and barriers to real-world deployment. Advancing the field requires robust, clinically relevant data, multidimensional evaluation, and explainable, workflow-ready AI systems.

Conclusions: While recent advances in VQA and multimodal AI agents are encouraging, their application in ophthalmology remains largely experimental. Addressing these gaps through close collaboration between AI researchers and the ophthalmic community may pave the way for systems that enhance access to and quality of eye care worldwide.

Abstract No.: 204871

Genetic Insights From Retinal Biological Aging Reveal Lifetime Risk of Systemic Diseases and Poor Eye Health

First Author: Qingsheng **PENG**

Co-Author(s): Ching-yu **CHENG**, Yu **HUANG**, Hengtong **LI**, Zhi Da **SOH**, Cancan **XUE**, Xiayin **ZHANG**, Zhuoting **ZHU**

Purpose: Retinal biological aging markers, such as RetiAGE and retinal age gap (RAG), can predict systemic disease. However, the ground truth of these aging markers is chronological age. We aimed to investigate whether the polygenic risk of retinal aging reflects the lifetime risk of poor health, regardless of the normal aging effects.

Methods: We applied a multi-traits analysis of genome-wide data (MTAG) to calculate the polygenic risk score (PRS) for retinal aging, as reflected by both RetiAGE and the retinal age gap (RAG), in UK Biobank participants with retinal photographs. We first tested the ability to predict mortality using the retinal aging PRS in participants without retinal photographs. Then, we utilized Cox proportional hazard models to assess whether retinal aging PRS can predict the lifetime risk of multiple systemic diseases and poor eye health.

Results: The study analyzed retinal photos from 31,271 UK Biobank participants, generating RetiAGE and RAG. Significant loci were identified, including ALKAL2 ($p=6.08E-113$), IRF4 ($p=2.44E-15$), and HERC2 ($p=4.22E-47$). Among 487,282 participants in the discovery set, each standard deviation increment of the retinal age PRS was significantly associated with higher risk of all-cause mortality (HR 1.029, $p=1.49E-07$), systemic diseases, including asthma (HR 1.019, $p=2.37E-05$), COPD (HR 1.045, $p=9.76E-11$), and myocardial infarction (HR 1.038, $p=1.20E-08$), and poor eye health, such as low vision and blindness (HR 1.038, $p=0.028$), glaucoma (HR 1.025, $p=0.004$), and vitreo-retinal diseases (HR 1.023, $p=0.003$).

Conclusions: Faster retinal aging suggests lifetime genetic susceptibility to systemic diseases and poor eye health.

Abstract No.: 202608

Global Assessment of Ocular Adverse Reactions to Systemic Drugs: Insights from a Multi-Country Spontaneous Reporting Database

First Author: Shi-nan **WU**

Co-Author(s): Wenying **GUAN**, Zuguo **LIU**

Purpose: Assessing the risk of ocular adverse reactions (OARs) of systemic medications in a large, real-world, multinational spontaneous reporting database.

Methods: Disproportionality analysis was performed on all OARs reports related to systemic medications in the FAERS database from the first quarter of 2004 to the third quarter of 2024. The OARs were categorized into disease-based and symptom-based classifications to identify systemic medications with positive signals.

Results: In the FAERS database, the top three OARs for systemic medications in ophthalmic diseases were cataract, dry eye, and glaucoma; the top three ophthalmic symptoms were blurred vision, visual impairment, and eye pain. Through disproportionality analysis, 141 systemic medications with positive signal drugs for OAR risks were identified, which were concentrated in the following categories: Antineoplastic Medication (30 drugs, Belantamab Mafodotin ROR [95% confidence interval (CI)]: 59.59 [56.25 to 63.13]), Central Nervous System Medication (21 drugs, Fingolimod, 2.69 [2.63 to 2.75]), Anti-infective Medication (15 drugs, Moxifloxacin, 6.52 [6.21 to 6.84]), Immunological and Inflammation-related Medication (15 drugs, Dupilumab, 4.74 [4.7 to 4.79]), Cardiovascular System Medication (10 drugs, Ivabradine, 3.06 [2.61 to 3.58]), Endocrine and Metabolic Disease Medication (10 drugs, Insulin lispro, 3.63 [3.4 to 3.89]), Respiratory System Medication (6 drugs, Telithromycin, 3.51 [3.14 to 3.93]), and Other Medication (34 drugs, Botulinum toxin type A, 4.24 [4.12 to 4.36]). The drug-induced time for anti-infective

medications was significantly shorter than that of other categories of systemic medications ($P < 0.001$).

Conclusions: This pharmacovigilance study underscores the importance of identifying underrecognized OARs from systemic drugs to prevent secondary eye diseases and improve drug safety.

Abstract No.: 206591

Imaging and Management of Keratitis Using AI Algorithms

First Author: Soufia **FARRUKH**

Co-Author(s): Faryal **WAHEED**

Purpose: Keratitis is a significant global cause of visual morbidity, with timely diagnosis and effective management being essential to prevent irreversible vision loss. Conventional diagnostic modalities, including slit-lamp biomicroscopy and confocal microscopy, are constrained by subjectivity, reliance on specialist expertise, and limited accessibility in many clinical settings. Recent advances in artificial intelligence (AI), particularly in machine learning (ML) and deep learning (DL), provide promising avenues for automated, accurate, and scalable analysis of corneal imaging, thereby addressing critical gaps in early detection and management.

Methods: This presentation reviews AI-driven approaches for the diagnosis and management of keratitis, with a focus on convolutional neural networks and advanced transfer learning architectures. Models such as ResNet, DenseNet, ResNeXt, SE-ResNet, and EfficientNets have been applied to external eye photographs and anterior segment images, enabling automated differentiation of bacterial, fungal, and viral keratitis. Evidence is further synthesized from diagnostic prediction models, deep learning-based classification systems, and multimodal imaging frameworks designed to enhance diagnostic accuracy and clinical applicability.

Results: Validation studies indicate that AI-based systems achieve diagnostic accuracies comparable to expert clinicians, with reported sensitivities frequently exceeding 90%. These technologies enable reliable differentiation among bacterial, fungal, and viral keratitis, support severity grading, inform treatment decision-making, and facilitate monitoring of therapeutic response. Moreover, integration with tele-ophthalmology platforms enhances accessibility and expands screening coverage, particularly in underserved and resource-limited settings.

Conclusions: Artificial intelligence represents a transformative advancement in the diagnosis and management of keratitis.

Abstract No.: 200929

Implementation of Artificial Intelligence-Assisted Diabetic Retinopathy (DR) Screening in Suburban Area of Yangon, Myanmar

First Author: Jasmine **GE**

Co-Author(s): Anna Cheng Sim **TAN**, Mya **WUT YEE**

Purpose: This study aimed to evaluate the effectiveness of the SELENA+ Artificial Intelligence (AI) system for diabetic retinopathy (DR) screening in Yangon, Myanmar. The research sought to assess the system's accuracy, efficiency, and potential to address the challenges of DR screening in resource-limited settings.

Methods: A prospective study was conducted in Taikkyi Township, located in the northernmost part of the Yangon region. A total of 414 eyes from 217 patients were examined using the SELENA+ AI system for DR screening. The AI-based assessments were compared with ophthalmologist grading to determine the level of agreement for diabetic retinopathy.

Results: The SELENA+ AI system demonstrated high agreement with ophthalmologist grading, with Kappa values of 0.821 ($p < 0.001$). After excluding cases with media opacities, the agreement improved to a kappa of 0.915 ($p < 0.001$). The AI system showed excellent sensitivity (96.5%) and specificity (100%) in detecting diabetic retinopathy. The majority of patients (74.4%) completed the AI DR screening in 15 minutes or less, indicating high time efficiency. The study also revealed potential cost benefits, with 98.1% of patients reporting a low cost was required to attend the DR screening.

Conclusions: The SELENA+ AI system proved to be a highly accurate, efficient, and cost-effective tool for DR screening in Yangon, Myanmar. Its performance was comparable to that of human specialists, while offering advantages in terms of accessibility and scalability.

Abstract No.: 200617

Improving Readability of Pediatric Cataract Education Materials With Large Language Models

First Author: Xinyi **QIU**

Co-Author(s): Hui **CHEN**, Weirong **CHEN**, Ka Yi **CHUNG**, Chaokun **LUO**, Qingruo **ZHANG**

Purpose: To evaluate the capacity of large language models (LLMs) to improve the readability of online patient education materials (PEMs) on pediatric cataracts through multilingual adaptation, content retrieval, and prompt engineering.

Methods: A total of 103 PEMs in various languages were collected from diverse online sources. Three LLMs (ChatGPT-4o, Gemini 2.0, DeepSeek-R1) were applied to optimize content. Readability of both original and LLM-converted PEMs was assessed using multiple established formulas. We also compared different

prompt engineering strategies, analyzed the effects of web-based content retrieval and Chinese language adaptation.

Results: LLM-generated PEMs initially exhibited high reading levels (>10th grade). However, LLM conversion significantly improved readability, with DeepSeek-R1 reducing the average reading level from 10.59 ± 2.20 to 7.01 ± 0.91 ($p < 0.001$). Prompt engineering strategies such as Zero-shot-CoT (APE) further reduced reading levels below the 6th-grade threshold. In Chinese materials, LLM conversions met national recommended readability standards across multiple metrics.

Conclusions: LLMs can effectively improve the readability of multilingual online PEMs on pediatric cataracts. When combined with web browsing and prompt engineering, they offer a promising strategy to optimize patient education.

Abstract No.: 203948

Innovations of Artificial Intelligence in Clinical Ophthalmology: Netradeep

First Author: Swati **SHARMA**

Co-Author(s): Rohan **CHAWLA**, Abhishek **KUMAR**

Purpose: To use artificial intelligence in the quantification of hard exudates in a prospective interventional comparative study.

Methods: A prospective interventional comparative study was done in 20 eyes of diabetic retinopathy patients having non-center-involving clinically significant diabetic macular edema. Patients were divided into two groups using simple randomization. In the first group, conventional focal laser was done, and in the second group, subthreshold micropulse laser was done, and both the groups were followed up for up to 6 months, and multimodal imaging was done to compare the results. Hard exudate quantification was done using AI and deep learning-based technology pre- and post-laser. Results were quantified on the basis of increase in BCVA, reduction in macular thickness, and decrease in hard exudates.

Results: The conventional laser group showed a greater reduction in hard exudates with a p-value of 0.031 at 3 months compared to the subthreshold laser group.

Conclusions: A DL-assisted system called Netradeep made it easier to accurately segment hard exudates from retinal fundus imaging. Further efforts may involve incorporating feedback from a wider pool of expert ophthalmologists.

Abstract No.: 204609

Machine Learning Models for Risk Prediction of Age-Related Macular Degeneration in Fujian Eye Study

First Author: Yang **LI**

Co-Author(s): Qinrui **HU**, Xiaoxin **LI**, Bin **WANG**

Purpose: Age-related macular degeneration (AMD) is a retinal disorder that significantly impairs vision. This study investigates various machine learning models for predicting AMD risk, laying the groundwork for further research using big data and determining the most effective predictive model.

Methods: Utilizing data from 8211 records with 39 features from the Fujian Eye Study, a cross-sectional epidemiological investigation, several machine learning models were developed and assessed. The models included logistic regression (LR), K-nearest neighbors (KNN), support vector machine (SVM), decision tree (DT), random forest (RF), light gradient boosting machine (LightGBM), and extreme gradient boosting (XGBoost). Data preprocessing, feature selection, and model training were all key components of the study.

Results: After evaluating multiple models, the logistic regression model emerged as the most accurate, achieving a balanced accuracy of 0.6364. Among the predictive features, educational background had the highest influence on the model's predictions, with an average SHAP (SHapley Additive exPlanations) value of 0.8199. Other significant factors included outdoor time and left eye spherical equivalent (OSSE), with SHAP values of 0.6474 and 0.6377, respectively.

Conclusions: This study confirms that logistic regression is the most effective machine learning model for predicting AMD risk, with educational background identified as the most critical risk factor.

Abstract No.: 202423

Macula-CoT: Macular Subregion-Aware Chain-of-Thought for AMD Prognostic Prediction

First Author: Jianing **WANG**

Co-Author(s): Xinyue **LI**, Xiaobing **YU**, Xiaodan **ZHANG**, Yue **ZHANG**

Purpose: This paper aims to improve the automated prognostic prediction of Age-related Macular Degeneration (AMD) using OCT images by proposing Macula-CoT, a model that emulates ophthalmologists' diagnostic workflow. It introduces subregion-aware multi-stage reasoning and patch-level visual encoding to enhance interpretability and prediction accuracy across two clinical tasks.

Methods: The proposed Macula-CoT model emulates the diagnostic workflow of ophthalmologists by sequentially focusing on key macular anatomical subregions in OCT images, including the fovea, nasal

region, and temporal region. It introduces a multi-stage chain-of-thought reasoning strategy to guide structured visual understanding at each stage. To enhance fine-grained visual perception, a Patch-to-Region module transforms patch-level tokens into spatially localized subregion images. These visual features are combined with task-specific language prompts and injected into a large language model to jointly predict subretinal fluid absorption and visual recovery, enabling accurate, transparent, and clinically credible AMD prognosis.

Results: Experimental results show that Macula-CoT achieves state-of-the-art (SOTA) performance on two AMD prognosis tasks: subretinal fluid absorption and visual recovery. Specifically, Macula-CoT reaches an accuracy of 0.773, precision of 0.817, recall of 0.919, and an F1 score of 0.865, demonstrating its robustness in handling imbalanced prediction tasks. Furthermore, the model attains an AUC of 0.685, confirming its effectiveness in distinguishing between different prognostic outcomes.

Conclusions: Macula-CoT, a subregion-aware chain-of-thought model for AMD prognosis based on OCT images. By integrating multi-stage reasoning and fine-grained visual encoding, the model produces accurate and interpretable predictions. The paper highlights the potential of structured multimodal reasoning for developing clinically aligned and reliable diagnostic tools.

Abstract No.: 209055

Multi-Organ Imaging Demonstrates a Multimodal Complex Association Network in the Retina-Heart-Brain Axis

First Author: Junyang LI

Purpose: Medical imaging provides numerous insights into the subclinical changes that precede serious diseases such as heart disease and dementia. However, most imaging research either describes a single organ system or draws on clinical cohorts with small sample sizes.

Methods: In this study, we use state-of-the-art multi-organ magnetic resonance imaging phenotypes to investigate cross-sectional relationships across the retina-heart-brain axis in 1,007 CHPP participants.

Results: Despite controlling for an extensive range of demographic and clinical covariates, we find significant associations between imaging-derived phenotypes of the heart, retina and brain. Simultaneous three-organ modelling identifies differentially important pathways across the retina-heart-brain axis with evidence of both direct and indirect associations.

Conclusions: This study describes a potentially cumulative burden of multiple-organ dysfunction and provides essential insight into multi-organ disease prevention.

Abstract No.: 200528

Novel Subclassification of Presbyopia Based on Lens Functional and Structural Features

First Author: Xiangjia ZHU

Purpose: The purpose of this study was to classify eyes with presbyopia using lens functional and structural features to aid in surgical decision making.

Methods: This cross-sectional observational study included healthy volunteers or those solely affected by presbyopia. Lens function was assessed using dysfunction lens index (DLI), whereas lens density was evaluated with Pentacam (LD-P) and swept-source optical coherence tomography (LD-S). Principal component analysis (PCA) and k-means clustering classified participants into non-lens surgery (NLS) and lens surgery (LS) groups. A scoring system was developed from the optimal cutoff values for simplified diagnosis, with a website created for automatic classification.

Results: Totally, 352 eyes of 176 patients were studied, with a mean age of 46.1 ± 6.2 years and a mean axial length of 24.42 ± 1.62 mm. Among them, 268 (76.1%) eyes were diagnosed with presbyopia. The top 5.2% (14/268) of presbyopia cases with the highest variability were excluded by PCA. Subsequently, 138 eyes (51.5%) were clustered into the NLS group, and 116 eyes (43.3%) into the LS group. The LS group presented lower DLI and higher lens density compared to the NLS group (all $P < 0.001$). Optimal cutoff values were determined as follows: DLI = 7.75, LD-P = 8.75, and LD-S = 60.05 pixel units. The scoring system demonstrated that combining DLI with LD-P achieved the highest diagnostic efficacy. A website (www.zhu-zhou-lf.com) was developed for automatic classification.

Conclusions: We proposed a novel classification of presbyopia using lens functional and structural features.

Abstract No.: 202862

OCTA-ARM: A Diffusion-Based Multi-Artifact Removal in Optical Coherence Tomography Angiography via Synthetic Data Training

First Author: Xujia LIU

Co-Author(s): Carol CHEUNG, Zheng CHUNWEN, Hongyang JIANG, Anran RAN, Bowen XU

Purpose: To develop and validate OCTA-ARM (Optical Coherence Tomography Angiography Artifact Removal Model), a diffusion-based framework for removing multiple artifact types in OCTA images.

Methods: We retrospectively collected 21,389 OCTA (DRI OCT Triton; Topcon Inc, Tokyo, Japan) superficial capillary plexus images from 2,475 eyes. To overcome the scarcity of real paired data (artifact-affected vs. artifact-free), a synthetic data training strategy was

implemented using CycleGAN-based generators to create shadow and defocus artifacts, combined with random pixel shifts for motion artifacts. The Brownian Bridge Diffusion Model (BBDM) was trained to remove these artifacts. Model performance was evaluated using 279 paired artifact-affected (79 ungradable and 200 gradable but unmeasurable) and artifact-free images, assessing gradability improvement and consistency of quantitative metrics (foveal avascular zone area, non-perfusion area, vessel density, fractal dimension, skeleton distance) using intraclass correlation coefficients (ICC). Additionally, diabetic macular ischemia (DMI) classification performance was compared using original versus OCTA-ARM preprocessed images.

Results: OCTA-ARM achieved 98.92% (276/279) gradability improvement, with 200 (100%) «gradable but unmeasurable» images to «measurable», 66 (83.5%) ungradable images to «measurable», and 10 (12.7%) ungradable images to «gradable but unmeasurable». All quantitative metrics showed significant consistency improvements (all $p < 0.0001$), with foveal avascular zone area ICC increasing from 0.771 to 0.909, vessel density from 0.416 to 0.673, fractal dimension from 0.385 to 0.757, and skeleton distance from 0.372 to 0.757. DMI classification accuracy improved by 1.04-1.39% across three neural network architectures when using OCTA-ARM preprocessed images.

Conclusions: OCTA-ARM is an effective diffusion-based framework trained on synthetic data that successfully addresses the critical challenge of simultaneously removing motion, shadow, and defocus artifacts in OCTA images. It significantly enhances image gradability and improves the reliability of essential quantitative OCTA metrics.

Abstract No.: 208390

Ozone Exposure, Retinal Microvasculature Alterations, and the Mediating Effect of Aging in Diabetic Population: A Retrospective Cohort Study

First Author: Senlin LIN

Purpose: Accumulating epidemiological evidence links ozone exposure with cerebrocardiovascular morbidity. This study aims to explore its microvascular impact.

Methods: Retinal microvasculature alterations have emerged as sensitive biomarkers of systemic endothelial dysfunction and predictors of cerebrocardiovascular events. Our study comprised 55,463 individuals diagnosed with type 2 diabetes mellitus (T2DM), recruited across 249 community health centers spanning all 17 administrative districts of Shanghai in 2017. Exposure assessment utilized satellite-derived ozone concentration estimates at 1*1 km spatial resolution, aggregating five-year (2013-2017) ozone exposure metrics. Retinal vascular phenotyping

included central retinal artery equivalent (CRAE), central retinal vein equivalent (CRVE), arteriole-to-venule ratio (AVR), vascular tortuosity (VT), and fractal dimension (Df). The retinal age gap (RAG) is adopted to reflect accelerated aging, defined as the difference between deep learning-predicted retinal age and chronological age.

Results: Multivariable regression analyses using double machine learning showed that for every 10 $\mu\text{g}/\text{m}^3$ increase in ozone, the decrease in the CRAE, CRVE, VT ($\times 10^4$) and Df ($\times 10^3$) were 4.03 (95 %CI: 3.04, 5.01) μm , 8.35 (95 %CI: 6.69, 10.00) μm , 0.38 (95 %CI: 0.28, 0.48) and 13.7 (95 %CI: 11.20, 16.21), respectively, and the increase in RAG was 2.29 (95 %CI: 2.04, 2.54) years. Mediation analysis revealed an association between ozone exposure and reductions in CRAE (indirect effect, standardized coefficient=-0.08, 95 %CI -0.09~-0.07), CRVE (-0.07, -0.08~-0.06), and Df (-0.11, -0.12~-0.09) through the pathway of accelerated aging.

Conclusions: Long-term ozone exposure correlates with accelerated retinal aging and microvascular remodeling, which provides novel biological evidence to elucidate the causal relationship between ozone exposure and cerebrocardiovascular risk.

Abstract No.: 208315

Parameter-Efficient Glaucoma Screening Using Foundation Models on Colour Fundus Photographs

First Author: Bowen XU

Co-Author(s): Carol CHEUNG, Hong Yu Ryan FONG, Anran RAN, Clement THAM

Purpose: Glaucoma screening requires accurate and scalable automated systems for early detection. We aimed to evaluate the performance of parameter-efficient fine-tuning of foundation models for glaucoma classification using colour fundus photographs (CFPs).

Methods: We applied Low-Rank Adaptation (LoRA) to fine-tune the VisionFM foundation model using 11,492 CFPs from the SMDG dataset, split into training (9,029), validation (615), and test (1,848) sets. The validation set was used for threshold optimization using Youden Index. Performance metrics included sensitivity, specificity, and overall accuracy.

Results: The classifier achieved acceptable performance on the SMDG test set with sensitivity of 85.0% (600/706 glaucoma cases detected) and specificity of 91.1% (1,040/1,142 healthy eyes correctly identified), yielding an overall accuracy of 88.7%. The Youden Index was 0.78 at the optimal threshold of 0.645. The LoRA adapter utilized only 0.9M trainable parameters, representing a 98.9% reduction compared to full fine-tuning.

Conclusions: Parameter-efficient fine-tuning through Low-Rank Adaptation enables glaucoma screening systems with acceptable performance on the SMDG

dataset. This approach offers a practical and scalable pathway for AI-assisted glaucoma screening in resource-limited settings.

Abstract No.: 200714

Performance of a Large Language Model in Predicting Myopia Progression in Korean Children

First Author: Jihae PARK

Co-Author(s): Guhn AHN

Purpose: To evaluate a large language model, Generative Pre-trained Transformer-5 (GPT-5), in predicting myopia progression in Korean children and compare an International Myopia Institute (IMI) guideline-trained GPT-5 model against a baseline GPT-5 model.

Methods: This retrospective study included 156 eyes of 88 children aged ≥ 6 years with baseline spherical equivalent (SE) ≤ -1.0 diopter (D). Eyes with visually significant comorbidities or on myopia-control therapy were excluded. Inputs to both GPT-5 models were age, sex, axial length (AXL), keratometry (K1, K2), sphere, cylinder, and SE at the first visit. The guideline-trained model was provided with IMI White Papers; the baseline model was not. Progression was defined as either an SE decrease ≥ 0.50 D or an AXL increase ≥ 0.20 mm at the 1-year follow-up. Outcomes included sensitivity, specificity, accuracy, positive predictive value (PPV), and negative predictive value (NPV).

Results: Myopia progression occurred in 106 of 156 eyes (67.9%). The guideline-trained model achieved 100% sensitivity, 24% specificity, 75.6% accuracy, 73.6% PPV, and 100% NPV. The baseline model had 100.0% sensitivity, 18% specificity, 73.7% accuracy, 72.1% PPV, and 100% NPV. The guideline-trained model showed superior overall performance with a higher Youden's index (0.24 vs. 0.18).

Conclusions: A GPT-5 model trained on the IMI White Papers demonstrates high sensitivity in predicting 1-year myopia progression in children, suggesting its usefulness as a screening tool to help avoid missing high-risk children. However, its low specificity requires adjunctive use with an ophthalmologist evaluation; clinical confirmation remains essential.

Abstract No.: 203298

Performance of an Artificial Intelligence (AI)-Based Diagnostic System for Diabetic Retinopathy Detection Using Fundus Photography

First Author: Bo Hee KIM

Co-Author(s): Jin-soo KIM, Yun Jeong LEE, Ki Young SON

Purpose: To evaluate the diagnostic accuracy and clinical utility of "WISKY," an artificial intelligence (AI)-

based system for detecting diabetic retinopathy (DR) through fundus photography.

Methods: This prospective, non-interventional cross-sectional study included patients (≥ 19 years) with type 1 or 2 diabetes who underwent fundus photography. DR severity was graded according to the International Clinical Diabetic Retinopathy (ICDR) standards. Diabetic macular edema (DME) was diagnosed by surrogate markers such as hard exudates within one disc diameter of the fovea. Patients without DR were defined as those not meeting these criteria. Referable DR was defined as moderate non-proliferative DR or worse, or the presence of DME. All fundus images were analyzed using the AI-based diagnostic system (WISKY). Diagnostic performance was evaluated using sensitivity, specificity, accuracy, and the area under the receiver operating characteristic curve (AUROC).

Results: A total of 101 gradable eyes from 60 patients (62.7% female, mean age 59.5 years) were analyzed. For distinguishing DR from no DR, the AI system demonstrated robust performance (AUROC = 0.884 [95% CI: 0.812–0.956], accuracy = 0.881, sensitivity = 0.788, specificity = 0.980). For differentiating referable DR from non-referable DR, the AI system also showed good diagnostic ability (AUROC = 0.887 [95% CI: 0.814–0.961], accuracy = 0.891, sensitivity = 0.860, specificity = 0.914).

Conclusions: The AI-based fundus diagnostic system demonstrated high accuracy and reliability in detecting both any DR and referable DR. These findings support its potential role as an effective screening tool for diabetic retinopathy in clinical and community settings.

Abstract No.: 206644

PocDoc Web-Based Visual Field Tool: Comparative Study With Humphrey Visual Field and Potential for Home-Based Testing

First Author: Chew Hans NG

Co-Author(s): Bryan ANG, Debbie Shuying BOEY, Joewee BOON, Jueshao GOH, William ROJAS-CARABALI

Purpose: To validate the novel PocDoc visual field (VF) application by comparing its performance against the current gold standard Humphrey Visual Field (HV).

Methods: At a tertiary eye centre, 81 participants (107 eyes) with glaucoma were recruited. All participants were tested sequentially on the same day with the reference-standard HVF and the novel PocDoc VF. The performance of PocDoc was assessed by calculating its sensitivity, specificity, and accuracy against the HVF for the entire visual field.

Results: PocDoc yields a positive correlation in identifying VF losses in the entire VF ($r=0.504$), superonasal ($r=0.551$), inferonasal ($r=0.443$), superotemporal ($r=0.357$) and inferotemporal quadrants ($r=0.362$). It had an overall accuracy of 85.1%, sensitivity of 94.7% (95% CI, 88.0% to 98.3%),

specificity of 15.4% (95% CI, 1.92% to 45.5%), positive predictive value of 89.0% and negative predictive value of 28.6%. Individual quadrants also showed higher sensitivity than specificity. For glaucomatous eyes, PocDoc had a moderately positive overall correlation ($r=0.477$), positive correlations in Stage 1 ($r=0.309$) and Stage 4 glaucoma ($r=0.975$), and negative correlation for Stage 2 ($r=-0.249$) and 3 ($r=-0.409$) glaucoma.

Conclusions: The novel PocDoc application demonstrated high sensitivity compared to the reference-standard HVF. While its low specificity indicates that it is not suitable as a standalone diagnostic tool, its accessibility profile suggests a potential role as an effective screening tool or home-based monitoring.

Abstract No.: 207093

Practical Challenges and Recommendations for the Implementation of an Artificial Intelligence-Based OCT Analysis in Multicentric Research: Insights From the Swiss RetinAI Consortium

First Author: Tahm **SPITZNAGEL**

Co-Author(s): Aude **AMBRESIN**, Chiara **EANDI**, Justus **GARWEG**, Gabor Mark **SOMFAI**, Sandrine **ZWEIFEL**

Purpose: To summarize the first experiences of the Swiss RetinAI Consortium in implementing artificial intelligence (AI)-based optical coherence tomography (OCT) analysis and to highlight key challenges and practical recommendations for multicenter research.

Methods: The Swiss RetinAI Consortium consists of six centers, that are using the FDA-approved Discovery[®]-platform (RetinAI, Bern, Switzerland) for collaborative research using OCT imaging. We systematically documented and complemented the challenges of our first protocols during expert discussions, with a common guidance for all centers.

Results: The following ten core challenges were identified in our multicenter implementation of RetinAI Analysis: (1) complex ethics submissions due to undefined effect sizes and justification of multiple biomarkers, (2) mandatory use of Swiss-based servers for data hosting imposed by regulatory and data protection requirements, (3) incomplete anonymization from heterogeneous export protocols, (4) lack of standardized OCT scan protocols, with heterogeneous scan sizes processed as equivalent despite covering different retinal areas, (5) inter-device variability, (6) ETDRS grid misalignment, (7) segmentation errors requiring extensive review, (8) unfiltered exports producing huge that are increasing the risk of errors, (9) absence of automated quality screening of OCTs, necessitating additional manual control, and (10) limited reproducibility data across centers. The above points helped us in the development of a common guidance for data acquisition and processing.

Conclusions: Addressing these challenges through standardized workflows and robust governance will unlock the full potential of AI-based OCT analysis, enabling multicenter studies, biomarker discovery, and deeper insights into retinal disease. Our recommendations provide a roadmap for future collaborative projects in ophthalmology.

Abstract No.: 210235

Programming and Designing an Ophthalmic Information Management System With Excel VBA

First Author: Liu **CUIHONG**

Co-Author(s): Bi **HONGSHENG**, Wang **JIAO**, Ji **PENG**

Purpose: Through the independent research and development of refractive surgery information management system, to make up for the lack of information collection and data analysis function of his system in the hospital under the condition of limited interface of special equipment, strengthen the construction of nursing information, contribute to the standardization of refractive surgery information registration, and improve the work efficiency of workload statistics and data analysis.

Methods: Using Excel VBA programming, nurse-led design, and independently developed a refractive surgery information management system. The basic information, diagnosis, operation position, operation mode, surgeon, assistant, nurse, operation process, and other items of the patient are edited in the structured user window. The nurse directly clicks, and the entered data is automatically stored in the Excel table; the patient information list interface is designed to query the history record and modify the habits, so as to protect the Excel database data. Through VBA program coding, the refractive surgery information and workload of one key statistical analysis are achieved efficiently, and an overall presentation of data and charts.

Results: This system has run more than 4000 pieces of data, and there is no data deviation. Compared with the manual work, the registration information time of the system designed and developed by Excel VBA is shortened from 96s per case to 26s, and the time of monthly workload summary and statistical analysis is shortened from 120min per case to less than 1min. According to the calculation of 500 cases per month, the time can be saved as much as 660 minutes, the work efficiency is significantly improved, and the registration of nursing information is standardized and unified. It improves the level of nursing information in the refractive operating room and realizes the paperless management of nursing information registration in the refractive operating room.

Conclusions: The Refractive Surgery Information Management System, which is developed by the nurse using Excel VBA programming, has a clear and

simple interface, meets the actual needs of nursing, optimizes the working process, and improves efficiency significantly.

Abstract No.: 200911

Quantitative Grading of Corneal Opacities Based on Deep Learning and Its Prediction of Postoperative Visual Outcomes in Cataract Patients With Corneal Opacities

First Author: Ma XINYU

Co-Author(s): Wen XU

Purpose: This study explores deep learning methods to quantify corneal opacities and evaluates their effectiveness in predicting postoperative visual outcomes in cataract patients. By integrating multimodal data and constructing predictive models for visual acuity, the research supports preoperative assessment and personalized treatment, advancing intelligent ophthalmic diagnosis and care.

Methods: This study included 300 cataract patients: 150 eyes with corneal opacity and 150 normal controls. Each eye underwent 16 AS-OCT scans, and three models (UDTransnet, R34UNet, MEGANET) were used for opacity segmentation, trained with combined cross-entropy and Dice loss. Model performance was assessed by Dice coefficient. Corneal opacity was quantified by pixel intensity, and its correlation with one-month postoperative BCVA was analyzed.

Results: All three models excelled in classifying corneal opacity regions (ROC 0.98), with MEGANET achieving the best segmentation (Dice 0.77, precision 0.79, recall 0.79). Pixel intensity differed significantly between normal and opaque corneas ($P < 0.001$). Corneal opacity in the central 3 mm was most strongly correlated with postoperative BCVA; average pixel intensity above 105 ADU indicated reduced visual acuity. Opacity outside the central 6 mm had no impact on visual acuity.

Conclusions: Deep learning-based methods for quantifying corneal opacity have significant value in predicting postoperative visual outcomes. In particular, precise quantification of opacity within the central 3 mm of the cornea provides a scientific basis for preoperative assessment and personalized treatment, enhancing diagnostic accuracy and promoting the advancement of intelligent ophthalmic care.

Abstract No.: 208553

Rapid Screening of Pseudoisochromatic Plates Based on Deep Learning Optimization

First Author: Jing WANG

Co-Author(s): Xiangui HE, Xiaowei TONG, Yulan WANG

Purpose: Pseudoisochromatic plates are the most famous type of color blindness test. This study aims to explore the use of deep learning to optimize the

combination of some pseudo iso color palettes and predict the test results of the entire set of pseudo iso color palettes, in order to find a fast color vision screening solution.

Methods: Children were randomly selected from the Shanghai arm of a national multicenter cohort study. VA examinations were conducted using the Tumbling E chart first, then the HOTV chart, followed by other ocular measurements in this pilot study. Testability and VA data (logMAR) are presented for comparison between the two charts.

Results: The itertools package and NumPy matrix operations of Python were used to implement permutations and combinations. Different combinations of 3 questions, 5 questions, and 7 questions were evaluated to predict the alternative of the whole set of pseudoisochromatic plates. The decision tree model in the Scikit learn library can effectively predict the inspection results of pseudoisochromatic plates. The ROC-AUC for predicting whether a patient has color blindness is (0.869 for 3 questions, 0.956 for 5 questions, and 0.967 for 6 questions), and the ROC-AUC for predicting whether a patient has color weakness is (0.813 for 3 questions, 0.961 for 5 questions, and 0.966 for 7 questions).

Conclusions: Through deep learning, it is possible to optimize the examination scheme of pseudoisochromatic plates and improve the efficiency of color vision examination.

Abstract No.: 208292

Real-World Prospective Validation and Economic Evaluation of Deep Learning-Based Diabetic Retinopathy Detection From Fundus Photographs: A Systematic Review and Meta-Analysis

First Author: Anran RAN

Co-Author(s): Carol Y CHEUNG, Jennifer DING, Sobha SIVAPRASAD, Clement C THAM, Tien Yin WONG

Purpose: Deep learning (DL) has shown promise in delivering diagnostic and economic benefits for detecting diabetic retinopathy (DR) from fundus photographs (FP). However, evidence synthesis of model validation in prospective, real-world settings remains limited. We conducted a systematic review and meta-analysis to assess the feasibility of implementing DL-DR systems using FPs across different countries by synthesizing prospective validation and economic evidence.

Methods: We searched five databases until August 13th, 2025. Studies prospectively assessing performance, and/or studies conducting economic analyses of DL-DR systems using FPs. Characteristics of all studies, performance parameters of prospective validation studies, and economic outcomes of economic analysis studies were extracted.

Results: Forty-seven studies were included in the meta-analysis. The pooled performance was the highest in detecting vision-threatening DR (AUROC 0.974), followed by any DR (AUROC 0.965), then referable DR (RDR) (AUROC 0.959). Study region, clinical pathway, mydriasis, image quality control, sample size, grading criteria, reference standard, and model architecture significantly affected model performance in RDR detection. Fifteen studies were included in the economic commentary, showing that DL-based DR screening was cost-effective in high-income countries, while results in middle-income countries were mixed, depending on compliance rates, glycemic control, and initial costs.

Conclusions: DL-DR systems using FPs had high discriminative performance in prospective real-world settings and hold promise to improve cost-effectiveness, especially in high-income countries.

Abstract No.: 204044

Smart Multimodal Monitoring With Graded Nonpharmacological Nursing Interventions for Pain Management During Neonatal Fundus Examination

First Author: Liping **XIONG**

Co-Author(s): Qiong **CHEN**, Jinwei **LI**, Yinyin **LIN**, Li **ZENG**, Qiqiao **ZENG**, Tao **ZI**

Purpose: Neonatal fundus examination, including retinopathy of prematurity screening, often causes pain and instability. Nonpharmacological interventions such as oral sucrose, nonnutritive sucking (NNS), and facilitated tucking are effective but usually applied without real-time adjustment. This study evaluated smart multimodal monitoring combined with graded nonpharmacological nursing interventions.

Methods: A randomized controlled trial was conducted in preterm infants. The control group received conventional care, while the intervention group received sucrose, NNS, and tucking supported by smart monitoring. Physiological signals—heart rate (HR), oxygen saturation (SpO₂), and heart rate variability (HRV)—were continuously recorded. Behavioral cues, including facial expression, crying, and limb movement, were assessed using the Premature Infant Pain Profile—Revised (PIPP-R). When thresholds were exceeded (HR rise >15 beats/min, SpO₂ drop ≥5%, HRV drop ≥20%, or PIPP-R >9), graded alerts were issued. Nurses implemented stepwise care: mild cases required swaddling adjustment or NNS verification; moderate cases added sucrose with maternal voice soothing; severe cases required pausing the exam and applying all interventions. Primary outcomes were PIPP-R scores and HR/SpO₂ stability; secondary outcomes were crying time, exam completion, and parental satisfaction.

Results: The intervention group is expected to show lower PIPP-R scores, fewer fluctuations, shorter crying, and higher completion and satisfaction rates (P<0.05).

Conclusions: Smart multimodal monitoring enables real-time pain recognition and graded alerts. Combined with nonpharmacological care, it supports precise, dynamic management and improves safety and quality.

Abstract No.: 204350

Strabismus-Net Based Mobile Application for Efficient Strabismus Diagnosis With Nine-Gaze Photographs

First Author: Dawen **WU**

Co-Author(s): Longqian **LIU**, Haixian **ZHANG**

Purpose: Early detection of strabismus is crucial for effective treatment. Traditional diagnostic methods require extensive expertise, which often results in diagnostic errors and delays, particularly in underserved areas, due to a shortage of trained professionals. To address these challenges, this study introduces Strabismus-Net, an integrated mobile application leveraging the largest nine-gaze dataset to date, to improve diagnostic efficiency and facilitate streamlined referrals for comprehensive care.

Methods: This retrospective and prospective cross-sectional study utilized a large dataset of nine-gaze photographs captured under diverse conditions. A YOLOv8-based algorithm cropped the eye regions, followed by synchronized data augmentation to enhance model generalization. Strabismus-Net was developed to classify orthotropia, horizontal strabismus (exotropia/esotropia), and vertical strabismus, incorporating advanced attention and aggregation mechanisms. The model underwent 10-fold cross-validation, with the best-performing version validated on an independent external test set. Performance was evaluated using Sensitivity, Specificity, F1-Score, and AUC, benchmarked against three junior doctors' assessments, with Grad-CAM heatmaps assessing interpretability.

Results: The study used 84,897 photographs from 9,433 individuals for cross-validation and 10,458 photographs from 1,162 individuals for prospective testing. The model achieved an AUC of 99.53% for binary strabismus screening and high AUC values for orthotropia (96.41%), exotropia (99.19%), esotropia (99.11%), and vertical strabismus (80.99%). It matched junior doctors in detecting exotropia and esotropia while outperforming them in orthotropia and vertical strabismus.

Conclusions: Leveraging the largest nine-gaze dataset to date, Strabismus-Net achieved state-of-the-art performance in strabismus screening and diagnosis, reducing missed diagnoses of complex cases. Prospective testing and an integrated platform support large-scale screening, aid non-specialists, and optimize workflows.

Abstract No.: 202361**Teleophthalmology in Action: Closing the Treatment Gap With Remote Care***First Author: Igor AZNAURYAN**Co-Author(s): Karmen ARTENIAN, Satenik AGAGULIAN, Victoria BALASANYAN*

Purpose: To evaluate the feasibility of using telemedicine in the practical work of an ophthalmologist for conducting video consultations, diagnostic examinations, and courses of therapeutic procedures for various oculomotor and refractive pathologies.

Methods: A study was conducted on 468 children aged 4 to 12 years (mean age 5.6 ± 1.2 years) with the following conditions: myopia 195 patients, hypermetropia and astigmatism 69 patients, amblyopia 112 patients, strabismus 92 patients. All patients initially underwent an in-person consultation with an ophthalmologist in the clinic, where a complete ophthalmological examination was performed. They were recommended a course of vision therapy. Due to the inability to receive treatment at the facility for various reasons (distance, patients from remote regions), they were advised to undergo the treatment course via the «Online Oko» telemedicine platform. The treatment course lasted 10 days.

Results: All patients with myopia showed an increase in accommodative reserve after the treatment course. On average, this increase was 2.0 ± 0.5 D (range: 0.5 to 3.5 D). Out of 112 patients with amblyopia, 97 patients showed an improvement in visual acuity, with an average increase of 1.3 ± 0.65 lines on the Snellen chart. Out of 92 patients with strabismus and absence of binocular vision, 56 patients successfully regained binocular vision from a distance of 1 meter within the 10-day course.

Conclusions: The study demonstrates the feasibility of a telemedicine platform for effectively administering vision therapy, showing significant improvements in accommodative reserve for myopia, visual acuity in amblyopia, and the restoration of binocular vision in strabismus.

Abstract No.: 202387**The Augmentational Effect of Vergence Exercises on Accommodative Facility and Accommodative Amplitude in Presbyopia Patients***First Author: Elsa L.c. MAI*

Purpose: The degree accommodation influences convergence is known as Accommodative Convergence to accommodation (AC/A) ratio. Given a fusional disparity in input, with the synkinesis of oculomotor near response, the degree to which fusional vergence influences accommodation is known as Convergence Accommodation to convergence (CA/C). With our

ADRRPs visual training machine to strengthen convergence function/ muscle power, we would like to see if it can induce improvement in Accommodative facility and accommodative amplitude.

Methods: ADRRPs or OrthoV is a Vergence training VR machine base on Risley prism, hence the name automatic dual rotational Risley prisms, 26 presbyopia patients were recruited from ophthalmology clinic with complain of accommodative spasm and eye strain. IRB consent form were signed and pre-training evaluation for Accommodative Amp, Accommodative facility (flipper), stereopsis test, Questionnaire (COVD-QOL) for Convergence Insufficient were given. One session of ADRRPs/OrthoV training lasting 30 mins with a 10 mins break in between were given. These patients repeats AA, Steropsis and AF testing immediately after training.

Results: Immediate post binocular visual training, a noticeable improvement was found over stereopsis which is as expected. A gain of accommodative Amp of $(0.24D \pm 0.14D)$ on the average was noticed. Post training accommodative facility with flipper increase only slightly, (gain of 2.2 cpm on the average).

Conclusions: CA/C ratio, or rather Convergence induced accommodation in presbyopia patients, can be use as augmentation for presbyopia symptoms. ADRRPs/OrthoV with it's visual training, proof to be effective and convenient for patient's self training after proper supervised. Training also provide a small gain in accommodative facility.

Abstract No.: 207334**The Fellow Whisperer: AI's Role in Phaco Skill Mastery***First Author: Sneha G V**Co-Author(s): Sriganesh*

Purpose: To assess and compare the surgical skills between two groups of residents with and without the use of a surgical optimiser app. To assess the individual surgical improvement of fellows at the beginning vs the end of the study

Methods: Six phacorefractive fellows were randomly assigned to two groups. Group A consisted of three surgeons who performed surgeries using the Zeiss Surgical Optimiser (ZSO), while Group B included three surgeons who operated without the ZSO. Each surgeon conducted 30 cataract procedures employing a standardized surgical technique.

Results: Group A, which operated with the Zeiss Surgical Optimiser (ZSO), demonstrated relatively faster surgical times, completing procedures in an average of 10 minutes compared with the non-ZSO group. Their OSCAR scores showed a steady improvement over successive cases. In addition, the effective phacoemulsification time was significantly shorter in the ZSO group, and the incidence of intraoperative complications was lower

Conclusions: These findings suggest that the ZSO can serve as a valuable adjunct in enhancing surgical training, enabling fellows to achieve greater efficiency and safety while reinforcing fundamental cataract surgery skills.

Abstract No.: 206342

The Use of Explainable Artificial Intelligence in Predicting the Response of Diabetic Macular Oedema to Intravitreal Anti-Vascular Endothelial Growth Factor Injections

First Author: Kelvin LI

Co-Author(s): Magdalene CHEONG, Xiuyi FAN, Sean NG, Wei Kiong NGO, Li Rong WANG

Purpose: Intravitreal anti-vascular endothelial growth factor (VEGF) injections is used to treat centre-involving diabetic macular edema (ciDME). Yet, patient response varies significantly, and there is currently no reliable way to predict outcomes. A predictive model could improve patient care by guiding personalised treatment, optimising treatment response and reducing overall treatment burden. This study proposes an explainable artificial intelligence (AI) framework integrating deep learning with interpretable models to predict treatment efficacy in ciDME.

Methods: We employed a ResNet18 deep learning model to extract features from spectral domain optical coherence tomography images of the macula and collected clinical data including patient demographics and haemoglobin A1C. These were used to train a Random Forest Regressor to predict post-treatment central macular thickness (CMT) and visual acuity (logMAR). To enhance interpretability, SHapley Additive exPlanations (SHAP) quantified feature contributions, while Integrated Gradients highlighted OCT regions driving predictions. The model was trained on a proprietary dataset of 164 eyes.

Results: Despite limited data, the framework achieved a mean absolute error (MAE) of $55.64 \pm 9.55\mu\text{m}$ for CMT ($\approx 17\%$ relative error). For visual acuity, the MAE was 0.123 ± 0.033 logMAR, equating to one ETDRS line (≈ 6 letters). This level of error falls within the test-retest variability of standard examinations, indicating clinically acceptable predictive accuracy.

Conclusions: Our explainable AI model demonstrates good accuracy in predicting ciDME patient responses to anti-VEGF therapy. Expanding the dataset and refining the framework will be key to improving predictive performance and clinical translation.

Abstract No.: 206810

Transfer Learning-Based Automated Retinal Vessel Segmentation in Fundus Photography

First Author: Suklengmung BURAGOHAIN

Co-Author(s): Priyank BHOLA, Henal JAVERI, Subham SINHA ROY

Purpose: This study seeks to assess a tailored DeepLabV3+ model for precise retinal vessel segmentation in fundus photographs, integrating contrast enhancement, optimised loss functions, and a reproducible, low-code workflow.

Methods: To improve vessel visibility, colour fundus images and annotated vessel masks were preprocessed using CLAHE. The segmentation model, DeepLabV3+ with a ResNet50 backbone, was optimised with a combined Dice and Binary Crossentropy loss to reduce the impact of class imbalance. The dataset was divided into training and validation subsets at a 4:1 ratio. Data augmentation and early stopping were incorporated during training, which was performed on Google Colab through a custom notebook. Predicted masks were thresholded to evaluate segmentation performance.

Results: Compared to the initial architectures, the optimised DeepLabV3+ network yielded superior segmentation performance, especially through a reduction in false negatives. Model convergence was observed after 40–60 epochs, with minimal signs of overfitting. Preliminary outputs revealed improved boundary preservation and more reliable identification of thin vessels. Qualitative assessment showed close alignment of predicted masks with ground truth, most notably for larger vascular structures. Training accuracy was maintained between 80 and 90%, with consistent validation results. Further quantitative evaluation using Dice, IoU, and precision/recall will follow.

Conclusions: The proposed method demonstrates that with contrast enhancement and optimised loss functions, DeepLabV3+ can effectively segment retinal vessels. This pipeline offers a reproducible, scalable, and semi-automated approach for researchers with minimal coding expertise, making it suitable for clinical and academic settings.

Abstract No.: 205057

Trust and Patient Information: A Prospective Study of Available Online Resources

First Author: Tim ROBERTS

Co-Author(s): Sasha KAIROUZ, Brandy MUNRO

Purpose: Misinformation can impact understanding of symptoms and potential treatment thereby undermining trust in medical practitioners and the clinical discussion. We aimed to determine where patients source information on their eye conditions, which sources they trust, and the impact this has on their decision to seek care or adhere to their treatment plan.

Methods: Prospective anonymous patient survey (HREC approved) of patients attending private ophthalmic clinics (Vision Eye Institute, Australia) between March-August 2025. Survey outcomes collated and analysed according to age group, education, and gender.

Results: N = 208 respondents completed the survey, with 51% female and 75+ years (36%) representing the largest age cohort. 71% indicated tertiary qualifications. The patient's main source of information came from the ophthalmologist (67%). Professional clinical websites remained the most trusted source (57% "a lot") compared to internet search engines and social media (8% and 1% respectively).

Conclusions: Results suggest that the clinic remains both the dominant source of patient information and the most trusted documentation for patients, particularly patients > 50 years. Trust in social media information regarding treatment options was minimal. The eye health information patients sought often influenced their decision to see a doctor and/or adjust lifestyle habits. Providing clear, readily available information is key to optimising patient understanding and adherence regarding potential treatment and follow-up.

Abstract No.: 206672

Uncertainty Evaluation-Enhanced RETFound: Achieving Higher Accuracy for Diabetic Retinopathy Screening

First Author: Xiaoyan **HU**

Co-Author(s): Carol **CHEUNG**, Danqi **FANG**, Xujia **LIU**, Truong **NGUYEN**, Anran **RAN**, Ka Ho **SZETO**

Purpose: While deep learning models demonstrate human-level performance in diabetic retinopathy (DR) detection, real-world deployment risks severe consequences from diagnostic errors. We aim to apply a novel technique for uncertainty evaluation, the area under Confidence Operating Characteristics (AUCOC), to the RETFound foundation model, which can enhance model accuracy and identify borderline cases while minimize human-delegated cases.

Methods: The training dataset was retrospectively drawn from the Chinese University of Hong Kong-Sight Threatening Diabetic Retinopathy (CUHK-STDR) study, containing 8254 retinal photographs. We split the data into training, validation, and test sets at a ratio of 7:1:2. We adapted RETFound using AUCOC for the referable DR detection (moderate NPDR or worse) task. AUCOC refers cases with confidence scores below the threshold to experts for review. Performance of RETFound with AUCOC was evaluated against baseline RETFound alone. In addition, we further analysed the performance when 20% of the total samples requiring human double-checked these samples manually to identify failure patterns.

Results: AUCOC-enhanced RETFound model achieved superior performance (the area under the receiver operating characteristic curve [AUROC] 0.934 vs. 0.924, p-value <0.001). When 20% of test images were flagged for expert review, 60% of these cases involved poor image quality, other abnormalities (e.g., drusen), or borderline DR manifestations. In addition, the accuracy, sensitivity, and specificity of the model after excluding these uncertain cases improved to 91.7% (95%CI 90.1-93.1), 88.3% (95%CI 85.6-90.8), and 94.9% (95% CI 93.2-96.5) from 85.5% (95% CI 83.8-87.2), 83.6% (95%CI 81.1-86.1), and 87.1% (95%CI 84.9-89.2), respectively.

Conclusions: The proposed uncertainty evaluation-enhanced RETFound model can potentially balance diagnostic accuracy and operational efficiency in real-world DR screening. By autonomously identifying uncertain cases and double-checking by human, the framework ensures model safety while optimizing specialist resource allocation.

Abstract No.: 201495

Universal Integrated Electronic Eyedrop Sleeve: A Novel Compliance Monitoring System

First Author: Shruti **MARU**

Co-Author(s): Neeraj **ISRANI**

Purpose: Is there a potential role for the use of alerts or reminders at drop-taking times, using smart-phone-enabled technologies? Purpose is to integrate technology that can register a successful drop delivery to the eye and communicate this information to both patients and providers.

Methods: To check the efficacy of the device using a validated questionnaire before & after the use of the device. We conducted 86 eyes of 74 pts among Post operative patients and used a semi-structured questionnaire to assess patient-reported problems and adherence to medications. This is the questionnaire including demographics, cause of noncompliance, number of medications, duration of treatment etc.

Results: We compared the compliance rate before & after the use of the device and found significant improvement.

Conclusions: This innovative device emphasizes the importance of compliance and improves patient adherence

Abstract No.: 203994

Validation Study of Huvitz Biometry HBM-1

First Author: Ungsoo **KIM**

Co-Author(s): Jae Hoon **JUNG**, Jaemin **KIM**

Purpose: To evaluate the repeatability and agreement of Huvitz optical biometer HBM-1 in Korean normal, cataract and pseudophakia eyes.

Methods: After a screening test, a total of 143 eyes were enrolled. Forty-eight normal eyes, 48 cataract eyes, 47 pseudophakia eyes. For each eye, measurements were attempted up to three times, with a maximum of five attempts allowed if blinking or inadequate eye opening interfered. Before each measurement, the biometer was repositioned relative to the eye and recentered. Repeatability (within-subject standard deviation Sw, intraclass correlation coefficient ICCrep) and agreement metrics – including mean difference $\pm$ standard deviation (Δ mean $\pm$ SD), Bland–Altman limits of agreement width (LOAwidth), and Pearson correlation coefficient (ρ) – were calculated for Keratometry (Kf, Ks) and biometry parameters; axial length(AL), lens thickness (LT), anterior chamber depth (ACD), and central corneal thickness (CCT). Results from HBM-1 were compared against those obtained with the IOLMaster 700 (Zeiss).

Results: In the normal-eye subgroup, no statistically significant differences were observed for AL, LT, and CCT between devices. In the cataract subgroup, only AL did not differ significantly between the two devices. In the pseudophakia subgroup, although the difference of AL(0.01 ± 0.02 mm) was statistically significant (p -value < 0.05), it was not considered clinically significant.

Conclusions: Huvitz optical biometer HBM-1 demonstrates high repeatability and good agreement with the IOLMaster 700 across normal, cataract and pseudophakia eyes. Axial length measurements showed excellent inter-device agreement, supporting their reliable use interchangeably between devices. However, other parameters (LT, ACD, CCT and keratometry) often exhibited broader limits of agreement and, in some cases, statistically significant differences, indicating that their interchangeability between devices should be approached with caution.

Abstract No.: 205115

Validity of AI Models in Diagnosing Infectious Keratitis

First Author: Madhu **UDDARAJU**

Purpose: To validate the efficacy & accuracy of various AI mobile applications in diagnosing infectious keratitis.

Methods: Seventy diagnosed Cases of Infectious keratitis caused by different organisms were uploaded to 4 different AI mobile platforms with detailed case history, and response was analysed based on response time, diagnostic accuracy, suggested management protocols, number of references made, and disclaimers given.

Results: Chat GPT had the quickest response time, Perplexity had more medical journal references, Google Gemini had the highest diagnostic accuracy, and common organisms like fungus and bacteria had more diagnostic accuracy than uncommon organisms like Acanthamoeba and Nocardia.

Conclusions: AI-based mobile apps have good screening value for infectious keratitis, especially fungal and bacterial infections, making it a good tool for practitioners in remote areas who do not have access to microbiology and specialist cornea care.

Abstract No.: 203646

Visual Field Patterns and Progression Factors in Primary Open-Angle Glaucoma Based on Machine Learning

First Author: Yu-tzu **PING**

Co-Author(s): Zidong **CHEN**, Gus **GAZZARD**, Yuzhen **JIANG**, Kezheng **XU**, Yangfan **YANG**, Qiaona **YE**, Minbin **YU**, Yuqing **ZHANG**, Songfu **ZOU**

Purpose: This study aims to utilize Principal Convex Hull Analysis (PCHA) to identify visual field (VF) patterns in patients with POAG and further investigate the relationship between VF patterns and the risk of VF progression under different IOP conditions.

Methods: The baseline VF data of POAG patients from the LiGHT China cohort were analyzed using PCHA. Then, participants were categorized into four groups based on whether they achieved the target IOP and whether GPA indicated VF progression during follow-up. The relationship between VF patterns and VF progression under different IOP conditions was further analyzed.

Results: A total of 859 eyes from 495 participants were included, with an average age of 48.2 ± 17.1 years. Among them, 547 eyes (63.7%) were diagnosed with mild POAG, 216 eyes (25.1%) were diagnosed with moderate POAG, and 96 eyes (11.2%) were diagnosed with severe POAG. PCHA determined 11 patterns were most representative with the highest AREV (80.1%) and lowest BIC (938.2). Pattern 2 had a higher weight in NTG patients ($P=0.003$). Pattern 11 had a higher weight in POAG eyes with pathological myopia ($P=0.008$). Pattern 2, superior arcuate defect with central VF damage, and pattern 10, nasal step VF defect, both had the highest weights in the IOP+/VF+ group ($P<0.0001$). Pattern 6, inferior and temporal peripheral VF defect, had the highest weight in the IOP-/VF+ group ($P<0.05$). Pattern 10 was strongly associated with IOP-dependent VF progression risk with a hazard ratio of 8.56 (95% CI: 1.92-38.18, $P<0.005$). Pattern 6 showed significant correlation with non-IOP-dependent VF progression risk with a hazard ratio of 11.84 (95% CI: 1.53-91.50, $P=0.02$).

Conclusions: This study successfully utilized PCHA to identify VF patterns in POAG patients from the LiGHT China cohort. The proportion of specific VF patterns serves as a predictive factor for distinguishing IOP-dependent or non-IOP-dependent progression risk factors, enabling more precise and timely intervention against glaucoma progression.

Abstract No.: 204904**Win-Win: Portable Nonmydriatic Fundoscopic Camera Plus AI Model for Retina Screening for Employees***First Author: Jen-hsiang SHEN**Co-Author(s): Chao-kai CHANG, Yih-shiou HWANG, I-hung LIN*

Purpose: We hope to provide free fundus photo examination plus AI Model to ensure the optimal health for our employees. Fundus examination is crucial, because many early fundus disease lack symptoms and still cause irreversible vision damage.

Methods: After passing IRB approval, our employees voluntarily received free Portable Nonmydriatic Fundoscopic Camera (JYE01) developed by Foxconn and Young Optics. Simultaneous marking was done by CoDoctor AI developed by Foxconn. Markings were later confirmed by senior ophthalmologist.

Results: One hundred and fifty-six employees joined the study, and all received the examination in 1 day. Ninety percent of participants are female. Mean age is 32.17 years old. Ninety percent of the image was qualified for CoDoctor AI analysis. Two employees were found to have diabetic retinopathy, and one employee was found to have age-related maculopathy. One hundred percent agreement was later confirmed by senior ophthalmologist.

Conclusions: Extreme reliability and convenience were demonstrated for this Portable Nonmydriatic Fundoscopic Camera Plus AI Model. We not only improved our employees' health, we can also promote this efficient model to other companies and general public. Vision healthcare could be more accessible, and health awareness would be further highlighted in society.

Abstract No.: 208453**Z-Calling: A Tool for dZ-DNA Detection and A/Z Base Calling Using Pacbio HiFi Reads***First Author: Bo WU**Co-Author(s): Ying CHEN, Wei CHI, Longjian NIU, Chuan-le XIAO, Jiayong ZHONG*

Purpose: The substitution of adenine (A) with 2,6-diaminopurine (Z) in phage genomes has critical biological and technological implications. Progress is hampered by the lack of reliable methods to detect dZ-DNA and accurately discriminate A from Z at single-nucleotide resolution. We developed Z-Calling to overcome this, leveraging kinetic data from PacBio CCS reads.

Methods: Z-Calling employs two machine learning modules: A/Z base calling and read classification. Z incorporation induces reproducible, context-dependent kinetic shifts, mainly in the pulse width (PW) signal. A Multilayer Perceptron (MLP), trained on mixed dZ-

DNA and hybrid datasets, handles base discrimination. The Z-probability output then feeds a Support Vector Machine (SVM) classifier to categorize reads as dZ-DNA or canonical DNA.

Results: The A/Z base-calling module demonstrated robust performance (AUC: 0.942 to 0.952). It accurately quantified the Z base frequency (26.4%) in an engineered yeast genome (expected ~27%). The read classification module showed exceptional sensitivity, distinguishing dZ-DNA sources with a minimum positive likelihood ratio (LR+) of 490. Z-Calling effectively and efficiently identified dZ-DNA sources in artificial metagenome datasets with low dZ-DNA content.

Conclusions: Z-Calling is the first machine learning tool to accurately identify Z bases at single-nucleotide resolution directly from PacBio HiFi data. Its high sensitivity and precise A/Z discrimination establish a generalizable platform, accelerating the study of natural Z-genome organisms and unlocking dZ-DNA's potential in synthetic biology and data storage.

Academia, Research, Teaching and Education in Ophthalmology**Abstract No.: 207377****A Digital Pathway in Vitreoretinal Fellowship: E-Logbook Insights***First Author: Debolina DEB**Co-Author(s): Prithvi*

Purpose: Traditional logbooks limit detailed documentation, impacting training quality.

Methods: We created a dynamic E-logbook during a 2-year vitreoretinal fellowship, integrating EMR and advanced imaging tools such as Zeiss slit lamp, Clarus 700, Spectralis, Cirrus OCT, Forus, and Ngenuity. It records clinical cases, surgical procedures, follow-ups, with multimedia content like annotated videos.

Results: Organized into clinical summaries, an image atlas, and a surgical log with hyperlinked videos, it supports unlimited entries and easy access. Rare cases including Oguchi disease, torpedo maculopathy, hybrid cavitory disc, staged ROP, retinoblastoma, FEVR, and choroidal osteoma are included.

Conclusions: This platform serves as an invaluable resource for academic discussions, presentations, and continuous learning, providing a visual, interactive archive that enhances understanding, retention, and professional growth in vitreoretinal training. The E-logbook enhances vitreoretinal training by providing detailed, multimedia documentation and easy access to rare cases, promoting deeper understanding,

improved clinical skills, and sustained learning—ultimately advancing diagnostic and surgical proficiency in ophthalmology.

Abstract No.: 205331

A New Subcluster of Müller Cells in Diabetic Retinopathy As Intervention Candidates by ScRNA-Seq Analysis

First Author: Yun ZHANG

Co-Author(s): Tianshu YU, Yu ZHOU

Purpose: Diabetic retinopathy (DR) causes irreversible vision loss. Müller cells, critical for retinal homeostasis yet drivers of DR progression, exhibit unelucidated functional heterogeneity. The aim of this study is to investigate the subclusters and function of müller cells in DR.

Methods: Retinal tissues from leptin receptor-deficient (db/db, type 2 diabetes model) mice and control db/m mice were identified by single-cell RNA sequencing (scRNA-seq) and bioinformatics analysis.

Results: We identified 7 distinct Müller cell subclusters in db/db mice model. Among these, the proportion of Müller_CO was significantly increased in db/db mice, enriched in stemness-related pathways including DNA repair and cell cycle regulation, and serves as the initiating origin of rod photoreceptor differentiation. Egr1⁺ is the core transcriptional regulator of Müller_CO, which targets genes (including Itgav) to activate stemness-associated pathways. Furthermore, Müller_CO acts as a dominant signaling hub in db/db mice, interacting with other subclusters via the Itgav/Itgb8 (αvβ8 integrin) axis.

Conclusions: These data provide a detailed analysis of Müller heterogeneity landscapes under diabetic and normal conditions, clarify the pathological role shift of Müller_CO in DR, and propose Egr1⁺/αvβ8 as promising therapeutic targets.

Abstract No.: 206919

A Simple Eye Model for Practicing Retinal Membrane Peeling Surgery

First Author: Simaporn SETTHAWONG

Co-Author(s): Supathida JIAMSADAW, Chinnapat MONTRISUKSIRIKUN, Nuttawut RODANANT, Nuttara SAPPHASO, Thanchanit SAWETRATANASTIEN

Purpose: To evaluate the effectiveness of a low-cost, simple eye model for retinal membrane peeling training.

Methods: A pilot study included five ophthalmology trainees with intraocular surgery experience but no prior peeling exposure, and five vitreoretinal experts. The model was created using 60-ml syringes, a plastic mask, a sponge, reused microforceps, a reused light probe, a BIOM, a microscope, and vinegar-soaked chicken eggshells. Peeling was assessed in two steps:

flap initiation and complete peeling, using a 3-point scoring system (0-2) and time measurement. Novices performed peeling before and after training in the BIOM setup, microscope adjustment, and microforceps handling. Experts evaluated the model's utility and realism using 3-point (1-3) and 4-point Likert scales (1-4), respectively.

Results: Novices demonstrated a significant reduction in complete peeling time (pre: 459.0 ± 299.3 s, post: 238.6 ± 163.9 s; p=0.043). Trend toward improvement was observed in flap initiation score (0.00 ± 0.00 vs. 1.40 ± 0.89; p=0.059), complete peeling score (0.60 ± 0.55 vs. 1.60 ± 0.42; p=0.063), and flap initiation time (67.80 ± 14.84 vs. 40.40 ± 47.26 s; p=0.225). Experts rated the model user-friendly and effective (2.60 ± 0.55), particularly for BIOM assembly (2.80 ± 0.45) and microforceps use (2.40 ± 0.55). The model was considered helpful for building surgical confidence (2.40 ± 0.89). Realism was rated high for BIOM assembly (3.60 ± 0.55) and instrument setup (3.40 ± 0.55), but moderate for tactile feedback (2.00 ± 1.22).

Conclusions: This simple, low-cost model is effective for practicing retinal membrane peeling and related surgical skills, with potential for refinement in tactile realism.

Abstract No.: 206415

ABC Stress Program for Nurses: Supporting Mental Health and Ophthalmic Care

First Author: Dr Zaidah Rizidah MURANG

Purpose: Nurses often experience high occupational stress, contributing to anxiety, depression, and fatigue, which can affect clinical performance and patient care, including ophthalmic services. This study evaluates the effectiveness of the ABC Stress Program—an online-based stress management program developed by the University of Tokyo—in improving psychological well-being, health-related quality of life, and work-related outcomes among nurses in Brunei Darussalam.

Methods: A randomized controlled trial is being conducted among registered nurses from both public and private hospitals in Brunei. Participants are randomly assigned to either a 6-week ABC Stress Program (intervention) or a control group. Assessments are conducted at baseline (T1), post-intervention (T2, week 6), and follow-up (T3, week 12) via Qualtrics. The primary outcome is psychological distress measured using the DASS-21. Secondary outcomes include health-related quality of life (EQ-5D-5L), absenteeism, and work performance (HPQ). Mixed-model analysis for repeated measures will be applied using an intention-to-treat approach.

Results: The study is ongoing and currently in the baseline recruitment phase. Completion of data collection is expected before the conference. We anticipate that participants in the intervention group

will demonstrate significantly greater reductions in anxiety, stress, and depression, alongside improvements in quality of life and work performance, compared to controls.

Conclusions: This trial will provide evidence on the effectiveness of the ABC Stress Program as an accessible, scalable intervention for nurses. Findings may inform strategies to reduce stress-related fatigue, enhance visual comfort, and improve workforce well-being, thereby supporting the quality of ophthalmic and general patient care.

Abstract No.: 203076

AI-Driven Readability in Dry Eye Diagnostic Explanations: A Comparative Study of GPT-4.5, Deepseek-R1, Gemini 2.5 Pro, and Claude Opus 4

First Author: Chenxuan **LIU**

Co-Author(s): Xiangyu **CHEN**, Xuan **LIAO**, Junyi **LOU**, Jiahao **NIU**

Purpose: Common readability metrics (e.g., Flesch-Kincaid) are designed for English and perform poorly on Chinese due to linguistic differences. We developed a Chinese-specific readability scale to evaluate AI-generated diagnostic explanations for dry eye syndrome, aiming to enhance patient understanding amid limited healthcare resources.

Methods: We evaluated Chinese text across five dimensions: average sentence length, average word length, total character count, sentence density, and formatting. Each dimension was weighed empirically (30%, 25%, 15%, 20%, and 10%, respectively) to form a 100-point scale. Based on this scale, scores were categorized into educational levels. We used 40 complete dry eye cases from the first half of 2025, each containing complaint, examination, and diagnosis data. Each case was input into four models—GPT-4.5, Deepseek-R1, Gemini 2.5 Pro, and Claude Opus 4—with three independent responses generated per case to ensure stability and reduce randomness. Readability scores were computed programmatically using Python.

Results: All models scored between 36.50–40.29 (mean ≈ 39), placing readability in the “college and professional” range (0–39.9). Gemini 2.5 Pro showed higher variability. Results indicate that AI explanations are most accessible to highly educated individuals.

Conclusions: AI-generated medical explanations remain challenging for those without higher education, potentially widening health literacy gaps. To improve accessibility, China should enhance basic education, promote AI literacy, and establish standardized readability metrics for public and professional use.

Abstract No.: 200506

Anterior Segment Parameters in Iridofundal Coloboma (IFC): A Comparative Analysis With Healthy Eyes

First Author: Manasi **TRIPATHI**

Co-Author(s): Ashish **MARKAN**

Purpose: To compare anterior segment biometric parameters between eyes with iridofundal coloboma (IFC) and healthy controls.

Methods: In this cross-sectional study, patients with IFC and healthy controls were enrolled for anterior segment evaluation. Parameters included central corneal thickness (CCT), endothelial cell density (ECD), coefficient of variance (CoV), hexagonality (Hex), axial length (AL), anterior chamber depth (ACD), and lens thickness via IOL Master, AS-OCT, and specular microscopy.

Results: Forty eyes with IFC and 40 age-matched controls were enrolled for analysis (Age 7-45 years). IFC eyes had significantly higher CCT ($610.12 \pm 62.33 \mu\text{m}$ vs $501.20 \pm 38.39 \mu\text{m}$, $p=0.0051$) and ECD (3457.50 ± 465.54 vs 3106.50 ± 335.86 , $p=0.004$). ACD was lower in IFC eyes ($2.59 \pm 0.33 \text{mm}$) than in controls ($3.51 \pm 0.91 \text{mm}$, $p<0.001$). In IFC group, eyes with microcornea had higher CCT than those without ($671.5 \pm 16.26 \mu\text{m}$ vs $577.14 \pm 47.76 \mu\text{m}$). Strong intercorrelations between biometric parameters (AL-ACD $r = 0.850$, ACD-LT $r = 0.991$) suggest coordinated developmental alterations in IFC, indicating that colobomatous malformation affects multiple anterior segment structures simultaneously.

Conclusions: IFC eyes demonstrate distinct anterior segment remodeling, with increased CCT and ECD suggesting structural adaptation.

Abstract No.: 200242

Apert Syndrome in a South Asian (Bangladeshi) Male Child- A Rare Case Report

First Author: Maliha **NAWAR**

Co-Author(s): Nirupam **CHOWDHURY**, Md Moinul **HOQUE**, Zahida **JABBAR**, Md Showkat **KABIR**, Mohammad Shish **RAHMAN**

Purpose: To report a case of Apert Syndrome in 9 years old South Asian Bangladeshi male child. This case is novel due to its rare combination of classical Apert syndrome features with notable ophthalmic findings and early multidisciplinary intervention, which is seldom reported in similar settings.

Methods: We presently describe the case of a 9-year-old male patient with prominent forehead, proptosis, short and broad nose, pseudo prognathism, crowding of teeth and ectopia, and severe bilateral syndactyly of hands and feet. Examination of the patient revealed the findings of abnormal contour of the head, symmetric syndactyly of hands and toes, mental

retardation, delayed milestones, mid-face hypoplasia, exophthalmos, exorbitism, high arched palate, crowded teeth.

Results: From the clinical characteristics and radiology evaluation, the patient concluded with suspicion of AS.

Conclusions: We reported a 9-year-old male patient with AS with craniosynostosis and acrocephalosyndactyly. The characteristics of clinical manifestation of AS should be aware by physicians to be able to diagnose the disease.

Abstract No.: 202122

Association Between EyeSi Simulator Scores and Intraoperative Complications in Resident Phacoemulsification Cataract Surgery

First Author: Warakorn **THIAMTHAT**

Co-Author(s): Teeravee **HONGYOK**, Pruksa **VICHAIYA**

Purpose: This study aims to elucidate the relationship between EyeSi simulator scores and the rate of intraoperative complications in phacoemulsification surgeries performed by third-year ophthalmology residents at Rajavithi Hospital

Methods: A retrospective cohort study was conducted at Rajavithi Hospital, Bangkok, Thailand, including third-year ophthalmology residents who completed EyeSi simulator training and performed phacoemulsification surgeries between January 1, 2022, and December 31, 2023. Data on patient characteristics, surgical outcomes, and resident performance on the EyeSi simulator were extracted from electronic medical records. Statistical analyses, including the Chi-square test, Fisher's Exact Test, Mann-Whitney U-test, and Spearman's rank correlation coefficient, were performed using IBM SPSS Statistics for Windows, version 26.0.

Results: Fourteen residents participated, performing a total of 979 phacoemulsification cases. The mean total EyeSi simulator score was $21,505.43 \pm 642.70$. The overall complication rate was 10.6%, with posterior capsule rupture occurring in 5.7% of cases. A weak positive correlation was observed between total EyeSi simulator scores and operative time (Spearman's $\rho = 0.162$, $p < 0.001$). No significant correlation was found between total EyeSi scores and overall complication rates.

Conclusions: EyeSi simulator training is beneficial for preparing residents for phacoemulsification surgery, providing step-by-step guidance and familiarization with intraocular navigation. While the overall simulator scores may not predict surgical proficiency, specific training in complications management may reduce the risk of posterior capsule rupture. Residency programs should consider comprehensive assessment strategies and personalized training plans to enhance the effectiveness of simulator-based training.

Abstract No.: 205984

Associations of Cardiovascular Health and New-Onset Age-Related Macular Diseases From UK Biobank

First Author: Tsz Fung Gavin **WONG**

Co-Author(s): Jason **YAM**, Peng **YU**, Yuzhou **ZHANG**

Purpose: The purpose of this study was to examine the correlation between cardiovascular health (CVH), assessed by metrics of the Life's Essential 8 (LE8) score, and the risk of new-onset age-related macular degeneration (AMD).

Methods: UK Biobank data of 271,274 participants free of both cardiovascular diseases and AMD at baseline were utilised for longitudinal analysis. Follow-up data were mainly obtained from online questionnaire assessments and electronic health records. An average LE8 score (0-100) was calculated from the individual scores of the 8 metrics, then categorised into three groups: low (<50 points), moderate (50 to <80 points) and high (≥ 80 points), with higher scores indicating better CVH. Cox proportional regression models were used to calculate hazard ratios (HR) and their corresponding 95% confidence intervals (CI), adjusted for covariates including age, sex, ethnicity, educational level, Townsend Deprivation Index (TDI), household income and drinking status. Furthermore, the population attributable risk (PAR%) was calculated for CVH and each individual LE8 component.

Results: During an average follow-up duration of 10.9 years, a total of 7468 (2.8%) cases of AMD were documented. Individuals with moderate and high CVH levels had a 14% (HR = 0.86; 95% CI, 0.78-0.94) and 23% (HR = 0.77; 95% CI, 0.69-0.86) reduced risk of AMD, respectively. A linear dose-response relationship was identified between cumulative LE8 score and AMD incidence. Moreover, adjusted PAR% suggested 9.4% (95% CI, 3.7%-15.1%) of AMD cases could be prevented by high CVH. Amongst individual CVH metrics, ideal blood glucose and blood pressure levels were associated with a reduction of 3.3% and 8.7% in AMD cases, respectively.

Conclusions: Enhanced CVH, as quantified by LE8, was significantly inversely associated with the risk of developing AMD. CVH promotion in accordance with the LE8 guidelines might potentially positively contribute to AMD prevention.

Abstract No.: 208516

Awareness of Refractive Errors: A Global Review of Current Knowledge and Assessment Methods

First Author: Yuhe **LIU**

Co-Author(s): Jun **CHEN**, Xiangui **HE**, Guangzhuang **JING**, Zhenglin **LIU**, Jingjing **WANG**, Xun **XU**

Purpose: To evaluate global awareness of refractive errors (RE) and its assessment methods, addressing the

critical gap between high correctability and the high prevalence of uncorrected RE, a major cause of vision impairment.

Methods: A systematic literature search was conducted in PubMed, Web of Science, and Scopus up to September 2025. Studies focusing on RE awareness, knowledge, attitude, or practice were included, resulting in the analysis of 237 articles.

Results: Global RE awareness is insufficient and characterized by significant geographical and socioeconomic disparities, with low- and middle-income countries bearing the highest burden. Common misconceptions include a lack of knowledge about myopia complications, the nature of presbyopia, and unfounded beliefs about spectacle wear (e.g., that it weakens vision). Research is often biased towards specific groups like parents of children or clinical patients, leaving general adult and rural populations underrepresented. A major limitation is the reliance on non-standardized, cross-sectional questionnaires, which hinders reliable cross-regional comparisons and longitudinal tracking.

Conclusions: Substantial gaps in RE awareness persist worldwide, exacerbated by the lack of validated assessment tools. An integrated global strategy is urgently needed. This should include developing standardized multidimensional awareness metrics, implementing targeted health education, expanding community-based screening, and leveraging digital technologies and team-based service models. These actions are vital for raising awareness, closing the correction gap, and achieving equitable eye health.

Abstract No.: 205747

Burnout and Engagement Among Ophthalmology Professionals in Nepal: A Cross-Sectional Analysis

First Author: Kaushal **POKHREL**

Purpose: To evaluate the prevalence and patterns of burnout and engagement among ophthalmology professionals of Nepal and examine associations with demographic and occupational factors.

Methods: A cross-sectional survey was conducted among 130 ophthalmology professionals, including consultants, and trainees (fellows and residents). Burnout was assessed using validated scales measuring emotional exhaustion, depersonalization, and personal accomplishment. Participants were categorized into five profiles: Engaged, Ineffective, Overextended, Disengaged, and Burnout. Statistical analyses included descriptive statistics, ANOVA, and chi-square tests to explore associations with gender, marital status, job role, and workplace type.

Results: While 42.3% of participants were classified as engaged, 36.6% exhibited signs of burnout across varying levels—ineffective, overextended,

disengaged, or full burnout. Residents showed the highest emotional exhaustion (Mean = 3.26) and depersonalization (Mean = 1.83), and the lowest personal accomplishment (Mean = 3.72). Senior consultants reported the lowest burnout scores. Workplace type significantly influenced burnout ($p < 0.01$), with higher emotional exhaustion in non-profit and government sectors. Job role was a strong predictor of burnout profile ($p < 0.001$), whereas gender and marital status showed no significant associations.

Conclusions: Over one-third of ophthalmology professionals experience some form of burnout, particularly trainees and those in non-profit or government sectors. Targeted interventions are needed to support early-career ophthalmologists and promote workplace well-being.

Abstract No.: 203145

Comparative Experience With Phaco-I and Kitaro Wet Lab Eye Models Among Ophthalmology Trainees in Malaysia

First Author: Ming Yean **ONG**

Co-Author(s): Mae-lynn **CATHERINE BASTION**, Teck Chee **CHENG**, Pei Rong **CHIUN**, Chenshen **LAM**, Ainal Adlin **NAFFI**

Purpose: This study aimed to evaluate and compare ophthalmology trainees' experiences with the Phaco-I and Kitaro eye models.

Methods: A cross-sectional study was conducted during a structured phacoemulsification workshop at Hospital Canselor Tuanku Mukhriz, Malaysia (August 2025). 19 ophthalmology trainees who completed simulation on both Phaco-I and Kitaro models were included. Participants rated their experience across four domains, namely surgical realism, skill development, confidence and skill transfer, and overall experience using a 20-item validated questionnaire on a 5-point Likert scale. Internal consistency was assessed using Cronbach's alpha. Comparative analysis was performed with the Wilcoxon signed-rank test.

Results: Both instruments demonstrated excellent reliability (Cronbach's $\alpha = 0.925$ for Kitaro; 0.878 for Phaco-I). Across all domains, Kitaro achieved significantly higher ratings than Phaco-I. Kitaro outperformed in surgical realism (3.88 ± 0.41 vs. 3.38 ± 0.53 ; $p = 0.011$), skill development (4.18 ± 0.62 vs. 3.50 ± 0.50 ; $p = 0.002$), confidence and skill transfer (4.21 ± 0.60 vs. 3.42 ± 0.43 ; $p = 0.0003$), and overall experience (4.39 ± 0.65 vs. 3.21 ± 0.71 ; $p = 0.0003$). Most participants (94.7%) preferred the Kitaro model, citing greater realism and ease of use, while Phaco-I was commended for its realistic anterior capsule and cost-effectiveness.

Conclusions: Among Malaysian trainees, Kitaro provided superior surgical realism, confidence,

and overall user experience compared to Phaco-I. Nonetheless, Phaco-I retains educational value as a cost-effective tool for foundational practice. A staged approach integrating both models may optimize phacoemulsification training in resource-conscious settings.

Abstract No.: 205513

Decoding the Immune-Inflammatory Landscape of Cataracts

First Author: Shreya SARAOGI

Co-Author(s): Swaminathan SETHU, Naren SHETTY, Arka Subhra GHOSH, Lubna ZAMEER

Purpose: Emerging evidence highlights the contribution of immuno-inflammatory mechanisms to cataractogenesis. In light of this, we conducted a comprehensive analysis of intraocular inflammatory mediators and characterized immune cell profiles across distinct cataract subtypes.

Methods: Subjects undergoing cataract surgery (n=78) were recruited following ethics committee approval and informed consent. Study includes subjects with nuclear sclerotic cataract (NS 1-5, n=38), posterior subcapsular cataract (PSC, n=34), mature cataract (n=4) and cortical cataract (CC, n=2). Aqueous humor (AH) collected by anterior chamber paracentesis were used to measure the levels over 25 inflammatory factors and 8 immune cell types by flow cytometry.

Results: A significantly higher AH levels of IL-17F and VEGF-A were observed in subjects with PSC and NS cataract compared to those with NS without PSC cataract. The proportions of neutrophils, monocytes, NK cells, and T cells were significantly different between types of cataracts studied. Neutrophils were higher in subjects with PSC cataract compared to those with NS and PSC cataracts. However, monocytes, NK cells and T cells were higher subjects with NS and PSC cataracts compared to those with PSC cataracts.

Conclusions: Immuno-inflammatory profile is distinct in patients with PSC compared to other types of cataracts. Our findings demonstrate cataract type-specific immune cell and molecular diversity has profound implication in the understanding of cellular and molecular basis of cataractogenesis. Hence, it has clinical applicability in prognostication, prevention, and management of post-cataract surgery outcomes and co-morbidities.

Abstract No.: 206620

DropRight: An Integrated Adherence Support Tool to Improve Eye Drop Compliance in Ophthalmology Patients

First Author: Saraa YOOSUF

Purpose: To introduce a low-cost, scalable tool designed to improve patient adherence to prescribed

eye drops, particularly for glaucoma and post-operative care, by combining education, behavioral nudges, and digital recall.

Methods: “DropRight” was conceptualized as a multi-component adherence support tool. Features include: (1) a color-coded dosing card affixed to bottles, (2) automated SMS/WhatsApp reminders aligned with prescription times, (3) a paper/app-based drop diary for daily self-tracking, (4) a feedback loop where clinicians review adherence logs during follow-up, and (5) short visual education materials for patients and caregivers. System requirements and user pathways were mapped to ensure feasibility in both high- and low-resource settings.

Results: This tool addresses common barriers to compliance: • Forgetting doses → solved by reminders and visible bottle cues. • Unawareness of importance → solved by education materials. • Poor accountability → solved by diary + physician feedback loop. • Complex regimens → simplified through color-coded dosing guidance. (results are conceptual)

Conclusions: “DropRight” offers a pragmatic, low-cost solution to one of ophthalmology’s most persistent challenges: poor adherence to eye drops. By combining behavioral nudges with digital support, it provides an adaptable framework that can be implemented in both resource-rich and resource-limited eye care systems to improve long-term outcomes.

Abstract No.: 205236

Effect of Silicone Oil Tamponade Duration on Peripapillary Microcirculation Assessed by Optical Coherence Tomography Angiography

First Author: Inara HAJI

Co-Author(s): Elmar GASIMOV

Purpose: To evaluate changes in peripapillary vessel density and flow index after removal of intraocular silicone oil and to assess the influence of tamponade duration.

Methods: A prospective observational study included 20 eyes of 19 patients who underwent pars plana vitrectomy with 1000-cSt silicone oil tamponade for complex retinal detachment or proliferative diabetic retinopathy. Optical coherence tomography angiography (OCT-A, 6x6 mm scans) was performed before oil removal and at 1, 3, 6, and 12 months postoperatively. Patients were divided into two groups according to tamponade duration: 1–6 months and 6–12 months. Main outcomes were peripapillary vessel density and flow index.

Results: Mean baseline peripapillary vessel density was 40.16 ± 1.34 in the short-term group and 37.94 ± 0.90 in the long-term group. At 12 months after oil removal, density increased to 45.13 ± 1.52 and 43.67 ± 0.87 , respectively ($p = 0.24$ between groups). Flow index rose from 0.341 ± 0.044 to 0.418 ± 0.015 in the short-

term group and from 0.245 ± 0.038 to 0.392 ± 0.020 in the long-term group ($p = 0.074$ between groups). No significant correlations were found with age, sex, refraction, or axial length.

Conclusions: Peripapillary vessel density and flow index significantly increased after silicone oil removal, indicating recovery of optic nerve head microcirculation. Eyes with shorter tamponade showed a tendency toward higher perfusion and flow recovery, suggesting that early oil removal may reduce the risk of microvascular compromise. Timely removal of silicone oil, whenever retinal status permits, should be considered to optimize postoperative microvascular outcomes and preserve long-term optic nerve health.

Abstract No.: 204346

Exploring the Establishment of a Standardized Animal Eye Model Training System for Cataract Surgery Among Primary Care Eye Doctors

First Author: Dan **HE**

Co-Author(s): Jia **GAO**, Chunli **LI**, Min **WU**

Purpose: To apply quality improvement (QI) principles to enhance cataract surgery training for primary care eye doctors, establish a standardized training system, and improve practical skill translation.

Methods: A 1.5-month specialized training program was conducted for 10 county-level doctors using a stepped closed-loop model: theoretical training, clinical observation, stepwise animal eye practice, video self-assessment, self-evaluation, and mentor feedback. Guided by QI principles, the OSCAR-SICS/Phaco scale assessed surgical skills. Key indicators included: OSCAR score attainment $\geq 90\%$, independent surgery rate $\geq 60\%$, and complication rate $\leq 8\%$. Continuous improvement was driven by PDSA cycles, with dedicated mentors and equipment. Skill assessments were performed pre- and post-training.

Results: At baseline, none of the county-level eye doctors were able to perform cataract surgery independently, or had any experience with animal eye surgery. After training, participants completed 3,083 animal eye cataract surgeries, achieving the following outcomes: 100% pass rate in the surgical skills assessment at final evaluation; 70% independent cataract surgery rate; reduction in the posterior capsule rupture rate from 12% to 5%; reduction in average surgery time per case by 34%; and 30% reduction in consumable waste. A scalable training manual was developed.

Conclusions: The closed-loop training model, improved through QI principles, combined with standardized assessment, significantly enhances animal eye surgical skills of primary care eye doctors. This approach lays a foundation for independently performing cataract

surgeries on human eyes, shortens the learning curve, and holds significant potential for broader application.

Abstract No.: 205605

Gut Microbiota and Metabolite Contributions to Diabetic Retinopathy: Novel Insights From a Preliminary Study

First Author: Yinhua **HUANG**

Purpose: Diabetic Retinopathy (DR) is associated with gut dysbiosis and metabolic disorders. However, the specific pathogenic mechanisms remain unclear. This study aims to clarify how gut microbiota and its key metabolite, sodium butyrate (NaB), contribute to DR progression.

Methods: Fecal samples from healthy controls and diabetic patients underwent 16S rRNA sequencing to identify DR-associated microbial markers. A disease classification model was built using random forest analysis. Diabetic mice received intragastric NaB. After 12 weeks of NaB intervention, we monitored body weight, blood glucose, retinal structure, retinal function, and gut morphology. Plasma short-chain fatty acids (SCFAs) were measured by LC-MS. Fecal microbiota was also analyzed.

Results: Significant gut microbiota dysbiosis was observed in DR patients. This was characterized by a reduction in SCFA-producing bacteria. A model based on 25 microbial families showed good diagnostic accuracy. In diabetic mice, NaB reduced blood glucose, improved retinal thickness, decreased the number of activated microglia, and enhanced ERG responses. NaB also restored intestinal barrier integrity, increased plasma SCFAs (butyrate, isocaproate, caproate), and corrected microbial dysbiosis by increasing SCFA-producing norank_f_Muribaculaceae while reducing Lactobacillus and Lachnospiraceae_NK4A136_group.

Conclusions: This study provides novel evidence that gut microbiota dysbiosis and a deficiency in its metabolic products, particularly butyrate, are significant contributors to DR pathogenesis. Supplementation with NaB demonstrates multifaceted therapeutic benefits, protecting the retina and improving systemic health via the gut-retina axis, highlighting its promising translational value.

Abstract No.: 205333

ITE Regulates Macrophage Polarization Through AHR to Inhibit Choroidal Neovascularization

First Author: Yu **ZHOU**

Co-Author(s): Juanjuan **JJ**, Yangyang **LUO**

Purpose: Neovascular age-related macular degeneration (nAMD) is the primary cause of irreversible vision loss in the elderly. As clinical needs remain unmet, there is an urgent need to identify new

therapeutic targets for nAMD. The present study is to systematically investigate the pathological regulatory mechanisms of nAMD mediated by aryl hydrocarbon receptor (AHR) and verify the inhibitory effect of indole-3-carbinol (ITE), an endogenous agonist of AHR, on abnormal angiogenesis in nAMD.

Methods: To validate the necessity of AHR in this process, we conducted experiments in *Ahr*^{-/-} CNV mice. To dissect the molecular mechanisms underlying AHR-mediated CNV inhibition, single-cell transcriptome analysis, bioinformatics analysis and cell biology experiments were further applied.

Results: Results showed that the progression of nAMD is closely associated with a specific macrophage subset, IL1B_{low} Mac. Although this subset exhibits a pro-inflammatory phenotypic tendency, its pro-inflammatory capacity is significantly impaired due to the abnormal inhibitory state of the nuclear factor κ B (NF- κ B) pathway, thereby presenting pro-angiogenic properties. After AHR is activated by ITE, it can activate the NF- κ B pathway by enhancing oxidative stress response, reverse the pro-inflammatory functional defect of IL1B_{low} Mac, and ultimately inhibit abnormal angiogenesis in nAMD.

Conclusions: This study promotes deep understanding of the pathological mechanism of nAMD and lays a foundation for the development of subsequent clinical therapeutic targets.

Abstract No.: 200232

Impression Cytology for Suspicious Ocular Surface Lesions: A Modified Method

First Author: Shital **NANNAWARE**

Co-Author(s): Puja **BANG**

Purpose: Impression cytology is minimally invasive, innovative, fast, and cost-effective. The purpose of this study is to investigate the use of exfoliative cytology as a diagnostic tool in OSSN, Pterygium mimicking OSSN, and any suspecting ocular neoplastic pathology

Methods: Impression cytology of the lesion was performed by collecting smears using 35 mm Whatman filter paper, followed by smearing the cells onto slides and subsequently fixing them in 90% alcohol in the microbiology laboratory. Usually, reports came within 6 hours, and further management planned accordingly.

Results: Of the 3 cases, the 1st was diagnosed with actinic keratosis, the 2nd with pterygium, and the 3rd with ocular squamous cell neoplasia.

Conclusions: Impression cytology is a sensitive and specific method for the detection of ocular surface tumors. It is a novel, cost-effective, alternative method for rapid and less invasive early detection of ocular pathology and can be a promising fast innovation leading to better prognosis for the patient with utmost care. Clinical implication-Exfoliative cytology simple

and easy to learn and handle technique for beginners and confident boosting for diagnosing and giving management on OPD basis rather than planning for invasive procedure and cutting off the waiting period of histopathology report in early staging patient.

Abstract No.: 202630

Improving Cataract Quality and Cultivating a Perioperative Quality Control Culture

First Author: Lei **WEN**

Purpose: In response to the World Health Organization (WHO) 2030 eye health targets and per China's 14th Five-Year National Plan for Eye Health requirement for continuous improvement in effective cataract surgery coverage (eCSC), we implemented a "Cataract Continuous Quality Improvement Project" with support from international partners. The aim of the Project is to improve the quality of cataract services.

Methods: A cataract clinical quality improvement (QI) system was developed based on standardized protocols, with full staff participation, and continuous improvement to systematically promote quality improvements in cataract diagnosis and treatment. Real-time monitoring and dynamic feedback on the health management information platform was leveraged for medical record quality. Training and incentive mechanisms were used to strengthen quality awareness and motivate medical staff to actively participate. A localized QI training program was developed to build capacity of key personnel. The "Plan-Do-Study-Action" (PDSA) cycle is employed to optimize processes, significantly enhancing the quality control capabilities of medical staff.

Results: The Project optimized processes and patient management, improving the 4-week post-operative follow-up rate from 73% to 95%, and a continuous increase in patient satisfaction. The Project resulted in establishment of a support platform for perioperative quality control in cataract surgery, strengthened clinical QI and scientific research, and scalable quality control standards.

Conclusions: The Project demonstrated the effectiveness of localized training and utilizing PDSA cycles in improving the quality of cataract services. This model provides a practical reference for developing a quality control culture in eye care and contributes to achieving global eye health goals.

Abstract No.: 201097

Innovative Education Pathways: Navigating the Landscape of Complementary Learning in Ophthalmology Undergraduate Curriculum

First Author: Daniel **YIM**

Purpose: The aim of this study is to raise awareness, educate, and encourage educators to modernize

their teaching techniques and curriculums with digitization in ophthalmology. This review reveals the current landscape of available tools, from social media platforms and digital tools to innovative simulation techniques. With many current medical students being “digital natives,” - born into a digital world, technological teaching approaches may also provide complementary learning that is more familiar, convenient, and personalised to their technology-enhanced preferences of learning.

Methods: A narrative review was conducted with the aim to present use cases to illustrate the implementation of various digital tools in medical education. Following a critical-interpretivist framework, cases were then qualitatively evaluated for their impact and application to ophthalmology medical education. PubMed indexing with key words were used to identify studies that described various digital education techniques with selection criteria focusing on ophthalmology education. Non-traditional sources were also used to analyse social media content. 30 articles and 30 social media platforms were reviewed and analyzed.

Results: The data shows that modern teaching approaches have statistically significant improvements in student engagement, comprehension, and enjoyment. With a majority of incoming medical students being Generation Z and future Generation Alpha, it is becoming more critical than ever to become an adopters of technology into our medical curriculums.

Conclusions: The outcome is to encourage more medical educators to be aware of various formats of teaching and utilize various formats to complement their own didactic approaches, thus to ultimately advance eye health care.

Abstract No.: 205865

Molecular Defects in RS1-KI (R102W) Mouse Model of X-Linked Retinoschisis

First Author: Shengru MAO

Co-Author(s): Jiansu CHEN, Zekai CUI, Xihao SUN, Shibo TANG

Purpose: The pathogenesis of X-linked retinoschisis (XLRS) remains unresolved, with no effective treatment approach and specific therapy time. Here, we aim to investigate the molecular defects of RS1-KI (R102W) mouse retinas at different time points and evaluate the suitable time to treat the disease.

Methods: The Rs1-KI mice (R102W) were created by co-injection of zygotes with Cas9 mRNA and sgRNAs in CRISPR/Cas9 system targeting Rs1. Retinal OCT and H&E stain, Immunofluorescence (IF) staining, TEM ultrastructure, and ScRNA-seq were performed at P14 and P28.

Results: OCT and H&E revealed inner nuclear layer (INL) schisis with edema at P14, progressing to cystoid atrophy at P28. Early extracellular matrix (ECM) disruption was detected at P14, with reduced adhesion molecules (NCAM, JAM3, CDH2), axonal mislocalization, and mitochondrial abnormalities. By P28, ECM collapse intensified, with loss of interphotoreceptor matrix (COL9, IMPG1, IRBP), synaptic triad breakdown, and degeneration. IF showed preserved rhodopsin at P14 but reduced and disorganized labeling at P28, while cone arrestin decreased at P14 and mislocalized to somas at P28. TEM confirmed abnormal mitochondrial accumulation in the inner segments at P28. ScRNA-seq revealed disrupted intercellular signaling, with loss of NT (retinal development) and VISFATIN (photoreceptor survival) pathways in R102W retinas compared to WT.

Conclusions: The R102W mouse retinas showed a progressive pathological process in photoreceptors from P14 to P28, and the abnormal intercellular communication in NT and VISFATIN pathway may play an important role in the progression of XLRS. This work supports that treatment may be more effective at the early stage of XLRS, such as edema systoid schisis stage at P14.

Abstract No.: 200176

Mozart's Music and the Reliability of Visual Field Testing

First Author: Rintra WONGVISAVAVIT

Co-Author(s): Tunyaluk PANYATA, Autsadawut PHOOLSAWAT, Pakin PIRIYALUKKUL, Smatya WATHAWATHANA

Purpose: This study investigates the impact of Mozart's music on the reliability of automated perimetry, a key visual field assessment influenced by patient factors such as fatigue, emotion, and attention. Music has been demonstrated to enhance emotional regulation and attentional focus, while concurrently mitigating anxiety. This study seeks to examine the effect of music on the reliability of visual field assessments.

Methods: Automated perimetry employing the Humphrey Field Analyzer III (24-2 protocol) was conducted on the right eyes of 163 perimetry-naive participants. Participants were randomly assigned to control, headphones (noise-canceling without music), or Mozart groups (exposed to Mozart's Sonata for Two Pianos in D Major, K.448) for 10 minutes prior to testing. Reliability indices and test metrics were analyzed using the Kruskal-Wallis test to assess the influence of auditory conditions on perimetric performance.

Results: The mean fixation loss (FL) percentages were 14.3%, 13.4%, and 6.4% for the control, headphone, and Mozart groups, respectively, with a statistically significant difference observed between the control and Mozart groups ($p = 0.03$). No significant group differences were identified in false positives (FP),

false negatives (FN), or test duration. Furthermore, mean deviation (MD), pattern standard deviation (PSD), total deviation (TD), and pattern deviation (PD) values remained within normal limits across all groups, without statistically significant variation.

Conclusions: Mozart's music may enhance concentration and spatial reasoning in individuals undergoing automated perimetry, thereby enhancing the reliability of visual field assessments, particularly by reducing fixation loss. This suggests its potential utility as an adjunctive tool in clinical practice to optimize test accuracy.

Abstract No.: 206285

PRESCR.EYE.BE: A Do-It-Yourself E-Log Atlas for Postgraduate and Fellowship Training

First Author: Prithvi **CHANDRAKANTH**

Co-Author(s): Brinda K **RAJ**

Purpose: Traditional written logbooks have been foundational in postgraduate (PG) medical education. However, given technological advances in ophthalmology—from basic torchlight examinations to smartphone-based imaging and multispecialty surgery—there is a need for modernisation. This study aimed to transform the conventional logbook into a digital, interactive, and collaborative tool.

Methods: A digital logbook system was developed using Google Forms for the documentation of clinical images from outpatient departments and medical camps. Images were captured via slit lamps, fundus imaging systems, and custom-made smartphone-compatible, three-dimensional (3D)-printed devices. Entries were reviewed by consultants who provided feedback and corrections. Curated entries were organised using Microsoft PowerPoint and utilised as educational material for oral and clinical examination (VIVA and Objective Structured Clinical Examination [OSCE]) preparation.

Results: Annotated and summarised entries were uploaded to the hospital's academic portal, forming a centralised, shared repository accessible to PG students, fellows, and consultants. The platform enhanced collaborative learning and streamlined clinical documentation.

Conclusions: This do-it-yourself (DIY) postgraduate E-log atlas sets a new standard for ophthalmology training. It promotes innovation, accessibility, and academic excellence by integrating modern technology into medical education.

Abstract No.: 205299

Preventive Strategies for Age-Related Macular Degeneration: Clinical Efficacy of Targeted Micronutrient Complex

First Author: Tatiana **VARGANOVA**

Purpose: Age-related macular degeneration (AMD) is a leading cause of irreversible central vision loss in older adults. Adequate nutrition and a healthy diet play a key role in AMD prevention. This study evaluated whether daily supplementation with MacuLux®, a complex containing 17 micronutrients including all 3 macular carotenoids and the AREDS-antioxidants which ensures its pathogenetic targeting to support macular function and visual performance in healthy individuals.

Methods: A randomized, open-label, controlled trial included 48 participants without signs of AMD (AREDS Category 1). 24 participants received MacuLux® (1 capsule daily) for three months, and 24 served as controls. Ophthalmic assessments included fundus autofluorescence, optical coherence tomography (OCT), OCT angiography, multifocal electroretinography (mfERG), and computer perimetry.

Results: After three months, the treatment group showed significant improvement in best-corrected visual acuity (0.95 ± 0.08 to 1.2 ± 0.05 , $p < 0.05$), while controls remained unchanged. mfERG revealed a 10% increase in retinal electrophysiological response in 60% of treated eyes, with decreased latency and increased amplitude ($p < 0.05$). A positive trend in visual field light sensitivity (HoV@10) was observed in 38% of participants, and OCT showed a trend toward increased total retinal thickness in the macular zone.

Conclusions: MacuLux® supplementation improved visual acuity and macular bioelectrical response, with favourable trends in retinal thickness and light sensitivity. These findings support the potential role of targeted micronutrient supplementation, alongside a healthy diet, in preserving macular function and visual performance in healthy adults.

Abstract No.: 201856

Research Progress in Psychosomatic Ophthalmology: An Evidence-Based Review, 2015–2025

First Author: Liyang **ZHANG**

Purpose: Systematically review 2015–2025 evidence on bidirectional links between depression/anxiety/chronic stress and glaucoma, dry eye disease (DED), central serous chorioretinopathy (CSCR), and translate findings into screening and integrated-care algorithms.

Methods: PubMed, Web of Science, CNKI, Wanfang searched for systematic reviews, meta-analyses, prospective cohorts, RCTs (English/Chinese). AMSTAR-2 and RoB-2 assessed quality; random-effects meta-analyses when possible.

Results: Comorbid depression/anxiety prevalence: glaucoma 15–30 %, DED 16–45 %, CSCR ~36 % (all > general population). Pathophysiology: chronic stress → HPA-axis/sympathetic hyperactivity → cortisol & pro-inflammatory cytokine excess → accelerated ocular disease. Screening: HADS, PHQ-9, GAD-7 plus visual-electrophysiology (P100 latency correlates with sleep disturbance). Interventions: mindfulness or CBT lowers IOP 2–4 mmHg in glaucoma and improves DED symptoms; SSRIs may slow glaucomatous field loss ~30 % and hasten CSCR fluid absorption, but larger RCTs needed.

Conclusions: Robust bidirectional relationships exist; mechanisms involve neuro-endocrine-immune dysregulation. Embed brief psychological screening in ophthalmic practice; offer CBT/mindfulness for mild–moderate disorders and psychiatric co-management plus pharmacotherapy for severe cases. Multicentre RCTs should confirm long-term efficacy and cost-effectiveness of integrated pathways.

Abstract No.: 202465

Single-Cell RNA Sequencing Highlights a Significant Retinal Müller Glial Population in Dry Age-Related Macular Degeneration

First Author: Chuanhe **ZHANG**

Co-Author(s): Dongcheng **LIU**, Bo **QIN**, Bing **ZENG**

Purpose: The main challenge in dissecting the cells and pathways involved in the pathogenesis of age-related macular degeneration (AMD) is the highly heterogeneous and dynamic nature of the retinal microenvironment. This study aimed to describe the comprehensive landscape of the dry AMD (dAMD) model and identify the key cell cluster contributing to dAMD.

Methods: A NaIO₃-induced mouse dAMD model was established and analyzed using single-cell RNA sequencing. Retinal cell heterogeneity was assessed, and findings were validated with human dAMD scRNA-seq datasets. Functional enrichment and immunofluorescence staining were performed to confirm changes in Müller cell subsets and to investigate underlying mechanisms.

Results: Twelve major retinal cell types were identified. Among them, Müller glia showed the strongest AMD-associated gene signature. A distinct Sox2-expressing Müller subpopulation, enriched in neuroprotective and homeostatic pathways, was significantly reduced in both the dAMD model and patient retinas. Mechanistic analyses revealed that ferroptosis and apoptosis contributed to the loss of these Sox2⁺ Müller cells. Immunofluorescence further confirmed the reduction of Sox2⁺ Müller cells, and markers of ferroptosis were detected in diseased retinas.

Conclusions: This study highlights a critical Sox2⁺ Müller cell population with neuroprotective potential

whose reduction is linked to dAMD progression. The findings reveal that ferroptosis and apoptosis are major contributors to Müller cell loss, suggesting that protecting this subpopulation may represent a novel therapeutic strategy for dAMD.

Abstract No.: 206626

Strong Eyes, Strong Minds: Building Mental Resilience Among Young Ophthalmologists

First Author: Saraa **YOOSUF**

Purpose: To explore the psychological challenges faced by young ophthalmologists (YOs) and propose a practical framework for strengthening mental resilience in training and early career practice.

Methods: A narrative review of physician wellbeing literature was combined with thematic reflections from YO networks in Asia-Pacific. Key stressors were mapped using a resilience framework (decision fatigue, empathy fatigue, and performance pressure). Interventions were adapted from clinical service operations and behavioral science, focusing on low-cost, scalable strategies.

Results: Three pillars of YO resilience were identified: 1. Personal Resilience — stress management techniques, reflection, and growth mindset practices. 2. Peer Resilience — confidential peer-support groups, shared narratives, and mentorship. 3. System Resilience — structural safeguards such as reasonable duty hours, psychological safety in training, and institutional wellness policies. Visual tools were designed to communicate this framework: • Infographic wheel showing the “Three Pillars of YO Resilience.” • Flowchart linking stressors to targeted coping strategies. • QR code linking to a resilience self-check guide.

Conclusions: Mental resilience is essential for young ophthalmologists navigating the dual pressures of surgical mastery and service delivery. Embedding structured resilience supports at personal, peer, and system levels can reduce burnout and enhance wellbeing, creating a healthier and more sustainable future ophthalmology workforce.

Abstract No.: 205707

Surgical Waste Production From a Cataract Surgery Centre in a Tertiary Hospital in Sarawak

First Author: Chin Ling **TAN**

Co-Author(s): Wendy Yen Nee **SEE**

Purpose: To report on the total surgical waste production, to determine the details of greenhouse emissions per cataract surgery performed and to identify sustainable ways to reduce the surgical waste production and carbon footprint from a cataract surgery daycare center in Sarawak General Hospital (SGH).

Methods: Observational, non-interventional retrospective study. The carbon footprint calculation from the cataract surgery included 3 main components: operating theatre waste disposal, total energy use and travel of cataract patients.

Results: Transportation was the largest contributor to carbon emissions, ranging from 10.023 kgCO₂eq to 12.691 kgCO₂eq per patient. Total energy use (TE) was the second most significant factor, with emissions between 2.063 kgCO₂eq and 2.340 kgCO₂eq. Implementing waste segregation substantially decreased landfill carbon emissions. Total general waste decreased from 78.5 kg before segregation to 12 kg after, and the corresponding carbon footprint reduced from 0.705 kgCO₂eq to 0.108 kgCO₂eq. Incineration of clinical waste resulted in total carbon footprint of 0.316 kgCO₂eq, with a single patient footprint of 0.002 kgCO₂eq.

Conclusions: This study highlights key areas for reducing the carbon footprint of cataract surgeries at SGH. Patient transportation and total energy consumption are the most significant contributors to greenhouse emissions. Implementing waste segregation strategies has already proven effective in reducing carbon footprint.

Abstract No.: 205645

Systemic Emergencies and Adverse Drug Reactions in High-Volume Ophthalmic Surgeries

First Author: Haripriya **ARAVIND**

Co-Author(s): Janish **PRABHAKAR**, Mano **PRAKASH**, Banu **SHREE**

Purpose: To evaluate the incidence and types of systemic emergencies and adverse drug reactions (ADRs) in a high-volume ophthalmic network.

Methods: A retrospective audit was conducted from January to December 2024 across 14 hospitals in an eye hospital network. Data were analyzed for systemic emergencies, types of emergencies and ADRs.

Results: A total of 199 systemic emergencies were reported during 542,380 surgeries (0.04% incidence). Most frequent emergencies were pulmonary edema (32%), other cardiac & respiratory complications (37%), neurological complications (12%) and other systemic causes (19%). 177 ADRs reported across all surgeries (0.03%) and 64 ADRs occurred during 15,586 FFA procedures (0.4% incidence).

Conclusions: Systemic emergencies and ADRs are rare but clinically relevant in ophthalmic practice. Cardiopulmonary complications were the most frequent emergencies, while FFA procedures accounted for a significant share of ADRs.

Abstract No.: 206098

The Effect of TMEM251 on Macular Epiretinal Membrane by Regulating Lysosomal Phagocytosis and Reactive Gliosis in Müller Cells

First Author: Zhao **YIMING**

Co-Author(s): Zhou **QIANG**

Purpose: This study aims to explore the function of TMEM251 in modulating lysosomal phagocytosis and glial response in Müller cells associated with macular epiretinal membrane diseases.

Methods: Macular epiretinal membranes from diverse etiologies—including idiopathic cases, those secondary to diabetic retinopathy, and branch retinal vein occlusion—were collected for clinical analysis. Immunofluorescence staining was utilized to assess the co-localization of TMEM251, a lysosomal transport factor, and GFAP, a marker of glial activation, within Müller cells.

Results: Consistent co-localization of TMEM251 and GFAP within Müller cells was observed across all collected epiretinal membrane samples.

Conclusions: These results indicate that TMEM251 may contribute to the regulation of the glial response in Müller cells through its involvement in lysosomal phagocytosis pathways in macular epiretinal membrane disorders.

Abstract No.: 205133

The Vitreous Body Floaters – To Observe or to Treat?

First Author: Tatiana **VARGANOVA**

Co-Author(s): Veryasova **ANASTASIYA G.**, Erysheva **EVGENIYA D.**

Purpose: Vitreous body degeneration (VBD) is a common ophthalmic condition that is challenging to manage. Non-invasive options are limited, and observation (“watchful waiting”) often frustrates patients, as floaters can significantly impair vision and quality of life. Invasive procedures, such as vitreolysis or vitrectomy, are generally reserved for severe cases. This study evaluated VitroCap®, a supplement containing vitamin C, grape seed extract, citrus fruit extract, and L-lysine. This case control study assessed ultrasound characteristics of the vitreous as well as visual discomfort and psychological impact under supplementation.

Methods: 32 patients were enrolled: 16 symptomatic patients received one capsule of VitroCap®N daily for three months; 16 controls had B-scan-confirmed floaters without active complaints. All participants underwent A- and B-scan echography at baseline and after three months. Visual discomfort was assessed on a 1–4 scale (1 = severe discomfort; 4 = no discomfort). Both groups completed a voluntary, anonymous

Minnesota Multiphasic Personality Inventory (MMPI) survey.

Results: Visual comfort remained stable in controls (t0: 3.6; t3: 3.7). In the treated group, scores improved from 1.4 to 3.8, with 76% reporting reduced or absent floaters. B-scan opacities decreased in 32% of cases, and A-scan echogenic spike height reduced in 80% ($p < 0.05$). Psychological assessment indicated therapy positively influenced emotional wellbeing.

Conclusions: VitroCap®N improves both subjective symptoms and objective echographic findings in VBD. Active treatment also benefits emotional wellbeing, addressing the visual and psychological burden of floaters. Given the significant impact of floaters, this supports treating rather than merely observing these patients.

Abstract No.: 208347

To Compare the Performances of GPT-3.5-Turbo and GPT-4.0 for Medical Education

First Author: Hong Yu Ryan **FONG**

Co-Author(s): Carol **CHEUNG**, Chun Hei **CHOW**, Xiaoyan **HU**, Sin Kiu **HUI**, Yuk Ming **LAI**, Sum Yuet **NG**, Ruyue **SHEN**, Lok Hang **TO**, Dawei **YANG**

Purpose: The performances of GPT-3.5-turbo (via Poe) and GPT-4.0 (via Microsoft 365 Copilot) were compared in terms of medical terminology translation (283 medical terms from six specialties), situational judgment (30 situations in seven contexts), medical knowledge (80 multiple choice questions and 80 clinical scenario questions), medical studies (10 case scenarios), and clinical communication (10 case scenarios).

Methods: The performances of GPT-3.5-turbo (via Poe) and GPT-4.0 (via Microsoft 365 Copilot) were compared in terms of medical terminology translation (283 medical terms from six specialties), situational judgment (30 situations in seven contexts), medical knowledge (80 multiple choice questions and 80 clinical scenario questions), medical studies (10 case scenarios), and clinical communication (10 case scenarios).

Results: GPT-4.0 outperformed GPT-3.5-turbo in accuracy in terms of medical terminology translation (98.6% vs 91.5%), situational judgment (83.3% vs 63.3%), medical knowledge (93.8% vs 85.0% on multiple choice questions and 82.5% vs 72.5% on clinical scenario questions), medical studies (in three of ten case scenarios), and clinical communication (in four of 10 case scenarios).

Conclusions: GPT-3.5-turbo and GPT-4.0 performed reasonably well on medical knowledge and medical studies, with GPT-4.0 performing slightly better in medical terminology translation, situational judgment, and clinical communication. These results are promising for the incorporation of large

language models in medical education. Nonetheless, overreliance should be avoided as responses can be inaccurate or irrelevant.

Cataract

Abstract No.: 205280

A Minimalistic Approach to the Modified Yamane Technique Scleral Fixated Intra-Ocular Lens– Safer, Faster, More Economical and Consistently Reproducible Good Outcomes, With No Infusion Line or Special Instruments Required

First Author: Lik Thai **LIM**

Co-Author(s): Mohammad Asyraf **ABDUL KADIR**, Yong Zheng **WAI**

Purpose: To share the surgical experience of performing a modified Yamane Technique sutureless scleral fixated intraocular lens (IOL) with a safer, minimalistic approach.

Methods: In the aphakic eye, standard Yamane Technique ocular surface markings are done. Then two 26G x 12mm needles are introduced at 180 degrees apart at the medial and lateral aspect of the sclera 2mm behind the limbus. Then, a 2.8mm keratome shelved incision is done superiorly. Viscoelastic is then filled in the anterior chamber (AC). Then the three-piece IOL is slowly introduced into the AC. When the tip of the leading haptic is visible from the lens injector bevel, the hand-shake technique is used to directly engage with the pre-placed needle. Then, by slowly introducing more of the leading haptic into the AC, finally, adequate engagement of the leading haptic and the needle is achieved, and the entire IOL is inserted into the AC. Then, with a tying forceps, the trailing haptic is guided to engage with the other needle. Then both haptics are externalised and flanged with low-temperature hand-held cautery. No infusion line is required. No special instruments, such as vitreo-retina micro-forceps, are required.

Results: Consistent reproducible results whereby the IOL is successfully fixed using the above-mentioned method, in the desired central position, and achieving good visual acuity post-operatively.

Conclusions: The minimalistic approach of the Yamane Technique scleral fixated IOL, without an infusion line and no need for special instruments such as vitreo-retina micro-forceps (which may not be readily available, and possibly costly), can be performed safely, efficiently, economically, and consistently with good post-operative outcomes.

Abstract No.: 203636

A Novel connexin50 Mutant Associated With Congenital Cataract Leads to Activation of the Unfolded Protein Response

First Author: Sha ZHU

Co-Author(s): Xiangjun CHEN, Ke YAO

Purpose: To elucidate the underlying mechanism of a novel mutation of Cx50 (c.660C>A, p.N220K) with autosomal dominant congenital cataract.

Methods: We identified a heterozygous change C>A at position 660 (c.660C>A) was identified in exon 2 of the GJA8 gene by Sanger sequencing. We constructed recombinant pEGFP-N1 plasmids containing the WT or mutant Cx50-N220K for the overexpression of recombinant protein in the Hek-293T cells. Fluorescence and Confocal Imaging and Western Blot were used to investigate the expression and subcellular localization of WT and mutant Cx50 protein.

Results: Confocal fluorescent experiments indicated that the N220K mutant protein mainly localized in the endoplasmic reticulum and golgi apparatus instead of plasma membrane. As N220 located at the end the fourth conserved transmembrane domain, charge analysis showed that N220K changed the isoelectric point of the whole fourth transmembrane domain. Further experiments indicated that the acid-base property in the N220 position matters to the correct transportation of connexin proteins, which may represent a possible new mechanism that leads to congenital cataracts. We also investigated UPR activation in the cells model of Cx50N220K using QPCR analysis and found that the expression of ATF-6, GRP78, PSCK1 and GM130 level was significantly higher in mutant cells.

Conclusions: We identified a new Cx50 mutation and analysed subcellular localization of the mutant proteins. Our results showed that N220K mutation fails to transport the mutant connexin50 protein to the plasma membrane, it's likely to cause loss of connexin50 function and eventually lead to congenital cataracts.

Abstract No.: 206683

A Surgical Technique to Reduce Risk of Silicone Oil Keratopathy for a Case of Retinal Detachment, Traumatic Aniridia and Aphakia After Eyeball Rupture

First Author: Ya Hui WANG

Co-Author(s): Wen-yu HSU, Chien-liang WU

Purpose: A new surgical technique to reduce the risk of silicone oil keratopathy.

Methods: Case report.

Results: This was a 28-year-old male without any underlying diseases. He had an eyeball rupture of the right eye by a luggage scale ten years ago, and he

received primary repair for the cornea immediately. After several months, retinal detachment of the right eye was noted. The patient then received scleral buckling, trans pars plana vitrectomy, and silicon oil injection of the right eye. However, photophobia and blurred vision in the right eye were still complained of. Visual acuity was hand motion at 90 cm/0.9. Slit lamp examination showed corneal opacity, traumatic aniridia, and aphakia of the right eye. Therefore, combined surgery for secondary intraocular lens implantation, artificial iris implantation, and penetrating keratoplasty were planned. First, a vacuum trephine was used to excise of host cornea in 7.5 mm diameter and dissect to the descemet membrane plain to provide a clearer surgical view. And then, pars plana vitrectomy with silicon oil injection was done. Fundus showed pale disc with subretinal band. Artificial iris and IOL were sutured together with 10-0 prolene by sandwich technique, and then were fixed at scleral with 6-0 prolene by flanged technique. Excision of donor tissue with punch in 7.75 mm diameter, and sutured with 10-0 Nylon interruptedly. After surgery, corneal graft was clear with visual acuity of 0.2/1.0. No silicone oil was observed in anterior chamber.

Conclusions: This surgical technique may keep silicone oil behind artificial iris and IOL complex and reduce risk of silicone oil keratopathy.

Abstract No.: 207789

Accelerated Biological Aging and Genetic Pleiotropy Contribute to Cataract

First Author: Yuelan GAO

Co-Author(s): Li Jia CHEN, Clement C. THAM, Jianmin XU, Jason C. YAM

Purpose: This study aims to assess the combined effects of biological age acceleration (BAA) and genetic risk on senile cataracts and blindness.

Methods: Biological age was estimated using the Klemmer-Doubal method (KDM-BA) and PhenoAge in 295,777 UK Biobank participants. Logistic and Cox models examined cross-sectional and longitudinal associations with cataract. Polygenic risk scores (PRS) quantified genetic susceptibility, and BAA-PRS interactions were tested. Genetic pleiotropy between BAA and cataract was assessed at the SNP, gene, and pathway levels. The association between BAA and vision-healthy life expectancy was further evaluated in cataract patients.

Results: Each SD increase in KDM-BA and PhenoAge acceleration was associated with 19% and 13% higher cross-sectional cataract risk, and 17% and 10% higher prospective risk, respectively. BAA significantly amplified cataract risk in interaction with genetic susceptibility, particularly in high-PRS individuals. Both BAA measures showed positive genetic correlations and genetic overlap with cataract. Pleiotropic analysis identified 1,388 candidate pleiotropic SNPs. Functional

mapping revealed 15 independent loci, mapped to 15 chromosomal regions, with colocalization pinpointing 7q36.1 (PRKAG2) as a shared causal variant. Multimarker analysis of GenoMic annotation identified 140 significant pleiotropic genes enriched in immune and lipid homeostasis pathways. Among cataract patients, those without accelerated aging had a significantly longer vision-healthy life expectancy.

Conclusions: BAA is strongly linked to higher cataract risk, especially in genetically susceptible individuals, and may reduce vision-healthy life expectancy. Identifying BAA individuals is crucial for cataract prevention and vision preservation. PRKAG2 is a shared genetic locus connecting BAA and cataract, representing a potential therapeutic target.

Abstract No.: 206129

Accuracy of New Intraocular Lens Calculation Formulas in Eyes Undergoing Combined Silicone Oil Removal and Cataract Surgery

First Author: Jiangjie **WANG**

Co-Author(s): Xiaopeng **JIANG**, Fei **XIA**

Purpose: This study aimed to compare the prediction accuracy of new-generation intraocular lens calculation formulas (Barrett Universal II [BUII], Emmetropia Verifying Optical [EVO], Kane, K6, Hill-Radial Basis Function [RBF] version 3.0 and Karmona) and traditional formulas (Haigis, Hoffer Q, Holladay 1, and Sanders Retzlaff Krapp/theoretical [SRK/T]) in patients undergoing combined silicone oil removal and cataract surgery.

Methods: A total of 89 eyes from 89 patients who underwent silicone oil removal combined with cataract surgery were enrolled and divided into 3 groups according to axial length. The outcomes were evaluated using standard deviation (SD), assessed with the Heteroscedastic test; root-mean-square absolute error (RMSAE), assessed with the bootstrap-t method; mean absolute error (MAE), assessed with the Friedman test; and the percentage of eyes within ± 0.25 D to ± 1.00 D of prediction error, assessed with Cochran's Q test.

Results: Most new-generation intraocular lens calculation formulas demonstrated higher accuracy than traditional formulas. Overall, the SDs of EVO, K6, and Hill-RBF 3.0 were significantly lower than those of Haigis, Hoffer Q, Holladay 1, and SRK/T ($P < 0.05$). The SD of Barrett Universal II (BU II) differed significantly from those of Haigis, Hoffer Q, and Holladay 1 ($P < 0.05$). Kane showed significant differences in SD compared with Hoffer Q and Holladay 1 ($P < 0.05$). The RMSAE of BU II differed significantly from that of Haigis ($P < 0.05$), and its MAE differed significantly from those of Hoffer Q, Holladay 1, and SRK/T ($P < 0.05$). Additionally, Kane and K6 showed significantly lower MAEs than Holladay 1 ($P < 0.05$).

Conclusions: New-generation formulas showed satisfactory prediction accuracy in eyes undergoing combined silicone oil removal and cataract surgery. Future studies should focus on conducting large-scale, multicenter validations to enhance the generalizability of the findings.

Abstract No.: 205062

Age-Related Variations in Anterior Segment Biometry: A Cross-Sectional Analysis Across a Large Private Ophthalmic Group

First Author: Tim **ROBERTS**

Co-Author(s): Joshua **WONG**, Tom **VAN DE VEEN**

Purpose: Biometric parameters are critical in cataract and refractive surgery. Changes in anterior segment anatomy occur with age, however the extent and pattern of changes across different age groups remain incompletely characterised. This study aims to evaluate changes in anterior segment parameters and relationships across a broad age range.

Methods: Retrospective cross-sectional study was conducted from patients undergoing routine ocular biometry (IOLMaster 700) at multiple ophthalmology clinics (Vision Eye Institute). Parameters included central corneal thickness, anterior chamber depth (ACD), lens thickness (LT), keratometry, and white-to-white diameter. Correlation heat map and outlier detection was utilised to understand relationships across variables and to characterise distribution across age groups.

Results: $N = 16,816$. Variables most correlated with age were LT and ACD ($r = +0.70$ and -0.46 respectively, $p < 0.001$). For LT, the percentage of patients with ≥ 1 outlier eye increases by age, ranging between 0% in the 1st decade and 10.8% (95% CI 6.2-15.4) in the 10th decade. For ACD, percentages follow a "U"-shaped distribution with lowest at 2.3% (95% CI 1.6-3.1) in the 4th decade.

Conclusions: Distinct age-related patterns exist across corneal biometric parameters, with LT increasing steadily with age, while ACD shows nonlinear distributions. This highlights the importance of considering age-specific biometric distributions during pre-surgical assessment. Identifying patients with atypical measurements may help refine risk stratification in cataract and refractive surgery.

Abstract No.: 201299

Analysis of Influencing Factors of Depth of Field After a Continuous-Range-of-Vision IOL Implantation

First Author: Shengnan **CHENG**

Purpose: To evaluate clinical outcomes following implantation of the TECNIS Synergy intraocular lens

(IOL) and identify factors influencing postoperative depth of field (DOF).

Methods: In this prospective study, 28 patients (49 eyes) with age-related cataracts underwent phacoemulsification with TECNIS Synergy IOL implantation. Uncorrected distance, intermediate, and near visual acuity (UDVA, UIVA, UNVA) were evaluated at 1 day, 1 week, 1 month, and 3 months postoperatively. DOF was derived from the defocus curve at 3 months. Preoperative ocular biometric parameters were analyzed using multiple linear regression to determine their influence on DOF.

Results: Postoperative UDVA improved significantly at all visits (all $P < 0.001$) and remained stable. UIVA improved from 1 day to 1 week ($P = 0.026$), stabilizing after 1 month. UNVA improved sequentially from day 1 to week 1 ($P = 0.003$) and week 1 to month 1 ($P = 0.020$), stabilizing by 3 months. The defocus curve demonstrated a smooth, bimodal profile. DOF correlated negatively with photopic and mesopic Kappa angle (PKA, MKA) and pupil diameter (PPD, MPD) (all $P < 0.0001$). Multiple regression identified MKA ($\beta = -3.742$, $P < 0.0001$) and MPD ($\beta = -0.399$, $P = 0.008$) as independent DOF predictors, represented by the equation: $Y = 5.887 - 3.742MKA - 0.399MPD$. ROC analysis indicated both MKA (AUC 0.92, cutoff 0.31mm) and MPD (AUC 0.93, cutoff 5.37mm) were strong predictors of $DOF \geq 2.5D$.

Conclusions: The TECNIS Synergy IOL provides excellent, continuous visual acuity across all distances. However, patients with larger MKA (> 0.31 mm) and MPD (> 5.37 mm) may experience reduced DOF, warranting careful patient selection.

Abstract No.: 206355

Anterior Capsule Shielding During FLACS to Protect Endothelium in a Cataract Patient With Low Endothelial Cell Density: A Case Report

First Author: Ardy **GISNAWAN**

Co-Author(s): Setiyo **BUDI RIYANTO**

Purpose: To report the use of the anterior capsule, obtained during femtosecond laser-assisted cataract surgery (FLACS), as an additional endothelial protection strategy in a patient with low endothelial cell density (ECD).

Methods: Case report.

Results: A 63-year-old male presented with bilateral senile cataract and high myopia. Preoperative best-corrected visual acuity (BCVA) was 1/60 in both eyes. Specular microscopy showed normal endothelial density in the right eye (2884 cells/mm²) and markedly low density in the left eye (1163 cells/mm²). FLACS was performed in both eyes with different time of surgery, followed by phacoemulsification with the stop-chop technique and capsular tension ring implantation. In the

left eye, the anterior capsule obtained from FLACS was preserved and placed against the corneal endothelium as a protective shield during phacoemulsification, in addition to dispersive ophthalmic viscoelastic device (OVD) use. Postoperative assessments included BCVA, ECD, endothelial cell hexagonality, and central corneal thickness (CCT). Postoperatively, UCVA improved to 1.0 in both eyes. In the left eye, ECD remained stable (1152 cells/mm² at 2 weeks, compared to 1163 preoperatively). Hexagonality improved from 63% to 72%, and CCT showed minimal change (568 μ m preoperatively to 584 μ m postoperatively). No intraoperative or postoperative complications occurred.

Conclusions: The anterior capsule may serve as a simple, safe, and cost-effective mechanical barrier to protect the endothelium in cataract surgery for patients with low ECD. This "capsular shield technique" may complement conventional OVD use and could be particularly useful in high-risk eyes or in resource-limited settings. Further evaluation in larger series is warranted.

Abstract No.: 202813

Anterior Pyramidal Congenital Cataract: A Clinical Case

First Author: Tatyana **SEMENOVA**

Purpose: To analyze a clinical case of successful surgical treatment of anterior pyramidal congenital cataract in a child using femtosecond guidance.

Methods: A 5-year-old girl complained of decreased vision in her left eye. Visometry before surgery: visual acuity OD - 0.5 n/a; OS - 1/ ∞ pr. l. incerte. Biomicroscopy: OD - translucent opacity of the lens measuring 0.5x0.5 mm, OS - diffuse opacity of the lens with a denser local cone-shaped opacity on the anterior surface of the lens, protruding into the anterior chamber and corresponding to the picture of anterior pyramidal cataract. Ophthalmoscopy: OD - fundus without pathologies; OS - ophthalmoscopy is difficult due to central opacity of the lens.

Results: Phacoemulsification with implantation of an intraocular lens using a femtosecond laser was performed to more reliably perform the capsulorhexis stage. Optical coherence tomography was performed intraoperatively using the Femto LDV Z8: the size, degree of prominence into the anterior chamber, and diameter of the altered base were determined, according to which clear parameters were set for performing capsulorhexis. The surgical intervention was performed without complications. In the early postoperative period, visual acuity OS increased to 0.01. However, its low level is probably due to the presence of obscuration amblyopia.

Conclusions: Anterior pyramidal cataract is a rare form of congenital lens pathology and requires a more careful approach to choosing a treatment

method. The use of modern surgical techniques, including intraoperative anterior segment optical coherence tomography, plays a key role in planning and performing surgery.

Abstract No.: 202756

Anterior Segment Characteristics and Spatial Variations of Different Crystalline Lens Diseases

First Author: Jianxia **FANG**

Co-Author(s): Yixuan **FENG**, Lirui **LIU**, Xinyu **MA**, Siting **SHENG**, Ce **SHI**, Jingwei **XU**, Wen **XU**, Zhe **XU**, Yu **ZHANG**, Huiling **ZHAO**, Sha **ZHU**

Purpose: To evaluate anterior chamber and crystalline lens morphology in patients with cataracts, lens subluxation (LS), and microspherophakia (MSP) using three anterior segment (AS) imaging instruments, and to develop a novel method for assessing the spatial characteristics of crystalline lens position through anterior chamber morphology measurements.

Methods: We examined 98 eyes (19 normal, 25 cataracts, 27 LS, 27 MSP) using AS optical coherence tomography (AS-OCT), ultrasound biomicroscopy (UBM), and IOLMaster700. Measurements included corneal thickness, anterior chamber parameters, and lens thickness (LT). We introduced the coefficient of variation (CV) of anterior chamber angle (ACA) and angle open distance (AOD) to quantify lens dislocation, and generated lens position alteration maps using AS-OCT and UBM to visualize the extent and distribution of lens dislocation.

Results: The LS and MSP groups showed significantly greater LT compared to normal and cataract groups ($P < 0.05$). The nasal ACA was reduced in LS and MSP groups, with MSP showing smaller nasal AOD compared to normal group ($P < 0.05$). Temporal ACA was significantly lower in the LS group compared to other groups ($P < 0.05$). AS-OCT measurements of ACA and AOD in the MSP group exceeded UBM values. The CV measurements and lens location alterations maps effectively illustrated the extent of lens dislocation and zonular weakness.

Conclusions: Each condition showed distinct AS features. The CV of ACA and AOD, along with location alteration maps from wide-field AS-OCT and UBM, might serve as valuable tools in diagnosing lens dislocation-related diseases, identifying dislocation areas, and assessing zonular weakness.

Abstract No.: 202527

Association of Air Pollution and Biological Aging With the Risk of Senile Cataract

First Author: Gongyue **WANG**

Co-Author(s): Mingchang **ZHANG**, Jiasong **WANG**, Huatao **XIE**

Purpose: Senile cataract is a major vision-impairing disease among the elderly, but the modification effects of air pollution and biological aging (BA) on senile cataract are uncovered. This study aimed to explore the association between long-term air pollution and incident risk of senile cataract.

Methods: This cohort included 314,118 participants from UK Biobank. Land use regression models estimated the concentrations of air pollutants and the composite air pollution score (APS) was constructed to capture the combined effects. The biological age was assessed by the phenotypic age algorithms (PhenoAge) and the Klemmera-Doubal method (KDM). We further evaluated the interactive and joint effects of BA acceleration.

Results: When compared with the lowest quartile of air pollutants NO₂, NO_x, PM_{2.5} and APS, those in the highest quartile had significantly increased incidence of senile cataract [HR (95 % CI) = 1.15 (1.11, 1.20), 1.17 (1.13, 1.22), 1.22 (1.18, 1.27) and 1.20 (1.15, 1.25), respectively]. We also observed positive associations between accelerated BA and senile cataract risk. There were significant additive interaction effects of NO₂, NO_x, PM_{2.5}, and APS with PhenoAge acceleration, with the relative excess risk due to the interaction (RERI) and 95% CIs of 0.07 (0.02, 0.12), 0.06 (0.01, 0.11), 0.10 (0.05, 0.14), and 0.10 (0.06, 0.16), respectively. Compared to participants exposed to the lowest levels of air pollution and with BA decelerated status, those with highest air pollutants exposure and BA accelerated status had 1.21~1.31fold risk of senile cataract.

Conclusions: Long-term exposure to air pollution may increase senile cataract incidence, particularly in BA accelerated participants.

Abstract No.: 208272

Associations Between the Mediterranean Lifestyle and Incident Age-Related Eye Diseases: A Cross-Sectional and Longitudinal Analyses From the UK Biobank

First Author: Yi **LI**

Co-Author(s): Li Jia **CHEN**, Jason C. **YAM**, Yuzhou **ZHANG**

Purpose: This study aims to assess the effect of Mediterranean lifestyle (MEDLIFE) on the risk of three common age-related eye diseases: cataract, glaucoma, and age-related macular degeneration (AMD).

Methods: This cohort study used data from UK Biobank participants who were free of age-related eye diseases at baseline and followed up prospectively for disease

occurrence. The Mediterranean lifestyle was assessed using the MEDLIFE index derived from 25 items, categorized under 3 blocks: "Mediterranean food consumption," "Mediterranean dietary habits," and "physical activity, rest, social habits, and conviviality". A Cox proportional hazard model was used to examine the associations of the MEDLIFE index with incident age-related eye diseases.

Results: A total of 122,705 participants were included in the analysis. During a median (IQR) follow-up of 10.5 (10.4-10.9) years, 10,695 cases of cataract, 2,142 cases of glaucoma, and 1,971 cases of AMD were identified. Overall, there was an inverse association between the MEDLIFE index and new-onset cataract (P for trend 0.002). Per one-point increment in the MEDLIFE score was associated with a 1.6% (95%CI, 0.9-2.4%) reduction in the risk of developing cataract, and with a 2.1% (95%CI, 0.3-3.9%) reduction in the incidence of AMD. However, no associations were found between MEDLIFE and the risk of glaucoma.

Conclusions: In this large cohort study, higher adherence to MEDLIFE was associated with decreased incidence of cataract and AMD. Our findings suggest that the Mediterranean lifestyle may act as a potential behavioral intervention approach for preventing cataract and possibly AMD.

Abstract No.: 203330

Autorefractive Versus Subjective Refraction After Extended Depth-of-Focus Intraocular Lenses Implantation

First Author: Wenjie **LIU**

Co-Author(s): Ying **CHANG**, Zeqi **FAN**, Zhijie **JIA**, Jiewei **LIU**, Lichun **YANG**

Purpose: To analyze the correlation between automated refraction (AR) and manifest refraction (MR) after extended depth-of-focus intraocular lenses implantation.

Methods: This cross-sectional study involved 77 eyes of 77 patients. Automated refraction was employed as the starting point for obtaining the manifest refraction. Automated refraction and manifest refraction measurements were analyzed and compared using the vector analysis 6 months after the surgery. A set of 5 different results was obtained in power vector notation (spherical equivalent [SE], Jackson cross-cylinder, axes at 180 degrees and 90 degrees [J0] and Jackson cross-cylinder, axes at 45 degrees and 135 degrees [J45]) for manifest refraction and autorefractive.

Results: Manifest refraction examination: S was $-0.66 \pm 0.64D$, C was $-0.55 \pm 0.45D$, SE was $-0.93 \pm 0.63D$, J0 was $-0.03 \pm 0.59D$, and J45 was $0.1 \pm 0.39D$. Automated refraction examination: S was $-0.32 \pm 0.61D$, C was $-0.41 \pm 0.48D$, SE was $-0.52 \pm 0.61D$, J0 was $-0.02 \pm 0.55D$, and J45 was $0.05 \pm 0.30D$. The differences between the two methods were statistically significant

($P < 0.05$). There was a high correlation between the two methods in S, C, SE, J0, and J45 ($r = 0.741, 0.764, 0.700, 0.946, 0.852$; $p < 0.05$).

Conclusions: Due to the depth of focus extension and chromatic aberration correction technologies used in the EDOF IOL, the subjective refraction results tend to shift towards myopia. Therefore, postoperative refraction should rely on objective refraction for accuracy.

Abstract No.: 204538

Breaking the Ring: Laser Management of Anterior Capsular Contraction Syndrome – A Case Report

First Author: Yunneke R. **XAVERINA**

Co-Author(s): Dimas A. **WIGID**

Purpose: Anterior capsular contraction syndrome (ACCS) is a complication that can occur after cataract surgery, and treatment to overcome this problem is with a laser or surgical approach. This case study aims to illustrate the laser approach for managing anterior capsular contraction syndrome.

Methods: A 67-year-old woman who had begun complaining of blurred vision in her left eye after undergoing cataract surgery 4 months prior underwent a routine ophthalmology examination. On visual acuity examination, the results obtained were decreased by just 0.1. From the slit lamp examination, there was opacity and wrinkling of the anterior capsule. The fibrosis ring was visible without dilatation of the pupil and was more clearly seen after we used dilating eye drops. The patient's intraocular pressure, funduscopy and optical coherence tomography (OCT) results were within normal limits. We performed laser anterior capsulotomy with the neodymium:yttrium-aluminum-garnet (YAG) laser. A radial Nd:YAG laser capsulotomy was performed in all four areas. One week following laser treatment, fibrosis was not visible at the visual axis and visual acuity improved to 1.0 with correction.

Results: The ACCS will negatively impact the patient's vision and visual quality. Neodymium:YAG (Nd:YAG) laser for anterior capsulotomy prevents further deterioration of ACCS, which may be related to the relaxation of stress on the anterior capsule after continuous curvilinear capsulorhexis (CCC).

Conclusions: Laser-assisted anterior capsulotomy with Nd:YAG is safe and effective as a non-surgical option for treating ACCS to improve patient visual acuity.

Abstract No.: 206345**Capsular Bag Distension Syndrome 6 Years After Cataract Surgery: A Case Report***First Author: John Jasper RAMOS**Co-Author(s): Patricio ASIO*

Purpose: Capsular bag distension syndrome (CBDS) is a rare complication of cataract surgery. The characteristic finding is the distension of the capsular bag caused by fluid accumulation and forward displacement of the intraocular lens. The trapped fluid develops a turbid consistency, resulting in reduced visual acuity. The purpose of this case report was to highlight that CBDS can occur years after a cataract surgery that was initially uneventful. It also aimed to demonstrate a successful surgical approach for treating late postoperative CBDS, particularly when the traditional laser method is complicated or contraindicated due to potential associated risks.

Methods: Case report.

Results: This is a patient who developed late postoperative capsular bag distension syndrome 6 years after cataract surgery. Presenting uncorrected distance visual acuity was 20/400. IOL repositioning and anterior chamber clean-up of the left eye was done under local anesthesia. The patient's visual acuity improved from 20/400 to 20/200, 20/25, and 20/50, 1 day, 1 week, and 1 month post operatively, respectively.

Conclusions: CBDS is a rare complication of cataract surgery that can develop even several years later. While laser posterior capsulotomy is the usual treatment, in late postoperative cases, alternative surgical approaches like intraocular lens repositioning and anterior chamber clean-up should be considered. The approach used in this case was safe and effective in removing the turbid fluid and improving the patient's visual acuity.

Abstract No.: 204654**Capsular Tension Ring Implantation for Intraocular Lens Decentration and Tilt in Highly Myopic Eyes: A Randomized Clinical Trial***First Author: Haowen LIN*

Purpose: To evaluate the influence of CTR implantation on IOL decentration and tilt in highly myopic eyes.

Methods: This randomized clinical trial was conducted between November 2021 and September 2023 at the Zhongshan Ophthalmic Center, Guangzhou, China. Patients with cataract and an axial length (AL) of 26 mm or longer were enrolled. Participants were stratified into 3 groups based on the AL (stratum 1, 26mm≤AL<28mm; stratum 2, 28mm≤AL<30mm; stratum 3, AL≥30mm), and further randomly assigned to the CTR group (a C-loop IOL combined with a CTR)

or the control group (only a C-loop IOL) within each stratum. IOL decentration at 3 months after cataract surgery was evaluated using anterior segment optical coherence tomography.

Results: A total of 186 eyes of 186 participants (mean [SD] age, 57.3 [10.9] years; 118 females [63.4%]) were randomized into the CTR group (93 [50%]) or control group (93 [50%]), with 87 eyes (93.6%) and 92 eyes (98.9%) completing follow-up at 3 months, respectively. The CTR group showed smaller IOL decentration and tilt at 3 months, and lower proportions of clinically significant IOL decentration and tilt at 3 months compared with the control group. Similar results were only found in eyes with an AL of 30 mm or longer. Additionally, the CTR group showed a smaller change in IOL decentration from 1 week to 3 months, higher prediction accuracy, and better visual quality and patient satisfaction in this stratum. No differences were observed between the CTR and control groups in eyes with an AL less than 30 mm.

Conclusions: CTR implantation reduced C-loop IOL decentration and tilt, increased position stability, and improved visual quality in eyes with an AL of 30 mm or longer. These findings support use of CTR implantation in eyes with an AL of 30 mm or longer and implanted with C-loop IOLs.

Abstract No.: 203246**Capsular Tension Ring Implantation for Intraocular Lens Position: A Systematic Review and Meta-Analysis***First Author: Haowen LIN*

Purpose: To evaluate the association of CTR implantation on IOL position.

Methods: PubMed, Embase, and Cochrane Library were searched from their inception to October 18, 2024. Randomized clinical trials (RCTs) or prospective cohorts reporting the effect or association of CTR on postoperative anterior chamber depth (ACD), IOL decentration, tilt, or rotation. Data extraction was conducted by 2 reviewers and verified by another for accuracy. Mean difference (MD) was used to synthesize the effect measures, and subgroup analyses were conducted according to IOL haptic design (C-loop and plate haptic) and whether the patient had high myopia.

Results: A total of 11 RCTs and 7 cohort studies, involving 809 eyes with CTR and 822 eyes without CTR, were included in this meta-analysis. The analysis revealed that IOL tilt (MD, -1.04°; 95% CI, -2.05° to -0.03°; P = .04) and rotation (MD, -0.82°; 95% CI, -1.27° to -0.37°; P < .001) were smaller in the CTR group compared with the control group. The subgroup analysis of ACD (I2 = 70.7%; P = .03), decentration (I2 = 66.5%, P = .08), and tilt (I2 = 76.7%, P = .01) revealed a heterogeneity between the subgroups stratified according to IOL haptic design. Additionally, subgroup

analysis demonstrated that CTR group showed a deeper ACD in eyes implanted with plate haptic IOLs (MD, 0.11 mm; 95% CI, 0.02 to 0.20 mm; $P = .01$), and a smaller IOL tilt in highly myopic eyes (MD, -1.43° ; 95% CI, -2.59° to -0.26° ; $P = .02$) compared with the control group.

Conclusions: CTR implantation was associated with enhanced stability of IOL rotation in this meta-analysis, while only reducing IOL tilt in high myopia. While the direct clinical relevance of these results could not be determined from this investigation, these findings provide evidence supporting use of CTR implantation when toric IOLs have been implanted or with high myopia, although a hyperopic refractive shift after implantation of plate haptic IOLs may require target refraction adjustment.

Abstract No.: 203234

Capsular Tension Ring Implantation for Intraocular Lens Power Calculation in Highly Myopic Eyes: Secondary Analysis of a Randomized Clinical Trial

First Author: Haowen LIN

Purpose: To evaluate the influence of CTR implantation on IOL power calculation in highly myopic eyes.

Methods: This is a secondary analysis of outcomes of a randomized clinical trial conducted between November 2021 and September 2023 at the Zhongshan Ophthalmic Center in Guangzhou, China. Predictive outcomes of 6 new-generation formulas and 4 traditional formulas were evaluated. The arithmetic and absolute prediction error (PE) and the percentages of eyes within ± 0.25 diopter (D), ± 0.50 D, ± 0.75 D, and ± 1.00 D of PE were analyzed.

Results: A total of 186 eyes of 186 participants were randomized into the CTR group (93 eyes [50%]) or control group (93 eyes [50%]). No differences were observed in arithmetic PE between the CTR and control groups in any strata. The CTR group showed smaller absolute PE in all new-generation formulas and a higher percentage of PE within ± 0.50 D in the Emmetropia Verifying Optical 2.0, Hoffer QST, LISA, and Pearl-DGS formulas only for eyes with an AL of 30 mm or longer compared with the control group. In traditional formulas, no differences were observed between the 2 groups in any strata.

Conclusions: In this secondary analysis, CTR implantation in highly myopic eyes did not affect the target refraction and can improve the prediction accuracy of new-generation IOL calculation formulas in eyes with AL of 30 mm or longer. These findings support use of CTR implantation in eyes with an AL of 30 mm or longer.

Abstract No.: 206886

Case of Decompression Retinopathy in a Post-Phacoemulsification Filipino Patient With Phacolytic Glaucoma

First Author: Dillon Edric GO

Co-Author(s): Paolo Nico ROGELIO, Arnold SALUD

Purpose: Decompression retinopathy is a rare post-operative complication commonly seen in glaucoma filtration surgery wherein rapid decrease in intraocular pressure causes diffuse intraretinal hemorrhages. This report describes one case wherein retinopathy appeared in a post-phacoemulsification Filipino patient with phacolytic glaucoma.

Methods: Two weeks prior to the consultation, the patient noted severe left eye pain, left-sided headache, and blurring of vision. The patient presented with visual acuity of light perception in the left eye. Slit lamp examination showed grade 2 corneal haze with diffuse microcysts, a Morgagnian cataract, a 1.5mm layer of white lens proteins deposited in the inferior anterior chamber, +1 cells, +3 flare, a deep anterior chamber, and intraocular pressure of 40mmHg. The patient was assessed as having phacolytic glaucoma. The patient then underwent phacoemulsification to remove the lens material. Anterior vitrectomy was done intra-operatively due to posterior capsule rupture.

Results: On the first post-operative day, the patient had a visual acuity of hand movement with good light projection. Intraocular pressures maintained at 40mmHg. On dilated funduscopy, there were multiple blot hemorrhages scattered across the retina until the mid periphery. Patient was then advised to observe the Interearetinal hemorrhages. Over the next few weeks, the intraretinal hemorrhages slowly spontaneously resolved until the retina was clear of any hemorrhages at 5 weeks post-operation. Visual acuity maintained at hand movement with good light projection during the observation period.

Conclusions: Decompression retinopathy does not only happen with glaucoma filtration surgeries, but can occur with any surgery that rapidly decreases intraocular pressures. Decompression retinopathy carries a benign course and resolves with prompt observation.

Abstract No.: 201272

Cataract Surgery and Caregiver Burden in Dementia Patients: An Exploratory Pilot Study in Japan

First Author: Reiko UMEYA

Co-Author(s): Koichi ONO, Yuto YOSHIDA

Purpose: To investigate whether cataract surgery reduces caregiver burden in dementia patients, beyond visual improvement, and to explore factors influencing postoperative caregiver outcomes.

Methods: This prospective exploratory study was conducted at a single hospital in Japan from 2021 to 2025. Eligible participants were dementia patients scheduled for cataract surgery who were living with a primary caregiver; those living alone were excluded. Visual acuity (VA, logMAR), cognitive function (Mini-Mental State Examination, MMSE), activities of daily living (Barthel Index, BI), and caregiver burden (Japanese version of the Zarit Burden Interview, J-ZBI) were assessed preoperatively and at 3 months postoperatively. Paired t-tests compared pre- and postoperative VA, MMSE, BI, and J-ZBI. Linear regression identified factors predicting postoperative caregiver burden.

Results: Thirty-five patients were enrolled. One patient did not undergo surgery and six were lost to follow-up, leaving 28 patients for the final analysis. Visual acuity improved significantly in all patients, however mean J-ZBI scores showed no significant change at 3 months. Higher preoperative caregiver burden was associated with persistently high postoperative burden ($p = 0.008$). Older caregiver age was associated with lower postoperative burden ($p = 0.047$). Other factors were not significant predictors.

Conclusions: Cataract surgery improved vision but had limited effect on caregiver burden. Outcomes were influenced by caregiver age and preoperative burden, indicating that relief is not solely determined by visual recovery. Multicenter studies are needed to establish and validate criteria for surgical indication in advanced dementia.

Abstract No.: 200802

Cataract Surgery and Cognitive Benefits in the Older Person – A Systematic Review and Meta-Analysis

First Author: Andrew TSAI

Co-Author(s): Brian YEO

Purpose: To determine the association between cataract surgery and the risk of cognitive impairment and dementia in older adults with cataracts.

Methods: Following PRISMA guidelines, PubMed, Embase, and the Cochrane Library were searched for studies evaluating cataract surgery in relation to cognitive outcomes. Maximally adjusted hazard ratios (HR) were pooled for dichotomous outcomes, and ratio of means (RoM) for continuous outcomes, using a random-effects model. Heterogeneity was explored with sensitivity and subgroup analyses. Study quality was assessed using the Newcastle–Ottawa Scale, Cochrane Risk-of-Bias Tool for Randomized Trials, and GRADE.

Results: Twenty-four studies involving 558,276 participants were included, with 19 studies qualitatively analysed. Risk of bias ranged from low to moderate, while GRADE ratings were very low to low. Cataract

surgery was associated with a 25% reduced risk of long-term cognitive decline compared with uncorrected cataracts (HR 0.75, 95% CI 0.72–0.78). Benefits were consistent across cognitive outcomes and robust in sensitivity analyses. Individuals who underwent cataract surgery had a similar risk of cognitive decline to healthy controls without cataracts (HR 0.84, 95% CI 0.66–1.06). In participants with normal cognition, cataract surgery was linked to a 4% improvement in short-term cognitive test scores (RoM 0.96, 95% CI 0.94–0.99), but no significant benefit was seen in those with pre-existing cognitive impairment.

Conclusions: Cataract surgery may reduce the risk of cognitive impairment and dementia, suggesting cataract-related vision loss is a potentially modifiable risk factor. Further randomized trials are needed to confirm these findings.

Abstract No.: 200345

Central Corneal Thickness Changes After Phacoemulsification: Its Association With Density of Cataract

First Author: Ambreen GULL

Purpose: Phacoemulsification is the most widely adopted technique for cataract removal but can cause transient endothelial trauma, leading to central corneal thickness (CCT) changes and artifactual elevation in intraocular pressure (IOP). To assess changes in central corneal thickness and intraocular pressure following phacoemulsification and examine their correlation with cataract density.

Methods: This observational analytical study was conducted on 80 eyes undergoing uneventful phacoemulsification at Benazir Bhutto Hospital, Rawalpindi Medical University. Preoperative and postoperative measurements of central corneal thickness (CCT) and intraocular pressure (IOP) were obtained using ultrasound pachymetry and Goldmann applanation tonometry, respectively, at day 1, week 1, and week 4. Cataract density was graded using the Lens Opacity Grading System. Visual acuity was recorded pre- and postoperatively using the decimal notation Snellen chart. Data were analyzed using paired t-tests, repeated measures ANOVA, and Spearman correlation.

Results: Mean CCT increased from 524.15 ± 40.54 μm preoperatively to 574.92 ± 44.72 μm on day 1 postoperatively, regressing to 525.89 ± 40.50 μm by week 4. IOP showed a transient rise from 15.59 ± 2.19 mmHg to 17.99 ± 2.17 mmHg at week 1, returning to baseline at week 4. A significant positive correlation was found between cataract density and both postoperative day 1 CCT ($p = 0.421$) and IOP ($p = 0.430$).

Conclusions: Phacoemulsification induces significant but reversible changes in CCT and IOP. Cataract density is moderately associated with early postoperative corneal edema and IOP elevation, emphasizing the

need for careful interpretation of IOP in denser cataracts.

Abstract No.: 201041

Clinical Case of Phacoemulsification in Traumatic Cataract

First Author: Kseniia ORLOVA

Co-Author(s): Anna MIRIDONOVA

Purpose: To evaluate clinical and functional result of implantation deep focus intraocular lens (IOL) to the patient with traumatic cataract.

Methods: To report a case of bilateral implantation deep focus IOL Lentis Comfort to the patient with traumatic cataract on the one eye and mild myopia on the another eye.

Results: A 50-year-old male presented at our ophthalmology clinic with progressive visual loss. Five months prior to the presentation, he had sustained blunt trauma to his left eye, leading to traumatic cataract. The patient underwent a cataract phacoemulsification and IOL implantation. Intraoperatively, seeing the intact capsular bag, we decided to implant the deep focus lens. On the first post-operative day, we got the result of distance vision 20/70. After 2 weeks of postoperative treatment we got the result of distance vision 20/20. Having received an excellent result, the patient wanted to get rid of myopia in the fellow eye. We performed refractive lens exchange on the right eye with the similar IOL. On the first post-operative day of the second eye, we got the result of distance vision 20/20 and and near vision 20/30, which completely satisfied the patient.

Conclusions: In patients with traumatic cataract and intact capsular bag, it is possible to implant an IOL with a deep focus to achieve higher visual functions at more than one distance.

Abstract No.: 201003

Clinical Classification and Management Outcomes of Anterior Segment-Dominated Persistent Fetal Vasculature: The CCPMOH Report

First Author: Hui CHEN

Co-Author(s): Wan CHEN, Weirong CHEN, Xiaoyan LI, Haotian LIN, Zhuoling LIN, Yongbin LIN, Fengqi ZHOU, Chaokun LUO

Purpose: To describe clinical features, management, and outcomes of anterior segment-dominated persistent fetal vasculature (aPFV).

Methods: The age and gender of each participant upon initial presentation, along with biological parameters, best-corrected visual acuity, and biomicroscopic assessments were collected. The aPFV eyes were categorized into 3 groups (type I: pupillary-iris-anterior lens plane, type II: retrolental-anterior hyaloid

membrane plane, and type III: combined) according to the location of the vascular abnormalities and further classified into mild(a) and severe (b) according to the degree of severity. The surgical techniques used in this investigation were reported. Visual outcomes, ocular hypertension, postoperative adverse events, and additional surgical interventions were recorded at each follow-up visit.

Results: Among 470 patients (619 eyes), type II was most common (67.9%). Cataracts were present in 81.6% of eyes, with subtype-specific patterns: type I—nuclear/membranous (24%); type II—subcapsular (53.6%); type III—complete cortex (30.4%). Type III had the shallowest anterior chamber and highest astigmatism. Surgery was performed in 96.9% of eyes, with postoperative complications including ocular hypertension (19.2%) and visual axis obscuration (9.4%). Visual acuity improved in 73.7% of eyes; types IIb and IIb had the worst outcomes.

Conclusions: The magnitude of aPFV can be usefully characterized by a classification protocol focusing on the location and disease severity. Here, we propose a surgical and medical management algorithm for aPFV to achieve favorable outcomes with limited intraoperative and post-operative complications.

Abstract No.: 206719

Clinical Spectrum of Intraocular Lens Opacification: A Photo-Documented Case Series With Systemic and Ocular Correlations

First Author: Sheetal SHARMA

Co-Author(s): Kusha CHAUDHARY

Purpose: To highlight the occurrence and clinical appearance of intraocular lens (IOL) opacification in pseudophakic patients, to correlate it with intrinsic patient factors and systemic conditions, and to create its awareness among ophthalmologists as a new and rarest complication after cataract surgery.

Methods: A descriptive case series of 4 patients who presented with decreased vision after cataract surgery. Detailed history was obtained regarding systemic illnesses (diabetes, hypertension, autoimmune diseases etc), ocular comorbidities, and previous intraocular procedures. Detailed slit- lamp examination was done, and high-resolution clinical photographs were captured to document the pattern of opacification.

Results: The most common pattern of IOL opacification being central almost lesser opacified zone of optic with peripheral more denser whitening including both the haptics, which is seen in 2 patients. 1 patient has 3-piece IOL with whole optic glistening in the form of snowflake pattern and last 1 patient has zebra stripes pattern of opacification with alternate stripes of dense homogenous opacification and lesser dense pattern of whitening. 3 out of 4 patients give a history of diabetes, and 1 out of 4 has ocular comorbidities in the

form of uveitis. All of the 4 patients had an uneventful phacoemulsification cataract surgery.

Conclusions: IOL opacification is not only associated with lens material properties but also with systemic and ocular risk factors. Correlating its occurrence with the patient's profile helps in identifying at-risk populations, guiding follow-up, and appropriately managing such cases.

Abstract No.: 204284

Clinical and Pathological Insights in Posterior Subcapsular Proliferative Membrane Post-Vitrectomy

First Author: Mingyang **WANG**

Co-Author(s): Shipeng **GUO**, Dian **JIAO**, Tian **TIAN**, Peiquan **ZHAO**

Purpose: To report the clinical manifestations and pathological characteristics of proliferative membranes observed underneath the posterior capsule in 8 eyes following 3-port pars plana vitrectomy (PPV).

Methods: This retrospective study collected clinical data of patients who developed posterior subcapsular proliferative membrane (PSPM) after PPV from March 2020 to July 2024. All patients underwent lensectomy or phacoemulsification due to cataracts post-PPV. The PSPM was collected during surgery and analyzed using hematoxylin & eosin (HE) staining and immunohistochemical staining.

Results: Eight eyes from eight patients with PSPM after PPV were studied, with an average age of 21 ± 11.86 years. The PPV indications included RRD (6 eyes, 75%), FEVR (1 eye, 12.5%), and PDR (1 eye, 12.5%). The average number of PPVs prior to cataract surgery was 2.63 ± 0.92 . One eye (12.5%) was filled with C3F8, and 7 eyes (87.5%) were filled with silicone oil before C3F8. PSPM was discovered during surgery after the lens cortex and nucleus were aspirated and were removed completely by intraocular forceps. Unlike granular opacities with small vacuoles typical of posterior subcapsular cataracts, these membranes appeared as dense white proliferative structures with irregular shapes adhering to the posterior capsule. HE staining revealed that PSPM comprised dense connective tissue fibers and spindle-shaped cells. Immunohistochemistry indicated positivity for Vimentin and Cytokeratin (CK), with some tissues positive for smooth muscle actin (SMA).

Conclusions: Immunohistochemistry suggests that PSPM formation is related to the epithelial-mesenchymal transition (EMT) of epithelial cells. Repeated PPV and intraocular silicone oil tamponade may be risk factors for its development.

Abstract No.: 203266

Combined Surgical Approach in Traumatic Cataract and Iridodialysis: A Case-Based Approach

First Author: Jessica **ZARWAN**

Co-Author(s): Rizki Amalia **PUTRI**

Purpose: This report aims to highlight different surgical approaches for iridodialysis repair, followed by cataract surgery.

Methods: This is a case report presenting two patients with traumatic cataract accompanied by iridodialysis following blunt ocular trauma.

Results: Case 1, a 36-year-old male, developed glare and tearing in the right eye 2 weeks after being struck by a grinder cutter, with a visual acuity of 6/9.5. There were 4-clock hours of iridodialysis and a hazy lens. Case 2, a 43-year-old male, experienced blurred vision and glare in the left eye for 1 month after being hit by a hydraulic pipe explosion, with visual acuity of 6/30, 5-clock hours iridodialysis, and a hazy lens. Both patients were diagnosed with traumatic cataract and iridodialysis and managed surgically using different iris repair techniques. The first used the Hang-Back technique and the second used the Sewing-Machine technique for iridodialysis repair, followed by phacoemulsification and intraocular lens implantation. After surgery, the corrected visual acuity in the first case is 6/6, and in the second case, it is 6/9. No subjective complaints reported. The iris and pupil are round in both cases, with a slight retraction towards the nasal area in the second case. The IOL remains stable.

Conclusions: Iridodialysis repair can be performed using different surgical approaches. Both the Sewing-Machine and Hang-back techniques provided good visual outcomes without added complications. Traumatic cataracts with iridodialysis may be managed in one or two steps, with single-stage surgery offering faster recovery and reduced patient burden.

Abstract No.: 205189

Comparison of Ocular Biometry and Refractive Outcome Between IOLMaster 700 and a Novel Segmental Optical Biometer

First Author: Haowen **LIN**

Purpose: To compare the ocular biometry and refractive outcome between two optical biometers.

Methods: This prospective observational study was conducted at the Zhongshan ophthalmic center, Guangzhou, China. A total of 953 cataract patients underwent preoperative biometry including ZW-30 sum-of-segments [SOS] method (ZWSM), ZW-30 composite method (ZWCM), and IOLMaster 700. Agreement of axial length (AL), with or without Cooke-modified AL (CMAL) adjustment, was analyzed

using Bland-Altman 95% limits of agreement (LoA). Subgroup analysis were used based on ALs (Short eyes: $AL < 22\text{mm}$; Normal eyes: $22\text{mm} \leq AL < 26\text{mm}$; Long eyes: $AL \geq 26\text{mm}$). Refractive prediction accuracy was evaluated using Emmetropia verifying optical (EVO) 2.0 formula and its SOS-optimized version (EVO 2.0SOS).

Results: In short and normal eyes, narrow 95%LoAs ($< 0.2\text{mm}$) were identified among three ALs. However, AL obtained by ZWSM was lower compared with this obtained by ZWCM and IOLMaster 700 (95%LoA: -0.39 to 0.01mm ; -0.38 to 0.04mm) in long eyes. CMAL adjustment enhanced the agreement of AL between ZWSM and ZWCM (95%LoA: -0.01mm to 0.02mm), ZWSM and IOLMaster 700 (95%LoA: -0.10mm to 0.07mm) in long eyes. Myopic prediction errors (PE) have been identified in the use of ocular biometric parameters obtained from ZWSM (Mean PE [ME]: EVO 2.0, -0.19D ; EVO 2.0SOS, -0.18D). After adjusting ME to zero, no difference was observed in PE calculated using any combination of formulas based on biometric measurements from three devices.

Conclusions: This novel segmented biometer demonstrates excellent agreement with IOLMaster 700 in short and normal eyes. However, ALs obtained by IOLMaster 700 are not interchangeable with the SOS method and require CMAL adjustment in long eyes. The application of the SOS method's ocular biometric parameters in refractive prediction led to myopic errors, which suggest constant optimization.

Abstract No.: 206173

Comparison of Surgically Induced Astigmatism After Cataract Surgery in Post-LASIK Eyes and Virgin Eyes With Long Axial Length

First Author: Xia **CHEN**

Co-Author(s): Yulan **WANG**

Purpose: To compare the surgically induced astigmatism (SIA) after microscopic cataract surgery between patients who underwent laser-assisted in situ keratomileusis (LASIK) surgery and virgin eyes with axial length (AL) $\geq 29\text{ mm}$.

Methods: In this retrospective single-center study, 62 eyes of 46 patients with $AL \geq 29\text{ mm}$ that underwent uneventful phacoemulsification cataract surgery were enrolled (31 eyes of 23 patients previously had LASIK surgery). Postoperative corneal astigmatism values were compared to preoperative astigmatism indices to determine the SIA at the postoperative 3-month (POM3) mark using the Alpins vector method.

Results: The preoperative mean corneal spherical aberration has no significant difference in both groups regarding magnitude and power vectors ($p > 0.05$). After microincision phacoemulsification cataract surgery, there were no significant differences in mean spherical and cylindrical values and mean keratometry readings (all

$p > 0.05$). However, surgically induced astigmatism and difference vector were significantly higher in post-LASIK eyes and microincision cataract surgery steepening effect on post-LASIK corneas was significantly higher than those in virgin eyes ($p = 0.016$, $p = 0.02$ and $p = 0.034$, respectively).

Conclusions: The SIA was significantly higher in the Lasik group. Cataract surgery has steepened the corneas in both groups with a significantly higher steepening effect in post-LASIK eyes.

Abstract No.: 202597

Comparison of Uncorrected Near Visual Acuity and Related Factors Between Enhanced Monofocal Intraocular Lens and Monofocal Intraocular Lens

First Author: Roo Min **JUN**

Co-Author(s): Yeong A **CHOI**, Kyung Eun **HAN**, Ji-ah **KIM**, Ji Young **MOON**

Purpose: To compare near uncorrected visual acuity (UCVA) and factors affecting near UCVA between eyes implanted with enhanced monofocal intraocular lenses (IOLs) and those implanted with standard monofocal IOLs.

Methods: A total of 119 eyes from 119 patients were included. Among them, 62 eyes received standard monofocal IOLs (Tecnis ZCB00) and 57 eyes received enhanced monofocal IOLs (Eyhance®). Near UCVA was assessed one month postoperatively. Correlations between near UCVA and potential influencing factors, including age, spherical equivalent, astigmatism magnitude and axis, pupil size, corneal higher-order aberrations within the central 4 mm zone, and axial length, were analyzed.

Results: Near UCVA (logMAR) was significantly better in the enhanced monofocal IOL group (0.26 ± 0.10) compared to the standard monofocal IOL group (0.41 ± 0.23) ($p < 0.01$) at one month postoperatively. In the standard monofocal IOL group, better near UCVA was associated with a more myopic spherical equivalent ($p < 0.01$) and a smaller pupil size ($p < 0.05$). In the enhanced monofocal IOL group, younger age ($p < 0.05$) and longer axial length ($p < 0.05$) were correlated with better near UCVA. Astigmatism magnitude, astigmatism axis, and corneal higher-order aberrations were not significantly related to near UCVA in either group.

Conclusions: Near UCVA was superior in eyes implanted with enhanced monofocal IOLs compared to those with standard monofocal IOLs. Factors associated with near UCVA differed between the two types of IOLs, suggesting distinct visual performance characteristics.

Abstract No.: 203154**Comparison of Visual Outcome EDOF IOL vs Monocular IOL's- a Comparative Longitudinal Study***First Author: Rakshya PANTA SITOULA**Co-Author(s): Indesh CHOUDHARY*

Purpose: EDOF IOL, or extended range of vision IOL, is a new technology in the treatment of intermediate vision-correcting lenses. The basic optical principle is to create a single-elongated focal point to enhance the depth-of-focus, on the contrary to monofocal IOLs in which light is focused on one single point or MF IOLs having two or three discrete points. This is the first study conducted in Nepal regarding EDOF lens.

Methods: A prospective study which included 100 patients who underwent implantation of the EDOF IOL and 100 eyes the monofocal IOL. The following preoperative and postoperative parameters were evaluated: spherical equivalent, uncorrected and corrected distance visual acuity, uncorrected and corrected intermediate visual acuity, and uncorrected and corrected near visual acuity at 1 week and 1 month.

Results: Patients after EDOF IOLs had significantly better uncorrected and corrected intermediate and near visual acuity compared to those with monofocal IOLs ($p < 0.001$). However, the distant visual acuity between the two groups was similar.

Conclusions: Both monofocal and EDOF lens had similar distant visual outcomes but intermediate and near visual acuity was superior for EDOF lenses. The results of this was comparable to other studies comparing the two IOL's.

Abstract No.: 204634**Comparison of Visual Outcomes and Higher-Order Aberration Between New Refractive EDOF IOL and Enhanced Monofocal IOL***First Author: Tae-im KIM**Co-Author(s): Ikhyun JUN, Do Young KIM, Hyunjo LEE, Ji Sang MIN, Kyoung Yul SEO*

Purpose: To compare visual performance and optical quality between a novel refractive extended depth-of-focus intraocular lens (EDoF IOL) with a myopic target and an enhanced monofocal IOL with emmetropic target.

Methods: In this single-center retrospective study, patients were implanted with either an EDoF IOL (TECNIS PureSee™, model ZEN00V; n=43) or an enhanced monofocal IOL (TECNIS Eyhance™, model ICB00; n=43). The EDoF IOL was targeted for a postoperative refraction of -0.50 to -1.00 D, whereas the enhanced monofocal IOL was targeted for emmetropia. Monocular distance visual acuity (VA) and iTrace aberrometry (Tracey Technologies, Houston, TX)

were assessed. A subgroup analysis of bilateral cases evaluated intermediate and near VA as well as photic phenomena.

Results: In this single-center retrospective study, patients were implanted with either an EDoF IOL (TECNIS PureSee™, model ZEN00V; n=43) or an enhanced monofocal IOL (TECNIS Eyhance™, model ICB00; n=43). The EDoF IOL was targeted for a postoperative refraction of -0.50 to -1.00 D, whereas the enhanced monofocal IOL was targeted for emmetropia. Monocular distance visual acuity (VA) and iTrace aberrometry (Tracey Technologies, Houston, TX) were assessed. A subgroup analysis of bilateral cases evaluated intermediate and near VA as well as photic phenomena. Dysphotopsia rates were similar between the two groups.

Conclusions: Implantation of the refractive EDoF IOL (TECNIS PureSee™) with a modest myopic target provides enhanced intermediate and near vision while maintaining distance acuity and overall optical quality, offering cataract surgeons a practical option to extend visual range without increasing photic disturbances.

Abstract No.: 206738**Comparison of Visual Performance With iTrace Analyzer Following Trifocal and Monofocal Intraocular Lenses Implantation in Pediatric Cataract***First Author: Fei LENG**Co-Author(s): Li LI, Lingfang ZHENG*

Purpose: To compare the early postoperative visual performance with an iTrace analyzer following trifocal and monofocal intraocular lenses (IOLs) implantation in pediatric cataract patients.

Methods: In this prospective cohort study, consecutive pediatric cataract patients who underwent phacoemulsification with in-the-bag IOL implantation from September 2024 to February 2025 were enrolled. Children were assigned to either the trifocal IOL group (Group A) or the monofocal IOL group (Group B) according to the type of IOL implanted. Study parameters included preoperative and postoperative corrected distance visual acuity (CDVA) at 5 m, objective visual qualities, and total high-order aberrations (HOAs) postoperatively. The postoperative complications were also recorded.

Results: A total of 45 eyes of 32 patients (Group A, n = 21; Group B, n = 11) were included in the study. Preoperative baseline characteristics between groups were not statistically significantly different (all $P > 0.05$). The mean follow-up period was 9.66 months. At the final follow-up, no significant intergroup difference was observed in corrected distance visual acuity (CDVA) ($P > 0.05$). Objective visual quality parameters improved postoperatively in both groups, with no significant differences between them (all $P > 0.05$).

Conclusions: Short-term data show that, in pediatric cataract patients without severe amblyopia, trifocal IOL implantation yields visual performance comparable to that achieved with monofocal IOL.

Abstract No.: 202576

Complications in YAG Laser Capsulotomy of Secondary Cataracts

First Author: Yazgul **ABDIYEVA**

Co-Author(s): Nizami **BAGIROV**, Jeyhun **NAZARLI**

Purpose: To study the causes of complications during YAG laser capsulotomy of secondary cataracts.

Methods: The study was conducted on 80 patients (82 eyes). After phacoemulsification of cataracts, YAG laser capsulotomy of secondary cataracts was performed 6-12 months later. Among the patients were 46 women (57.5%) and 34 men (42.5%) aged 34 to 79 years (48±3.9 years). Before and after surgery, all patients underwent the necessary ophthalmological examinations. In all patients, visual acuity gradually decreased from 0.8-0.9 to 0.2-0.3 over a period of time (up to 2-3 years).

Results: Complications after surgery were observed in 6 (6 eyes) patients. During YAG laser capsulotomy, involuntary movements of the head and eyes in some patients caused the focused laser beams to damage the lens. All patients were prescribed 1 drop of 0.5% timolol once a day for 1 month after surgery.

Conclusions: During posterior capsule dissection, patients should remain completely still and not interfere with the operation (even involuntarily).

Abstract No.: 207077

Congenital Aniridia Associated With Cataract: A Surgical and Visual Rehabilitation Challenge

First Author: Siva Sathi **KANESAN**

Co-Author(s): Ng **HONG KEE**, Nanthini **SELVARAJA**

Purpose: To describe the clinical presentation, associated ocular findings and management outcomes in case series of patients diagnosed with aniridia.

Methods: Case report.

Results: We report two cases of congenital aniridia. A 36-year-old female and a 15-year-old male, both presenting with progressive bilateral visual impairment since childhood. Clinical examination of the first patient revealed a best corrected visual acuity (BCVA) of counting fingers in the right eye (RE) and 5/60 in the left eye (LE). In the second patient, the BCVA was 2/60 in the RE and 6/60 in the LE. Clinically, both patients presented with bilateral aniridia, dense cataracts, and nystagmus. Intraocular pressure (IOP) was within normal limits in both patients, and fundus examinations were unremarkable. There was no family history of ocular disease in the female patient, whereas

the male patient's father has a history of glaucoma. The female patient underwent extracapsular cataract extraction with implantation of intraocular lens (IOL) in the more severely affected eye. Special consideration was given to zonular instability and corneal clarity during the procedure. Postoperative recovery was uneventful, with marked improvement in visual acuity. The male patient is currently awaiting a scheduled date for cataract surgery.

Conclusions: This case highlights the complex clinical spectrum of congenital aniridia and underscores the importance of individualized surgical planning in the presence of cataract. Long term follow up is essential to monitor for secondary glaucoma and other progressive complications.

Abstract No.: 205119

Consensus on the Benefits of Presbyopia-Correcting Intraocular Lenses in Cataract Surgery: A Delphi Study

First Author: Tetsuro **OSHIKA**

Co-Author(s): Margaret **AINSLIE-GARCIA**, Hiroyuki **ARAI**, Hiroshi **SASAKI**, Wendy (zhi) **WANG**, George **WRIGHT**

Purpose: A Delphi study was conducted to build consensus on the clinical and economic value of presbyopia-correcting intraocular lenses (PC IOLs), including trifocal and extended-depth-of-focus (EDOF) IOLs among age-related cataract surgery patients in Japan.

Methods: The Delphi panel included 22 practicing cataract surgeons across Japan; three of whom constituted the steering committee for the study. Two anonymous consensus-building rounds of electronic questionnaires were used to reach consensus on key topics. Questionnaires collected demographic information, quantitative items (PC IOL usage rates), qualitative items rated on a 5-point Likert scale to assess agreement (e.g., clinical benefits, economic concepts, adoption barriers), and open-ended responses. Consensus was defined a priori as ≥80% agreement.

Results: The panelists had an average of 30.1 (range 12-47) years of cataract surgery experience. Consensus was reached on 33 statements. The panel agreed that PC IOLs substantially improve satisfaction and vision-related quality of life when appropriately selected for cataract surgery patients in Japan. Compared to monofocal IOLs, trifocals are preferred for patients prioritizing intermediate vision. EDOFs offer broader range of clear vision and better contrast compared to monofocals. Optimal results may be delivered through appropriate patient selection and education to overcome adoption barriers such as out-of-pocket cost, low familiarity with payment models, and comparative evidence gaps.

Conclusions: These findings highlight the need for personalized IOL selection, patient education, and cost transparency to improve satisfaction and overcome barriers to PC IOL adoption in Japan and worldwide.

Abstract No.: 200325

Descemet Membrane Detachment Associated With Inadvertent Intrastromal Viscoelastic Injection: A Rare Complication of Phacoemulsification

First Author: Melissa Pei Yin WANG

Co-Author(s): Koon Ling KOH, Siti ROHA, Nanthini SELVARAJA

Purpose: To report a case of extensive central Descemet's membrane detachment precipitated by inadvertent intrastromal viscoelastic injection during phacoemulsification

Methods: Case report

Results: A 74-year-old man with no systemic comorbidities underwent right eye phacoemulsification. During viscoelastic injection via the temporal paracentesis, sudden ocular movement led to iatrogenic Descemet membrane Detachment (DMD) extending from the side-port incision to the central cornea. An intracameral air bubble was applied intraoperatively for tamponade. At one week postoperatively, best-corrected visual acuity (BCVA) was 6/60, with corneal edema and a linear stromal track extending centrally. Anterior segment optical coherence tomography (AS-OCT) revealed central DMD with intralaminar viscoelastic vacuolation. As the patient was not keen on surgical intervention, he was managed conservatively. By the second week, visual acuity showed mild improvement, with spontaneous reattachment of the peripheral detachment. Serial AS-OCT over six weeks demonstrated progressive reduction of vacuolation and gradual reattachment of the Descemet membrane. At final review, BCVA improved to 6/12 ($-0.75/-1.50 \times 110$), with minimal residual central stromal scarring and resolution of corneal edema.

Conclusions: Iatrogenic central Descemet membrane detachment following phacoemulsification may resolve with conservative management when partial spontaneous reattachment occurs. Serial AS-OCT is a valuable tool for monitoring resolution, favorable visual outcomes are achievable without surgical intervention.

Abstract No.: 202645

Descemet Membrane Loss During an Uneventful Cataract Surgery

First Author: Kristina Radika Hipa KURNIA

Co-Author(s): Heni RIYANTO

Purpose: to report a case of Descemet membrane loss during an uneventful cataract surgery, and its

management to prevent the patient from having permanent visual loss

Methods: A 74 year old male patient came to the clinic with blurred vision in the right eye. Visual acuity was 5/20 (not improved with pinhole) and cataract lens. There was a slight increase in intraocular pressure (IOP) before surgery, but it was controlled with anti-glaucoma agent. During the surgery, there was a Descemet membrane detached from the main incision site, and expanded to the central to the visual axis. Uneventfully, despite a slow and careful irrigation and aspiration, the Descemet membrane accidentally sucked by the irrigation-aspiration tip. Before corneal hydration, full bubble was administered to the anterior chamber (AC). Systemic and topical steroid were given to the patient, along with systemic and topical hyperosmotic agents, anti-glaucoma agents, and topical non steroid anti-inflammatory drugs (NSAID) with close monitoring.

Results: First day after surgery, visual acuity decreased to hand movement, the cornea was severely edema, IOP reached 46.2 mmHg, and bubble still covered more than half of the AC. One month after surgery, his visual acuity improved to 5/20 and best corrected visual acuity was 5/12.5, IOP was normal (10.0 mmHg), the cornea had already clear with trace of the missing Descemet membrane.

Conclusions: Descemet membrane loss could effect the clarity of the cornea, causing a visually threatening condition. With proper management, we could prevent the patient from having permanent visual loss.

Abstract No.: 205008

Early Experience With a Swept-Source OCT Biometer With Image Guidance

First Author: Fook Meng CHEONG

Co-Author(s): Eunice HIEW, Ivy LAI

Purpose: To evaluate the consistency and predictability of a new OCT-based biometer with reference to a pre-existing OLCR based biometer.

Methods: The first 36 eyes of 18 patients to be measured with the new OCT biometer were evaluated in the study. Each patient underwent biometric measurements in a standard manner using both the new OCT-based biometer and the OLCR-based biometer. Outcome measures were acquisition speed and rate, differences in measured axial length values, predictability and refractive outcomes including comparison with true axial length outcome measures.

Results: The acquisition speed was found to be faster than that of the OLCR-based biometer. There was 100% acquisition rate in all eyes, which included grade 4 nucleosclerotic cataracts and posterior sub-capsular opacifications. The measured axial lengths were longer in an eye shorter than 22mm and shorter in eyes longer than 26mm, but the differences were not statistically

significant. Using the manufacturers' lens constants and Barrett's IOL formula, 61.9% of eyes were within 0.25D of target refraction, 90.5% were within 0.50D and 100% were within 0.75D. These were comparable with results obtained from the OLCR based biometer.

Conclusions: The new swept-source OCT biometer was faster in its acquisition speed with 100% acquisition rate in all 36 eyes. The sum of segments mode of measurement seem to give shorter axial length values in eyes that were longer than 26mm, compared to the OLCR biometer. The predictability and refractive outcomes were comparable to the pre-existing biometer.

Abstract No.: 205043

Early Postoperative Outcomes of Light Adjustable Lens+ in Japanese Patients

First Author: Yukihito **KATO**

Co-Author(s): Rie **HORAI**, Kazuo **ICHIKAWA**, Kei **ICHIKAWA**, Yukihiro **SAKAI**, Melvin **SARAYBA**

Purpose: To report the early postoperative outcomes of Light Adjustable Lens(LAL)+ in Japanese patients.

Methods: This study included 33 eyes of 18 patients (61.5±10.4 years old) who underwent cataract surgery alone and had Light Adjustable Lens+ implanted. Visual acuity, subjective refraction, and objective refraction were measured the day after cataract surgery, one month, and one month after postoperative adjustment.

Results: The percentages of eyes whose postoperative refractive manifest refraction spherical equivalent (MRSE) were within 0.5D of their desired final refractive power were 48.5%, 66.7%, and 81.8% the day after surgery, one month after surgery, and one month after refractive adjustment, respectively. The percentages of eyes whose postoperative refractive MRSE were within 1.0D of their desired final refractive power were 84.8%, 93.9%, and 100%. The percentages of eyes whose postoperative refractive cylinders were within 0.5D of their desired final refractive power were 51.5%, 42.4%, and 90.9%. The percentages of eyes whose postoperative refractive cylinder was within 1.0D of their desired final refractive power were 78.8%, 78.8% and 100%.

Conclusions: LAL+ is an intraocular lens that can be adjusted postoperatively without affecting corrected visual acuity and has the potential to reduce refractive error in the same way as LAL.

Abstract No.: 204106

Effective Lens Position and Refraction Prediction in Pseudophakia

First Author: Andry **LUKANDY**

Co-Author(s): Anne **UMBOH**, Reinhard Arie **UMBOH**

Purpose: To analyze the influence of effective lens position (ELP) determination on refractive outcomes.

Methods: This was a prospective cohort observational study conducted at Prof. R. D. Kandou General Hospital from October 2024 to June 2025. Inclusion criteria included patients aged 2–18 years undergoing intraocular lens (IOL) implantation, with available biometric and UBM examination data. Data collected included gender, BCVA, IOP, ELP, axial length, keratometry, anterior chamber depth (ACD), lens thickness, predicted refraction, actual refraction, and refractive status.

Results: Of 26 eyes examined, 12 met the inclusion criteria. The majority were male (75%) with a median age of 11 years. The median axial length was 22.56 mm, mean BMD was 3.75 ± 0.52 mm, keratometry was 43.59 ± 2.21 D, and mean lens thickness was 2.85 ± 1.31 mm. The median predicted refraction was +0.46 D with an average IOL power of 21 D. One month postoperatively, mean BCVA was 0.70 ± 0.64 LogMAR, mean IOP was 14.08 ± 3.14 mmHg, mean ELP was 4.37 ± 0.40 mm, and mean actual refraction was -0.08 ± 1.45 D. The median refractive prediction error was 0.54 D. Statistical analysis showed no significant association between ELP at one month and predicted refraction ($p > 0.05$), while a significant association was found between predicted and actual refraction ($p < 0.05$). Regression analysis using actual refraction at one month yielded nonsignificant results ($p > 0.05$).

Conclusions: There was no association between effective lens position (ELP) and actual refraction at one month postoperatively at Prof. R. D. Kandou General Hospital. The median difference between predicted and actual postoperative refraction in pediatric patients was 0.5 diopters.

Abstract No.: 202028

Efficacy of Pre-Operative Eyelid Hygiene Combined With Peri-Operative Artificial Tears After Phacoemulsification Cataract Surgery: A Randomized Controlled Trial

First Author: Krittaya **CHITSUTHIPAKORN**

Co-Author(s): Nawat **WATANACHAI**

Purpose: Dry eye frequently occurs after phacoemulsification and may impair comfort and visual recovery. This study evaluated whether pre-operative eyelid hygiene with peri-operative artificial tears improves postoperative ocular surface outcomes.

Methods: In this single-center, single-blind randomized controlled trial, 80 patients were randomized 1:1 to intervention (eyelid hygiene twice daily for 7 days preoperatively plus 0.18% sodium hyaluronate artificial tears four times daily from 7 days pre-op to postoperative day [POD] 28; n=40) or control (standard care; n=40). The primary outcome was fluorescein tear break-up time (FTBUT). Secondary outcomes included Schirmer I, Ocular Surface Disease Index (OSDI), Oxford corneal staining, and meibomian gland dysfunction (MGD) grading. Outcomes were assessed at baseline,

POD7 and POD28 using mixed-model ANCOVA adjusted for baseline values.

Results: Baseline characteristics were comparable. At POD7, the intervention group showed smaller decline in FTBUT (-0.75 vs -1.98 s; mean difference $+1.23$ s, $p=0.178$), and Schirmer I (-0.10 vs -1.25 mm; $+1.15$ mm, $p=0.260$). OSDI improved significantly more in the intervention group (-4.20 vs -1.05 ; -3.15 , $p=0.032$). At POD28, FTBUT decline was also less (-0.87 vs -2.51 s; $+1.64$ s, $p=0.112$), Schirmer I decreased less (-0.30 vs -1.87 mm; $+1.56$ mm, $p=0.176$), and OSDI improvement remained significant (-6.47 vs -1.60 ; -4.87 , $p=0.011$). Oxford staining and MGD grading showed no significant differences. No adverse events occurred.

Conclusions: Pre-operative eyelid hygiene with peri-operative artificial tears significantly improved postoperative symptoms as early as POD7, with sustained benefit at POD28 and favorable trends in tear function. This simple, safe regimen may enhance ocular surface recovery after cataract surgery.

Abstract No.: 205226

Evaluation of Clear Corneal Incision Following Manual and Femtosecond Laser-Assisted Cataract Surgery

First Author: Samaresh **SRIVASTAVA**

Co-Author(s): Ishrat **ANIS**, Abhay **VASAVADA**, Shail **VASAVADA**, Vaishali **VASAVADA**

Purpose: To compare the occurrence of incisional Descemet's detachments (DD) in manual phacoemulsification (PE) versus femtosecond laser-assisted cataract surgery (FLACS).

Methods: Prospective interventional case series in 450 eyes (450 patients) undergoing cataract surgery were randomized to: group I ($n = 150$) PE with a 2.2mm near square limbal incision, group II ($n = 150$) PE with 2.2mm external entry and internal flare created with the same anterior bevel knife as group I, and group III—FLACS where the laser was used to create a trapezoidal incision with external 2.2mm and internal 2.3mm. standardised Phacoemulsification was performed. Outcome measures presence of DD noted clinically at the end of surgery, DD on anterior segment optical coherence tomography (OCT) performed within an hour of surgery, epithelial / endothelial misalignment. Additionally, manual 2.2mm square and femtosecond laser trapezoidal 2.2mm incisions were created in 5 human cadaver eyes each, and incision architecture compared on histomorphology.

Results: Intraoperatively, varying degrees of DD at the incision were seen in 14,13 and 5.3% eyes in groups I,II, and III, respectively. Postoperatively, DD on OCT in 58, 79 and 30% eyes within an hour. The differences were statistically significant ($P < 0.05$). Histomorphologic evaluation of collagen showed misalignment of the

roof and floor of incision in manual group compared to FLACS. There was greater collagen disorganisation around the incision in the manual group.

Conclusions: FLACS incisions had a lower incidence of DD as well as lesser collagen architecture distortion. The femtosecond laser allows creation of precisely sized trapezoidal incisions for more wiggle space at the internal entry causing less trauma.

Abstract No.: 200706

Evaluation of Distance, Intermediate, and Near Vision of Presbyopia Patients With Synergy Implantation at Different Contrast Energy

First Author: Jun **ZHANG**

Purpose: To evaluate visual performance, contrast sensitivity under various contrast energy conditions, and patient satisfaction after bilateral implantation of the TECNIS Synergy ZFR00V EDOF IOL in presbyopia.

Methods: This prospective single-arm observational study involved 40 Chinese patients (80 eyes) underwent Synergy intraocular lenses (IOLs) implantation conducted from October 2024 to April 2025. Postoperatively, distance, intermediate, and near visual acuity were evaluated with various contrast energy charts, for both monocular and binocular outcomes. Patient satisfaction was evaluated using the VF-14 questionnaire.

Results: At 3 months postop, the mean refractive spherical equivalent was -0.32 ± 0.30 D, with 84% of eyes within ± 0.50 D and 99% within ± 1.0 D. Mean binocular logMAR acuities were: UDVA -0.06 ± 0.05 , UIVA 0.00 ± 0.07 , UNVA (33cm) -0.02 ± 0.05 ; corrected acuities (CDVA/DCIVA/DCNVA) were $-0.06 \pm 0.05/0.05 \pm 0.10/0.02 \pm 0.07$ at 100% contrast, $0.04 \pm 0.08/0.12 \pm 0.10/0.06 \pm 0.09$ at 80% contrast, and $0.18 \pm 0.10/0.26 \pm 0.13/0.21 \pm 0.11$ at 40% contrast. Contrast sensitivity decreased notably with lower contrast: most patients lost about 1 line of vision at 80% contrast and 2-4 lines at 40% contrast. Patient outcomes were excellent, showing 97.5% spectacle independence and a mean VF-14 satisfaction score of 53.4/60.

Conclusions: Synergy provides Chinese presbyopic patients with satisfying full-range vision and spectacle independence. This comprehensive assessment will provide a more nuanced understanding of the impact of the Synergy IOL on vision across different distances and contrast energy conditions, contributing to improved patient selection and postoperative outcomes.

Abstract No.: 206666

Evaluation of Rotational Stability of Toric Trifocal Intraocular Lens in Patients Undergoing Cataract Surgery

First Author: Purnima DHAND

Co-Author(s): Madhav GOEL, Sonu GOEL

Purpose: To evaluate the rotational stability, refractive outcomes, and patient-reported visual quality after implantation of the FineVision POD toric trifocal intraocular lens (IOL).

Methods: One hundred eyes of 100 patients with senile cataract and ≥ 1.0 diopter (D) corneal astigmatism underwent phacoemulsification with FineVision POD toric trifocal IOL implantation. Intraoperative toric alignment was guided by the Callisto Eye digital marking system, and postoperative verification was performed using Slit lamp Examination and iTrace ray-tracing aberrometry. Follow-up was at day 1, week 1, and month 1. Outcomes included uncorrected distance, intermediate, and near visual acuity (UDVA, UIVA, UNVA), best corrected visual acuity (BCVA), residual astigmatism, IOL rotation, and subjective photic phenomena.

Results: At 1 month, 91.9% achieved UDVA $\geq 20/20$, and 98.5% $\geq 20/25$. Mean residual astigmatism was 0.32 ± 0.20 D, with 93% of eyes within ± 0.50 D of target refraction. Mean IOL rotation was $2.3^\circ \pm 1.5^\circ$, with 96% of eyes $\leq 5^\circ$ rotation. Glare/halos were reported in 14% but were mild and non-bothersome.

Conclusions: The FineVision POD toric trifocal IOL demonstrated excellent rotational stability, accurate astigmatism correction aided by digital guidance, and high levels of spectacle independence. Visual quality was generally good, with mild photic phenomena consistent with trifocal optics.

Abstract No.: 201104

Evaluation of Sub Tenon's Block Using 26G Needle in Routine Cataract Surgery

First Author: Shah Md Rajibul ISLAM

Co-Author(s): Shah Md Bulbul ISLAM, Golam RABBANI

Purpose: Evaluating subtenon's block during routine phacoemulsification surgery.

Methods: This cross-sectional observational study was done from March 2021 to December 2021. Pre-operative and post-operative visual acuity, IOP, per-operative pain, complications of subtenon's anesthesia and duration of surgery were noted. All the patients underwent temporal approach Phacoemulsification with PCIOL by a single surgeon.

Results: Out of 50 patients 60% were male. Mean age was 57.6 ± 9.07 (22-78) years. There was significant improvement of visual acuity from 0.17 ± 0.084 to 0.73 ± 0.16 in decimal ($p < 0.001$). IOP was significantly lower (13.12 ± 1.51 vs 10.74 ± 1.34 mm Hg) in the post-

operative period ($p < 0.001$). 76% patients complained of discomfort during the block. Per-operatively there were no complains. Subconjunctival hemorrhage occurred in 4% and chemosis in 6%. Sudden spike of blood pressure occurred in 4%. Duration of surgery was 19.36 ± 4.21 (13-32) minutes. Two patients needed eye patching for 02 hours following surgery

Conclusions: Subtenon's block using a 26G needle carefully is an effective and safe technique for routine cataract surgery. It minimizes complications and maximizes surgeons' and patients' comfort. It can also be used to augment cases done under topical anesthesia when patients feel discomfort. It is an excellent technique that can be utilized by surgeons switching over to topical surgery from regional block.

Abstract No.: 204624

Five-Year Real-World Comparison of Visual Quality and Patient Satisfaction Between AcrySof IQ ReSTOR SN6AD1 and Lentis Comfort LS-313 MF30 Multifocal Intraocular Lenses

First Author: Li LI

Purpose: To compare the visual quality and patient satisfaction outcomes of two multifocal intraocular lenses (MIOLs) at five years after cataract surgery in a real-world setting.

Methods: Eyes were grouped based on the MIOL implanted: MIOL-A group (Lentis Comfort LS-313 MF30 +3.0 D, 62 eyes) and MIOL-B group (AcrySof IQ ReSTOR SN6AD1 +3.0 D, 38 eyes). Data collected at 5 years postoperatively included: visual acuity; Area under the defocus curve (AUC); higher-order aberrations (HOA); Patient satisfaction questionnaire; and Incidence of posterior capsule opacification (PCO).

Results: Near visual acuity was significantly better in the MIOL-A group compared to the MIOL-B group (0.16 ± 0.09 vs. 0.24 ± 0.11 , $p = 0.01$). Distance (0.10 ± 0.09 vs. 0.18 ± 0.17 , $p = 0.09$) and intermediate (0.17 ± 0.09 vs. 0.19 ± 0.14 , $p = 0.76$) visual acuity were also better in the MIOL-A group. The AUC was larger in the MIOL-A group (5.68 ± 0.78) than in the MIOL-B group (5.60 ± 0.61), but this difference was not statistically significant ($p = 0.68$). Coma was significantly lower in the MIOL-A group compared to the MIOL-B group (0.05 ± 0.05 vs. 0.12 ± 0.08 , $p = 0.001$). The Nd:YAG laser capsulotomy rate was significantly lower in the MIOL-A group compared to the MIOL-B group (6.5% vs. 26.3%, $p = 0.001$).

Conclusions: Both multifocal IOLs provided long-term stable refractive outcomes. The Lentis Comfort LS-313 MF30 demonstrated significant advantages over the AcrySof IQ ReSTOR SN6AD1 in near visual acuity, coma control, and long-term PCO rate.

Abstract No.: 208430**From Lens Density to Cataract: A Predictive Model Using Ocular Biometric Parameters***First Author: Yue WEN**Co-Author(s): Yongzhen BAO, Qiong XU, Mingwei ZHAO*

Purpose: To explore the lens density to predict cataract and its correlation with demographic and ocular biometric parameters.

Methods: A cross-sectional study was performed. A total of 2000 participants (2000 eyes), ranging from 3 to 98 years old, were enrolled. Lens images were obtained from IOL Master 700 and processed by an OpenCV-based method. The receiver operating characteristic analysis was used to select the predictor for cataract. A logistic and linear regression model were chosen to illustrate the correlation of lens density with demographic and ocular biometric parameters.

Results: The mean age was 40.84 ± 22.97 years, and 44.8% were male. A total of 491 patients were diagnosed with cataracts. The axial length (AL), anterior aqueous chamber (AQD), and white-to-white (WTW) were greater in the group with AL > 26 mm (all $P < 0.001$), while the LT was thicker in the group with AL < 26 mm ($P = 0.002$). The areas under the receiver operating characteristic (ROC) curve (AUC) of the lens average density were the most (0.975, 95% CI: 0.969 to 0.981, $P < 0.001$), and the cutoff value of the lens average density was 68.66. The multivariate logistic regression analysis demonstrated that age (OR = 1.104, 95% CI: 1.090 to 1.118, $P < 0.001$), AL (OR = 1.360, 95% CI: 1.265 to 1.462, $P < 0.001$), AQD (OR = 0.275, 95% CI: 0.169 to 0.448, $P < 0.001$), and lens thickness (LT) (OR = 2.013, 95% CI: 1.287 to 3.150, $P = 0.002$) were independently associated with cataract. The multivariate linear regression analysis showed that the lens average density was significantly associated with age (standardized $\beta = 0.709$, $P < 0.001$), AL (standardized $\beta = 0.192$, $P < 0.001$), AQD (standardized $\beta = -0.173$, $P < 0.001$), LT (standardized $\beta = 0.084$, $P < 0.001$), and WTW (standardized $\beta = 0.027$, $P = 0.027$).

Conclusions: We proposed the lens average density to predict cataract. We found that old age, long AL, shallow AQD, and thick LT are risk factors for cataract. Besides, increased lens average density is associated with older age, longer AL, shallower ACD, thicker LT, and larger WTW.

Abstract No.: 204675**From Spectacle Discomfort to 6/6 Day 1 Postoperative: Eyehance Toric II DIU225 +22.0 D With Incision-Axis Optimization***First Author: Muhammad Zidny FAHMI*

Purpose: While toric intraocular lens (IOL) calculators are widely validated, most studies emphasize lens power accuracy rather than the impact of incision-axis choice and surgically induced astigmatism (SIA)

assumptions. Reports directly comparing Barrett Toric TK with the Kane formula in real-world incision planning remain limited. This case highlights how optimizing the incision axis based on different SIA settings can eliminate residual astigmatism and restore 6/6 vision in early nuclear cataract.

Methods: A 69-year-old male presented with persistent spectacle discomfort despite multiple refractions. Pre-operative UCVA was 0.10 OU. Slit-lamp revealed a nuclear cataract graded NO3–NC3 (LOCS III). Biometry (OD, IOLMaster 700) showed AL 23.69 mm, ACD 3.16 mm, LT 5.0 mm, and TK astigmatism -1.87 D @ 83° . Barrett Toric TK (SIA 0.30 D @ 135°) suggested Eyehance Toric II DIU225 +22.0 D (2.25 D cyl) with predicted residual -0.39 D @ 87° . Kane formula with optimized SIA 0.20 D predicted residual 0.10 D if incision placed at 100° , but ≈ 0.00 D if revised to 180° . Based on this convergence, the incision was placed at 180° and the IOL implanted at 175° .

Results: On postoperative day 1, UCVA improved from 0.10 to 1.0 (6/6). The patient reported stable, comfortable vision and resolution of spectacle-related complaints.

Conclusions: This case illustrates that even in “immature” nuclear cataracts, optimizing incision axis with dual-formula guidance (Barrett Toric TK vs Kane with optimized SIA) can virtually eliminate residual astigmatism, highlighting a critical yet under-reported factor in toric IOL surgery.

Abstract No.: 202071**GJB2 Deficiency Causes Congenital Cataract via Impaired Gap Junctions and Caspase-Mediated Lens Cell Apoptosis***First Author: Ailifeire HAILAITI*

Purpose: To identify GJB2 as a novel congenital cataract (CC) pathogenic gene, clarify its mechanism in lens opacification, and validate its role via in vitro/in vivo models, aiding therapeutic target exploration for connexin-related CC.

Methods: Clinical/genetic analysis: WES/Sanger sequencing of a 3.5-year-old CC proband's family; CLUSTALX for Cx26 amino acid conservation. In vivo: CRISPR/Cas9-generated *gjb2*^{-/-} zebrafish; stereomicroscopy (lens opacity) and TEM (mitochondria/apoptosis). In vitro: siRNA-mediated GJB2 knockdown in HLECs; assays for gap junction (Lucifer yellow), calcium (Fluo-4/Rhod-2 AM), mitochondria (JC-1/DCFH-DA), apoptosis (Western blot/flow cytometry); RNA-seq/LC-MS/MS.

Results: Proband had homozygous GJB2 c.235del (Leu79 conserved). GJB2 knockdown impaired HLEC gap junctions ($p < 0.001$), caused calcium overload ($p < 0.01$), mitochondrial dysfunction ($\Delta\Psi_m \downarrow$, ROS $\uparrow$, $p < 0.01$), and apoptosis (caspase-3 $\uparrow$, Bax/Bcl-2 $\uparrow$, $p < 0.01$). 649 DEGs enriched in gap junction/mitochondrial/apoptotic

pathways. 86.2% *gjb2*^{-/-} zebrafish had lens opacity (TEM: mitochondrial swelling, apoptotic bodies ↑, $p < 0.001$).

Conclusions: *GJB2* is a novel CC gene; its deficiency disrupts gap junctions/calcium homeostasis, induces mitochondrial apoptosis, and causes lens opacity, highlighting calcium-mitochondrial axis as a therapeutic target.

Abstract No.: 200212

Genotype-Phenotype Correlations of Ocular Posterior Segment Abnormalities in Marfan Syndrome

First Author: Yan **LIU**

Co-Author(s): Tianhui **CHEN**, Yongxiang **JIANG**

Purpose: Marfan syndrome (MFS) is a connective tissue disorder caused by mutations in the *FBN1* gene. This study aims to investigate the correlations between *FBN1* genotype and posterior segment abnormalities within a Chinese cohort of MFS.

Methods: Retrospective study. 121 eyes of 121 patients with confirmed *FBN1* mutations between January 2015 and May 2023 were initially recruited. A comprehensive ophthalmological examination was performed, and the incidence of retinal detachment (RD), atrophic / tractional / neovascular maculopathy (ATN classification) and posterior staphyloma (PS) were analyzed between different genotype groups.

Results: A total of 60 eyes (49.59%) exhibited posterior segment abnormalities, including RD (4, 3.31%), maculopathy (47, 38.84%), and PS (54, 44.63%). The mean age was 11.53 ± 11.66 years, with 79.34% of patients below 20 years old. The location and region of mutations were found to be associated with the incidence of maculopathy ($P=0.013$, $P=0.033$) and PS ($P=0.043$, $P=0.036$). Mutations in the middle region had a lower incidence of maculopathy and PS ($P=0.028$ and $P=0.006$). Mutations in the TGF- β regulating sequence exhibited a higher incidence of maculopathy and PS ($P=0.020$, $P=0.040$). Importantly, the location and region of mutations were also associated with the incidence of atrophic maculopathy ($P=0.013$ and $P=0.033$). Mutations in the middle region had a significantly lower probability of atrophic maculopathy ($P=0.006$), while mutations in the TGF- β regulating sequence had a higher incidence of atrophic maculopathy ($P=0.020$).

Conclusions: Maculopathy and PS were associated with the location and region of *FBN1* mutations. Patients with mutations in the TGF- β regulating sequence faced an increased risk of developing retinopathy.

Abstract No.: 206358

Hard Cataract in Iris Coloboma: Surgical Approach and Visual Outcomes

First Author: Ainun **NADZIROH**

Co-Author(s): Nina **HANDAYANI**

Purpose: Iris coloboma is a congenital ocular anomaly caused by incomplete closure of the embryonic optic fissure, typically appearing as a keyhole-shaped defect may present with significant complications including cataracts and increased risk of retinal detachment, particularly when involving posterior segment structures. This report aims to present the surgical outcome of hard cataract with iris coloboma and to underline the importance of evaluating possible posterior abnormalities.

Methods: A 58-year-old male with bilateral iris coloboma and mature cataract, presenting with progressive vision loss and photophobia. Preoperative evaluation revealed dense nuclear with normal corneal diameter. The posterior segment could not be adequately evaluated; however, the B-Scan Ultrasound examination was within normal limits.

Results: The patient underwent cataract extraction and IOL implantation in the right eye, whereas the iris coloboma was left uncorrected. Despite intraoperative challenges, including a hard nucleus and miosis, the operation was successfully completed. Postoperative visual acuity improved from hand motion to 0.30 LogMAR, with no significant complications; however, a choroidal coloboma was identified.

Conclusions: Proper surgical technique and anticipation of intraoperative challenges are critical for successful cataract surgery in eyes with iris coloboma. Although the iris and choroidal coloboma was not surgically addressed in this case, the functional outcome was satisfactory. Further therapeutic consideration is warranted for the choroidal coloboma in order to prevent potential complications, particularly retinal detachment.

Abstract No.: 203647

ICO-OSCAR-Based Evaluation of Phacoemulsification Performed by Ophthalmology Residents at Hasanuddin University

First Author: Dian Perwitasari **SUMARWOTO**

Co-Author(s): Ahmad Ashraf **AMALIUS**, Muhammad Abrar **ISMAIL**, Muhammad Irfan **KAMARUDDIN**

Purpose: To evaluate the characteristics of phacoemulsification surgeries performed by ophthalmology residents at Hasanuddin University using the ICO-OSCAR assessment tool, as part of efforts to enhance surgical training quality.

Methods: A descriptive study was conducted on 19 phacoemulsification surgery videos performed by

residents. Each video was assessed by Cataract and Refractive Surgery Consultant in Ophthalmology Department of Hasanuddin University, Makassar-Indonesia, using ICO-OSCAR assessment tool.

Results: Nineteen videotaped surgeries were analyzed. Most procedures were performed by third-year residents, predominantly in the seventh semester. The average ICO-OSCAR score was 4.4, and the average of total surgery was 72 surgeries. The greatest challenges were observed during the cracking procedure, as well as nucleus rotation and manipulation. The most frequently reported postoperative complication was corneal edema, this associated with inadequate intraoperative control of intraocular instrument, prolonged surgical time, and excessive intraocular maneuvers.

Conclusions: Phacoemulsification surgeries performed by ophthalmology residents at Hasanuddin University demonstrated overall competency but revealed specific challenges in nucleus management. Targeted training focusing on cracking and nucleus manipulation techniques is recommended to improve surgical outcomes and reduce postoperative complications.

Abstract No.: 205549

IOL Power Calculation Using Different Formulas

First Author: Leyla BILANDARLI

Co-Author(s): Gulmin AHMADOVA, Beyim BABAYEVA

Purpose: Comparative analysis of calculating IOL power using 6 formulas.

Methods: In this study we calculated the optical power of the Technis ZCB00 (Johnson&Johnson) in 107 patients (145 eyes) using 6 formulas: Hoffer Q, Holladay, Barrett, Hill-RBF, Kane, Pearl-DGS. Calculations were performed on IOL Master 500 (Carl Zeiss Meditec, AG) and using ESCRS online calculator (<https://iolcalculator.es CRS.org>). All eyes were divided in 4 groups in accordance with the eye's axial length (AL): up to 22.00mm (29 eyes), 22.00-24.00mm (42 eyes), 24.00-26.00mm (46 eyes), and more than 26.00mm (28 eyes).

Results: Calculation of IOLs in the 2 middle groups revealed almost identical results for all formulas. The spread of results was 0.2D for group 2 (IOL power: 22.2-22.4D) and 0.3D for group 3 (17.1-17.4D). For short eyes obtained spread was higher – 0.5D (26.4-26.9D). In long eyes group we observed the highest spread -1.7D (8.6-10.3D).

Conclusions: According to results of our research, IOL power calculation in eyes with AL from 22.00 to 26.00mm does not cause controversy and gives consistently good postoperative refractive results. A seemingly small difference of 0.5D in short eyes with AL up to 22.00mm and fairly large spread of 1.7D in long eyes with AL more than 26.00mm can cause a serious

errors in postsurgical period. These errors become especially critical when implanting multifocal lenses with averagely designed near and middle focuses.

Abstract No.: 201662

Incorporating Simulation and Framework-Based Teaching to Improve Surgical Skills and Learner Engagement in Ophthalmology Training: A Case Study

First Author: Channdarith KITH

Co-Author(s): Sreyla CHORK, Kossama CHUKMOL, Sokunsowattra KAK

Purpose: To assess the effectiveness of integrated teaching methodologies, such as simulated learning, active feedback, and outcome-based education, in improving ophthalmology residents' engagement, confidence, and skill acquisition, particularly for cataract surgery.

Methods: A two-month wet lab training program was created to focus on manual small incision cataract surgery (MSICS). Several teaching methods were applied in clinical and classroom settings. These featured structured feedback, well-known learning resource frameworks, active peer engagement, and real-life and simulated case scenarios. Residents were separated into four groups (3 to 4 residents each) and given weekly two-hour hands-on training sessions. Prior to each session, there were tests on surgical procedures and instrument knowledge. Throughout, formative feedback was given, and the results were evaluated using a summative post-test.

Results: Residents showed increased confidence and retention after structured simulation and mentorship. More than 60% of participants voluntarily completed the training, which resulted in significant improvements in suturing and microscope handling. Active learning strategies, such as immediate feedback and peer interaction, have proven effective in increasing learner motivation and developing clinical competence.

Conclusions: In ophthalmology training, simulation-based, feedback-rich, and outcome-focused teaching methods greatly enhance student performance and motivation. These approaches are flexible and scalable, resulting in a more confident, disciplined, and patient-centred learning environment.

Abstract No.: 200348

Inflammatory Cytokine Profiles in Diabetic vs. Senile Cataract: Analysis of Aqueous Humor and Lens Epithelium

First Author: Cindy HARTONO

Co-Author(s): Muhammad Abrar ISMAIL, Habibah S. MUHIDDIN, Hamzah

Purpose: This study aims to compare the expression and levels of inflammatory mediators, interleukin-6

(IL-6) and tumor necrosis factor-alpha (TNF- α), in lens epithelial cells and aqueous humor between diabetic and non-diabetic cataract patients.

Methods: A cross-sectional study was conducted involving 66 cataract patients, comprising 33 with type 2 diabetes mellitus (DM) and 33 non-diabetic controls. IL-6 and TNF- α levels were quantified in aqueous humor using ELISA, and immunohistochemistry was used to assess their expression in the anterior lens capsule.

Results: IL-6 expression was markedly higher in the diabetic group, with 51.5% of samples showing strong immunoreactivity (IHC score 3), compared to only 9.1% in the non-diabetic group. In contrast, TNF- α expression was low in both groups, with most samples scoring 0. Aqueous IL-6 levels were elevated in diabetic patients (17.83 ± 13.66 pg/mL) versus non-diabetics (9.40 ± 3.83 pg/mL), while TNF- α levels were comparable (15.47 ± 1.58 vs. 16.91 ± 3.71 pg/mL, respectively). Additionally, hyperplastic lens epithelial cells were frequently observed in diabetic samples.

Conclusions: Diabetic cataract patients exhibit a distinct inflammatory profile, particularly with elevated IL-6 expression and levels, suggesting a local proinflammatory state within the anterior segment. These findings underscore the importance of addressing inflammation in the management of cataracts in diabetic individuals.

Abstract No.: 200481

Is SIA = 0 a Reliable Assumption in Toric IOL Planning? A Vector Analysis Using a Custom Calculator

First Author: Zain KHATIB

Purpose: To evaluate whether assuming a Surgically Induced Astigmatism (SIA) of 0 D provides acceptable accuracy in toric intraocular lens (IOL) planning, using a custom-built vector analysis calculator. The study also aims to explore whether such an approach offers ergonomic and surgical workflow benefits by allowing incisions at the surgeon's preferred location.

Methods: This retrospective observational study included 80 eyes that underwent phacoemulsification with toric IOL implantation. Postoperative SIA was calculated using corneal topography. For each case, a custom SIA error calculator was used to simulate and compare the vector error when SIA was assumed to be 0.0, 0.1, 0.2, 0.3, 0.4, or 0.5 D. The actual SIA (magnitude and axis) was derived from postoperative topographic changes, and the vector error for each assumed SIA was calculated against this ground truth. Outcomes were analyzed in terms of mean error, standard deviation, and frequency of least and most error values across the range of SIA assumptions.

Results: Assuming SIA = 0 D yielded the lowest mean error (0.39 ± 0.23 D), followed by 0.1 D and 0.2 D. In

41.3% of cases, the least vector error occurred with SIA = 0 D, while in only 11.3% of cases was it the worst assumption. Error magnitude increased progressively with higher assumed SIA values.

Conclusions: Assuming SIA = 0 D is acceptable in a significant proportion of cases and allows for greater surgical flexibility. It facilitates incision placement at the surgeon's preferred axis, potentially reducing surgery time and simplifying preoperative planning without compromising refractive accuracy.

Abstract No.: 203240

Lens Parameters and Myopic Shift in Nuclear Cataract After Vitrectomy

First Author: Haowen LIN

Purpose: To evaluate the relationship between lens parameters and spherical equivalent refraction in the development of nuclear cataract following pars plana vitrectomy (PPV).

Methods: This prospective cohort study included patients who were scheduled for unilateral PPV surgery. All patients underwent subjective refraction, ocular biometry, and swept-source anterior segment optical coherence tomography (SS-ASOCT) before and after PPV. Lens power and equivalent refractive index were calculated based on the Bennett and Lensmaker formula, and lens nuclear density was quantified based on SS-ASOCT images.

Results: A total of 110 patients who developed nuclear cataract after PPV were included in the analysis, with a mean follow up of 10.38 ± 3.12 months. The operated eyes showed a myopia refractive shift (-2.81 ± 2.36 D), along with an increase in lens power, lens refractive index, and lens thickness, as well as a protruding of the radius of posterior lens surface. Multivariate linear regression analysis showed that the lens power was the main factor contributing to the myopic refractive shift (R-squared: 0.80, $P < 0.001$). Additionally, the refractive index of the lens was found to be the primary determinant of changes in the refractive power of lens (R-squared: 0.98, $P < 0.001$). Lens density showed a linear correlation with both the refractive index and lens power (correlation coefficient: 0.48 and 0.50, respectively).

Conclusions: Changes in lens refractive index are the main cause of lenticular myopia induced by nuclear cataract after PPV. Lens density can be used to assess the change of lens refractive index and lens power in vivo.

Abstract No.: 207049**Long-Term Complications of Phakic Intraocular Lens Implantation for Myopia***First Author: Wen-yu HSU**Co-Author(s): Ya Hui WANG, Chien-liang WU*

Purpose: To report the long-term complications in patients who underwent phakic intraocular lens (pIOLs) implantation for myopia.

Methods: Twenty-eight eyes of 14 patients underwent implantation of phakic intraocular lenses (pIOLs) for the correction of myopia between January 2014 and December 2024 in Taipei Municipal Wanfang Hospital. All pIOLs were done by one surgeon. Eight eyes of four patients were lost to follow-up.

Results: The mean age of the patients was 38.9 ± 10.89 years (range, 23–53 years), and the mean follow-up duration since pIOL implantation for myopia was 4.9 ± 2.84 years (range, 2–10 years). Phakic IOL explantation was performed with phacoemulsification and posterior-chamber intraocular lens in 2 eyes due to cataract formation and in 4 eyes due to decreased endothelial cell counts (<1500 cells/mm). Dislocation of phakic IOLs occurred in 2 eyes of 2 patients, both of which underwent immediate reposition surgery. No eye required corneal transplantation due to corneal decompensation.

Conclusions: A careful follow-up is required for possible complications after pIOL implantation.

Abstract No.: 206859**Long-Term Visual Performance of the Increased Range of Focus RayOne EMV® Premium IOL Under Mesopic Conditions in Filipino Eyes***First Author: Maureen Anne REYES**Co-Author(s): Victor Jose CAPARAS, Isabel Mara CAPARROS, Ma. Isabela DE GUIA-MAYUGA*

Purpose: To evaluate the visual outcome under mesopic conditions after bilateral implantation of the increased range of focus RayOne EMV® intraocular lens (IOL) (Rayner, Worthing, UK).

Methods: Six patients (12 eyes) who underwent phacoemulsification for cataract were implanted with RayOne EMV® on both eyes, targeting emmetropia post-operatively. At 12–18 months post-surgery, monocular/binocular uncorrected and distance-corrected visual acuity (UDVA/CDVA) was tested for distance at 4m under mesopic conditions (3 cd/m²). Additionally, the defocus curve, contrast sensitivity (CS), and photic phenomena (Halo and Glare Simulator, ViSU-L GmbH, Germany) were evaluated.

Results: Mean spherical refraction ($\pm$ SD) was $-0.50 (\pm 0.58)$ diopters (D) during the post-surgery follow-up. Mean ($\pm$ SD) binocular UDVA at follow-up was 0.00 (± 0.15) logMAR, while mean ($\pm$ SD) binocular CDVA was

0.10 (± 0.17) logMAR. Binocular defocus curve showed a mean CDVA of at least 0.30 logMAR from +1.0 up to -1.5 D. Mean binocular halo size and intensity were low at 25/100 and 36/100; mean binocular glare size and intensity were also low at 30/100 at 29/100. Far (1m) mean binocular CS ($\pm$ SD) was 0.95 (± 0.25) logCS.

Conclusions: Bilateral implantation of the RayOne EMV® offers an extended range of clear distance vision under mesopic conditions. Although a slight reduction in mesopic contrast sensitivity may occur—often attributable to factors such as posterior capsular opacification or ocular surface disease—the lens remains a strong option for patients requiring reliable visual acuity in low-light settings.

Abstract No.: 206368**Management of Cataract With Persistent Pupillary Membrane***First Author: Fajri IRIAN**Co-Author(s): Laksono BAGUS SASMITO*

Purpose: To report a case of coexisting cataract and persistent pupillary membranes (PPMs) in an adult patient, and to elucidate the surgical approach and visual outcomes following PPM excision combined with phacoemulsification.

Methods: This case report describes a 46-year-old male presenting with longstanding blurred vision and the presence of a thread-like structure in the right eye since birth. Slit-lamp biomicroscopy revealed bilateral PPMs adherent to the anterior surface of immature cataractous lenses. Preoperative best-corrected visual acuity (BCVA) was 20/200 in the right eye and 20/50 in the left eye, with no improvement upon pinhole testing. The patient underwent surgical excision of PPMs at the iris base, followed by phacoemulsification cataract extraction and intraocular lens (IOL) implantation in the right eye.

Results: At one week postoperative follow-up, the BCVA of the right eye improved markedly from 20/200 to 20/20. No intraoperative or postoperative complications, including amblyopia, were noted. The left eye was monitored without surgical intervention due to similar but less severe pathology.

Conclusions: Persistent pupillary membranes are generally benign embryonic remnants; however, when extensive or concomitant with cataracts, they may impede visual function. Surgical excision of PPMs in conjunction with cataract extraction via phacoemulsification can yield excellent visual outcomes. Thorough preoperative evaluation and meticulous surgical planning are imperative for optimal patient results.

Abstract No.: 205948

Management of Traumatic Cataract With Vertical Corneal Scar in Visual Axis

First Author: Indri **WAHYUNI**

Co-Author(s): Dicky **HERMAWAN**, Rozalina **LOEBIS**, Ifan **ROMADON LUKMANA**

Purpose: Traumatic cataracts account for 29% of all childhood cataracts. Managing traumatic cataracts in children is a daunting task requiring highest levels of clinical skills, each cases different and had difficulty. The aim is to report management of traumatic cataract with vertical corneal scar in visual axis.

Methods: A 7-year-old boy had a history in which his right eye was affected by a wire clothes hanger one year ago, and stitches were performed at 12 o'clock until 6 o'clock vertically. After the stitches were removed, the vertical corneal scar and traumatic cataract formation made visual acuity become hand movement, irregularly, and posterior synechiae pupil. The operation area visualization is divided vertically into two areas by the corneal scar. Cataract extraction, pupilloplasty and IOL implantation performed.

Results: One month after cataract extraction, the best corrected visual acuity became 6/6, Hirschberg 15 degrees, and the patient was diagnosed with sensory deprivation esotropia.

Conclusions: Cataract extraction with central corneal scar complications requires planning regarding visualization during surgery and because the scar area is central, it can be estimated that changes in the position of the eyeball will occur post-operatively. Traumatic cataract in childhood even though accounted for less than other causes. Majority of the eyes had successful IOL implantation during surgery with different challenge and give visual acuity improvement. Long-term eye and vision monitoring are needed for glaucoma, strabismus, and capsular opacification.

Abstract No.: 203202

Measured Corneal Astigmatism vs. Predicted Refractive Astigmatism in Determining Astigmatism Correction in Cataract Patients With Low Astigmatism

First Author: Xiaohang **XIE**

Co-Author(s): Haowen **LIN**

Purpose: To compare the performance of measured corneal astigmatism and predicted refractive astigmatism in guiding astigmatism correction for cataract patients with astigmatism < 0.75 D.

Methods: Patients with preoperative simulated keratometric (SimK) astigmatism < 0.75 D were included. All participants underwent phacoemulsification and monofocal intraocular lens (IOL) implantation. Preoperative SimK astigmatism, total keratometric (TK) astigmatism, predicted

refractive astigmatism (PRA) calculated by Barrett Toric with predicted posterior corneal astigmatism (PCA) and measured PCA were evaluated with a 0.75D indication for astigmatism correction. Receiver Operating Characteristic (ROC) curves were further constructed to determine whether a suitable indication was better than 0.75D. Sensitivity analysis was also conducted with 0.50 D as a threshold value.

Results: In total, 723 patients (723 eyes) were included with a mean age of 63.34±10.26 years. Of these, 275 eyes (38.04%) had postoperative refractive astigmatism ≥ 0.75 D and 504 eyes (69.71%) had residual astigmatism ≥ 0.50 D when SimK was applied in preoperative evaluation. Using PRA yielded significantly lower mean centroid and mean absolute prediction errors than SimK or TK astigmatism (P < 0.05). Two modes of the Barrett toric calculator showed comparable performance for predicting the risk of residual astigmatism ≥ 0.75 D (the area under the ROC curve: 0.76-0.77, threshold value: 0.615-0.645).

Conclusions: In patients with low corneal astigmatism, PRA showed higher accuracy and better decision-making performance than SimK or TK astigmatism. We recommend using the PRA as preoperative reference guide to assess the need for correction in these patients.

Abstract No.: 203106

Miscalculated IOL in Bilateral Nystagmus: How to Deal With It?

First Author: Andita **CAESARY**

Purpose: To evaluate the factors that can influence the accuracy of biometry analysis in bilateral nystagmus.

Methods: Diagnosis is based on history taking, ophthalmology examination, and biometry analysis.

Results: A patient with bilateral nystagmus and cataract was scheduled for cataract surgery and achieved visual acuity after cataract surgery with a correction of 10 D, reaching 0.7, which made the patient uncomfortable. In the pre- and post-operative biometry results, there was a significant difference in the axial length. This is suspected due to the bilateral nystagmus condition, where the patient could not fixate during the pre-operative biometry examination, resulting in a refractive surprise. Therefore, an IOL exchange is planned for this patient.

Conclusions: This case report discusses how to minimize the occurrence of refractive surprise after cataract surgery in patients with bilateral nystagmus by systematically and thoroughly identifying pre-operative biometry to obtain the appropriate IOL power calculation.

Abstract No.: 203500**Multifactorial Judgment for Fall Screening Among Older Cataract Adults in Day Surgery Setting***First Author: Yaping WANG**Co-Author(s): Can DAI, Ping OUYANG*

Purpose: To evaluate the feasibility of a multifactorial judgment for fall screening among older cataracts adults in day surgery setting.

Methods: A historically controlled study was conducted for older cataract adults (≥ 60 years old) who underwent day surgery at a municipal ophthalmic hospital from July 2020 to June 2022. The patients for whom the Morse Fall Scale was used for fall screening from July 2020 to June 2021 were taken as the MFS group ($n=2235$), and patients for whom the multifactorial judgment was used for fall screening from July 2021 to June 2022 were taken as the MJ group ($n=963$). Multifactorial judgment was a method that directly determined the fall-risk level with different weights of common fall risk factors without scores. Propensity score matching was performed to balance baselines.

Results: After matching, 935 patients were selected from the MFS group and the MJ group, respectively. No serious fall-related injuries were reported. The MJ group showed a significantly shorter and more stable fall screening time (14 [5-179] s vs. 27 [12-272] s, $P<0.001$), significantly higher patient satisfaction (98.17 ± 1.62 vs. 96.77 ± 0.35 , $P<0.001$), significantly higher sensitivity of high-risk screening in visual impairment (90.68% vs. 26.71%, $P<0.001$) and a non-significantly lower fall rate ($P=0.625$). The monthly change of median screening time in the MFS group was more stable after 3 months.

Conclusions: The multifactorial judgment may be feasible for rapid fall screening among older cataract adults and has wider benefits beyond screening scores in day surgery settings.

Abstract No.: 204759**Nd:YAG Laser Anterior Capsulotomy for Management of Anterior Capsule Fibrosis: Clinical Case Review***First Author: Olesia ZIATDINOVA**Co-Author(s): Chun Chun HE, Lina ZHOU*

Purpose: To evaluate the efficacy and safety of Nd:YAG laser anterior capsulotomy for the management of anterior capsule fibrosis.

Methods: A retrospective review of 10 eyes implanted with monofocal or trifocal intraocular lenses that developed significant anterior capsule contraction 3–6 months after uncomplicated phacoemulsification. All patients underwent Nd:YAG laser anterior capsulotomy under pharmacologic mydriasis, using pulse energy

between 1.3–1.5 mJ. Two patients required a second capsulotomy session 1 month later previous shot to further enlarge the capsular opening.

Results: At one-year follow-up, all patients demonstrated stable visual outcomes without recurrence of capsular fibrosis. Both uncorrected (UCVA) and best-corrected visual acuity (BCVA) improved by 1–2 lines at one month post-procedure. No intraoperative or postoperative complications were observed.

Conclusions: Nd:YAG anterior capsulotomy is an effective, safe, and minimally invasive option for managing anterior capsule fibrosis, providing sustained visual improvement and preventing further contracture progression.

Abstract No.: 210126**New Surgical Approach for Posteriorly Dislocated Lens Simultaneously Using Phacoemulsification and Vitrectomy***First Author: Dalan JING**Co-Author(s): Han ZHANG*

Purpose: To report the clinical outcomes of a new method for quickly and effectively removing posteriorly dislocated lens.

Methods: This is a retrospective, noncomparative, and interventional case series that reveals the results of removing dislocated lens on the surface of the retina using a new method which achieved through the simultaneous use of phacoemulsification and vitrectomy. All patients underwent the abovementioned surgery and were followed up for at least 3 month.

Results: Four eyes of 4 patients with a median age of 63.5 years. There were two males and two females. The best-corrected visual acuity three month after surgery of patients were 20/20. All dislocated lens were removed through the incision for cataract surgery, and a sutureless-intrascleral fixation of IOL was underwent in each patient without major complications. However, longer-term data are needed to evaluate the macular edema condition.

Conclusions: This method is a safe and effective technique for surgical removal of an posteriorly dislocated lens in present series cases.

Abstract No.: 203595**Not Hyphaema, Not Vitreous Haemorrhage: The Hidden Endocapsular Haematoma***First Author: Shew Fei CHEE*

Purpose: To report a case of spontaneous endocapsular haematoma, highlighting its rarity, diagnostic challenge, and management.

Methods: Case report.

Results: An 86-year-old woman, with no systemic illness and not on anticoagulants, presented with sudden painless blurring of vision in the left eye (OS) for 3 days. She had undergone bilateral cataract surgery more than 20 years ago. A history of a fall 4 months earlier was noted, without ocular trauma. Visual acuity was 6/24 in the right eye (OD) and hand movement in OS. Examination of OS revealed microhyphaema in the anterior chamber. Gonioscopy showed bleeding at the inferior angle, without neovascularisation or angle recession. Fundus view was initially obscured, and B-scan demonstrated vitreous opacity suggestive of vitreous haemorrhage. The provisional diagnosis was vitreous haemorrhage with microhyphaema. On follow-up, a distinct blood level posterior to the intraocular lens was observed, with a clear fundus view, leading to a revised diagnosis of endocapsular haematoma. Conservative management was initially chosen, but no spontaneous absorption occurred after one month. Nd:YAG capsulotomy was not feasible due to clotting. The patient subsequently underwent surgical evacuation of the endocapsular haematoma.

Conclusions: Endocapsular haematoma is a rare entity that can mimic hyphaema or vitreous haemorrhage. Serial examinations are essential for accurate diagnosis. Surgical evacuation may be required when spontaneous resolution does not occur and laser intervention is not possible.

Abstract No.: 206253

Novel CMT-Flex Scleral Fixated Intraocular Lens Use and Guide in the Philippines

First Author: Jose Timothy Martin Lim CHUA
Co-Author(s): Jill Cristine Galvez GENUINO

Purpose: The novel CM-T flex IOL, launched in late 2024, is a type of scleral-fixated lens, designed to treat aphakia, a condition where the eye lacks a lens. It is a foldable, hydrophilic lens with specialized T-shaped haptics. The lens's unique design is meant to simplify the surgical procedure for scleral fixation. This study aims to showcase a step-by-step guide in placing and securing the CM-T Flex for aspiring surgeons. The initial surgical results and outcomes will then be presented to solidify this technique as part of an ophthalmologist's surgical armament.

Methods: CM-T Flex is an SFIOL manufactured by Appasamy Associates from India. It is made up of hydrophilic material with a water content of 26% and a refractive index of 1.460. The overall diameter is 13.75 mm, with an optic diameter of 6.00 mm. The angulation of the IOL is 10°. The initial steps for CM-T Flex Intraocular Lens placement are explained with detailed photos.

Results: The initial results of six surgical aphakia patients who underwent secondary intraocular lens implantation using scleral fixated intraocular lens CM-T flex proved to be promising. All patients had

improvement from pre-operation vision. There was a minimum two-fold improvement in vision which gradually improved with the ensuing follow-up. Immediate intraocular pressures were elevated above twenty percent on average.

Conclusions: This local Philippine study supports the positive claims in 2021 and 2025 that indicated that the CM-T Flex IOL from Appasamy Associates is a safe and effective option for managing aphakia. This is a useful armament for eye surgeons.

Abstract No.: 202134

Objective and Subjective Refractions in Eyes With Continuous Range of Vision Intraocular Lenses

First Author: Hiroko BISSEN-MIJAJIMA
Co-Author(s): Rina FUJISAKI, Keiichiro MINAMI, Yuka OTA

Purpose: To retrospectively assess the differences between objective and subjective refractions following implantation of a continuous range of vision intraocular lens (IOL).

Methods: This study included 50 eyes of 25 patients who underwent bilateral cataract surgery with implantation of a continuous range of vision IOL, TECNIS Odyssey™ (DRN00V/DRT150-375; Johnson & Johnson). At 1 month postoperatively, objective refraction (sphere, cylinder, spherical equivalent [SE]) was measured with an autorefractometer (TONOREF III, Nidek). Subjective refraction was determined as the sphere, cylinder, and SE values yielding the best-corrected distance visual acuity. The mean differences and correlations between objective and subjective refractions were evaluated. In addition, subjective SE was analyzed in eyes achieving uncorrected visual acuity (UCVA) $\geq 20/20$.

Results: Mean objective refraction (D) was sphere -0.96 ± 0.43 , cylinder 0.69 ± 0.34 , and SE -1.30 ± 0.40 . Mean subjective refraction (D) was sphere 0.12 ± 0.32 , cylinder 0.23 ± 0.39 , and SE -0.01 ± 0.26 . The differences between objective and subjective refractions were statistically significant: sphere -1.08 ± 0.35 , cylinder 0.46 ± 0.27 , and SE -1.31 ± 0.31 (Wilcoxon, $P < 0.001$). Regression analysis revealed significant positive correlations for sphere, cylinder, and SE ($R^2 = 0.34, 0.54, 0.39$; $\beta = 0.77, 0.65, 0.96$), indicating a consistent myopic shift ($P < 0.001$). UCVA $\geq 20/20$ was achieved in eyes with subjective SE values ranging from -0.50 D to $+0.63$ D.

Conclusions: Eyes implanted with a continuous range of vision IOL demonstrated significant differences between objective and subjective refractions, and such differences should be taken into account when assessing postoperative visual acuities.

Abstract No.: 207226**Opacified Intraocular Lens Presenting As Cataract: A Case Report and Surgical Management With Iris-Claw Implant***First Author: Nadya **NAPITUPULU****Co-Author(s): Susanti Natalya **SIRAIT***

Purpose: To describe a case of late-onset intraocular lens (IOL) opacification that closely resembled cataract progression, causing diagnostic confusion, and its successful management with a secondary iris-claw IOL.

Methods: A 79-year-old patient presented with gradually worsening vision in the right eye, with an unclear history of previous ocular surgery. Slit-lamp examination revealed dense, diffuse whitening of the intraocular lens (IOL) optic, resembling posterior capsular opacification (PCO). The fundus could not be visualized, and posterior segment optical coherence tomography (OCT) was inconclusive due to poor media clarity. B-scan ultrasonography was performed to assess the posterior segment. Because of the atypical presentation, Nd:YAG capsulotomy was deferred.

Results: Late-onset IOL opacification was diagnosed. The affected IOL was carefully explanted, and a secondary posterior chamber iris-claw IOL was implanted. The surgery was smooth and uneventful. The iris-claw design was chosen due to favorable ocular anatomy, lower surgical risk, and quicker recovery compared to scleral-fixated options. At one-week follow-up, best-corrected visual acuity improved, with a well-centered lens and clear visual axis. No postoperative complications were noted.

Conclusions: Late IOL opacification can mimic cataract recurrence or PCO, leading to delayed treatment if unrecognized. Careful slit-lamp assessment and anterior segment imaging are key to diagnosis. Secondary iris-claw IOL implantation is a safe and effective solution for visual rehabilitation after IOL explantation in such cases.

Abstract No.: 207313**Pars Plana Toilet Vitrectomy for Shallow Anterior Chamber Phacoemulsification***First Author: Henal **JAVERI****Co-Author(s): Suklengmung **BURAGOHAIN**, Ajay **DUDHANI***

Purpose: Cataract surgery in the presence of a shallow anterior chamber (AC) poses several challenges, including the risk of corneal endothelial damage, difficulty in performing continuous curvilinear capsulorhexis (CCC), and limited maneuvering space for phacoemulsification. We describe a simple and effective solution: the use of pars plana «toilet vitrectomy» to facilitate safe surgery in such situations.

Methods: A pars plana vitrectomy was performed 4 mm posterior to the limbus using a 23-gauge

vitrector in eyes with shallow AC. The procedure allows controlled decompression and deepening of the anterior chamber. Incremental vitrectomy can be repeated as required to achieve adequate space for safe phacoemulsification.

Results: The technique provided consistent deepening of the AC, enabling safer capsulorhexis, lens rotation, and phacoemulsification by reducing the risks associated with shallow AC, such as corneal endothelial damage, capsulorhexis extension, and inadequate maneuvering space. In cases with PAS and vitreous prolapse, safe separation and adequate vitrectomy were achieved under direct visualization. The procedure was reproducible and adaptable with both 23- and 20-gauge vitrectors.

Conclusions: Pars plana «toilet vitrectomy» is a safe, simple, and reproducible method to address shallow anterior chamber in diverse clinical situations. By providing adequate surgical space and reducing intraoperative risks, it facilitates safer cataract and combined anterior segment surgeries.

Abstract No.: 206555**Pilot Evaluation With Vector Analysis of a Toric Refractive Multifocal IOL With Continuous Transitional Focus Technology: Rotational and Refractive Outcomes***First Author: Ronald Steven Li **MEDALLE****Co-Author(s): Jorge **ALIÓ**, Antonio **MARTINEZ ABAD***

Purpose: To evaluate the visual and refractive outcomes, rotational stability, and astigmatic correction using the Alpíns method in eyes implanted with the Precizon Presbyopic Toric 575 intraocular lens (IOL).

Methods: This was a monocentric, prospective, single-arm study involving 22 eyes from 11 patients undergoing bilateral cataract surgery or refractive lens exchange with implantation of the Precizon Presbyopic Toric 575. Preoperative and postoperative assessments included uncorrected and corrected visual acuities (distance, intermediate, near), contrast sensitivity, defocus curve, and vector analysis of astigmatic correction using the Alpíns method. Patient-reported outcomes were evaluated using validated questionnaires.

Results: Significant improvements were observed in monocular UDVA (0.91 ± 0.69 to 0.03 ± 0.08 logMAR), UIVA (0.14 ± 0.09), and UNVA (0.03 ± 0.07), maintained through 6 months. Refractive cylinder significantly reduced from -1.52 ± 0.76 D to -0.24 ± 0.27 D ($p < 0.01$). Vector analysis showed a mean TIA of 1.52 D and a mean SIA of 1.39 D; the correction index was 0.91, and the index of success was 0.15, indicating effective and accurate astigmatism correction. The defocus curve revealed a broad range of functional vision, while contrast sensitivity remained within normal limits. Photoc phenomena were mild and

infrequent; 90% of patients reported high overall satisfaction, with 77% reporting complete spectacle independence.

Conclusions: The Precizon Presbyopic Toric 575 IOL demonstrated excellent rotational stability, effective astigmatic correction, and high levels of visual acuity and patient satisfaction across all distances, making it a viable option for presbyopic patients with preexisting astigmatism.

Abstract No.: 207201

Posterior Polar Cataract in Pregnancy

First Author: Ankit AHIR

Co-Author(s): Madhusmita MAHAPATRA

Purpose: To assess the surgical challenges in operating on a case of posterior polar cataract in the second trimester of pregnancy.

Methods: A 28-year-old female in her second trimester with hyperthyroidism and hypertension presents to OPD with right eye diminution of vision. • A clinical diagnosis of OD posterior polar cataract was made with a normal posterior segment. OS anterior and posterior segment WNL. • Surgical intervention of the right eye as phacoemulsification with FIOIOL under topical anesthesia was planned after obstetrics clearance. • The operation was accomplished by placing the patient in the left down decubitus position along the patient's hips, abdomen, and thighs were rotated to the left while maintaining a normal head position.

Results: Phacoemulsification with topical 2% lidocaine and subconjunctival lidocaine was performed with anaesthetic back up and foldable IOL was implanted under 10 minutes of total surgical time. • She and her fetus tolerated the procedure well, and postoperative moxifloxacin and difluprednate eye drops were used. • The mother gave birth to a healthy baby at 38 weeks of gestation with a birth weight of 2,750 grams and an Apgar score of 10.

Conclusions: • There comes many challenges in surgery in pregnancy like positioning, anesthesia complications, side effects of medication. • But with careful consideration regarding medication and surgery as discussed above, these patients may undergo incisional surgery with good outcomes for the patient with no risk to the fetus.

Abstract No.: 202074

Postoperative Amblyopia in Children With Congenital Cataracts: A Systematic Review and Meta-Analysis

First Author: Ailifeire HAILAITI

Purpose: This systematic review and meta-analysis aimed to estimate the prevalence of amblyopia following congenital cataract surgery in children and evaluate key prognostic factors, including age

at intervention, cataract phenotype, and follow-up duration.

Methods: We systematically searched PubMed, EMBASE, and the Cochrane Library for studies published between January 1, 1981, and March 1, 2023. We included clinical trials, case series, and observational studies to analyze surgical timing, visual outcomes, and complications.

Results: Among 28 studies (2,167 patients, 3,371 eyes), the pooled amblyopia prevalence was 62% (95% CI: 0.55–0.69, I²=91.7%). Early surgery (≤8 weeks for unilateral, ≤12 weeks for bilateral cases) significantly reduced amblyopia risk ($P<0.001$) but increased complications, notably glaucoma (26% vs. 6%, $P=0.001$). In contrast, intraocular lens (IOL) implantation timing had no significant effect on visual outcomes ($P=0.096$). Unilateral partial obstruction conferred a higher amblyopia prevalence than bilateral complete obstruction (68% vs. 36%, $P=0.003$), and prolonged amblyopia therapy beyond 6 years of age showed limited efficacy.

Conclusions: These findings highlight the critical role of timely surgery in optimizing visual recovery, despite its association with complications. Early IOL implantation demonstrated no significant clinical benefits, and the therapeutic window for amblyopia rehabilitation in congenital cataracts is narrower than in other forms.

Abstract No.: 201548

Predictability of the Rayner RayTrace Calculator in Early Outcomes With RayOne Galaxy

First Author: Chan SUET MEI

Purpose: To report the early clinical experience with the Rayner RayTrace online calculator by evaluating its refractive predictability in eyes implanted with the RayOne Galaxy intraocular lens (IOL).

Methods: This observational case series included up to 60 eyes undergoing routine cataract surgery with RayOne Galaxy implantation. All refractive targets were planned using the RayTrace calculator. Postoperative assessments were performed at Day 1 or Week 1, 1 month, and 3 months. The main outcome measures were manifest refraction spherical equivalent (MRSE), residual cylinder, and the proportion of eyes achieving outcomes within ± 0.50 D and ± 1.00 D of the predicted refraction. Additional measures included uncorrected and corrected distance visual acuity, refractive stability across follow-up, patient-reported quality of vision (photopic phenomena and overall satisfaction), and safety parameters such as intraocular pressure and complications.

Results: The majority of eyes achieved postoperative refraction close to the intended target, with most falling within ± 0.50 D. Visual acuity improved consistently across follow-up intervals, and refraction showed early

stability from one month. Patients generally reported good satisfaction and only mild photic disturbances. No relevant safety issues or secondary interventions were recorded.

Conclusions: RayTrace provided reliable refractive predictability, while the RayOne Galaxy demonstrated favorable early outcomes with excellent visual performance, high satisfaction, and a low incidence of photic disturbances. These results support the value of combining RayTrace planning with RayOne Galaxy implantation in routine practice.

Abstract No.: 204635

Profile of Visual Function After Phacoemulsification at a Secondary Hospital in Gresik Regency, East Java, Indonesia

First Author: Christina **ARITONANG**

Co-Author(s): Sarah **AMRU**

Purpose: To evaluate the visual function outcomes after phacoemulsification conducted through a social service program at a secondary hospital in Gresik Regency, East Java, Indonesia.

Methods: This retrospective observational study included 40 patients who underwent phacoemulsification surgery between April 22 and May 15, 2025. Eligible patients had mature or immature cataracts with preoperative vision ranging from mild impairment to blindness based on WHO criteria. Visual function assessments included visual acuity (Huvitz Digital Chart), contrast sensitivity (Pelli-Robson chart). Postoperative evaluations were conducted on day 1 and day 14. Data were retrieved from medical records and analyzed with Wilcoxon and Friedman tests using SPSS version 27.

Results: Among 40 patients, 37.5% were severely visually impaired and 32.5% were blind preoperatively. Postoperatively, blindness declined to 11.5% on day 1 and 2.5% on day 14, with 45% achieving good vision. Visual acuity and contrast sensitivity significantly improved postoperatively (both $p < 0.001$). Surgical complications included mild iritis, descemet's membrane detachment, elevated intraocular pressure, and one patient did not receive an implant due to a posterior capsular rupture during the surgery.

Conclusions: Visual function significantly improved after phacoemulsification through this social service program at day 1 and day 14 postoperatively. The program demonstrated its effectiveness in increasing accessibility and reducing the burden of visual impairment. However, challenges such as limited follow-up and constrained resources highlight the need for ongoing support and infrastructure development.

Abstract No.: 206237

Reduction of IFIS and Related Complications in Cataract Surgery Following Temporary Discontinuation of Alpha-Blockers in BPH Patients: Analysis of 160 Cases

First Author: Amod **NAYAK**

Purpose: Intraoperative Floppy Iris Syndrome (IFIS) is a well-recognized complication of cataract surgery, commonly associated with alpha-1 adrenergic antagonists prescribed for benign prostatic hyperplasia (BPH). IFIS can lead to increased intraoperative complications and surgical difficulty. This study evaluates the impact of withholding alpha-blockers for 10 days preoperatively on the incidence and severity of IFIS and related complications.

Methods: A prospective analysis of 160 eyes in BPH patients on alpha-1 blockers (tamsulosin, alfuzosin, etc.) undergoing phacoemulsification was performed. Patients were advised to discontinue alpha-blocker therapy 10 days prior to surgery after clearance from their urologist. Incidence of IFIS, surgical modifications required, intraoperative complications (posterior capsular rent, iris trauma, dropped nucleus), and postoperative outcomes were compared with historical controls from the same surgical unit.

Results: Temporary discontinuation of alpha-blockers resulted in a significant reduction in IFIS incidence (from historical 60 % to 12.5%). Reduced need for surgical adjuncts (iris hooks) (down from 20% to 0.6%). Visco-mydriasis was done in all cases. Lower intraoperative complication rate: posterior capsular rents and iris prolapse/trauma. Postoperative outcomes, including best-corrected visual acuity and corneal clarity, were comparable to non-BPH patients.

Conclusions: Withholding alpha-blockers for 10 days preoperatively significantly reduces the incidence and severity of IFIS and associated complications during cataract surgery, without adversely affecting postoperative outcomes. Close interdisciplinary coordination between ophthalmologists and urologists is recommended to optimize surgical safety in BPH patients undergoing cataract surgery.

Abstract No.: 200805

Refractive Stability and Timing of Spectacle Prescription Following Cataract Surgery in Myopic Eyes

First Author: Rui **FENG**

Purpose: To investigate the postoperative refractive stabilization time and provide evidence for the optimal timing of spectacle prescription in myopic cataract patients.

Methods: A total of 116 consecutive myopic cataract patients were recruited in Zhongshan Ophthalmic Center in this prospective study. Subjective refraction

postoperative in 1 week and 1 month (4-6 weeks) were investigated. Interval for new spectacle acquisition were recorded. Visual Function Index-14 (VF-14) questionnaires were used for vision-related life quality assessment.

Results: Of 116 patients, there was no significant difference in spherical ($P=0.325$), cylindrical ($P=0.648$) and spherical equivalent ($P=0.453$) between postoperative 1 week and 1 month, indicating the patients achieved refractive stability in 1 week. In the subgroups of different age and axial length, there were also no significant differences between 1 week and 1 month. The spherical equivalent refractive shift between 1 week and 1 month were significantly correlated with the postoperative prediction error ($R=0.350$; $P<0.001$). Only 5 (4.3%) of 116 patients obtained new spectacles after bilateral cataract surgery in 1 week. The VF-14 values improved from 85.77 ± 7.24 to 90.45 ± 5.39 after acquiring new spectacles ($P<0.01$).

Conclusions: The stabilization of subjective refraction could be achieved in 1 week in myopic cataract patients. Shortening the interval of new spectacle prescription should be recommended in myopic cataract patients to improve the vision-related life quality.

Abstract No.: 202183

Regional and Demographic Heterogeneity of Risk Factors for Early-Onset Cataract in Western China: A Comparative Retrospective Study Between the Northwest and the Southwest

First Author: Yuecong **REN**

Co-Author(s): Hao **LIANG**, Hong **YAN**

Purpose: To compare the distribution of risk factors for early-onset cataract between Northwest and Southwest China (Shaanxi and Guangxi provinces) and to identify the overall spectrum of risk factors in the general population.

Methods: We analyzed 1,226 patients aged between 18 and 45 who underwent cataract surgery in Shaanxi province from January 2021 to December 2023, and 493 patients in Guangxi province during the same period. Twenty-three risk factors were recorded, and the distribution and comorbidity patterns of these risk factors in early-onset cataract patients were described and compared between the two centers. Logistic regression was applied to assess the association of risk factors in the overall cohort, with subgroup analyses stratified by sex and unilateral/bilateral surgery.

Results: In the standardized analysis, the leading risk factors were idiopathic cataract, high myopia, trauma, PPV history, refractive error and uveitis. Significant regional differences were observed: In Shaanxi, the top three were idiopathic cataract, high myopia, and

refractive error, while in Guangxi they were trauma, idiopathic cataract, and high myopia. Multivariate logistic regression revealed that idiopathic cataract, trauma, male gender, uveitis, and PPV history were associated with unilateral surgery. Sex-stratified analysis showed that uveitis was more common in females.

Conclusions: In Northwest and Southwest China, early-onset cataract shows distinct regional heterogeneity in risk factors, indicating the need for region-specific prevention. Idiopathic cataract has surpassed high myopia as the leading risk factor, suggesting unexplored etiologies in young patients and an earlier trend in surgical age, which need further investigation.

Abstract No.: 202378

Retained Lens Fragments in the Anterior Chamber After Uneventful Phacoemulsification

First Author: Heni **RIYANTO**

Purpose: To report a case of a patient with retained lens fragments in the anterior chamber after uneventful phacoemulsification.

Methods: A 67-year-old woman had phacoemulsification and posterior chamber intraocular lens (IOL) implantation in her right eye. One day post-surgery, her visual acuity was 6/6, and her intraocular pressure (IOP) was 11.4 mmHg. Five weeks following the surgery, she complained that her visual acuity had decreased, eye redness, and moderate pain in her right eye. On the examination, her visual acuity was 6/18, and her intraocular pressure was 25.3 mmHg. A white-greyish material in the anterior chamber, moderate inflammation, and corneal edema were identified during the slit-lamp examination. A retained lens fragment was discovered in the anterior chamber. The aspiration of the retained lens material was scheduled to address this problem.

Results: One day after surgery, the visual acuity was 6/15 and the intraocular pressure was 9.0 mmHg. The clarity of the cornea improved, and there was a mild reaction in the anterior chamber. At one week following the surgery, her visual acuity had improved to 6/10. Three weeks following surgery, her visual acuity was 6/9, her best corrected visual acuity was 6/6, the cornea was clear, and there was no inflammation.

Conclusions: Retained lens fragments are a rare complication of phacoemulsification. These fragments may be hidden in the posterior chamber behind the iris at the time of the initial surgery. Early finding and proper management might avoid worsening complications such as persistent corneal edema and severe ocular inflammations.

Abstract No.: 205202**Retinal Perfusion During Cataract Surgery With Varying Intraocular Pressure in Comorbid Eyes***First Author: Samaresh SRIVASTAVA**Co-Author(s): Shyamal DWIVEDI, Abhay VASAVADA, Shail VASAVADA, Vaishali VASAVADA*

Purpose: To study the effect of Phacoemulsification using a physiological intraocular pressure(IOP) and high IOP on the retinal and optic nerve head (ONH) perfusion.

Methods: Prospective, randomized, single masked Clinical Trial in 80 eyes (80 patients) with non-proliferative diabetic retinopathy undergoing cataract surgery. Eyes undergoing cataract surgery will be randomized to: group I (low IOP, 20mmHg) or group II (high IOP, 55mmHg). Intraoperatively, cumulative dissipated energy (CDE), fluid used and patient comfort on the visual analog scale. Retinal vessel density, perfusion density at superficial retinal layers at the posterior pole, as well as perfusion and flux index at the RPC layer, were documented by optical coherence tomography angiography (OCTA) at the following time points: within 2 hours of surgery, 1 day and 1 month postoperatively. Anterior chamber inflammation compared on postoperative day 1 and week 1.

Results: Ongoing studies, results to be updated.

Conclusions: Ongoing studies, results to be updated.

Abstract No.: 206717**Rosette Cataract***First Author: Shagun KORLA**Co-Author(s): Aditi BANSAL*

Purpose: Traumatic cataracts occur after penetrating or blunt ocular trauma. The damage to the lens fiber disruption leads to crystallin lens clouding. Cataracts may occur immediately or late after blunt trauma.

Methods: A seventy-one-year-old man with a history of blunt trauma to the right eye seven years back presented with gradual painless diminution of vision. The best corrected visual acuity (BCVA) was counting fingers at 1 meter for the right eye and 20/20 for the left eye. Anterior segment of the right eye showed iridodonesis, phacodonesis with disruption of zonules temporally from 8 o'clock to 10 o'clock with posterior subcapsular rosette-shaped cataracts. Fundus examination and intraocular pressure did not reveal any significant abnormalities in both eyes.

Results: The patient underwent cataract extraction with implantation of an intraocular lens with restoration of vision in the right eye.

Conclusions: Blunt trauma may result in coup, contrecoup injury, or axial expansion of the lens. The coup ocular injury is a result of direct impact,

and results in the formation of a Vossius ring due to compression of the pigmented posterior iris epithelial cells against the anterior lens capsule. The contrecoup injury generates shock waves along the line of impact of trauma, which results in posterior cortical opacification in a rosette or stellate shape. The axial expansion causes anteroposterior expansion and leads to disruption of the lens capsule and/or zonules as seen in our patient.

Abstract No.: 206957**Small Eye, Big Pressure***First Author: Cheun Seng WONG**Co-Author(s): Chai Keong TAN*

Purpose: To report a case of glaucoma secondary to microcornea.

Methods: Case report

Results: A 22-year-old high myope with no systemic illness presented with a 3-week history of headache and was referred for left eye glaucoma. He had no other ocular complaints, no steroid use, and no family history of glaucoma. Visual acuity was 6/19 in both eyes, with hyperopic refraction. IOP was 10 mmHg (right) and 26 mmHg (left). Both corneas were small (10.5 mm), with thick CCTs. Slit-lamp exam showed a deep anterior chamber in the right eye and moderate depth nasally in the left. Gonioscopy revealed open angles in the right eye and closed angles in the left. Fundoscopy showed a crowded disc (CDR 0.2) in the right and glaucomatous cupping (CDR 1.0) in the left. He was started on anti-glaucoma drops and underwent left eye lens aspiration with IOL implantation, but IOP remained high. Gonioscopy post-op showed persistent angle closure. He was planned for left eye glaucoma implant for better IOP control.

Conclusions: In a patient with microphthalmos and microcornea, there is a higher risk of secondary angle-open or angle-closure glaucoma. Early cataract surgery should be offered for optimum IOP control. However, due to the short AL and ACD, a proper planning and IOL selection is important for the outcome. Subsequent follow up with IOP monitoring is required and to proceed with glaucoma surgery if indicated.

Abstract No.: 200767**Structural and Functional Outcomes of Cataract Surgery in Asian Patients With Epiretinal Membrane***First Author: Ning CHEUNG**Co-Author(s): Gavin TAN, Daniel TING, Andrew TSAI, Doric WONG*

Purpose: To examine the structural and functional outcomes of cataract surgery in Asian patients with epiretinal membrane (ERM)

Methods: A prospective study of 50 patients with primary ERM who were recruited consecutively from the Singapore National Eye Centre. All patients had standardised phacoemulsification and intraocular lens implant, comprehensive clinical examinations and investigations, including M-chart testing for metamorphopsia and microperimetry for macular sensitivity. All patients were followed up for at least 1 year.

Results: Of the 50 patients, the mean age was 70.6 years, 55.8% were female, and 88% were Chinese. After cataract surgery alone, good visual acuity outcome was achieved among 61%, 79%, 81% and 91% after 1-month, 3-month, 6-month and 12-month follow-up. Over the follow-up period, central retinal thickness and macular volume increased at 1-month after cataract surgery but reduced back to baseline from 3-month onwards, with 36.6% of the patients who developed cystoid macular edema at 1-month after cataract surgery. There was no significant change in metamorphopsia and macular sensitivity.

Conclusions: Cataract surgery alone may achieve good visual outcome for patients with ERM. Postoperative cystoid macular edema may occur in one-third of the patients, with minimal impact on visual outcomes in the long-term.

Abstract No.: 206266

Surgical Outcomes of Scleral Fixated Intraocular Lens: A Case Series

First Author: Soumya **NAIR**

Co-Author(s): Shailaja S

Purpose: Implantation of a scleral-fixated intraocular lens (SFIOL) for the surgical management of aphakia in the absence of capsular support is a safe procedure with a low risk of complications in the early postoperative period. The purpose of this study is to assess the visual outcome and complication profile of SFIOL implantation using sutures in three patients.

Methods: Three patients who had undergone secondary SFIOL implantation were retrospectively reviewed for visual outcomes and complications. Patients' demographic data, indication for surgery and baseline preoperative visual acuity, postoperative complications and 1month postoperative visual acuity were collected and analysed.

Results: Out of the three, one patient had iatrogenic aphakia with iris tissue loss. The second patient had traumatic near total posteriorly subluxated Intraocular Lens (IOL) with iris prolapse and iridodialysis. The third patient had an Open globe injury with retinal detachment, iris prolapse and posterior IOL dislocation. The first two patients had favourable visual outcomes postoperatively. The patient with retinal detachment showed minimal improvement postoperatively. All the three patients had stable SFIOL without any tilt or

suture exposure and well formed anterior chamber postoperatively.

Conclusions: SFIOL implantation is a valuable technique for the management of aphakia in the absence of capsular support and adequate iris tissue. The visual outcomes were satisfactory in the absence of any preexisting retinal detachment. The intermediate term postoperative stability of sutured SFIOLs was good in these patients.

Abstract No.: 208293

Suture-Assisted Gas Tamponade: A Novel Technique for Managing Post-Phacoemulsification Descemet Membrane Detachment

First Author: Zhaole **LI**

Co-Author(s): Jianhao **CAI**, Zeyi **LI**, Ruyue **SHEN**

Purpose: To report the efficacy of 16% octafluoropropane (C3F8) in the anterior chamber to restore severe Descemet membrane detachment (DMD) in phacoemulsification.

Methods: This retrospective case series involved two patients who underwent phacoemulsification with IOL implantation in 2020. Both developed severe Descemet membrane detachment (DMD) during corneal incision closure. Initial air injection failed to reattach the membrane, but a 16% C3F8 anterior chamber injection after incision suturing successfully restored it. Outcomes were evaluated by visual acuity (VA), intraocular pressure (IOP), and optical coherence tomography (OCT).

Results: Significant resolution of corneal edema in both cases was observed following 16% C3F8 injection on postoperative day 1. OCT revealed that the Descemet membrane was restored, and the gas had filled approximately 2/3 of the anterior chamber. In case A, the VA was 3/50 OS, and the IOP was 10 mmHg OS. The VA was 3/20 OD, and the IOP was 12 mmHg OD in case B. In postoperative week 4, the VA improved to 8/20 OS in case A. In case B, the visual acuity improved to 14/20 OD with a small C3F8 gas bubble remaining in the anterior chamber.

Conclusions: This is the first report demonstrating effective restoration of severe DMD after phacoemulsification using a 16% C3F8 anterior chamber injection. Further randomized controlled trials are needed to compare its efficacy with other techniques.

Abstract No.: 201105**Targeting 1.00 Diopter Myopia in Cataract Patients: A Tale of 50 Cases***First Author: Shah Md Rajibul ISLAM**Co-Author(s): Quazi Sazzad IFTEKHAR, Shah Md Bulbul ISLAM, Golam RABBANI***Purpose:** To evaluate the results of targeting 1:00 diopter myopia for both eyes in cataract patents.**Methods:** This cross sectional interventional study was conducted from 2023 to 2024. 50 cases (100 eyes) were selected as per inclusion criteria. Following pre-operative assessment, Phacoemulsification with PCIOL (single piece hydrophobic acrylic) implantation was done by temporal incision. Biometry was done by immersion method. Topical antibiotic and steroids were prescribed post-operatively. Surgery in each eye was deferred by at least 01 month. All the surgeries were performed by a single surgeon. All the surgeries were uneventful. Followup was done at POD 1, 15 and 30. The visual acuity at near and distance was noted.**Results:** Preoperatively the mean BCVA LogMAR was 0.84 ± 0.139 . At POD 30, the unaided mean was 0.186 ± 0.040 . p value is less than 0.05. 82% had a binocular LogMAR unaided distant visual acuity of 0.20, 16% had 0.1 and 2% had a binocular LogMAR unaided distant visual acuity of 0.30. and in case of near vision, 96% had N6 binocularly and the rest had N8 unaided. 47 (94%) patients out of 50 did not want optical correction for distant or near. 01 (02%) patient wanted optical correction for distant and near vision and 02 (04%) wanted optical correction for near.**Conclusions:** Targeting 1 diopter myopia for both eyes is an easy, acceptable and affordable approach to address post-operative optical status in carefully selected patients.**Abstract No.: 200844****Technique: Implantable 6-0 Polypropylene Capsular Hook Combined With Flange Intrasceral Fixation to Stabilize the Multifocal Intraocular Lens***First Author: Rui FENG**Co-Author(s): Chao QU***Purpose:** To describe a novel technique using implantable 6-0 polypropylene capsular hooks with flanged intrasceral fixation to stabilize a multifocal intraocular lens (IOL) in subluxated cataracts.**Methods:** In eyes with subluxated cataracts, phacoemulsification was performed with the support of a capsular tension ring (CTR). A multifocal IOL was placed in the preserved capsular bag. A 6-0 nonabsorbable polypropylene suture with a curved needle was used to manually create a capsular hook. The hook was inserted through the corneal incision and passed through the sclera near the site

of zonular weakness. After adjusting the hook to maintain centration of the IOL–capsular bag complex, the externalized tip of the hook was trimmed and cauterized with an ophthalmic cautery device to create a flange, which was then buried subconjunctivally.

Results: Five eyes of five patients with subluxated cataracts underwent the technique and were followed up for 11.80 ± 3.27 months. Postoperatively, uncorrected visual acuity was 0.10 ± 0.09 logMAR at distance and 0.14 ± 0.05 logMAR at near. All patients achieved prediction errors within ± 0.50 D. Slit-lamp examinations confirmed that the IOL remained well centered and the 6-0 polypropylene capsular hook was in situ. Anterior segment optical coherence tomography revealed a mean IOL tilt of 2.22 ± 1.23 degrees. The mean corneal endothelial cell loss was $11.00 \pm 4.02\%$. No suture exposure or conjunctival inflammation was observed.**Conclusions:** The implantable 6-0 polypropylene capsular hook combined with flanged intrasceral fixation can effectively stabilize the multifocal IOL–capsular bag complex in subluxated cataracts.**Abstract No.: 202711****The Disease Burden of Clinically Significant Cataracts Among Elderly Patients Triaged Into Routine Appointments for Chronic Blurring of Vision for 3 Months or More in Hong Kong***First Author: Shuhan CAO**Co-Author(s): Kendrick SHIH***Purpose:** Hong Kong's ageing population increases ophthalmic care demand. Public sector routine ophthalmic appointment wait times have reached 48 months in recent years. This study aims to investigate the prevalence of clinically significant cataracts in patients referred for vision blurring for 3 months or more and given routine appointments for their first visit.**Methods:** This study recruited consecutive routine appointment patients aged 50 and above referred to government ophthalmology specialist outpatient clinics for vision blurring ≥ 3 months. Subjects underwent comprehensive eye assessment by ophthalmologists, including presenting and best-corrected visual acuity, automatic and subjective refraction, intraocular pressure, slit-lamp anterior segment examination and funduscopy posterior segment examination. Consistent with the Hong Kong public sector's cataract surgery listing criteria, patients with Best Corrected LogMAR Visual Acuity greater than 0.3 and no other found causes for poor vision were deemed to have clinically significant cataracts.**Results:** A total of 599 consecutive patients referred to government ophthalmology specialist outpatient clinics were recruited. Amongst them, 241 (40.2%) were

male, 471 (78.6%) had some degree of cataracts upon presentation, and 192 (32.1%) had clinically significant cataracts, requiring surgery listing. Only 54 patients (9.0%) had already had cataract surgery for both eyes. Mean Best Corrected LogMAR visual acuity was 0.246 (± 0.658) OD/0.249 (± 0.636) OS overall, and 0.401 (± 0.696) OD/0.414 (± 0.709) OS in clinically significant cataract patients.

Conclusions: In patients referred for poor presenting visual acuity, cataract is the commonest reason. Steps must be taken to enhance triage for earlier attendance and treatment.

Abstract No.: 205666

The Final Visual Outcomes of Outreach Cataract Surgery in Remote Area of Viqueque Municipality in Timor-Leste

First Author: Frenky Ramiro **DE JESUS**

Purpose: To evaluate visual outcomes of outreach cataract surgeries and its intra and post operative complications in remote area of Viqueque municipality in Timor-Leste.

Methods: The total of 92 patients had cataract surgeries at the outreach camp from June 2-6. Pre-operative, one-day and one-week visual acuity (VA) were collected and analyzed from the surgical sheets. Visual acuity $\geq 6/18$ was considered normal.

Results: Total of 92 patients (M: 57,60%, F: 42,40%) cataract surgeries were performed for five days. All patients had pre-operative VA of $\leq 6/60$. Of the total, 85 (92,39%) had no complications during the surgery, while 7 (7,61%) had posterior capsular rupture which required anterior vitrectomy and ACIOL insertion. For accurate interpretation of the visual outcome, patients were divided into three groups depending on first day of post-operation. Vision of $\geq 6/18$ or normal was 47 (51,09%) patients; while regular vision (6/24-6/60) and poor visual outcome ($< 1/60$) were 24 (26,09%) and 21 (22,82%) respectively. From 45 patients with regular and poor visual outcome, 39 (86,66%) had corneal edema, while 6 (13,34%) had IOP high. After one week, VA improved to normal in 76 (82,60%) patients. 11 (11,96%) had regular vision, while 5 (5,44%) had poor visual outcome. The reasons for poor visual outcome due to co-morbidities associated, such as macular degeneration 2 (40%), Glaucoma 2 (40%) and permanent corneal edema 1 (20%).

Conclusions: Even with limitations, however the cataract surgeries were successful performed at outreach camp in remote area of Viqueque municipality with good outcomes.

Abstract No.: 205324

The New Sophi Phaco System: Results of a Safety and Efficacy Study

First Author: Victor **CAPARAS**

Co-Author(s): Keshia Lourdes **DUYONGCO**

Purpose: To assess the safety of the Sophi Phaco System (Rayner, Worthing, UK) in cataract surgery by evaluating corneal health markers and comparing ultrasound energy use with torsional phacoemulsification.

Methods: This prospective study included 15 patients (30 eyes) undergoing bilateral surgery: one eye with Sophi, the fellow with torsional phaco. Cumulative Dissipated Energy (CDE) for the torsional group was converted to Effective Phaco Time (EPT) to compare to the Sophi group. Endothelial cell density, pachymetry, and hexagonality were measured preoperatively and at one week using the Konan CellChek 20®. All surgeries were by a single surgeon using identical technique, materials, and perioperative regimen.

Results: All procedures were uneventful. Mean EPT (sec) was 12.94 ± 4.38 (torsional) versus 5.68 ± 2.17 (Sophi). Comparing mean pre- to post-operative endothelial cell counts, pachymetry and cell hexagonality showed no significant difference in either Sophi or torsional groups. Endothelial cell count change was $-0.1\% \pm 0.14$ (torsional) versus $-0.6\% \pm 0.11$ (Sophi). Pachymetry change was $-1.8\% \pm 3.8$ (torsional) versus $-2.0\% \pm 4.5$ (Sophi). Hexagonality change was $-2.8\% \pm 6.3$ (torsional) versus $-2.8\% \pm 3.7$ (Sophi). No significant differences were observed ($p > 0.05$).

Conclusions: The Sophi Phaco System caused no greater endothelial loss, corneal swelling, or cell hexagonality reduction than torsional phaco. Apparent higher torsional energy likely reflects CDE conversion limits. With all cataracts successfully removed and no complications, Sophi appears safe and effective. Its mobility, efficiency, and waste reduction make it a valuable addition to the operating theater.

Abstract No.: 200959

The No-Pain Lane for Ocular Surgery – Sub Tenon's Block

First Author: Nishanth S

Purpose: To evaluate if sub-tenons block is better than peri-bulbar block in terms of safety, efficacy, complications, patient compliance and surgeon's comfort in patients undergoing SICS for both eyes on 2 different days.

Methods: Patients undergoing both eyes SICS by the same surgeon, who are given peri-bulbar block for one eye and sub-tenons block for the other eye are considered. A questionnaire-based survey is done for both eyes separately, which includes pain during anesthesia, during surgery, and post-surgery. The

surgeon is also asked questions about his comfort during the surgery, the safety, and the efficiency of the block.

Results: When efficacy and surgeon's comfort were considered, both blocks were almost similar, with peri-bulbar giving more akinesia, which was not statistically significant. Patients' compliance and safety were better with subtenon block.

Conclusions: Having considered a number of parameters, including pain, we can conclude that sub-tenons block is a much better alternative to the peri-bulbar block as it is safer, has better patient compliance, and has similar efficacy to peri-bulbar block. The surgeon was comfortable with both blocks in a similar fashion. It is a unique study as no one has actually studied the two routes of block in the same patient, where there will be no subject bias owing to their pain tolerance and sensitivity

Abstract No.: 210234

The Utilization of Excel VBA in Cross-sectional Survey of Cataract Surgery Quality

First Author: Liu **CUIHONG**

Co-Author(s): Li **CHAOFENG**, Liu **DONGMEI**, Bi **HONGSHENG**, Li **YANG**

Purpose: To explore the application of Excel VBA in the cross-sectional survey of cataract surgery quality, so as to carry out the quality control of cataract surgery through information means.

Methods: In this study, the statistical items and their domain values were determined according to the clinical pathway diagnosis and treatment specifications of cataract. By compiling Excel VBA code, the cross-sectional survey software of cataract surgery quality based on Excel VBA was independently developed by medical personnel. Using this software, the medical records of 368 patients with simple cataract who underwent surgery in the Affiliated Eye Hospital of Shandong University of Traditional Chinese Medicine in May 2020 were investigated. Combined with Excel PivotTable, the postoperative visual acuity, the incidence of intraoperative and postoperative complications and the implementation of diagnosis and treatment norms were analyzed.

Results: In this program designed by using VBA language, the field values of survey items are automatically formed into multiple options and automatically saved in the questionnaire. The survey content is standardized and the interface is easy to operate. The index items can be quickly counted by using Excel pivot table, which improves the efficiency and accuracy of statistics.

Conclusions: The independent development and application of the survey software improves the work efficiency and management ability of the quality management team, lays a foundation for the

management of single disease in the hospital, and also provides a new idea for the development of disease quality control management tools.

Abstract No.: 207376

Topical Prednisolone Acetate vs Topical Bromfenac Sodium in Controlling Complications After Surgery

First Author: Nitin **RAMANUJAM**

Purpose: To compare the efficacy of Topical Prednisolone Acetate 1% with Topical Bromfenac Sodium 0.09% in controlling complications post cataract surgery.

Methods: A total of 126 eyes underwent uneventful phacoemulsification and were randomized into two groups. Group I received tapering Prednisolone along with Gatifloxacin Eye Drops, Group II received Bromfenac along with Gatifloxacin Eye Drops twice daily for four weeks. Follow-up was on POD 1, 7, 30, and 45.

Results: Both groups had similar inflammatory control. Iritis was slightly higher in the Prednisolone group on POD 1 ($p=0.031$), with no difference afterward. IOP was significantly lower in the Bromfenac group across all visits ($p<0.001$).

Conclusions: Topical Bromfenac is as effective as Topical Prednisolone in inflammation control, with better IOP outcomes and patient compliance.

Abstract No.: 203635

Two Cases of Congenital Distichiasis Treated With Lamellar Splitting and Posterior Lamella Cauterization

First Author: Sayuri **SUMI**

Co-Author(s): Sujin **HOSHI**, Yuka **MORITA**, Tetsuro **OSHIKA**

Purpose: To report two cases of congenital distichiasis successfully treated with lamellar splitting and posterior lamella cauterization combined with a modified Hotz procedure.

Methods: Case 1: A 6-year-old girl presented with photophobia. Family history revealed distichiasis treated with electrolysis in the mother and maternal grandfather. Best-corrected visual acuity (BCVA) was 1.0 in both eyes. Slit-lamp examination showed severe corneal epithelial damage due to distichiasis of both upper and lower eyelids. Lamellar splitting and posterior lamella cauterization were performed on all four eyelids, along with a modified Hotz procedure for the lower eyelids. Case 2: A 6-year-old girl with a history of cleft palate surgery presented with photophobia and tearing. BCVA was 1.2 in the right eye and 0.9 in the left. Examination revealed distichiasis along the full length of both upper and lower eyelids, punctate superficial keratopathy, right superior oblique

palsy, and intermittent exotropia. The same surgical procedures as Case 1 were performed.

Results: At postoperative follow-up (4 months in Case 1; 14 months in Case 2) corneal epithelial damage had resolved and photophobia and tearing disappeared. BCVA improved or remained stable in both cases with no complications.

Conclusions: Lamellar splitting combined with posterior lamella cauterization and the modified Hotz procedure was effective in managing congenital distichiasis. Long-term follow-up is required to monitor for dry eye and potential systemic associations.

Abstract No.: 200346

Uncertain Inflammation After Cataract Surgery: Suspected Endophthalmitis, Toxic Anterior Segment Syndrome (TASS), or Postoperative Uveitis in a Resource-Limited Setting

First Author: Muhammad Fadhil RAHMADIANSYAH

Purpose: To report a diagnostically challenging case of postoperative intraocular inflammation with unclear etiology following uneventful phacoemulsification, managed non-invasively in a resource-limited rural setting.

Methods: We conducted comprehensive evaluation of a 64-year-old woman who underwent uneventful phacoemulsification for mature cataract. On day one, diffuse corneal edema was noted. By the end of the first week, the patient presented with a red, painless eye, a clear cornea, a quiet anterior chamber, posterior synechiae, and a brownish membrane covering the intraocular lens (IOL). Visual acuity was hand movement, and B-scan ultrasonography was not available. A presumptive diagnosis of endophthalmitis was established, with toxic anterior segment syndrome (TASS) and postoperative uveitis as differential diagnoses. As invasive interventions were not accessible in the rural setting, the patient was managed conservatively with high-dose systemic corticosteroids and antibiotics, hourly topical steroids and antibiotics, mydriatics, and close outpatient monitoring.

Results: Clinical improvement was observed within three days. Synechiae resolved, the membrane regressed, and vision improved to 5/60. B-scan showed a relatively clear vitreous with mild reflectivity near the IOL. By week two, vision reached 6/40 with a quiet anterior chamber and clear IOL. Invasive diagnostics remained unavailable, and a definitive diagnosis could not be established.

Conclusions: This case illustrates the complexities of managing postoperative ocular inflammation without access to full diagnostics or intervention. A strong clinical approach and close follow-up enabled recovery despite the diagnostic uncertainty. Similar situations

are common in rural areas and require pragmatic, resource-based decision-making.

Abstract No.: 202954

Urinary Metal Mixtures and Cataract: Findings From a U.S. Population-Based Study and Network Pharmacology Analysis

First Author: Runzi YANG

Co-Author(s): Jing LI, Rui LIU, Jianmin MA, Tingting REN, Nan WANG, Liangyuan XU

Purpose: To analyze the effects of various urinary metals on cataract using National Health and Nutrition Examination Survey data.

Methods: Multivariate logistic regression was used to analyze the relationship between 9 kinds of urinary metals and cataract. Weighted quantile sum (WQS) was used to analyze the positive and negative effects of various metals on cataract. The global and independent effects were analyzed using Bayesian kernel machine regression (BKMR). Network pharmacological analysis was used to explore the mechanism of metals on cataract.

Results: A total of 2207 participants participated in the study. After excluding the influence of covariates, it was found that the concentrations of Ba, Sb, and Tl were significantly correlated with the prevalence of cataract. WQS showed that Cd, Pb, and Ba had the strongest negative effects on cataracts, while Tu and Co had the strongest positive effects. BKMR showed that the overall effect of nine urinary metals had no significant relationship with cataract, there was a significant positive correlation between Co and cataract, and a significant negative correlation between Pb and cataract under certain conditions. Co and cataract interact through various pathways, including interleukin-4 and Interleukin-13 signaling. AKT1 may be the key protein in the correlation.

Conclusions: Urinary metal concentrations may be associated with the risk of ocular outcomes. While our findings suggest potential links between Co and cataract, these results should be interpreted with caution due to the cross-sectional nature of the data. Further longitudinal studies are needed to confirm associations and to explore possible threshold levels for public health monitoring.

Abstract No.: 201932

Use of EDOF Intraocular Lens in Cataract Surgery

First Author: Tommy Chung Yan CHAN

Purpose: To investigate the results of a novel EDOF intraocular lens in cataract surgery.

Methods: The results of eyes implanted with an EDOF intraocular lens were retrospectively reviewed and analyzed.

Results: Eighty-eight were included in the study. Eighty percent of the eyes had an UNVA of J3 or better when targeted plano. There was no drop in CDVA in all cases, and all eyes retained a UDVA of 20/25 or better. The results of patients with minimonovision showed a wide range of vision after bilaterally implanted with the EDOF intraocular lens.

Conclusions: This new type of EDOF intraocular lens was safe and effective in reducing the spectacle independence in cataract surgery.

Abstract No.: 202343

VISCO– Assisted Modified Tilt-and-Tumble Nucleotomy – a Technique for Safe Nuclear Emulsification in Soft Cataract

First Author: Shalini KUMARI

Purpose: We are presenting an easy and safe modified technique of 'VISCO– Assisted Tilt-and-Tumble nucleotomy' in very soft cataract phacoemulsification procedure. Soft Cataract (Lens Opacities Classification System III (LOCS III), grades 1) is characterized by a minimally dense endonucleus with abundant sticky soft cortical matter. Aspiration & perforation of soft nucleus by phaco tip, difficulty in achieving & sustaining occlusion, undivided bowl of nucleus & 'cheese wiring' by second instrument (chopper), sudden penetration of nucleus and subsequent, posterior capsular rupture, are quite common in hands of newer surgeons. Therefore, we need safer technique.

Methods: We proceed with gentle hydrodelineation of soft nucleus after routine steps. One pole of endonucleus is prolapsed out of bag. Prolapsed endonucleus is maneuvered vertically with viscoelastic agent and its canula. Viscoelastic agent, both dispersive and cohesive, serve dual purpose of coating endothelium and providing a viscous medium, wherein, endonucleus is supported vertically. Subsequently, chopper is introduced through side-port to support it from behind to prevent its fall back into nuclear bed. This step is followed by introduction of phaco-probe and impaling of endonucleus with aspiration mode. This step further continues as routine chopping technique.

Results: All cases had successful outcome with no incidence of posterior capsular rupture (PCR). No corneal-related complications were observed intra-operatively. All cases had clear cornea on 7th day.

Conclusions: Our VISCO– Assisted Tilt-and-Tumble Nucleotomy is simple, safe and, reproducible for soft cataract phacoemulsification even in hands of novice surgeons.

Abstract No.: 205471

Visual Outcomes Following Bilateral Implantation of a Rotationally Asymmetric C-Loop Hydrophobic Extended Depth of Focus Intraocular Lens

First Author: Mun Wai LEE

Purpose: To evaluate visual and patient-reported outcomes following bilateral implantation of the Acunex Vario extended depth of focus (EDOF) intraocular lens (IOL).

Methods: Prospective interventional case series of patients with bilateral cataracts undergoing phacoemulsification and implantation of the Acunex Vario. Dominant eyes were targeted for emmetropia and non-dominant eyes for -0.75 D. Primary endpoints were binocular uncorrected distance (UDVA), intermediate (UIVA, 66 cm), and near (UNVA, 40 cm) visual acuities at 3 months. Secondary outcomes included best-corrected distance (CDVA), distance-corrected intermediate (DCIVA) and near (DCNVA) visual acuities, refractive accuracy, rotational stability, binocular defocus curve, contrast sensitivity, Patient Reported Spectacle Independence Questionnaire (PRSIQ), dysphotopsia, and Visual Function Index (VF-14) scores.

Results: Thirty patients (60 eyes) were enrolled; results from the first 16 patients at 1 month are reported. Mean binocular logMAR UDVA, UIVA, and UNVA were 0.02 ± 0.05 , 0.16 ± 0.14 , and 0.23 ± 0.12 , respectively. Mean CDVA, DCIVA, and DCNVA were -0.01 ± 0.05 , 0.21 ± 0.14 , and 0.33 ± 0.16 , respectively. Mean refractive spherical equivalent was -0.27 ± 0.38 , with all eyes within 1 D of target. No patient required spectacles for distance or intermediate vision; four used near correction occasionally. Four patients reported starbursts; none reported halos or glare. Mean VF-14 score was 97.05.

Conclusions: Bilateral Acunex Vario implantation provided excellent binocular distance and intermediate vision with functional near vision. High levels of spectacle independence and patient satisfaction were achieved, with minimal photic phenomena.

Abstract No.: 206260

Visual Outcomes and Subjective Experience With Three Types of Extended Depth of Focus Intraocular Lens Implants

First Author: Manoj VASUDEVAN

Co-Author(s): Sridhar BARATAN, Nivean MADHIVANAN, Shiva Mohan REDDY

Purpose: To compare the visual outcomes of three EDOF type of intraocular lens (IOL) after bilateral implantation by a retrospective comparative study among patients who underwent phacoemulsification with bilateral implantation of three types of EDOF IOLs- Evolux IOL from SIFI group, RayOne EMV from Rayner

USA and Swissphob from Appasamy group which falls under Extended depth of focus type of presbyopia correcting IOLs.

Methods: The outcomes of the study included visual acuity (VA) near, intermediate, distant, contrast sensitivity, spherical equivalent, visual quality, spectacle independence, and patient satisfaction.

Results: Among the total 75 patients, each group consisted of 25 patients. There were 11 males and 14 females in all the 3 groups. The mean age in the EVOLUX group was 60+/- 18.5 years, RAYNER group was 60.92+/- 15.5 years and in the SWISS PHOB group was 63.80+/- 12.5 years. The axial length of the patients who underwent the surgery was 23.0+/- 1.5 mm in the EVOLUX group, 21.74+/-0.5 mm in the RAYNER group and 24.33+/-0.5 mm in the SWISS PHOB group. Uncorrected unocular and binocular distance, intermediate and near vision were recorded at 1 week and 1 month after the surgery and monocular defocus curves from +1.0 D to -4.0 D in decrements of 0.5 D were evaluated.

Conclusions: Across all time points and conditions, the three IOLs performed similarly for distance vision, with no significant statistical differences based on the reported p-values. The study demonstrated that all the 3 IOLs were effective in providing excellent intermediate and distance vision with minor variations in near vision outcomes.

Abstract No.: 206856

Visual Outcomes of Cataract Surgery in Eyes With Pre-Existing Corneal Haziness: A Systematic Review

First Author: Edianti **RATNINGPOETI**

Co-Author(s): Rafida Sofi **KAMILA**, Reni **RATNAWATI**, Isma Zahira **SUHAIMA**, Jessica **ZARWAN**

Purpose: Corneal haziness is the fifth leading cause of blindness in Indonesia, with corneal transplantation being the definitive treatment to restore vision. However, the limited availability of donor corneas restricts the feasibility of transplantation. Consequently, while it does not address the corneal pathology, cataract surgery has emerged as a more accessible intervention in eyes with coexisting cataract and corneal opacity to improve visual acuity (VA) to a functional level. This systematic review aims to evaluate the impact of cataract surgery on VA in patients with pre-existing corneal haziness.

Methods: A systematic search (2015—2025) was conducted using PubMed, Proquest, Scopus, and Google Scholar. Studies were screened based on predefined inclusion and exclusion criteria.

Results: Four studies encompassing 380 eyes were included. Three used phacoemulsification with intraocular lens (IOL) implantation, and one used Manual Small Incision Cataract Surgery (MSICS). All

studies reported significant VA improvement. One study comparing phaco-IOL to the triple procedure found that phaco-IOL patients maintained longer ambulatory vision, likely due to the absence of graft-related complications. No significant postoperative changes in corneal thickness were observed. Corneal edema was the most common early complication (15.7–76%), while posterior capsular opacification was the predominant late complication (5.6–60%).

Conclusions: Cataract surgery represents a viable alternative to keratoplasty to improve visual acuity in patients with pre-existing corneal opacity and may serve as an interim procedure while awaiting keratoplasty, particularly in regions with limited donor availability. The degree of corneal opacity remains a key determinant of postoperative visual outcome.

Abstract No.: 207320

Visual Outcomes of Cataractous Eyes With Epiretinal Membrane and Macula-On Retinal Detachment Implanted With Lentis Comfort Mf15 Segmented Bifocal Intraocular Lens – A Case Series

First Author: Paul **SIOPONGCO**

Co-Author(s): Erika Jean **SALVAME**

Purpose: The most commonly used treatment for patients with cataracts and retinal pathologies such as epiretinal membrane (ERM) and retinal detachment is a combined phacoemulsification and pars plana vitrectomy using a monofocal IOL as implant. The use of a segmented bi-focal IOL is still currently controversial.

Methods: This is a case series of patients with retinal pathologies (epiretinal membrane and macula-on retinal detachment) who had undergone phacoemulsification with segmented bifocal IOL implantation.

Results: Five eyes with retinal pathologies who had undergone phacoemulsification were included in this series. Three out of the 5 eyes had stage 1 epiretinal membrane and underwent standard phacoemulsification. One eye had stage 2 epiretinal membrane with metamorphopsia pre-operatively, then underwent phacoemulsification combined with vitrectomy and membrane peeling. The last eye had macula-on retinal detachment and underwent phacoemulsification with retinal detachment surgery. Pre-operative distance UCVA ranged from 0.2 to 0.7 (logMAR), and near UCVA ranged from 0.5 to 1.3. One month post-operatively, distance UCVA ranged from 0.0 to 0.2, and near UCVA ranged from 0.1 to 0.2. There were no post-operative complaints of dysphotopsias from all cases.

Conclusions: Implantation of multifocal and extended depth of focus IOLs in patients with retinal pathologies such as ERM and retinal detachment remains

debatable. But patient demand for post-operative spectacle freedom is increasing. This series highlights that segmented bifocal IOLs, such as Lentis Comfort MF15, are a viable option for patients presenting with mild epiretinal membrane and macula-on retinal detachment.

Abstract No.: 206263

Visual Outcomes of a Monofocal Intraocular Lens With Enhanced Intermediate Function in Posterior Segment Pathologies

First Author: Jeewan **TITIYAL**

Co-Author(s): Manpreet **KAUR**, Sridevi **NAIR**, Jyoti **RAWAT**

Purpose: To evaluate the visual outcomes of a monofocal intraocular lens (IOL) with enhanced intermediate function in patients with posterior segment pathologies.

Methods: This prospective interventional study included 68 eyes of 34 patients: 17 patients with moderate NPDR without macular edema and 17 patients with mild to moderate glaucoma who underwent bilateral phacoemulsification with TECNIS Eyhance IOL implantation. Outcomes assessed at 3 months postoperatively included uncorrected distance (UDVA), intermediate (UIVA), and near (UNVA) visual acuity, Strehl ratio, modulation transfer function (MTF), contrast sensitivity (CS), stereopsis, colour vision, and patient-reported satisfaction.

Results: The mean age was 65.5 ± 4.6 years. At 3 months, mean UDVA, UIVA, and UNVA (logMAR) were 0.08 ± 0.11 , 0.25 ± 0.17 , and 0.49 ± 0.15 , with 74% achieving UIVA of 20/40 or better. Significant improvements were observed in postoperative stereopsis [Near: 57.2" (NPDR); 67.6" (Glaucoma)], CS [CS-Avg: 1.71 ± 0.14 (NPDR); 1.66 ± 0.13 (Glaucoma)], and color vision [TES: 61.6 ± 16.4 (NPDR); 64.5 ± 11.5 (Glaucoma)]. Glaucoma eyes showed marginally lower CS values than NPDR at higher frequencies (CS-C $p=0.05$; CS-D $p=0.02$). Strehl ratio and MTF improved significantly in NPDR ($p<0.001$) but not in glaucoma ($p>0.4$). Glare (4%) and halos (3%) were minimal, with 40% requiring spectacles for near.

Conclusions: Eyhance IOL provided excellent acuity and functional vision in NPDR and glaucoma. Optical quality gains were more pronounced in NPDR, but glaucoma eyes maintained good contrast sensitivity and colour vision, supporting its role even in eyes with posterior segment disease.

Abstract No.: 204919

Visual Performance Comparison: Galaxy vs Vivity PC-IOLs

First Author: Santaro **NOGUCHI**

Co-Author(s): Asuka **NOGUCHI**

Purpose: To compare Galaxy and Vivity multifocal IOL performance across pupil sizes using defocus curve analysis (+2.0D to -4.0D).

Methods: Visual acuity was measured with defocus lenses (+2.0D to -4.0D, 0.25D steps) at three pupil diameters (2mm, 3mm, 4mm). Performance was assessed using logMAR units, with ≤ 0.2 logMAR considered good vision.

Results: Depth of Focus (logMAR ≤ 0.2): • Galaxy: Superior with 2mm pupils (11 steps, +0.75D to -1.75D) • Vivity: Excellent intermediate vision with 3mm pupils (6 steps, +1.0D to -0.25D) • Both IOLs: Reduced near performance with 4mm pupils Near Vision (+2.0D to 0D): • Galaxy 2mm: 0.40 logMAR average • Vivity 2mm: 0.37 logMAR average (superior) Pupil Effects: • Smaller pupils enhanced depth of focus for both IOLs • Galaxy: Consistent myopic range performance • Vivity: Better stability with larger pupils

Conclusions: Galaxy provides superior extended depth of focus, ideal for intermediate vision needs. Vivity offers balanced near-distance performance with better optical quality at larger pupils. IOL selection should be individualized based on patient lifestyle and pupil characteristics.

Abstract No.: 206244

Visual and Refractive Outcomes of 300 Cataract Surgeries With Enhanced Monofocal Intraocular Lenses

First Author: Amod **NAYAK**

Purpose: Enhanced monofocal intraocular lenses (IOLs) aim to deliver an improved range of vision and spectacle independence while maintaining high visual quality. This study evaluates outcomes of cataract surgeries using enhanced IOLs, comparing toric and non-toric designs, with a subset of cases where multifocal IOLs were contraindicated.

Methods: A retrospective analysis of 300 eyes undergoing phacoemulsification with enhanced IOL implantation was performed. 116 eyes (38.6%) received toric enhanced monofocal IOLs, while 184 eyes (61.4%) received non-toric enhanced monofocal IOLs. 90 eyes were implanted with enhanced monofocal IOLs due to relative contraindications to multifocal IOLs, including ocular comorbidities and visual demands. Outcomes assessed at 1- and 3-month follow-ups included uncorrected distance visual acuity (UDVA), uncorrected intermediate visual acuity (UIVA), uncorrected near visual acuity (UNVA) and residual refractive error.

Results: Distance vision: Over 92% of eyes achieved UDVA of 6/9 or better. Intermediate vision: 85% achieved functional UIVA (N10 or better) for tasks such as computer and dashboard viewing, with comparable results between toric and non-toric groups. Near vision: Around 70% achieved functional UNVA (N12 or better) without additional correction, sufficient for most daily tasks while readers were prescribed when required for fine near tasks

Conclusions: Enhanced monofocal IOLs, both toric and non-toric, provide excellent visual and refractive outcomes with high patient satisfaction. Enhanced monofocal IOLs are also a reliable option in cases where multifocal IOLs are contraindicated. Enhanced IOL technology supports a broader range of functional vision, particularly for intermediate tasks, thereby improving quality of life post-cataract surgery.

Abstract No.: 206425

When Calcium Meets the Lens: Bilateral Complicated Cataracts and Argentinian Flag Sign in a 26-Year-Old Woman

First Author: Talita ISMA

Purpose: Young adults who have undergone a parathyroidectomy may be at risk for metabolic imbalance, which could result in complex cataract development sooner than anticipated. It is crucial to anticipate the Argentinian flag sign with preventive decompression, dye staining, and viscoelastic-assisted maneuvers, as it remains a significant risk in intumescent cataracts.

Methods: A 26-year-old woman with a history of parathyroidectomy presented with progressively decreased vision in both eyes. Best corrected visual acuity was hand movement in the right eye and 3 meters counting fingers in the left eye. Slit-lamp examination revealed dense white cataracts on the right eye and a posterior subcapsular cataract on the left eye, consistent with complicated cataracts. No other ocular abnormalities were detected. Phacoemulsification was planned in the right eye first. During capsulorhexis in the right eye, the Argentinian flag sign occurred due to sudden tear extension in the intumescent white cataract. Slow phacoemulsification technique and intraocular lens (IOL) implantation were performed uneventfully.

Results: Postoperative recovery was satisfactory, with Snellen visual acuity improving to 6/15 OD. Funduscopy examination was unremarkable. The patient has no symptoms and is happy with her sight.

Conclusions: This case highlights how systemic conditions such as parathyroid dysfunction can lead to bilateral complicated cataracts in young patients. Excellent postoperative visual outcomes can be achieved with careful technique and the right surgical maneuvers; however, the Argentinian flag sign

remains a challenging intraoperative complication in intumescent cataracts and could be a take home message for the future second eye surgery preparation in this patient.

Cornea, Dry Eyes, External Eye Diseases and Eye Banking

Abstract No.: 206320

A Case Report on an Atypical Case of Epidemic Keratoconjunctivitis in a Pediatric Patient Admitted in a Tertiary Hospital in Manila, Philippines

First Author: Isabella BONDOC

Co-Author(s): Cristina TAN

Purpose: Epidemic keratoconjunctivitis (EKC) is a highly contagious disease with no effective treatment, with severe cases of EKC causing corneal epithelial lesions, inflammation and severe eye pain lasting for more than 2 weeks. These cases are especially difficult to manage in the pediatric population, wherein physical examination and supportive management may be a challenge. This case report aims to guide and support health care practitioners and ophthalmologists in making appropriate decisions in the management and care of pediatric patients with severe EKC.

Methods: An 8-year-old female with a two-week history of eye pain and redness, previously treated with a combination of topical antibiotics and steroids (Levofloxacin+ Dexamethasone), was admitted due to swollen lids and inability to open her eyes. Frequent cold compresses, as well as topical moxifloxacin, prednisolone acetate, and preservative-free lubricating drops, were administered. She also underwent corneal filament removal and conjunctival membrane peeling with 5% povidone-iodine wash under general anesthesia. Gram stain and culture were also done.

Results: Supportive management regimen through membrane peeling under general anesthesia, cold compress, topical steroids, antibiotics, and povidone iodine wash was effective in alleviating patient symptoms in 1 week, with gradual improvement of eye pain.

Conclusions: Management of EKC in the pediatric population creates challenges from the history taking to the physical exam and supportive management for the patient. More pediatric case studies should be brought forward to guide ophthalmologists and the healthcare team in providing optimal management for the best outcomes and comfort for the child.

Abstract No.: 202760**A Case of Capecitabine(Xeloda)-Related Limbal Stem Cell Deficiency***First Author: Wing Sum LI**Co-Author(s): Gillian Denise Ji-yee SIU*

Purpose: To report the clinical presentation of limbal stem cell deficiency associated with Capecitabine (Xeloda) treatment for metastatic breast cancer.

Methods: We present a case of a 72-year-old female with triple-negative breast cancer (ER-, PR-, HER1+) and suspected mediastinal nodal metastases. She underwent a right mastectomy in 2018, followed by adjuvant targeted therapy and chemotherapy with lifelong Capecitabine since September 2020. Due to secondary hand-foot syndrome, the dose was reduced but later re-escalated to 1500 mg twice daily following mild rises in tumor markers (CEA and CA15-3). The patient complained of teary, dry eyes and bilateral blurring of vision in August 2023 and was referred to us.

Results: On assessment, her visual acuities were 0.1 and pin-hole 0.2 for both eyes, with both eyes showing whorl-like degeneration of superior corneal epithelium and inferior raised corneal scar. The patient was managed with lubricants and subsequently underwent bilateral cataract surgery. Given stable metastatic disease, symptomatic improvement with lubricants, and no progressive visual decline, the patient chose to continue capecitabine with ophthalmic follow-up. Capecitabine was later reduced to 1000 mg twice daily in December 2024 due to worsening hand-foot syndrome. At the most recent follow-up in June 2025, visual acuities were 0.3 (OD) and 0.7 (OS). Superior limbal stem cell deficiency with whorl epitheliopathy remained static.

Conclusions: Capecitabine (Xeloda) is an oral antimetabolite widely used in metastatic breast and colorectal cancer. Its ocular toxicity remains poorly understood. To our knowledge, this is the first reported case in Asia of limbal stem cell deficiency associated with Capecitabine therapy.

Abstract No.: 207262**A Case of Stevens-Johnson Syndrome With Ocular Complication***First Author: Faria Tifat TIMA**Co-Author(s): Tanvir AHMED, Rajashree DAS*

Purpose: To report a case of Stevens-Johnson Syndrome (SJS) presenting with significant corneal involvement highlighting the ocular manifestations, clinical course, and management approach to prevent long-term visual impairment.

Methods: A 28-year-old female complained about FB sensation, blurring of vision, pain, redness, and photophobia in the right eye for 5 days. FB sensation

in LE for the same duration. According to the statement of the patient, she was reasonably well 4 months back. Then she gave a H/O of viral fever & joint pain. Azulfidine (Sulfasalazine) was prescribed by a rheumatologist for her joint pain. After taking sulfasalazine, the patient developed rashes involving the trunk & extremities. Involvement was not widespread. These were followed by ocular discomfort 15 days later in BE. Then he consulted with a local doctor in nearby hospital for her skin problems & for ocular complaints treated with some topical eye drops but her ocular condition didn't improve. With these, she came to us for better management.

Results: Ocular examination -VA-6/60 RE, 6/9 LE. Slit lamp Examination: O/E: conjunctival congestion, Conjunctival scar with inflammation in BE, corneal epithelial erosion with SPK present in BE. No specific tests are used for diagnosing SJS. Instead diagnosis is based on symptoms, medical history & an examination of eyes and eyelids & skin. Patient treated with frequent artificial tears, topical steroids, steroid eye ointment, Antibiotic eye drops & eye ointment. Referred to a skin specialist for the blister on her skin. Suspected medication discontinued immediately. After medical treatment, the epi erosion almost resolved in RE, leaving a scar.

Conclusions: Ocular involvement in Stevens-Johnson Syndrome can be vision-threatening and requires urgent ophthalmologic intervention. Early diagnosis & collaboration between specialties are essential to improve outcomes.

Abstract No.: 204068**A Deoxyribonuclease-Based Nanosystem With Sequential and Enhanced Biofilm Disruption for the Treatment of Bacterial Keratitis***First Author: Xiaolin QI*

Purpose: Bacterial keratitis (BK) can lead to rapid vision loss if not treated effectively. The therapeutic effects would be greatly attenuated once the formation of bacterial biofilms.

Methods: We fabricated a nanoplatform (D-HIC) composed of deoxyribonuclease (DNase) functionalized hollow manganese dioxide (D-HMnO₂) loading with indocyanine green (ICG) and ciprofloxacin (CIP), which presented superior outcomes in the biofilm disruption and bactericidal activity.

Results: The Mn²⁺ provided by the D-HMnO₂ could substantially improve the cleavage intensity and rate of D-HIC for extracellular DNA (eDNA), thereby resulting in rapid breakdown of the superficial stubborn structure of biofilms and providing channels for the penetration and delivery of nanoparticles into the biofilm. Subsequently, upon near-infrared-light (NIR) irradiation, the nanoparticles could boost

the level of singlet oxygen ($1O_2$) in the inner biofilm locally, which performed further elimination for the remanent biofilms and enabled the synergistic bactericidal action of CIP at a lower concentration, achieving a potent antibacterial efficacy above 99% against both *Staphylococcus aureus* and *Pseudomonas aeruginosa* related biofilms. Furthermore, the designed nanoplatform successfully repaired bacterial biofilm-induced injury in a BK mice model with greatly accelerated therapeutic effects than commercially available CIP eye drops.

Conclusions: Our findings highlight an innovative concept of sequential biofilm disruptions for the treatment of BK and offer a clinically relevant strategy for combating biofilms related infections.

Abstract No.: 201653

A Forgotten Punctal Plug: Delayed-Onset Canaliculitis and Granuloma Formation

First Author: Yu Ting Tina **SHEN**

Co-Author(s): Maryanne Chew **ROMERO**, Gangadhara **SUNDAR**, Kong Bing **TAN**, Anas **YASIN**

Purpose: To describe a rare case of delayed-onset canaliculitis and punctal granuloma formation secondary to a retained punctal plug inserted post-LASIK decades ago, and to highlight the importance of long-term vigilance in patients with chronic ocular inflammation and prior plug insertion.

Methods: A 73-year-old woman presented with persistent left eye redness and mucopurulent discharge. She had undergone LASIK years earlier, followed by punctal plug insertion and subsequent bilateral cataract surgeries. Initial treatment with Tobradex® for presumed viral conjunctivitis was ineffective. Slit-lamp examination revealed a 2mm pedunculated pyogenic granuloma at the lower punctum. Anterior segment optical coherence tomography showed no foreign body. She was referred to Oculoplastics team and started on topical antibiotics. Surgical excision of the granuloma with lacrimal system exploration under local anaesthesia revealed cream-colored concretions with a central hard core, strongly suggestive of a retained punctal plug.

Results: Histopathology showed bacteria, inflammatory cells confirming chronic inflammation, and non-polarizable amorphous material, suggestive of a possible exogenous source. Microbiological cultures grew *Fusobacterium* species and *Streptococcus anginosus*, consistent with polymicrobial biofilm-associated infection. The patient recovered uneventfully and was scheduled for further canalicular evaluation.

Conclusions: This case highlights the potential for delayed complications from punctal plug retention, including chronic canaliculitis and granuloma formation. Clinicians should maintain a high index

of suspicion in patients with unexplained chronic conjunctivitis and prior punctal plug insertion. Timely diagnosis, prompt removal of plugs, and consideration of long-term dry eye management strategies including definitive surgical options are essential to prevent these complications.

Abstract No.: 204879

A Hole Lot of Trouble: A Case Report on Corneal Perforation From Stubborn Staphylococcal Blepharoconjunctivitis

First Author: Kristine **NATIVIDAD**

Co-Author(s): George **SOSUAN**

Purpose: Corneal perforation is a sight threatening ophthalmic emergency that carries a high risk of ocular morbidity and necessitates immediate intervention to re-establish the continuity of the globe.

Methods: This is a case report on a 21-year-old gentleman was referred due to 2-months history of right eye redness, discharge, foreign body sensation, and frequent eye rubbing that didn't resolve after self-medication. 1 month prior, sought outside consult and was started on Levofloxacin 1.5% and lubricants which didn't provide relief. 1 week prior, after swimming, noted more frequent eye rubbing and photosensitivity, he manifested with corneal perforation with iris prolapse - bandage contact lens (BCL) placed and oral antibiotics started. Past medical history reveal recurrent external hordeolum, conjunctivitis, and dry eye disease. Right eye examination, vision's 20/100 with matting and crusting at the base of the lashes, multiple chalazion and scarring, mucopurulent discharge, inspissated glands, erythema and edema of the eyelid margin, anterior lid telangiectasia with areas of madarosis, hyperemic conjunctiva, 360 pannus, grade 3 inferior corneal haze, 3.2x4.3mm descemetocoele, papillae on the palpebral conjunctiva. Corneal Patch Graft with Iris Prolapse Excision was done.

Results: Third post-operative week, vision was 20/70 with lash matting, loose sutures, and leakage on Seidel test. Medications were continued, loose sutures removed and BCL was placed.

Conclusions: Management of corneal perforation is influenced by the lesion's characteristics. When less invasive measures fail, corneal patch grafting serves as a reliable technique for preserving ocular integrity.

Abstract No.: 205505**A Meta-Analysis on the Efficacy and Safety of Tacrolimus in Treating Allergic Conjunctivitis***First Author: Charmaine Yuk Wah TSANG**Co-Author(s): Julia Yan Yu CHAN, Vanissa Wing See CHOW*

Purpose: Allergic conjunctivitis represents an inflammatory response of the conjunctiva to allergens. While tacrolimus is an established immunomodulator in transplant medicine and dermatology, its topical application in allergic conjunctivitis remains off-label due to pending FDA approval. This meta-analysis aims to evaluate the efficacy and safety profile of tacrolimus in allergic conjunctivitis management.

Methods: Literatures were retrieved from PubMed, Cochrane Library, Scopus, and Embase databases in September 2025, reviewed by 2 independent reviewers based on inclusion and exclusion criteria, with data extraction. Primary outcomes are objective signs with a 4-point grading scale generally on the palpebral conjunctiva, bulbar conjunctiva, limbus, and cornea (0 = Normal; 1+ = Mild; 2+ = Moderate; or 3+ = Severe). Secondary outcomes consisted of subjective symptom scores, e.g. tearing, itching, and photophobia. Data analysis was performed using R. Risk of bias was performed with the ROBINS-I framework.

Results: Of the 474 studies screened, 6 met the inclusion criteria, encompassing 3060 eyes. Meta-analysis demonstrated significantly reduced objective sign scores (Mean Difference [MD]: -1.30, 95% Confidence Interval [CI]: -1.65 to -0.95, $p < 0.001$) and subjective symptom scores (MD: -1.82, 95% CI: -2.34 to -1.31, $p < 0.001$) in individuals treated with tacrolimus compared to baseline. Subgroup analysis revealed similar efficacy of tacrolimus suspension formulation (MD: -1.30, 95% CI: -1.90 to -0.70, $p < 0.001$) and ointment formulation (MD: -1.30, 95% CI: -1.80 to -0.81, $p < 0.001$).

Conclusions: This meta-analysis provides robust evidence supporting tacrolimus as an effective therapeutic option for allergic conjunctivitis, with similar outcomes observed with suspension formulation and ointment formulation.

Abstract No.: 203729**A Multifunctional Nanoplatfom With Dual-Targeted Antibacterial and Cascaded Immunomodulatory Strategy for the Treatment of Bacterial Keratitis***First Author: Xiaolin QI*

Purpose: Bacterial keratitis (BK) is a serious ocular infection and frequently causes irreversible damage to the corneal tissue and even blindness. Current clinical treatments using antibiotics achieve unsatisfactory outcomes due to the lower bioavailability, high risks of drug resistance, and limited therapeutic functions.

Methods: We proposed a dual-targeted antibacterial and cascaded immunomodulatory therapy strategy, constructing a multifunctional nanoplatfom (HPBH@GLA/AMP) using the 3-aminophenylboric acid (NBA) and hyaluronic acid (HA) co-modified hollow polydopamine (HPDA) to serve as a functional nanocarrier (HPBH) for loading antimicrobial peptide (AMP) and glycyrrhizic acid (GLA).

Results: The HPBH@GLA/AMP presented excellent targeting and bactericidal performance to *Pseudomonas aeruginosa* (*P. aeruginosa*), coupled with its capacity to alleviate the bacteria-triggered excessive immune response via an ingenious cascaded immunoregulatory process. Notably, the study of the underlying anti-inflammatory mechanism revealed that the functional nanocarrier of HPDA could effectively scavenge the reactive oxygen species (ROS) for controlling early inflammatory responses, while inhibiting the expression of late mediator high mobility group box 1 (HMGB1) chemokine through released GLA. Specially, the dual-targeted characteristic enabled this nanoplatfom to recognize both the bacteria and inflammatory cells precisely and aggregate the location where bacteria and/or inflammatory cells exist persistently, effectively increased the therapeutic concentration of drugs. Featuring the antibacterial synergistic yet sequential regulation for the inflammatory response, the HPBH@GLA/AMP achieved satisfactory therapeutic effects in a BK mouse model in vivo.

Conclusions: This study provides a bright prospect for clinical treatment of refractory bacterial keratitis (BK) and even extended to other immunotherapy in infectious disease.

Abstract No.: 204989**A Rare Bilateral Varicella Zoster Epithelial Keratitis Secondary to Zoster Vaccination: A Single-Case Report***First Author: Oranat PITUCKANOTAI**Co-Author(s): Somporn CHANTRA, Peranut CHOTCOMWONGSE, Napon HIRANBURANA*

Purpose: To report an unusual case of bilateral varicella-zoster virus (VZV) keratitis occurring four weeks after administration of the first dose of recombinant zoster vaccine, adjuvanted (Shingrix®).

Methods: Retrospective case report.

Results: A 63-year-old Thai man presented to the ophthalmology clinic with bilateral ocular redness without pain or visual impairment. His past medical history included a complete remission of diffuse large B-cell lymphoma for 30 years, with no current immunosuppressive therapy. Four weeks prior to symptom onset, he had received both the first dose of Shingrix® and an influenza vaccine (Influtetra®). He reported no previous history of herpes zoster infection.

On examination, bilateral conjunctival injections were noted. Slit-lamp evaluation showed multiple tiny vesicles of epithelium and fluorescein-stained pseudodendritic lesions, with no anterior chamber inflammation. Posterior examination findings were unremarkable. He reported no systemic symptoms such as myalgia or fever. A clinical diagnosis of bilateral VZV epithelial keratitis was made. Treatment with oral acyclovir 800 mg five times daily and topical ganciclovir gel five times daily was initiated. After two weeks, the vesicles, pseudodendritic lesions, and conjunctival injection had completely resolved without visual impairment sequelae.

Conclusions: Although activation or recurrence of VZV keratitis following zoster vaccination is not common, clinicians should remain aware of this potential association, even in patients without a prior history of ocular VZV infection. Furthermore, bilateral VZV keratitis is particularly rare. Prompt recognition and treatment are essential to prevent complications and preserve vision.

Abstract No.: 204653

A Rare Case of Ocular Cicatricial Pemphigoid: First Biopsy-Proven Case in a Young Filipino Male

First Author: Richard Dean Clod **DELA CRUZ**
Co-Author(s): Jamaine Melisse **CRUZ-REGALADO**,
Sharmaine Anjanette **NG**, *Raymond Nelson* **REGALADO**

Purpose: To report the first biopsy-proven case of ocular cicatricial pemphigoid (OCP) in a young, healthy Filipino male, an atypical demographic for OCP.

Methods: A 34-year-old male presented with a two-year history of intermittent eye redness, tearing, and foreign body sensation of both eyes with unremarkable ophthalmic history. Slit lamp examinations revealed subepithelial fibrosis, inferior fornix shortening (4.6mm in the right, 4.8mm in the left) and symblepharon formation of both eyes. Excision of the symblepharon with ocular surface reconstruction using an amniotic membrane graft was performed. Excised conjunctival tissue was subjected to hematoxylin and eosin (H&E) staining and direct immunofluorescence (DIF).

Results: DIF showed strong linear deposits of IgG and fibrinogen in the basement membrane zone of the conjunctival tissue, which confirms the diagnosis of OCP. Postoperatively, the right eye demonstrated deepening of the fornix and improved motility with the graft well-apposed. The patient was referred for systemic immunosuppression to control inflammation.

Conclusions: OCP is a rare autoimmune disease that primarily affects older females, and is uncommon for younger males. Early ocular symptoms are often nonspecific and may mimic chronic conjunctivitis or dry eye, delaying diagnosis. In younger patients, OCP may progress more rapidly and severely, emphasizing

the need for prompt and early diagnosis. This case report highlights the need for increased awareness among clinicians in the Philippines to consider OCP as a differential diagnosis for chronic conjunctivitis, even in patients outside the typical older female demographic, thereby improving diagnostic accuracy, treatment approach and patient outcomes.

Abstract No.: 205198

A Rare Case of Salzmann Nodular Degeneration in Adolescent Age

First Author: Shital **NANNAWARE**
Co-Author(s): Puja **BANG**

Purpose: Salzmann Nodular Degeneration (SND) is a corneal condition typically seen in older individuals, but it can occur in young people as well, though less commonly. Here we are presenting a case of 17 17-year-old male with both eyes with corneal opacity.

Methods: A seventeen-year-old male presented with defective vision in both eyes for a few years with whitish discoloration. The patient had gradually progressive painless defective vision for many years. It was not associated with fever or redness in the eyes. Patient is not using any spectacles, though prescribed already. No previous history of trauma or surgery. Medical history not significant. Family history is also not significant. Birth is a full-term normal vaginal delivery.

Results: On examination, visual acuity in RE -6/36, LE -6/24, not improving with pinhole, Ocular examination BE-Had presenile arcus. RE suggestive of temporal paracentral corneal anterior stromal raised leucomatous opacity with surrounding edema. Rest examination is normal. The left eye is suggestive of a temporal paracentral 2mm subepithelial opacity; the rest of the examination was normal. Both eye horizontal nystagmus present. The posterior segment was normal. Facial symmetry with a broadened nasal present. Post-segment evaluation was normal. Central corneal thickness noted in RE-664um and LE-512 um. After examination decided for cyclorefraction, kept under observation, and started on topical hyperosmotics

Conclusions: Salzmann nodular degeneration occurs rarely at a young age, appears more in central to paracentral cornea than typical peripheral or mid-peripheral locations in old age, and is differentiated from peripheral hypertrophic subepithelial corneal degeneration and spheroidal degeneration. It can be treated by conservative management if asymptomatic or can go for superficial keratectomy. Hence, this case shows the need for early intervention in such cases.

Abstract No.: 203973**A Septic Shock in Periorbital Necrotizing Fasciitis: A Case Report***First Author: Maria Yovita Saraswati **PELE ALU****Co-Author(s): I Gusti Ayu Made **JULIARI***

Purpose: Periorbital necrotizing fasciitis (PNF) is a life-threatening skin infection that can rapidly involve the periorbital tissues. Delayed management increases the risk of mortality due to rapid hematogenous spread.

Methods: A case report. A 68-year-old male presented with swelling and a wound below the right eye for three days prior to hospital admission. The lesion ruptured and discharged pus two days earlier. Systemic symptoms included weakness, vomiting, and the appearance of a palatal mass one month earlier that progressively enlarged before rupturing into an open wound. On examination, the right inferior eyelid showed edema, spasm, hyperemia, purulent discharge, crusts, necrotic tissue, an unclean wound base, and tenderness. Ocular movement was limited toward the inferior and inferonasal directions.

Results: Laboratory tests revealed leukocytosis. Based on the Laboratory Risk Indicator for Necrotizing Fasciitis score, the patient was highly suspected of having PNF with C-Reaktif Protein 207. Gram stain of the wound showed both Gram-positive and Gram-negative bacteria, each at 3+. He was treated with metronidazole, clindamycin, gentamicin eye ointment, and levofloxacin eye drops. During hospitalization, the patient developed septic shock and died within three days of admission.

Conclusions: The presence of edema, induration in erythematous areas, with necrotic tissue, should raise suspicion of PNF. Severe complications include vision loss and septic shock, which are life-threatening. In this case, septic shock led to mortality. Early recognition and prompt intervention are essential to reduce mortality rates. Once the condition worsens, optimal management becomes significantly limited.

Abstract No.: 205200**Actinic Keratosis of the Conjunctiva in Scar Tissue Presenting as Temporal Pterygium***First Author: Shital **NANNAWARE****Co-Author(s): Puja **BANG***

Purpose: Case-report of a rare presentation of actinic keratosis of the conjunctiva: its clinical presentation, diagnosis, and management.

Methods: A 64-year-old female presented with a fleshy growth in the Right Eye (RE), gradually increasing in size since 2 years, associated with intermittent redness and discomfort. The patient had undergone bilateral pterygium excision with conjunctival autograft, 3 years back, and bilateral cataract surgery 2 years ago. She gave no history of exposure to chemicals or of trauma

to RE. LE had an uneventful post-operative course. On examination, distant vision OU was 6/6, near vision N6. Ocular examination revealed RE temporal pterygium with fibrosis, cystoid, and calcific changes extending 2-3mm over the cornea, inciting suspicion of OSSN. LE post-terygium surgery autograft was in place with no recurrence. Impression cytology of the RE lesion was sent to the pathology laboratory on OPD basis. During surgical dissection, the lesion was found adherent to the underlying clear-corneal temporal phaco incision. Excisional biopsy of the lesion with 2mm margin was performed followed by 0.04% Mitomycin-C application and conjunctival autograft.

Results: The cytology report was negative for malignant cells, showing scattered anucleated squames. Biopsy showed stratified squamous epithelium with regular differentiation and intact basement membrane.; sub-epithelial tissue showing large eosinophilic necrotic material (solar actinic changes) with no atypia. Topical steroids in tapering dosage with lubricating eyedrops were administered postoperatively.

Conclusions: Temporal pterygium with actinic changes in scar tissue is hitherto unreported, to our knowledge. Actinic keratosis has a high chronicity, recurrence or pre-cancerous potential. Preventive measures combined with effective surgical techniques and careful followup are essential for effective management and minimizing recurrence.

Abstract No.: 200222**Afatinib-Associated Bilateral Peripheral Ulcerative Keratitis: A Case Report***First Author: Joyce Teo **WEI TING****Co-Author(s): Hah **YAN YEE***

Purpose: To describe a rare case of bilateral peripheral ulcerative keratitis (PUK) potentially induced by afatinib in a patient with metastatic lung adenocarcinoma.

Methods: A 78-year-old man with underlying metastatic lung adenocarcinoma, previously treated with afatinib, was referred for sudden-onset bilateral ocular pain and headache. Best corrected visual acuity was counting fingers in the right eye and 6/20 in the left eye. Slit-lamp examination revealed a shallow anterior chamber in the right eye with signs of a sealed old corneal perforation and adherent leucoma. The left eye demonstrated peripheral corneal thinning with an impending descemetocoele. The patient was promptly referred to a rheumatologist for systemic evaluation. Autoimmune and infectious workups were negative, supporting a drug-induced aetiology.

Results: Initial treatment included the initiation of intensive topical corticosteroids, topical antibiotics, and chloramphenicol ointment. Despite treatment, the left eye progressed to frank corneal perforation within one week. Urgent application of cyanoacrylate glue and bandage contact lenses were applied on

bilateral eye to stabilize the perforation. Topical steroid was discontinued, and supportive treatment with lubricants, topical, and oral antibiotics were started. Unfortunately, due to terminal disease progression, the patient was transferred to palliative care and subsequently passed away.

Conclusions: Afatinib, an EGFR tyrosine kinase inhibitor, may be associated with peripheral ulcerative keratitis, which is a rare but vision-threatening complication. Early recognition and prompt ophthalmologic intervention are crucial to minimize the risk of permanent visual impairment in patients receiving EGFR-targeted therapies.

Abstract No.: 205576

Analysis of Clinical Features and Risk Factors for Intraocular Lens Opacification After Endothelial Keratoplasty in Pseudophakic Eyes

First Author: Xu **MAN**

Co-Author(s): Jie **BAI**, Ling **LI**, Shaowei **LI**, Chang **LIU**, Fangqi **LV**, Lin **ZHAO**

Purpose: To analyze the incidence, clinical features, and risk factors for intraocular lens (IOL) opacification following endothelial keratoplasty (EK) in pseudophakic eyes.

Methods: The retrospective case study included 281 patients (292 eyes) who underwent endothelial keratoplasty at Beijing Aier Intech Eye Hospital between September 2015 and May 2025. Patient demographics, surgical details, and postoperative complications were recorded. Potential risk factors were analyzed.

Results: Among the 292 eyes, IOL opacification occurred in 8 eyes, yielding an overall incidence rate of 2.74% (8/292). All opacification cases occurred in hydrophilic IOLs. The opacification was located on the anterior optical surface of the IOL in all cases. Among the 8 eyes with IOL opacification, 62.5% (5/8) had received additional air injection. In the subset of 98 eyes with clearly documented IOL material, there were 36 eyes with hydrophilic IOLs and 62 eyes with hydrophobic IOLs. The opacification rate was 22.22% (8/36) in the hydrophilic IOL group, whereas no opacification occurred in the hydrophobic IOL group. Within the hydrophilic IOL subgroup, the incidence of IOL opacification was 45.45% (5/11) in eyes that received additional air injection, compared to 12% (3/25) in those that did not. Regarding the type of gas used, one eye received long-term inert gas (C_3F_8) tamponade, while seven eyes received short-term (2-hour) pressurized air injection.

Conclusions: Hydrophilic IOL material is the primary risk factor for IOL opacification following EK, and additional air injection further increases this risk. Clinically, the use of hydrophilic IOLs in high-risk patients should be

avoided, intraoperative and postoperative gas contact time should be minimized.

Abstract No.: 202913

Analysis of the Clinical Characteristics of Dry Eye Patients With Type 2 Diabetes Mellitus at Different Disease Durations

First Author: Yangyang **ZHANG**

Co-Author(s): Lixin **XIE**

Purpose: To observe and analyze the clinical characteristics of ocular surface lesions, including symptoms and signs, in patients with type 2 diabetes mellitus (T2DM) and dry eye of different disease durations.

Methods: Ocular symptoms were assessed using the OSDI questionnaire. Ocular surface function was evaluated using the Cochet-Bonnet esthesiometer, CFS, Schirmer I tear test, TMH, NIK-BUT, and MGL scores. CCET and CCT were measured using AS-OCT. Corneal nerve fiber parameters were assessed using IVCM.

Results: In T2DM complicated by dry eye, key ocular surface indices—including SIT, NIKf-BUT, NIKav-BUT, LLT, CCET, and CS—were significantly reduced, while OSDI, MGL grading, and CFS scores were elevated. Corneal nerve parameters such as p-CNFL, p-CNFD, p-CNBD, i-CNFL, i-CNFD, and i-CNBD were also significantly decreased. Notably, changes in OSDI, SIT, MGL grading, NIKf-BUT, and several corneal nerve parameters were evident within the first five years of disease onset. These indices correlated significantly with disease duration. In later stages (more than 10 years), OSDI and MGL scores continued to rise, while p-CNFD, i-CNFL, i-CNFD, and i-CNBD declined further. The change of CFS, CS, CCET, and NIKav-BUT were significantly only after disease duration exceeded 10 years and were closely linked to disease progression.

Conclusions: In early-stage type 2 diabetes (duration ≤ 5 years), main ocular features include reduced tear secretion, loss of meibomian glands, unstable tear film, and decreased corneal nerve density. After more than 10 years, additional changes such as impaired corneal nerve function, corneal epithelial thinning, and weakened epithelial barrier function occurred.

Abstract No.: 200762

Assessment of the Clinical Efficacy of a Single Systane iLUX Treatment in Chinese Patients With Meibomian Gland Dysfunction: After 6 Months Study

First Author: Yiran **HAO**

Co-Author(s): Ying **JIE**

Purpose: To assess the efficacy of a single Systane iLUX treatment on meibomian gland dysfunction (MGD) signs and symptoms in Chinese patients over a 6-month period.

Methods: This prospective, single-arm study enrolled 30 subjects (60 eyes) with a Standard Patient Evaluation of Eye Dryness (SPEED) questionnaire score > 6 and a total meibomian gland secretion (MGS) score ≥ 6 in each eye. Participants attended four visits: screening, 1-month, 3-month, and 6-month follow-up. The primary endpoint was MGS. Secondary endpoints included orifices plugging score (OPS) and SPEED scores. Exploratory endpoints comprised tear breakup time (TBUT) and corneal fluorescein staining (CFS). The effect of follow-up time on the study endpoints was evaluated by one-way repeated measures ANOVA.

Results: As of the latest follow-up, a total of 30 subjects (60 eyes), comprising 4 males and 26 females with a mean age of 36.77 ± 12.43 years, have completed the 6-month follow-up period. Following 6 months of a single treatment, MGS for both the upper ($F=95.112$, $P<0.001$) and lower ($F=72.432$, $P<0.001$) eyelids demonstrated marked enhancement. Similarly, OPS showed significant reductions for both the upper ($F=89.808$, $P<0.001$) and lower ($F=58.489$, $P<0.001$) eyelids. Additionally, SPEED scores ($F=8.163$, $P<0.001$), TBUT ($F=11.011$, $P<0.001$), and CFS ($F=4.499$, $P=0.013$) exhibited notable improvements.

Conclusions: The Systane iLUX treatment has demonstrated significant clinical efficacy over a 6-month period. The sustained benefits observed suggested Systane iLUX may offer long-term therapeutic advantages for managing MGD.

Abstract No.: 204399

Atypical Stevens–Johnson Syndrome Induced by Ornidazole

First Author: Aditi **BANSAL**

Co-Author(s): Shagun **KORLA**, Gian Chand **RAJPUT**, Sahildeep **SINGH**

Purpose: To report a rare case of Stevens–Johnson syndrome (SJS) with isolated ocular involvement after ornidazole intake, and to highlight the diagnostic and therapeutic role of ophthalmologists in such atypical presentations.

Methods: A 67-year-old female with epilepsy developed ocular and oral symptoms approximately one hour after ingesting ornidazole for acute diarrhea. She presented with bilateral swollen eyelids, photophobia, excessive lacrimation, pricking sensation, lips swelling and oral mucosal ulceration, without cutaneous manifestations. Best-corrected visual acuity was 3/60 in both eyes, with normal intraocular pressure. Examination revealed bilateral conjunctival hyperemia with chemosis and punctate keratitis, which rapidly progressed to a large epithelial defect within two days. Based on clinical features and medical history, a diagnosis of drug-induced SJS with mucosal and ocular involvement was made.

Results: The patient was managed with multimodal therapy including topical antibiotics, preservative-free lubricants, pad and patching, oral corticosteroids, and subsequently bandage contact lens application. Over two weeks, ocular surface healing was achieved with stabilization of visual acuity.

Conclusions: This case underscores that SJS may rarely present without skin involvement, making ophthalmic evaluation crucial for early diagnosis. Ornidazole, though uncommon, should be recognized as a potential trigger. Prompt recognition and intensive ocular management are essential to prevent vision-threatening complications in such atypical cases.

Abstract No.: 204481

Atypical Viral Epithelial Keratitis After Ophthalmic Surgery

First Author: Vijaylaxmi **B**

Co-Author(s): Vineeth **BHIMSHETTY**

Purpose: To report a series of three cases of herpetic epithelial keratitis occurring after cataract surgery, vitrectomy in patients with no prior history of viral keratitis

Methods: Three patients underwent uncomplicated phacoemulsification with intraocular lens implantation, and one patient underwent vitrectomy. Postoperative treatment included topical antibiotics, corticosteroids, nonsteroidal anti-inflammatory drugs (NSAIDs), and lubricating eye drops. Upon the appearance of corneal epithelial lesions, topical steroids were discontinued and treatment was initiated with topical ganciclovir and oral antiviral agents.

Results: The immediate postoperative period was uneventful in all cases. Corneal epithelial lesions suggestive of herpetic keratitis were noted approximately five to eight weeks after surgery. All lesions resolved with antiviral treatment

Conclusions: Herpetic epithelial keratitis can present atypically following intraocular surgery, even in patients without a prior history of the disease. Prompt recognition and antiviral treatment are critical to achieving a favorable outcome.

Abstract No.: 201250

Averting Perforation: Medical Management of Fungal Corneal Ulcer in a Low-Resource Setting

First Author: Clarissa **LISTER**

Co-Author(s): Fajri **IJRIAN**, Cindy Prajna **METTA**, Gede **PARDIANTO**, Kristo Hadi Audric **SUGIAMAN**

Purpose: This case report details the medical management of a severe fungal corneal ulcer with impending perforation, a condition that frequently leads to evisceration in low-resource settings. With limited diagnostic tools available, this case underscores

the critical role of clinical acumen, meticulous physical diagnostic, and persistent medical therapy in preserving the globe and visual function.

Methods: A 42-year-old male presented with a two-week history of severe right ocular pain, redness, and a visual acuity of 1/300. Slit-lamp examination revealed a central stromal infiltrate with feathery borders and corneal thinning, suggestive of neglected fungal corneal ulceration resistant to initial topical therapy. The patient's self-application of betel leaf extract worsened the condition, inducing hypopyon. Despite limited available diagnostic investigations and therapy selections, the patient was admitted for aggressive medical therapy of topical Natamycin 5%, systemic Ketoconazole, and systemic antibiotics (intravenous and oral), with the regimen adjusted weekly over two months.

Results: The patient's condition improved following the intensified medical therapy, averting a threatened perforation. The hypopyon and corneal ulcer resolved without surgical intervention, successfully saving the eyeball and preventing devastating complications including endophthalmitis. Uncorrected visual acuity improved to 1/60.

Conclusions: The high rate of evisceration for fungal corneal ulcer in developing countries, estimated at 8-11.5% in similar case series. This case demonstrates that early identification and aggressive medical management may be an alternative to surgical intervention, offering a replicable strategy to prevent globe loss and preserve visual function in resource-constrained environments.

Abstract No.: 200669

Beyond Conventional Therapy: Meropenem for Pseudomonas Keratitis

First Author: Adrian Jian Zhi CHIN

Co-Author(s): Nurul Fatin FADZULLAH SHUHAIMI

Purpose: To report on the usage of meropenem eye drops in multidrug-resistant *Pseudomonas aeruginosa* corneal ulcer and to highlight the importance of tailoring management according to the sensitivity.

Methods: A case report.

Results: The 62-year-old patient, with an underlying history of diabetes mellitus and end-stage kidney disease, was diagnosed with multidrug-resistant *Pseudomonas keratitis*. 2 weeks prior to presentation, he was admitted for MRSA-positive occipital carbuncle and diabetic foot ulcer. Readily available antimicrobial eyedrops were proven to be ineffective, which led to the usage of Gutt Meropenem 5%, which we tailored according to the sensitivity of the organism. The patient eventually developed endophthalmitis and scleritis, which we also treated him with IVT Meropenem, however, the patient ended up with evisceration of the affected eye.

Conclusions: Multidrug-resistant ophthalmic infections are difficult to treat as per our report. It is important to tailor the management early according to the sensitivity of the culture to prevent deterioration and poor visual prognosis which can negatively affect patients' well-being.

Abstract No.: 204819

Beyond The Cloudy Cornea: A Five-Year Clinical Profile of Corneal Endothelial Decompensation in Indonesia

First Author: Izza ZUKHRUFIA

Co-Author(s): Faraby MARTHA, Rio RHENDY, Syska WIDYAWATI, Jessica ZARWAN

Purpose: To describe the demographic, clinical characteristics, and treatment outcomes of patients with corneal endothelial decompensation at a national tertiary hospital in Indonesia.

Methods: A retrospective descriptive study was conducted using medical records of patients diagnosed with corneal endothelial decompensation and related disorders. We analyzed data on demographics, clinical presentation, etiology, and treatment. One-year graft survival rate was evaluated in eyes that underwent definitive surgical treatment (keratoplasty).

Results: A total of 318 patients' medical records (371 eyes) were included in the analysis. The mean age was 59.8 years, and 63% of the population was male. Pseudophakic bullous keratopathy (40.2%) was the most common clinical entity of endothelial decompensation, with prior intraocular surgery (57.9%) as the leading etiology. Over half (55.3%) of eyes were classified as blind at presentation. Keratoplasty was performed in 52 eyes (14%): 45 underwent penetrating keratoplasty (PKP), and seven underwent Descemet stripping endothelial keratoplasty (DSEK). Among 37 eyes with sufficient follow-up, the one-year graft survival rate was 54.8% for PKP and 83.3% for DSEK. Non-definitive surgeries were performed in 17% of eyes, mainly for intraocular lens-related problems.

Conclusions: History of prior intraocular surgery was the predominant cause of endothelial decompensation. Most cases presented with severe disease and blindness. While keratoplasty remains the definitive therapy, limited donor availability is a barrier. DSEK demonstrated superior short-term outcomes compared to PKP.

Abstract No.: 207429**Bilateral Corneal Perforation Following Post-PRK Fungal Keratitis Managed With Tenons Patch Graft***First Author: Somasheila MURTHY**Co-Author(s): Prajakta DANDEKAR, Suresh PALINISAMY*

Purpose: To report an unusual case of bilateral post-PRK corneal melt initially presumed as viral or immune-mediated keratitis, subsequently developed secondary fungal infection, and its successful management with bilateral Tenon's patch grafts.

Methods: Case report.

Results: A 22-year-old female underwent bilateral photorefractive keratectomy (PRK) for correction of low myopia. She developed bilateral central corneal melt three weeks post-operatively. There was no response to oral antivirals (for presumed necrotizing stromal keratitis) and oral steroids (for presumed immune-mediated melt). She gradually developed pigmented corneal infiltrates, and microbiology revealed fungal infection. Despite intensive antifungal therapy, she developed corneal perforations. She was referred for further management after applying tissue adhesive as a temporary measure. Bilateral Tenon's patch grafts (TPG) were performed, and the infection resolved with antifungal therapy. Three months later, her vision improved to 20/40, which was maintained even at one-year follow-up.

Conclusions: Bilateral corneal melt following PRK is rare. A high index of suspicion is required to identify microbial keratitis as a potential cause, especially since sterile infiltrates are also known post-PRK. Tenon's patch graft serves as an effective option in such a situation.

Abstract No.: 204421**Bilateral Peripheral Hypertrophic Subepithelial Corneal Degeneration Documented With Anterior Segment Optical Coherence Tomography***First Author: Law JIN XING**Co-Author(s): Syarifah Nur Humaira BINTI SYED MOHD KHOMSAH, Wan Nur Asyiah BINTI WAN AHMAD HAZIM*

Purpose: To describe a rare case of bilateral peripheral hypertrophic subepithelial corneal degeneration (PHSD) and highlight the role of anterior segment optical coherence tomography (AS-OCT) in diagnosis.

Methods: A 55-year-old woman with low myopia and a past history of treated pulmonary tuberculosis was reviewed during routine ocular follow-up. She reported no visual symptoms. Comprehensive ophthalmic examination and AS-OCT imaging were performed.

Results: Best-corrected visual acuity was 6/7.5 in both eyes. Slit-lamp examination revealed elevated

subepithelial opacities at the nasal and temporal corneal periphery bilaterally, with superficial corneal vascularization and a brown demarcation line resembling Stocker's line in the left eye. The anterior chamber was quiet, and fundus findings were normal. AS-OCT demonstrated dense hyperreflective subepithelial fibrotic layers with epithelial thickening and extension into the anterior stroma in both eyes, consistent with PHSD. Intraocular pressure was normal. The patient was managed conservatively with lubricants and scheduled for follow-up.

Conclusions: PHSD is an uncommon, often underrecognized corneal degeneration that may mimic other peripheral corneal disorders. Bilateral presentation is frequent but the condition itself is rare. AS-OCT provides valuable structural confirmation, aiding accurate diagnosis and preventing unnecessary interventions.

Abstract No.: 206299**Blinded by Numbness – From Neuralgia to Neurotropy***First Author: Aanchal SINGHAL**Co-Author(s): Shreya BHADANI, Matuli DAS, Siddhartha KAR, Srinidhi N, Shrutakirti PARIDA*

Purpose: To report a rare case of recalcitrant corneal ulcer developing after radiofrequency ablation for trigeminal neuralgia.

Methods: A 65-year-old hypertensive male presented with pain and decreased vision in the left eye (LE) for 15 days. Best-corrected visual acuity (BCVA) was 6/6, N6 in the right eye (RE) and counting fingers at ½ meter in the left eye (LE). He underwent radiofrequency ablation for trigeminal neuralgia 2 months earlier. On examination, RE showed grade 1 nuclear sclerosis. LE had circumcorneal congestion, corneal edema, inferior corneal ulcer, a dense 1–2 mm hypopyon, and grade 2 nuclear sclerosis. RE fundus was normal. B-Scan (LE) demonstrated a clear vitreous cavity with attached retina.

Results: The patient was started on vitamin A gel and lubricants. After two weeks, vision worsened to perception of light (PL+), hypopyon increased to 4–5 mm, the anterior chamber filled with exudates, and the corneal ulcer progressed. Clinically, it resembled a fungal corneal ulcer. Patient recalled a possible vegetative injury while working in fields 20 days back. Topical and oral antifungal therapy with cycloplegics was initiated. Anterior chamber paracentesis and intracameral voriconazole injection (0.1 ml) were performed, followed by bandage contact lens application. Final diagnosis of fungal corneal ulcer overlapping neurotrophic keratitis was made. At 2 weeks, BCVA improved to 4/60, hypopyon resolved, and symptoms markedly reduced.

Conclusions: Corneal sensory denervation following radiofrequency ablation for trigeminal neuralgia predisposes to impaired blink reflex and defective epithelial healing. Secondary infection in this setting acts as a “double-edged sword,” compounding the morbidity. Awareness among neurologists and ophthalmologists is critical to enable early recognition and prevention of sight-threatening sequelae.

Abstract No.: 201276

Blue Light Induces Corneal Epithelial Damage by Activating the NLRP3 Inflammasome Pathway

First Author: Jiayun GE

Co-Author(s): Ye SHEN, Jiaping TONG

Purpose: The rapid adoption of digital devices and LED lighting has led to increasing exposure to blue light (BL), raising concerns about its potential harmful effects on ocular health. However, the molecular mechanisms underlying BL-induced corneal damage remain insufficiently explored. This study investigates the role of the NLRP3 inflammasome in BL-induced corneal epithelial injury, aiming to identify potential therapeutic targets for preventing BL-associated ocular surface diseases.

Methods: Corneal injury was assessed through fluorescein staining, wound healing assays, and tear break-up time (TBUT). Cell viability, migration were assessed. Bioinformatic analysis identified NLRP3 as a key target of BL-induced damage. Pharmacological inhibition of NLRP3 was achieved using MCC950, and its effects were assessed in vitro and in vivo.

Results: In vivo, BL exposure resulted in significant corneal damage, as evidenced by increased fluorescein staining and a higher injury score. In vitro, HCECs exposed to BL exhibited time- and intensity-dependent dysfunction. Bioinformatic analysis identified 60 common differentially expressed genes related to corneal damage, wound healing delay, and BL exposure. NLRP3 was identified as a central mediator, and BL exposure significantly upregulated NLRP3 in both mouse corneas and HCECs. Pharmacological inhibition of NLRP3 alleviated BL-induced cellular damage. In vitro, MCC950 treatment restored HCEC viability, while reducing oxidative stress, ROS production, and mitochondrial dysfunction. In vivo, MCC950 treatment significantly reduced corneal epithelial injury, accelerated wound healing, and prolonged TBUT in BL-exposed mice.

Conclusions: These findings highlight the potential of targeting NLRP3 inflammasome as a therapeutic strategy for preventing and treating BL-associated corneal damage.

Abstract No.: 205138

Bowman's Layer Stromal Transplantation for Advanced Keratoconus - Our Five Years of Experience With 42 Cases

First Author: Madhu UDDARAJU

Co-Author(s): Shanthi PENMATSA

Purpose: To evaluate the efficacy of Bowman's layer transplantation in advanced keratoconus in evading a corneal transplantation.

Methods: Cases with advanced keratoconus not suitable for CXL and who were willing to avoid a transplant were enrolled in the study. After the donor cornea was mounted over an artificial chamber, a 100 micron incision was made with a guarded knife and dissected to get the Bowman's layer along with the anterior stroma with the help of lamellar dissectors, and then trephined to 7.5mm. This lenticule is then inserted into the recipient after creating a mid-stromal pocket with the help of manual lamellar dissection.

Results: The primary objective of disease stabilisation was achieved in all the cases, K Max decreased, ranging from 2D to 6D, over a period of 3 months, and HOAs decreased by 40-60%. BCVA improved with CL. We could avoid a PKP/DALK in all cases.

Conclusions: Bowman's layer stromal transplantation is a tissue sparing innovative procedure that can be safely tried in cases of advanced keratoconus not suitable for CXL in whom we want to avoid corneal transplantation

Abstract No.: 203855

Bowman's Membrane Transplantation in Progressive Keratoconus

First Author: Madhuvanthi MOHAN

Co-Author(s): Sujatha MOHAN

Purpose: To describe the clinical outcome of Bowman's membrane transplantation (BMT) in a young patient with advanced progressive keratoconus unsuitable for collagen cross-linking.

Methods: A 21-year-old female with advanced keratoconus presented with progressive visual decline and contact lens intolerance. Corneal topography revealed Kmax of 73D and thinnest pachymetry of 430 µm. Owing to lower corneal thickness and a mire central cone, we decided on Bowman's membrane transplantation. It was performed using a donor Bowman's layer and inserted into a mid-stromal pocket created with a manual dissection technique.

Results: The procedure was uneventful. Postoperatively at 1 week, Kmax showed a significant reduction and was 57.5D. The cornea remains stable, and the patient is still under follow-up. The patient reported a subjective reduction in visual distortion.

Conclusions: Bowman's membrane transplantation may offer a promising tissue-sparing option for young patients with advanced keratoconus.

Abstract No.: 205225

Breaking Ground: First Case of Conjunctivitis With Cowdry Type A Inclusion Bodies in Upper Tarsal Follicles After Herpes Zoster

First Author: Rakhi P DCRUZ

Purpose: To present the first reported case of conjunctivitis caused by herpes simplex virus manifesting after herpes zoster infection, marked by the unprecedented detection of Cowdry type B inclusion bodies in upper tarsal conjunctival follicles. This report aims to document the unique clinical presentation, diagnostic challenge, and multidisciplinary management.

Methods: A 41-year-old male with a history of left-sided herpes zoster 1 month back experienced persistent ocular discomfort, including foreign body sensation and large conjunctival follicles with gelatinous, pearly material on the upper tarsal conjunctiva. Initial treatment with lubricants, steroids, and antibiotics failed. Excision biopsy of the follicles was performed, followed by histopathological and immunological evaluation.

Results: The excised conjunctival follicles released multiple pearly cysts containing whitish fluid. Histopathology confirmed the presence of Cowdry type A inclusion bodies consistent with herpes simplex virus within these cysts, a finding not previously described in tarsal conjunctival follicles post-herpes zoster. The patient underwent systemic valacyclovir treatment after consulting an immunologist; combined with topical steroids & antivirals, and required surgical excision with adjunctive corticosteroid injections and cauterisation to base and betaine application to manage persistent lesions. Recurrences were managed successfully with repeated excision, cautery, and prolonged systemic antiviral therapy. Complete symptom resolution was achieved at 3 months follow-up. He is on follow up for past 1.5 yrs with no recurrences till date.

Conclusions: This first-of-its-kind case expands the spectrum of post-herpes zoster ocular complications and emphasizes the critical role of early histopathological confirmation, targeted systemic antiviral management, coordinated care with an immunologist, and combined surgical and medical treatment in recurrent follicular conjunctivitis

Abstract No.: 203923

Breaking the Cycle: Managing Recurrent Pterygium With the P.E.R.F.E.C.T Approach

First Author: Enzo SAPUANDI

Co-Author(s): Rio RHENDY

Purpose: To report a case of recurrent pterygium after multiple prior surgeries and evaluate the outcome of the P.E.R.F.E.C.T (Pterygium Extended Removal with Extended Conjunctival Transplantation) technique combined with conjunctival-limbal autograft (CLAU) and amniotic membrane transplantation (AMT).

Methods: A 31-year-old woman presented with recurrent pterygium in the left eye, complaining of persistent redness, tearing, and foreign body sensation. She had undergone four excision procedures between 2017 and 2023, including fibrovascular removal, conjunctival autografting, mitomycin C (MMC) application, and AMT. In September 2024, examination revealed recurrent pterygium with restrictive abduction. Surgical management consisted of the P.E.R.F.E.C.T technique with CLAU and multilayer AMT under general anaesthesia.

Results: The surgery achieved complete removal of fibrovascular tissue and stable placement of the conjunctival-limbal autograft and AMT. At early follow-up, the ocular surface was well covered without signs of fibrovascular regrowth. However, the patient developed transient blurred vision, pseudopterygium formation, and entropion, which were managed with intensive topical steroids, systemic anti-inflammatory therapy, and referral to oculoplastic services. Despite these complications, no recurrence of pterygium was observed during the initial postoperative period.

Conclusions: This case illustrates the complexity of managing recurrent pterygium in multiply operated eyes. The P.E.R.F.E.C.T technique combined with CLAU and AMT provided wide excision and stable ocular surface coverage, effectively preventing early recurrence. Nonetheless, secondary complications such as pseudopterygium and entropion highlight the importance of individualized surgical planning and long-term follow-up.

Abstract No.: 205723

Calotropis-Induced Corneal Decompensation: A Curse in the Desert

First Author: Lipi MITTAL

Co-Author(s): Sandeep CHOUDHARY, Mayank SHARMA

Purpose: To assess the spectrum of ocular toxicity of Calotropis Procera, complications, and management.

Methods: All prospective patients presenting to our centre with complaints of ocular exposure of latex of calotropis procera were included in this study. A total of 15 cases (13 males, 2 females) were studied.

Results: All of the patients were noted to have increased corneal thickness due to corneal oedema (766+92.1 microns) and decreased visual acuity (0.82+0.17). None of the patients was noted to have a corneal epithelial defect. A decrease in endothelial cell density (20.11+276.8 versus 2394+373.2, $p=0.0007$), increased coefficient of variation (34.9+5.9 versus 25.3+2.7, $p=0.00001$), and decreased hexagonality (46.2+4.1 versus 49.3+3.62, $p=0.001$) as compared to the fellow eye was noted. We treated the patients with frequent application of topical steroid eye drops, hyperosmotic agents, cycloplegic agents, and prophylactic antibiotics. All the patients had good visual outcomes with mean visual acuity improving from 0.82 to 0.17 ($p<0.05$).

Conclusions: Local application of Calotropis latex is known to cause an inflammatory response. Early recognition and timely treatment are key aspects of management.

Abstract No.: 206663

Case Report on Ophthalmologic Manifestations in Eczema Herpeticum

*First Author: Juan Paulo **RIEGO DE DIOS***

*Co-Author(s): Victor Ephraime **PAULINO***

Purpose: This is a case of eczema herpeticum that primarily affected the face and periorbital area of a patient. While there have been case studies about eczema herpeticum before, none have focused on the ophthalmological aspect.

Methods: The patient is a 31-year old Icelandic male with history of atopic dermatitis and bronchial asthma. He presented with a 4-day history of multiple, painful pruritic erythematous vesicles on the face, primarily on the eyelids. These lesions developed into punched out erosions on the periorbital area. Initial management included confirmatory tests, and treatment of intravenous acyclovir, topical antibiotics, oral antihistamine, supportive medication and cleaning of the affected areas.

Results: Physical examination showed multiple erythematous based vesicles, some leaving punched out erosions and dried hemorrhagic crusts on the face, mainly affecting bilateral eyelids, associated with bilateral periorbital swelling. There was also hyperemic conjunctivae, and matting and crusting of eyelashes. Visual acuity was 20/20 for both eyes. Complete blood count revealed normal results. Intravenous acyclovir was started prior to release of Tzanck smear results which eventually showed multinucleated cells which supports the diagnosis of eczema herpeticum.

Conclusions: In this patient, management was started early due to the high index of suspicion. Because of this, the patient improved promptly. In other cases where it is left undiagnosed and untreated, complications from eye HSV may cause blindness and in the worst cases,

death. This emphasizes the importance of considering eczema herpeticum as a differential in atopic patients presenting with periorbital dermatologic lesions.

Abstract No.: 207414

Case Series of Infectious Scleritis

*First Author: Apoorva **OJHA***

Purpose: We must keep the diagnosis of infectious scleritis in mind while seeing a case of any scleritis.

Methods: We have studied the causative organism and the visual outcome of 3 cases. We have ruled out autoimmune causes and biopsy if indicated. Out of three cases, 1 has a history of trauma. All patients had a good visual outcome, as they were treated on time. Two patients had nodules with discharge. Smear preparation is done with nodular scraping. One patient showed nodular-like thickening with a uveal show. All autoimmune causes were ruled out. Infectious disease expert opinion taken. All tests were negative. Bronchoalveolar lavage was positive for gene Xpert. Nodular scraping was done in the other two patients, as discharge was present.

Results: Culture reports showed Nocardia species in one case and Klebsiella pneumonia in another case. Patients were treated as per the culture sensitivity report. K. Pneumonia patient was given tablet ciprofloxacin. The patient showing growth with Nocardia species was given sulphamethoxazole and trimethoprim combination. Patient with gene xpert positive on BAL started on AKT. One patient was lost to follow-up, and another patient is posted for scleral patch grafting. Patient on AKT has improved symptoms.

Conclusions: In every case of scleritis, we must keep the differential diagnosis of infectious scleritis in mind. Nearly 50% of cases are due to an associated collagen vascular disease, and an infectious etiology is comparatively rare. Visual outcome is poor in infectious scleritis because of a delay in diagnosis. An organism can be virulent.

Abstract No.: 206009

Celastrol Nanomedicine Eye Drops Restore Redox Homeostasis and Prevent Keratoconus Progression via PI3K/AKT/AP-1 Signaling

*First Author: Ruixing **LIU***

*Co-Author(s): Xingchen **GENG**, Jingguo **LI**, Zhanrong **LI**, Ruojun **MA**, Nan **ZHANG**, Lei **ZHU***

Purpose: Keratoconus (KC) is a progressive corneal disease driven by oxidative stress, yet its molecular mechanisms are not fully elucidated, and effective drugs are unavailable. This study investigated the role of oxidative stress and the PI3K/AKT/AP-1 pathway in KC and evaluated the therapeutic potential of cationic polymeric nanomicelles loaded with celastrol (CPNM) to halt disease progression.

Methods: Human KC corneas underwent proteomic analysis, with key findings validated by immunohistochemistry and Western blot. An in vitro oxidative stress model was established using hydrogen peroxide-treated rabbit corneal stromal cells. CPNM was synthesized to improve corneal permeability and enable sustained drug release. A rabbit KC model was employed for in vivo studies, with outcomes assessed via slit-lamp exam, histology, pachymetry, corneal curvature, and biochemical assays. Pathway analysis and MMP activity were also examined.

Results: Proteomic and subsequent analyses of KC corneas revealed significant oxidative stress signatures, characterized by a pronounced Nox/Nrf-2 redox imbalance (elevated Nox-4/Nox-2 and suppressed Nrf-2) and activation of the PI3K/AKT/AP-1 signaling axis. In the rabbit KC model, CPNM treatment effectively attenuated corneal curvature progression, increased stromal thickness, and reduced ROS levels. Mechanistically, CPNM downregulated the PI3K/AKT/AP-1 pathway, restored Nox/Nrf-2 balance, and suppressed MMP activity in corneal tissues. In vitro experiments confirmed that CPNM suppressed ROS, rebalanced the Nox/Nrf-2 system, and inhibited PI3K/AKT/AP-1 activation.

Conclusions: CPNM effectively halts KC progression by simultaneously reducing oxidative stress via Nox/Nrf-2 rebalancing and suppressing ECM degradation through PI3K/AKT/AP-1 inhibition, representing a promising therapeutic strategy.

Abstract No.: 200563

Cell-Free Matrix Derived From Adipose Mesenchymal Stromal Cells Enhances Corneal Rehabilitation via Delivery of Nerve Regenerative PGRN

First Author: Dan **YAN**

Co-Author(s): Xuguang **SUN**

Purpose: Promotion of corneal dense network of nerves is a promising method to treat severe corneal injury, yet there are limited effective drugs. In our previous work, decellularized matrix of adipose-derived mesenchymal stromal cells (ADMSCs), named DMA, presented excellent conjunctival repair capacity with proper suture resistance and immune modulatory characteristics. Thus, we aimed to investigate the potential application of DMA in facilitating corneal repair after alkali burn.

Methods: We used DMA as novel ocular bandages with nutritious function due to its transparent characteristic. The study compared corneal recovery after treatment with DMA and amniotic membrane (AM) using fluorescein staining, slit-lamp examination, OCT, and corneal nerve immunostaining.

Results: Corneas treated with DMA showed accelerated recovery compared to those treated with

AM, as evidenced by fluorescein staining, slit-lamp examination, OCT, and corneal nerve immunostaining.

Conclusions: DMA is an effective treatment for corneal repair after alkali burn, promoting faster recovery than AM. Further investigation is needed to identify key components responsible for this enhanced recovery.

Abstract No.: 203062

Characteristics of Corneal Donors From Local Eye Bank Procurement in Jakarta, Indonesia

First Author: Lily Silva **ARDIANI**

Co-Author(s): Rommi **ADERIYANSAH**, Sharita Rosalyne **SIREGAR**

Purpose: To present demographics of corneal donors from local procurement at Jakarta Eye Bank, Indonesia.

Methods: This retrospective study was conducted from 2018 to 2025. Donor demographic data were collected. Corneal tissue grading, based on endothelial cell count (ECC), was performed using the EBAA standard. Spearman's correlation coefficient was used.

Results: A total of 35 patients (69 eyes) were included, with a mean age of 60.77 years (SD 18.98; range 10-94). The most common age group was >65 years (16, 45.7%), with a female preponderance (18, 51.4%). Cardiac arrest (13, 37.1%) was the leading cause of death, followed by cerebrovascular disease (10, 28.6%). Most retrievals were performed at funeral homes (25, 71.4%). Grade A (62, 89.9%) corneal tissues dominated our cohort, with a mean ECC of 2297.18 cells/mm² (SD 320.30; range 1418-2985). Penetrating keratoplasty (35, 50.7%) and DSAEK (23, 33.3%) were the most common surgeries, with a mean preservation-to-surgery time of 9.07 days (SD 2.9; range 1-14). There was a significant negative correlation between ECC grade and age ($R^2 = -0.250$, $P = 0.043$) and death-to-procurement time ($R^2 = -0.363$, $P = 0.003$). However, no significant correlation was found between ECC grade and gender ($R^2 = -0.004$, $P = 0.976$) or preservation-to-surgery time ($R^2 = -0.207$, $P = 0.116$).

Conclusions: Older age, female gender, and cardiac arrest were the most common donor profiles. Grade A corneal tissues were predominant, and penetrating keratoplasty was the most frequent surgery. Donor age influenced ECC grade; the older the donor, the lower the ECC grade. Death-to-procurement time also affected ECC grade; the longer the retrieval, the lower the ECC grade.

Abstract No.: 202949

Characteristics of Dry Eye Syndrome in Patients With Mild Graves' Ophthalmopathy

First Author: Thi Huong Giang BUI

Co-Author(s): Son BUI, Tung MAI, Quoc Anh NGUYEN, Dong PHAM, Van PHAM

Purpose: This study aimed to assess dry eye in patients with mild Graves' ophthalmopathy (GO) at the Vietnam National Eye Hospital.

Methods: This cross-sectional descriptive study evaluated dry eye syndrome in 40 eyes from 20 mild Graves' ophthalmopathy patients from January 2021 to December 2021 at the Vietnam National Eye Hospital. As an age-matched control group, 44 eyes of 22 adults without thyroid disease were selected. The Ocular Surface Disease Index (OSDI), tear break-up time (TBUT), Schirmer I tear test, and Corneal fluorescein staining (CFS) were assessed.

Results: The results showed that 65% dry eye in patients with mid GO disease was significantly higher, 3.98 times, compared to the control group (65% and 30%, $p < 0.001$, OR=3.98). The mean Schirmer I tear test score, TBUT score, CFS score, and OSDI score had a significant difference between GO and controls. Dry eye indices (TBUT, Schirmer I test, CFS) in mild GO patients were linearly correlated with proptosis, margin to reflex distance 1 (MRD1), and Clinical Activity Score (CAS). In the group of patients with active GO, the results of TBUT, Schirmer I test, CFS, and OSDI were statistically significantly higher than the inactive group ($p < 0.05$). Dry eye in the inflammatory group was 5.14 times higher than in the noninflammatory group (85.7% vs 53.8%, $p < 0.001$, OR = 5.14).

Conclusions: Dry eye syndrome was frequently damaged in patients with mild GO, 3.98 times higher than in the control group. Dry eye findings and the ocular surface damage in GO were severe in the group with active mild GO, 5.14 times higher than in the inactive group.

Abstract No.: 201192

Characteristics of Patients With Hay Fever Who Experience Symptom Exacerbation During PM2.5 and Yellow Dust Exposure: A Digital Cohort Study

First Author: Ken NAGINO

Co-Author(s): Atsuko EGUCHI, Takenori INOMATA, Akie MIDORIKAWA-INOMATA, Yuki MOROOKA, Shintaro NAKAO

Purpose: To investigate the characteristics of patients with hay fever who perceive symptom exacerbation during PM2.5 and yellow dust exposure.

Methods: Individuals with hay fever who used the smartphone application AllerSearch for hay fever research from February to May between 2018 and

2023 were enrolled. Participants reporting that their symptoms worsened during PM2.5 and yellow dust exposure were classified as the exacerbation group, while those reporting no worsening or being unsure were classified as the non-exacerbation group. Background factors, 9-item hay fever symptom scores, and 17-item Japanese Allergic Conjunctival Disease Quality of Life Questionnaire (JACQLQ) scores were compared using multiple regression analysis.

Results: A total of 368 individuals (mean age 40.6 years; 208 females [56.5%]) were classified into the exacerbation group, and 605 individuals (mean age 39.8 years; 276 females [45.6%]) into the non-exacerbation group. Compared with the non-exacerbation group, the exacerbation group had significantly higher proportions of females (regression coefficient 1.1, $P = 0.006$), psychiatric disorders (1.6, $P = 0.039$), atopic dermatitis (1.7, $P = 0.004$), and dry eye (1.4, $P = 0.004$). Regarding hay fever symptoms, the exacerbation group reported stronger nasal itching ($P = 0.033$) and ear/mouth itching ($P = 0.001$). JACQLQ scores were significantly higher in 9 of the 17 items, and the total JACQLQ score was significantly higher in the exacerbation group ($P = 0.016$).

Conclusions: Patients with hay fever who perceive symptom exacerbation during PM2.5 and yellow dust exposure present distinct characteristics, and such exacerbation appears to have a substantial negative impact on quality of life.

Abstract No.: 204991

Chronic Ambient Air Pollution and the Incidence of Blepharitis and Blepharoconjunctivitis: A Nationwide Population-Based Cohort Study

First Author: Yu-ling LIU

Co-Author(s): Cheng-hsien CHANG, Shu-han CHUANG

Purpose: To determine whether chronic exposure to ambient air pollutants increases the risk of blepharitis and blepharoconjunctivitis in a nationwide population.

Methods: We assembled a retrospective cohort of 552 965 adults (≥ 20 years) in Taiwan's National Health Insurance Research Database who were free of ocular surface disease at baseline and followed them from 2000 to 2013. Ten-year mean concentrations of sulfur dioxide (SO₂), carbon monoxide (CO), particulate matter $\leq 10 \mu\text{m}$ (PM₁₀) and $\leq 2.5 \mu\text{m}$ (PM_{2.5}), nitrogen oxides (NO_x), nitric oxide (NO), nitrogen dioxide (NO₂), total hydrocarbons, non-methane hydrocarbons, and methane (CH₄) were assigned by linking residential postcodes to 76 monitoring stations. Cox proportional-hazards models estimated hazard ratios (HRs) per 1-standard deviation (SD) increase, adjusting for demographics, socioeconomic status, smoking, comorbidities, ambient temperature, season, and short-term pollutant levels.

Results: Over 6.4 million person-years, 20,752 participants developed blepharitis/blepharoconjunctivitis. Kaplan–Meier curves demonstrated progressively higher cumulative incidence across increasing tertiles of 10-year pollutant exposure (log-rank $P < 0.001$). Adjusted HRs (per 1-SD) were: SO₂ 1.33, CO 1.98, PM₁₀ 1.76, PM_{2.5} 1.95, NO_x 1.72, NO 1.55, NO₂ 1.75, total hydrocarbons 1.90, non-methane hydrocarbons 1.34, and CH₄ 2.65 (all $P < 0.001$). Estimates were similar in sex-stratified analyses.

Conclusions: Decade-long exposure to multiple common air pollutants is independently associated with a 33 %–165 % increase in the risk of blepharitis and blepharoconjunctivitis. Reducing ambient pollution may help mitigate the population burden of ocular surface disease.

Abstract No.: 204674

Clinical Characteristics and Treatment Outcomes of Infectious Keratitis in Elderly Patients

First Author: Atitaya **ANAN**

Co-Author(s): Napaporn **TANANUVAT**

Purpose: To compare the clinical presentation, microbiological profiles, and treatment outcomes of infectious keratitis (IK) between elderly and adult patients, and to identify prognostic factors for visual outcomes.

Methods: This retrospective study analyzed 251 patients with IK (113 elderly, 138 adults) treated at a tertiary eye center in Northern Thailand from January 2021 to December 2023. Data collected included demographics, clinical features, microbiological findings, treatment modalities, and outcomes. Multivariable regression analysis was performed to identify prognostic factors associated with poor visual outcomes.

Results: Elderly patients (mean age 70.8 ± 7.0 years) presented with a significantly longer duration of symptoms (mean 20.3 vs. 14.6 days, $p = 0.07$) and worse initial visual acuity compared to adults (mean age 45.1 ± 11.6 years). Prior ocular surgery, topical steroid use, and systemic diseases were more common among the elderly ($p < 0.01$), whereas trauma and contact lens use were more prevalent among adults (all $p < 0.01$). Fungal keratitis was the most common pathogen in both groups. Elderly patients had a higher rate of treatment failure (67.0% vs. 52.8%, $p = 0.05$). Surgical interventions, including therapeutic penetrating keratoplasty (14.2% vs. 9.4%), were also more frequent in the elderly. Failed medical treatment and higher treatment costs independently predicted poor visual outcomes.

Conclusions: Elderly patients with IK present with more severe disease and have poorer outcomes than adults, with higher rates of treatment failure and

surgical intervention. Early identification of risk factors is essential for improving visual prognosis in this vulnerable population.

Abstract No.: 206645

Clinical Features of Infectious Corneal Ulcers

First Author: Yunanda Rizki Amalia **HARAHAP**

Co-Author(s): Marina Yusnita **ALBAR**

Purpose: Infectious corneal ulcer remains a significant cause of visual impairment, particularly in developing regions. Understanding its epidemiological characteristics, microbiological profiles, and treatment outcomes is crucial for improving management strategies. This study aims to analyze the clinical features, risk factors, and visual outcomes of corneal ulcer patients at Prof. Dr. CPL Universitas Sumatera Utara Hospital.

Methods: A retrospective observational study was conducted on patients diagnosed with infectious corneal ulcers at Prof. Dr. CPL Universitas Sumatera Utara Hospital from March 2023-January 2025. Patients' demographics, predisposing factors, microbiological findings, and visual acuity before and after treatment were collected and analyzed.

Results: A total of 29 cases were included, with a male predominance 82.7% and a mean age of 47.1 years. Eye pain was the most chief complaint in 26 patients 89.6%. Trauma was the leading predisposing factors and plant material as the most cause 37.9%. Microbiological analysis revealed positive gram coccus as the most frequently isolated pathogens 34.4%, followed by negative gram bacilli 31.0%, fungal elements 17.2% and no microbial growth 17.2% from Gram and KOH staining. Before treatment, 58.6% of patients had profound visual impairment or blindness (logMAR > 1.30), which decreased to 37.9% after treatment. However, a significant proportion still experienced residual visual impairment.

Conclusions: Infectious corneal ulcers predominantly affect middle-aged males, with ocular trauma associated with exposed to plant as a major risk factor. Despite medical interventions, a substantial proportion of patients retain visual impairment, highlighting the importance of preventive strategies such as protective eyewear and better public awareness.

Abstract No.: 204806

Clinical and Visual Outcomes of Manual Descemet Stripping Endothelial Keratoplasty: A Six-Year Retrospective Analysis

First Author: Anitha **VENUGOPAL**

Co-Author(s): Mangala **PERIASAMY**

Purpose: To evaluate visual and clinical outcomes of manual Descemet Stripping Endothelial keratoplasty (DSEK) in 183 eyes, including eyes with complex anterior segment status.

Methods: A retrospective analysis of 183 consecutive eyes undergoing manual DSEK/DSAEK was performed. Baseline demographics, lens status, surgical combinations, visual acuity (VA), IOP at serial follow-ups, and early and late complications were analyzed. Statistical comparisons were done using ANOVA with Tukey post-hoc testing.

Results: Mean age was 63.3 ± 13.4 years (range 11–95); 54.6% were female. The majority were pseudophakic (PCIOL 62.5%), with 25% having complex lens status (AC/Iris claw/SFIOL/aphakia). Isolated DSAEK was the most common surgery (74.9%). Pre-op VA was 1.33 ± 0.52 logMAR ($\sim 20/425$). A transient dip occurred on day 1 (1.53 logMAR), followed by progressive improvement to 0.84 ± 0.63 logMAR ($\sim 20/140$) at 12 months ($p < 0.001$). Mean pre-op IOP was 12.9 mmHg, with a significant day-1 spike (18.5 mmHg, $p < 0.001$) that normalized by day 7 and remained stable thereafter. Early postoperative complications were noted in 34.3%, most commonly air-bubble induced pupillary block (7.5%) and graft detachment/non-attachment (8%). Primary graft failure was 4.5%. About 34.9% developed late complications. Graft failure occurred in 12–13%, rejection in 10%, and secondary glaucoma in 6%. Interface haze/scarring (4%) and late infectious keratitis (2%) were uncommon. Overall, two-thirds of eyes remained complication-free both early and late.

Conclusions: Manual DSEK offers significant and sustained visual improvement, especially with a high proportion of complex anterior segments. While transient IOP spikes and graft-related events remain the main challenges, outcomes are comparable to automated EK series, underscoring the value of manual dissection in resource-limited settings.

Abstract No.: 207030

Cogan Syndrome in an 11-Year-Old Vietnamese Girl

First Author: Thao NGUYEN

Purpose: To report a case of Cogan syndrome in an 11-year-old Vietnamese girl.

Methods: Case report.

Results: Our patient, an 11-year-old girl, came for her first examination in July 2024 due to photophobia and red eyes. In November, she experienced episodes of prolonged fever and fatigue accompanied by red eyes, light sensitivity, and left-sided hearing loss, but all tests failed to identify the cause of the fever. The initial diagnosis was bilateral interstitial keratitis and fever of unknown origin. Upon reevaluating her symptoms, we diagnosed her with Cogan's syndrome. The patient was transferred to a Pediatric Hospital, where she received a pulse methylprednisolone in 3 days, followed by a tapering oral dose. After one month of treatment, the patient was afebrile, with partial hearing recovery;

however, permanent hearing loss remained in the left ear, requiring a hearing aid.

Conclusions: Cogan syndrome is a very rare disorder characterized by ocular involvement and sensorineural hearing loss, often accompanied by unexplained fever. Ocular symptoms may precede or occur simultaneously with systemic manifestations such as fever, requiring careful correlation of ocular and systemic findings to establish the final diagnosis.

Abstract No.: 202379

Combined Treatment by Customised Corneal Allogeneic Intrastromal Ring Segments (CAIRS) Followed by Accelerated Corneal Collagen Cross-Linking (CXL) for Advanced Keratoconus

First Author: Nikit SARWATE

Co-Author(s): Jayant SARWATE

Purpose: To evaluate the results of combined custom corneal allogeneic intrastromal ring segments (CAIRS) with corneal collagen cross-linking (CXL) in patients with advanced keratoconus.

Methods: A retrospective study of 12 eyes with advanced keratoconus that underwent customised CAIRS followed by CXL was included. Patients with $K_{max} > 50$ D and thinnest pachymetry of 390 microns at 5–7 mm zone on corneal topography were included. Uncorrected (UDVA) and best spectacle corrected (BSCDVA) distance visual acuity, flat keratometry (K1), steep keratometry (K2), maximum keratometry (Kmax), root mean square (RMS) of higher (HOA) order aberrations, vertical coma, and spherical aberration were also studied.

Results: Mean age was 26.55 years (Range 17–33 years). Mean BSCVA improved from 0.74 to 0.44 (logMAR) with $P < 0.001$ (Paired t Test), which was statistically significant. Mean Kmax significantly decreased from 61.77 to 56.6 D ($P = 0.0014$) postoperatively, which was statistically significant. Mean RMS of HOA, coma, and spherical aberrations also decreased significantly postoperatively ($P < 0.05$). The average follow-up duration was a minimum of 6 months up to 15 months. No intraoperative and postoperative complications were encountered. No patient complained of any glare or halos postoperatively. All patients showed better spectacle acceptance postoperatively.

Conclusions: Combined CAIRS with CXL can be used as a safe and effective treatment for advanced keratoconus. It helps in improving quantitative and qualitative vision as a better alternative to artificial intra-corneal ring segments (INTACS).

Abstract No.: 203682**Comparative Analysis of Intense Pulsed Light Therapy in Patients With Meibomian Gland Dysfunction, With and Without Glaucoma Medication***First Author: Jieun LEE**Co-Author(s): Kwang-eon HAN*

Purpose: This study assessed the efficacy of intense pulsed light (IPL) therapy for treating meibomian gland dysfunction (MGD), a key contributor to evaporative dry eye disease (DED), by comparing outcomes in patients with idiopathic MGD versus those with MGD induced by glaucoma medications.

Methods: In a retrospective analysis of 45 patients, divided into groups based on glaucoma medication use (20 patients) and non-use (25 patients), all underwent four IPL sessions combined with meibomian gland expression (MGX) at 3-week intervals. Key metrics evaluated included Ocular Surface Disease Index (OSDI) scores, tear breakup time (TBUT), Schirmer I test scores, and meibography scores, pre- and post-treatment.

Results: Significant improvements were observed in both groups across all parameters post-treatment, indicating enhanced tear film stability and meibomian gland function. The non-glaucoma group showed slightly greater improvements, suggesting the potential impact of glaucoma medications on MGD management.

Conclusions: These findings underscore IPL therapy's effectiveness in improving DED symptoms and meibomian gland function, highlighting its utility as a treatment option for patients with MGD, including those on glaucoma medications.

Abstract No.: 202348**Comparative Evaluation of Autologous Platelet-Rich Plasma and Artificial Tears for the Treatment of Chronic Evaporative Dry Eye: A Prospective Interventional Study***First Author: Pooja SINGH**Co-Author(s): J.I. GOYAL, Amarnath PANDEY, Divya SINGH*

Purpose: This study aimed at the comparative evaluation of the clinical outcomes of autologous PRP eye drop and artificial tear eye drop (AT) therapy in the treatment of chronic evaporative dry eye patients with moderate to severe symptoms.

Methods: One hundred patients with chronic evaporative moderate to severe DED in the 18 to 45 years age group were included. Patients were randomized into two groups (n = 50 each). One group received autologous PRP eye drops and the other AT drops. Outcome measures evaluated were subjective symptoms (OSDI) score, objective tear film

parameters (Oxford CFS score, TBUT and ST score, and BCVA (LogMAR, with improvement defined as gain of ≥ 1 line). Within the group and between the group, comparisons were done at the end of 6 months using paired and unpaired student's t-tests, respectively.

Results: Both the treatment groups (PRP and AT) showed significant improvement in OSDI and CFS scores, whereas TBUT and BCVA improved significantly only in the PRP group. No significant changes were observed in ST in either group. The post-treatment, between-the-groups analysis also favored PRP in all the parameters except ST. No significant adverse effect was noted throughout the study.

Conclusions: In chronic evaporative DED patients, autologous PRP showed significantly better clinical outcomes than AT and was found to be safe when given for a 6-month duration.

Abstract No.: 204864**Comparative Outcomes of CAIRS and INTACS in Keratoconus: A Consecutive Case Series***First Author: Madhuvanathi MOHAN**Co-Author(s): Sujatha MOHAN*

Purpose: To compare the short-term outcomes of Corneal Allogenic Intrastromal Ring Segments (CAIRS) and INTACS in keratoconus patients undergoing surgical management at a tertiary eye care center

Methods: A consecutive case series included patients undergoing CAIRS (n=12 eyes) and INTACS (n=8 eyes) between 2023–2024. Preoperative refraction and uncorrected distance visual acuity (UDVA) were recorded. Postoperative UDVA was assessed at 1 month and 3 months. Primary outcomes were the proportion of eyes achieving UDVA $\geq 6/12$ and mean reduction in cylinder. Safety was assessed by postoperative complications, including extrusion, infection, and visual loss.

Results: At 1 month, 58% of CAIRS eyes and 50% of INTACS eyes achieved UDVA $\geq 6/12$. By 3 months, this improved to 75% for CAIRS and 62% for INTACS. Mean cylinder reduction was -3D in the CAIRS group and -2.2D with INTACS. Both groups showed stable improvements in spherical equivalent and UDVA at 3 months. No sight-threatening complications were noted. Cosmetic outcomes were superior in CAIRS, while INTACS patients occasionally reported glare and halos.

Conclusions: Both CAIRS and INTACS significantly improved visual outcomes in keratoconus. CAIRS provided better cosmesis, while INTACS remained a safe synthetic option. These findings support CAIRS as a promising biological alternative to synthetic intrastromal ring segments

Abstract No.: 200795

Comparative Visual Outcomes After Refractive Laser Corneal Surgery vs Phakic IOL in Amblyopic Eyes

First Author: Bhupesh **SINGH**

Co-Author(s): Neha **BHARTI**

Purpose: To compare the outcomes of laser corneal surgery and phakic IOL surgery in adult amblyopic eyes.

Methods: Retrospective chart review of 688 amblyopic eyes of 950 patients who either underwent laser vision correction or phakic IOL for anisometropic amblyopia or suboptimal corrected distance visual acuity (CDVA). Postoperative uncorrected visual acuity (UCVA) was compared with preoperative best spectacle corrected visual acuity (BSCVA) individually for every patient.

Results: Group 1 includes 436 eyes, out of which 380 eyes underwent LASIK and 56 eyes underwent PRK. Group 2 includes 164 eyes which underwent phakic IOL implantation. No intraoperative complications were noted in any of the eyes. In group 1 postoperatively 2 eyes had DLK (Diffuse lamellar keratoplasty) 1 eye had macrostriae, 2 eye had microstriae.

Conclusions: Laser vision correction and phakic IOL surgery for amblyopic eyes showed better outcomes than glasses. Phakic IOL showed better visual outcomes than Laser corneal procedures for treating amblyopia in adults.

Abstract No.: 206420

Comparative Ocular Cytotoxicity of Polyethylene, Polyvinyl Chloride, and Polystyrene Microplastics in Human Corneal and Conjunctival Epithelium

First Author: Yujiao **JIN**

Co-Author(s): Woojin **KIM**, Ria **KANG**, Dong Hyun **KIM**, Junfeng **PIAO**, Jong Suk **SONG**

Purpose: Microplastics (MPs) are ubiquitous in air, water, and personal-care products and have been detected in human tear fluid, meibum, and aqueous humor, indicating ocular surface risk. Polymer-specific toxicity remains unclear. We compared polyethylene (PE), polyvinyl chloride (PVC), and polystyrene (PS) microplastics for toxic effects on corneal and conjunctival epithelium and explored mechanistic cues.

Methods: Human corneal epithelial cells (HCECs) and human conjunctival epithelial cells (HCjECs) were exposed to 50-nm PE, PVC, or PS. Endpoints included cell viability (WST-8); ELISA of supernatant TNF- α , IL-6, and IL-1 β ; and apoptosis measured by Annexin V-FITC/PI flow cytometry.

Results: PVC produced a marked loss of viability at lower concentrations, exceeding the reduction observed with PE or PS at higher test concentrations, indicating greater toxic potency. Under endpoint-specific assay conditions, PVC elicited the largest

increases in IL-6, IL-1 β , and TNF- α and yielded the highest apoptotic fractions. Across endpoints, HCECs responded more strongly than HCjECs, indicating more vulnerable to microplastic exposure.

Conclusions: Microplastic toxicity to ocular surface epithelium is polymer-dependent. PVC exhibits the greatest toxicity, and HCECs are more vulnerable than HCjECs. These comparative data support risk stratification of microplastics for ocular exposure and inform preventive strategies.

Abstract No.: 200851

Comparison of 25% Autologous Serum and 0.05% Cyclosporine A in Treating Severe Dry Eye Disease

First Author: Ming-hwei **TSAI**

Co-Author(s): Yi **WAN**

Purpose: To compare the efficacy of 25% autologous serum (AS) eye drops and 0.05% cyclosporine A ophthalmic emulsion (COE) in patients with severe dry eye disease (DED).

Methods: A retrospective study was conducted on 40 patients (80 eyes) with severe DED. Patients received either 25% autologous serum eight times daily or 0.05% cyclosporine A twice daily for 3 months. Clinical assessments included Ocular Surface Disease Index (OSDI), tear break-up time (TBUT), and Schirmer's test at baseline and months 1, 2, and 3.

Results: Both groups exhibited improved OSDI scores, with Group AS showing slightly greater symptomatic relief; however, no significant differences in OSDI were found between groups at 1, 2, and 3 months. Both groups demonstrated significant improvements in TBUT and Schirmer's test results over three months ($p < 0.001$). Slightly greater improvements in Schirmer scores and TBUT were observed in Group COE, though differences between groups were not statistically significant.

Conclusions: Both treatments are effective for severe DED. Autologous serum may provide better symptom relief, while cyclosporine A may improve tear parameters.

Abstract No.: 200693

Comparison of Systane iLUX With Warm Compress and Meibomian Gland Expression for the Treatment of Meibomian Gland Dysfunction Patients With Different Severities

First Author: Yuqian **WANG**

Co-Author(s): Jiandong **LI**, Zuguo **LIU**, Ying **WEN**, Yue **YUAN**

Purpose: To compare the clinical efficacy of Systane iLUX and meibomian gland warm compress massage in treating meibomian gland dysfunction (MGD) of different severity levels.

Methods: A multicenter, prospective, randomized controlled trial. Participants were randomly assigned in a 1:1 ratio to either the Systane iLUX treatment group (iLUX) or the meibomian gland warm compress massage group (MGX). Each group was further divided into two cohorts: mild-to-moderate and severe. Data were analyzed using a mixed-effects model.

Results: A total of 178 eyes from 89 MGD subjects were randomized to receive iLUX (n = 44) or MGX (n = 45). In mild-to-moderate MGD, at the 4th week, the lsmean (95%CI) change from baseline in the MGS score after treatment with the iLUX and MGX was -0.02 (-3.52 to 3.48) and -1.45 (-5.03 to 2.12), at the 12th week was 5.26 (1.76 to 8.76; P<0.001) and 4.07 (0.49 to 7.64; P<0.01). In severe MGD, at the 4th week, the lsmean (95%CI) change from baseline in the MGS score after treatment with the iLUX and MGX was 6.52 (2.82 to 10.23; P<0.001) and 5.35 (1.81 to 8.89; P<0.01), at the 12th week was 8.52 (4.82 to 12.23; P<0.001) and 8.26 (4.72 to 11.80; P<0.001).

Conclusions: The findings suggest that both Systane iLUX and MGX improve symptoms and signs in the treatment of MGD. Systane iLUX demonstrated comparable therapeutic efficacy to warm compress massage. Systane iLUX represents a valuable therapeutic option for managing meibomian gland dysfunction.

Abstract No.: 200504

Comprehensive Analysis of Corneal Endothelial Cell Mesenchymal Transition Mechanisms: Insights From Gene Expression and Raman Spectroscopy

First Author: Zhaoxiang LU

Co-Author(s): Yun FENG

Purpose: This study investigates the molecular mechanisms and dynamic processes of endothelial-mesenchymal transition (EndMT) in corneal endothelial cells (CECs), to provide insights into related disease pathogenesis and improve in vitro culture techniques.

Methods: Transcriptome sequencing identified differentially expressed genes during EndMT. Key markers were validated via qPCR, Western blot, and immunofluorescence. Time-series expression changes were analyzed at 0, 2, 12, and 24 hours. Raman spectroscopy was applied to detect biochemical alterations in cells undergoing EndMT.

Results: A total of 615 differentially expressed genes were identified, including 452 upregulated and 163 downregulated. Enriched pathways involved ECM regulation and PI3K-Akt signaling. Hub genes such as THBS1, ITGA5, COL1A1, and SNAI1/2 showed dynamic expression trends. Time-series clustering revealed six distinct expression patterns. Raman spectroscopy distinguished cell types and detected dynamic changes in lipids, RNA, and proteins.

Conclusions: This study elucidates key molecular and dynamic features of EndMT in CECs, offering novel perspectives for disease mechanism research and supporting the development of new diagnostic and culture strategies.

Abstract No.: 200393

Contact Lens-Related Pseudomonas aeruginosa Keratitis: Clinical and Microbiological Characteristics

First Author: Mai NGUYEN THI TRUC

Co-Author(s): Huong DUONG, Vinh LAM, Phuc NGUYEN, Huan PHAM, Huy TRAN

Purpose: To describe the clinical and microbiological features of Pseudomonas aeruginosa keratitis associated with contact lens wearing, and to evaluate the antibiotic susceptibility profiles of the isolates.

Methods: A retrospective study was conducted at the Cornea Department, Ho Chi Minh City Eye Hospital, between 2018 and 2023. Fifteen cases of contact lens-related Pseudomonas aeruginosa keratitis were analyzed.

Results: The mean age was 23.5 ± 4.7 years and total range was 17-33 years old. The majority of subjects were female (60.0%) and most of patients were student (60.0%). The proportion of patients wearing orthokeratology and soft contact lenses was 13.3% and 86.7%, respectively. Among soft contact lens wearers, the rate of patients used color or decorative lenses to change the appearance of the eyes was 4/13 (30.8%). Most patients had initial visual acuity (VA) under 3/60 (12 cases, 80.0%), which categorized as blindness according to the WHO classification. All of cases had central corneal stromal infiltration, 66.7% patients had hypopyon, and 33.3% cases were impending perforation. Regarding the outcome of treatment, 7/15 eyes (46.7%) required surgical intervention. Antibiotic susceptibility testing revealed high sensitivity (92.9–100%) to tobramycin, imipenem, levofloxacin, ciprofloxacin, ofloxacin, and ceftazidime. Sensitivity to moxifloxacin was 50%, while resistance to amoxicillin-clavulanate, cefuroxime, and cefotaxime was approximately 95.0%.

Conclusions: Contact lens-related Pseudomonas aeruginosa keratitis predominantly affects young adults and carries a high risk of severe vision loss. Early diagnosis and tailored antibiotic therapy based on susceptibility patterns are essential to optimize clinical outcomes.

Abstract No.: 206071

Corneal Atypical Fibroxanthoma in Xeroderma Pigmentosum

First Author: Jasmine RASHID

Co-Author(s): Siti Farhah 'adilah BASIRON, Liew On HEONG

Purpose: To report a rare case of corneal atypical fibroxanthoma (AFX) in xeroderma pigmentosum (XP) mimicking ocular surface squamous neoplasia (OSSN).

Methods: A case report.

Results: A 53-year-old lady with no known medical illness presented with progressive right eye (RE) blurring of vision for four weeks, which was accompanied by a rapidly enlarging corneal mass for two weeks. She reported longstanding hyperpigmented skin lesions since childhood, but was not on proper follow-up. General examination showed multiple hyperpigmented macules over her face, neck, trunk, and extremities. Ocular examination revealed RE visual acuity of counting fingers at 1 foot. On slit lamp examination, a 5 x 6 mm pink, fleshy, vascularised inferotemporal corneal lesion with surrounding corneal haziness. There is also the presence of deep corneal vascularisation and a feeder vessel. She was referred to dermatology for her skin lesions and was diagnosed with XP. The corneal lesion appeared suspicious for OSSN. Excisional biopsy of the corneal lesion was performed, and histopathological analysis revealed atypical fibroxanthoma. The patient was advised to use sun protection in addition to regular ophthalmology follow-up to monitor for recurrence of the corneal mass. At her most recent visit, the best corrected visual acuity was 6/60, with evidence of recurrence, and she is planned for excision of the mass with penetrating keratoplasty.

Conclusions: This case highlights the importance of considering unusual mesenchymal neoplasms in the differential diagnosis of corneal masses and underscores the need for histopathological confirmation, vigilant follow-up, and strict photoprotection to reduce recurrence risk and preserve vision.

Abstract No.: 201098

Corneal Thickness and Endothelial Cell Morphology in the Mongolian Population: A Cross-sectional Study

First Author: Bayarmaa KHUYAG

Co-Author(s): Uranchimeg DUGARSUREN, Batzaya DUGARSUREN, Bayarmagnai LKHAGVASUREN, Bayasgalan PUREVDORJ

Purpose: To evaluate corneal thickness and endothelial cell morphology in healthy Mongolian adults.

Methods: A cross-sectional study was conducted involving 240 healthy adults (480 eyes), aged 20–79

years, selected through simple random sampling. All participants underwent comprehensive ophthalmic examinations. Corneal thickness (CT), endothelial cell density (ECD), average cell area, coefficient of variation (CV), and percentage of hexagonal cells (HEX) were assessed in the central, paracentral, and peripheral corneal regions using non-contact specular microscopy.

Results: The mean participant age was 47.2 ± 14.8 years; 51.7% were female. Mean ECD was 2855.95 ± 282.49 cells/mm², CCT was 524.21 ± 32.71 μm, average cell area was 334.12 ± 37.86 μm², HEX was $64.82 \pm 3.87\%$, and CV was 0.31 ± 0.04 . Age was significantly associated with lower ECD and HEX, and higher cell area and CV ($p = 0.0001$). No significant differences were observed between sexes or between eyes. The estimated annual ECD loss was 0.3% ($r = 0.2107$, $p < 0.0001$). Paracentral and peripheral ECD values were 4.02% ($p < 0.05$) and 8.71% ($p < 0.01$) higher than central ECD, respectively.

Conclusions: This study provides the first normative data on corneal endothelial parameters in a Mongolian population. The mean ECD was lower than values reported in Japanese and Chinese populations, while higher than those in Nigerian, Thai, and Iranian populations. These findings highlight ethnic and regional differences in corneal morphology and may inform clinical decision-making in anterior segment surgery.

Abstract No.: 205670

Corneal Transplantation Strategies for Acanthamoeba Keratitis: A Systematic Review and Meta-Analysis

First Author: Shangyang JIANG

Co-Author(s): Qingfeng LIANG, Leying WANG

Purpose: To evaluate the optimal surgical approach and timing for keratoplasty in Acanthamoeba keratitis (AK) to guide clinical decision-making.

Methods: A comprehensive search was conducted in PubMed, EMBASE, Web of Science, and the Cochrane Library. Clinical studies reporting outcomes of at least five AK cases treated with keratoplasty were included. Primary outcomes were best-corrected visual acuity (BCVA), graft survival, recurrence, regraft rate, and postoperative complications. Meta-analysis compared therapeutic penetrating keratoplasty (TPK), optical penetrating keratoplasty (OPK), and therapeutic deep anterior lamellar keratoplasty (TDALK). The optimal interval for TPK and ideal lesion size for TDALK were identified. (PROSPERO ID: CRD420251147226).

Results: 24 studies involving 487 eyes were included. OPK demonstrated the best visual outcomes with the lowest recurrence and regraft rates. TDALK showed superior graft survival and fewer postoperative complications. In contrast, TPK yielded poorer visual outcomes, higher rates of graft failure, recurrence

and regrant, and more complications. The optimal interval for TPK was identified as 3.6 to 5.2 months after disease onset. Additionally, TDALK yielded better results when the lesion size was < 8 mm. Meta-analysis also revealed that OPK was associated with better prognosis than TPK.

Conclusions: In the visual rehabilitation of AK controlled with medical therapy, OPK is recommended. Conversely, when medical therapy fails, timely surgical intervention with TDALK or TPK is required. TPK within the optimal interval appears to be associated with improved outcomes.

Abstract No.: 204666

Crystalline Clues: Unveiling Plant Sap as a Rare Cause of Inflammatory Keratopathy

First Author: Reiner **MOLDEZ**

Co-Author(s): Sharlene **NOGUERA**

Purpose: To report the first documented case of Alocasia macrorrhiza plant sap-induced inflammatory crystalline keratopathy in our country, which was successfully managed with Levofloxacin, Dexamethasone, and Sodium Hyaluronate eye drops.

Methods: We present the case report of a 53-year-old male construction worker who presented with acute ocular symptoms following accidental exposure to Alocasia macrorrhiza plant sap. The patient reported sudden onset of redness, foreign body sensation, and blurred vision in the left eye. On slit-lamp biomicroscopy, conjunctival hyperemia, diffuse punctate epithelial erosions, and multiple fine, refractile, pin-like crystalline deposits were observed within the corneal stroma. Anterior segment optical coherence tomography (OCT) of the left eye revealed hyperreflective pin-like lesions corresponding to the crystalline deposits noted clinically. Based on these characteristic clinical findings, a diagnosis of Alocasia macrorrhiza plant sap-induced inflammatory crystalline keratopathy was established.

Results: The patient was managed conservatively with topical Levofloxacin 0.5% eye drops, later shifted to Levofloxacin-Dexamethasone combination, along with supportive therapy using Sodium Hyaluronate 0.15% lubricating drops. Progressive clinical improvement was observed over the following three weeks, with complete resolution of both symptoms and ocular findings documented at the three-month follow-up.

Conclusions: This case highlights the potential for plant sap to induce toxic and crystalline-like corneal changes, underscoring the importance of early recognition and supportive management to prevent long-term visual sequelae.

Abstract No.: 203730

Cyclic Guanosine Monophosphate-Adenosine Monophosphate Synthetase (cGAS)/Stimulator of Interferon Genes (STING) Signaling Aggravated Corneal Allograft Rejection Through Neutrophil Extracellular Traps (NETs)

First Author: Xiaolin **QI**

Purpose: The activation of innate immunity following transplantation has been identified as a crucial factor in allograft inflammation and rejection. However, the role of cyclic guanosine monophosphate-adenosine monophosphate synthase (cGAS)/stimulator of interferon genes (STING) signaling-mediated innate immunity in the pathogenesis of allograft rejection remains unclear.

Methods: Utilizing a well-established murine model of corneal transplantation, recipient mice were subconjunctivally injected with a cGAS inhibitor on postoperative days. Topical administration of specific cGAS small-interfering RNA and negative control siRNA before corneal transplantation and on postoperative days were performed to assess corneal transplantation rejection.

Results: Increased expression of cGAS and STING in rejected-corneal allografts compared with syngeneic (Syn) and normal (Nor) corneas, along with significant activation of the cGAS/STING pathway, as evidenced by the enhanced phosphorylation of TANK-binding kinase 1 and interferon regulatory factor 3. Pharmacological and genetic inhibition of cGAS/STING signaling markedly delayed corneal transplantation rejection, resulting in prolonged survival time and reduced inflammatory infiltration. Furthermore, we observed an increase in the formation of neutrophil extracellular traps (NETs) in rejected allografts, and the inhibition of NET formation through targeting peptidylarginine deiminase 4 and DNase I treatment significantly alleviated immune rejection and reduced cGAS/STING signaling activity. Conversely, subconjunctival injection of NETs accelerated corneal transplantation rejection and enhanced the activation of the cGAS/STING pathway.

Conclusions: NETs contribute to the exacerbation of allograft rejection via cGAS/STING signaling, highlighting the targeting of the NETs/cGAS/STING signaling pathway as a potential strategy for prolonging allograft survival.

Abstract No.: 202143

Decoding Refractive Neutralization With Concurrent Excimer Laser Ablation in Eyes With Anterior Corneal Opacities

First Author: Amrin Fatema Afzal Hussain **NAYANI**

Purpose: To evaluate visual and refractive outcomes after refractive neutralization with concurrent excimer laser ablation for anterior corneal opacities.

Methods: This was a prospective, cross-sectional observational study conducted at a tertiary eye care centre in northern India. Preoperative patient selection and evaluation are done for systemic diseases as well as for assessment of the depth and size of stromal involvement. Detailed ophthalmological evaluation is done to evaluate the depth and amount of stromal involvement by Anterior segment OCT and epithelial thickness mapping. Topographical evaluation was done for refractive planning. Per-operative refractive error and BCVA were diligently evaluated. Excimer laser ablation was done to ablate the diseased Stromal ablation as per standard protocols with residual bed thickness >300 μm . A customized algorithm was planned for each patient. Post-operative evaluation and visual rehabilitation are done with routine follow-up.

Results: Statistical evaluation was done by SPSS 23.0 software. Mean improvement in visual acuity was calculated for all participants. BCVA was >6/12 for all patients.

Conclusions: refractive neutralization with PTK can aid in faster visual rehabilitation with better patient satisfaction. Although anterior stromal diseases are amenable to PTK, the visual outcomes are often understated.

Abstract No.: 200806

Detection of Biofilms in Contact Lens Cases of Affected and Fellow Eyes in Acanthamoeba Keratitis

First Author: Yuichi **KAJI**

Co-Author(s): Hiroyasu **KAJI**, Tetsuro **OSHIKA**

Purpose: The most significant risk factor for Acanthamoeba keratitis is inadequate contact lens care. We investigated the presence of biofilm and Acanthamoeba in contact lens cases used for both the affected and fellow eyes in patients with Acanthamoeba keratitis.

Methods: From 2023 to 2025, lens cases were collected from 7 patients (7 eyes) diagnosed with Acanthamoeba keratitis. Biofilm was detected using brilliant blue staining, and cultures were performed on proteose-yeast-glucose agar plates. Lens cases from asymptomatic contact lens users (n=10) served as controls.

Results: In all 7 patients diagnosed with Acanthamoeba keratitis (1 case using hard contact lenses, 6 cases using biweekly replacement soft contact lenses), biofilm was observed on the lens cases for both the affected and fellow eyes. Acanthamoeba was detected within the biofilm. In contrast, in the control group, slight biofilm was observed in only one case, and Acanthamoeba was not detected.

Conclusions: Our findings indicate that the development of Acanthamoeba keratitis is associated with the presence of biofilm containing Acanthamoeba in lens cases, resulting from inadequate lens case care. The presence of biofilm in the cases for both the affected and fellow eyes suggests that these patients are likely engaged in improper daily lens care.

Abstract No.: 207728

Determining Levels of Microbial Contamination of Multi-User Preserved Ophthalmic Drops at an Out-Patient Clinic in a Tertiary Government Hospital in the Philippines

First Author: Nexie **LIBRE**

Co-Author(s): Ricardo Tobias **PAPA**, Raymond Nelson **REGALADO**

Purpose: The study aimed to determine the microbial contamination of multi-user preserved ophthalmic drops (POD) used in the Ophthalmology Outpatient Department (OPD) in a tertiary-level hospital in the Philippines.

Methods: This study used an experimental, in-vitro study design, with a sampling size of 104 multi-user POD, conducted at the OPD clinic of a Tertiary Level Hospital. Each bottle's dropper tip and residual contents were aseptically swabbed at four intervals—opening (T0), day 3 (T3), day 14 (T14), and day 30 (T30)—with five replicates per timepoint. The inclusion criteria included recently opened POD bottles, while exclusion criteria included POD bottles with broken seals on new bottles, and bottles with missing caps or tips on the day of collection, and control bottles that exhibit contamination during the initial T0 assessment. Samples were then cultured on blood, chocolate, MacConkey, and Sabouraud agar plates and incubated at 37 °C in 5% CO₂ for seven days. Positive cultures would undergo Gram stain and biochemical identification. The Statistical Package for the Social Sciences version 29 was used to analyze contamination prevalence and tip versus contents comparison.

Results: Following our sampling protocol and culture methods, the study showed that out of 104 samples, no contamination was detected across the duration of their usage in the OPD clinic.

Conclusions: This outcome supports the efficacy of the institution's handling and aseptic protocols. It also shows the effectiveness of preservatives, and proper

hygiene in significantly decreasing the contamination rates in multi-user preserved ophthalmic drops.

Abstract No.: 203952

Devastating Complication of Bilateral Simultaneous Cataract Surgery—Reactivation of Peripheral Ulcerative Keratitis With Secondary Infection

First Author: Abhishek KUMAR

Co-Author(s): Pranita SAHAY, Saloni UNE

Purpose: To present a rare case of peripheral ulcerative keratitis with secondary polymicrobial infection after cataract surgery.

Methods: A 60-year-old female presented to the clinic with complaint of sudden onset painful diminution of vision in both eyes for 2 weeks associated with redness, pain, and photophobia, left more than right eye. Symptoms started after a week post simultaneous cataract surgery (phacoemulsification). On systemic examination, patient had no systemic illness. On ocular examination, BCVA in RE was 6/60 and LE was 2/60; intraocular pressure was within normal limits. On slit lamp examination, both eyes revealed crescentic juxtalimbal ulcers with infiltrates, 6 clock hours in the left and 4 clock hours in OD with circumcorneal congestion.

Results: Corneal scraping was done elsewhere, which revealed gram-negative bacilli and yeast (Candida), and the patient was started on fortified amphotericin B and polymyxin B with cycloplegic and antiglaucoma agents. USG B Scan was anechoic in both eyes; infiltrates were decreasing, and surrounding edema was resolving within a week; however, progressive thinning was persisting on ASOCT, and the epithelial defect was healing. ANA, ANCA, and RA factor were negative; CRP and ESR were raised. Systemic and low-potency topical steroids were added to stop the progression. Final BCVA was 6/18 in the right eye and 5/60 in the left eye.

Conclusions: Peripheral ulcerative keratitis reactivation is rare after phacoemulsification. However, SICS/ECCE can be planned with the incision site away from the scar with a rheumatologist's opinion for immunosuppression if required.

Abstract No.: 205160

Development of a Digital Platform for Dry Eye Management: Survey-Based Design of a Prototype in South Korea

First Author: Se Hyun CHOI

Co-Author(s): Daejoon HWANG

Purpose: Dry eye disease (DED) is a multifactorial condition requiring complex diagnostics, yet time constraints often limit comprehensive evaluation in clinical practice. This study aimed to assess the unmet needs of patients and ophthalmologists regarding DED

management and to develop a mobile application supporting input and interpretation of diagnostic data.

Methods: A cross-sectional survey was conducted among 55 patients diagnosed with DED and 44 ophthalmologists across South Korea. The survey evaluated preferences for mobile platforms, commonly used diagnostic tools, and interest in an application-based management system. Based on the responses, a prototype Android application was developed incorporating user input for OSDI, Schirmer test, and tear breakup time (BUT), allowing interpretation of results and longitudinal tracking.

Results: Most respondents preferred Android OS (patients: 74.5%; ophthalmologists: 54.5%). Interest in the app was high among both groups (patients: 98.2%; ophthalmologists: 70.5%). Among patients, the most requested features were MMP-9 (50.9%) and Schirmer test (41.8%), while ophthalmologists prioritized OSDI (90.6%) and BUT (87.5%). Time limitations were a barrier to performing diagnostics: 50% of clinicians used OSDI in less than 10% of new patients, and 31.8% reported inadequate testing in over half of consultations. Over 80% of ophthalmologists indicated they would use an app supporting OSDI entry. The resulting prototype includes modules for OSDI, Schirmer, and BUT input with automated interpretation.

Conclusions: Survey data confirm high demand for a digital DED management tool among patients and clinicians. The developed Android prototype supports standardized diagnostic input and interpretation, and may help improve real-world DED care in time-constrained settings.

Abstract No.: 202255

Development of a Translational Platform for Corneal Tissue Culture, Biobanking, and Exosome Therapeutics

First Author: Shih-chung LAI

Co-Author(s): Wei Chen (eric) LAI, Keng-liang OU

Purpose: To isolate and culture limbal stem cells from corneal donor specimens and define key factors influencing tissue viability and utilization. This work seeks to establish an integrated research platform encompassing corneal tissue procurement, primary cell culture, biobanking, and exosome-based applications, with the ultimate goal of advancing translational strategies in regenerative ophthalmology.

Methods: Twenty research-designated corneal donor specimens were processed for limbal stem cell isolation and culture. Culture outcomes were assessed in relation to donor age and preservation time, with success defined as establishment of viable primary cultures.

Results: The overall success rate of primary limbal stem cell culture was 60%. Higher viability and growth

potential were observed in cultures derived from donors younger than 50 years and when retrieval was initiated within 21 days post-donation. In contrast, advanced donor age and extended storage times were significantly associated with culture failure. These findings identify donor age and preservation duration as critical determinants of corneal culture viability.

Conclusions: This study demonstrates the feasibility of establishing a clinical-grade corneal cell bank as a foundation for future regenerative applications. Ongoing work will expand specimen collection and evaluate cornea-derived exosomes as therapeutic candidates in preclinical models of ocular surface disease, including dry eye syndrome and limbal stem cell deficiency. By integrating corneal cell banking with exosome-based therapies, this platform represents a key step toward translational strategies to restore ocular surface integrity and vision.

Abstract No.: 206563

Diagnostic Challenge of Adult Onset Shield Ulcer Secondary to Atopic Keratoconjunctivitis: A Case Report

First Author: Lisa Yik Lin **LING**

Co-Author(s): Edwin Chin Meng **PHENG**

Purpose: We report a case of adult onset shield ulcer secondary to atopic keratoconjunctivitis that demonstrate significant improvement following administration of anti-inflammatory agent.

Methods: Case report

Results: A 30-year-old gentleman presented with 1 month history of right eye blurry vision, watery discharge and a central whitish spot. He had a past medical history of bronchial asthma and atopic dermatitis. Slit lamp examination revealed central corneal thinning with marked corneal vascularisation and paracentral infiltrates. Blepharitis was observed on lids examination. Scarring was noted over the palpebral conjunctiva with associated yellowish discharge. Right eye corneal scrapping was taken and sent for culture, yielding no microbial growth. He was first treated with oral and topical antibiotics. Olopatadine and steroid eyedrops were initiated following the release of formal culture report. Corneal debridement was also performed. His shield ulcer healed with improvement of the corneal inflammation and scar formation. Adult onset of shield ulcer is rare, leading to a diagnostic challenge in this case.

Conclusions: This case highlights the importance of a prompt diagnosis of adult onset shield ulcer which enables timely treatment to prevent further complications such as infective keratitis, which can be devastating.

Abstract No.: 201575

Does Gut Surgery Affect Dry Eye? A 17-Year Nationwide Cohort Study

First Author: Se Hyun **CHOI**

Co-Author(s): Dae Myoung **YOO**

Purpose: Recent studies suggest gut microbiota influence dry eye disease (DED) via the gut-eye axis. We investigated whether major gastrointestinal surgeries—gastrectomy or colectomy—alter long-term DED risk, using a nationwide cohort.

Methods: This retrospective cohort study used Korea's National Health Insurance Service–Sample Cohort (2002–2019). Patients undergoing gastrectomy (n=2,346) or colectomy (n=3,086) were 1:4 matched with controls. DED was defined by diagnostic and treatment codes. Propensity score overlap weighting and Cox regression estimated adjusted hazard ratios (HRs).

Results: Gastrectomy was associated with increased DED risk (HR: 1.09; 95% CI: 1.02–1.16), especially total gastrectomy (HR: 1.40). Subtotal gastrectomy showed reduced risk (HR: 0.90). Colectomy showed no significant association.

Conclusions: Gastrectomy may elevate DED risk through gut microbiome disruption, supporting gut-eye axis mechanisms. Monitoring ocular surface health post-gastrectomy is warranted.

Abstract No.: 201452

Doughnut Refractive Lenticule Transplantation for Advanced Keratoconus: Visual, Tomographic, and Biomechanical Outcomes in a Prospective Study

First Author: Zaman **SHAH**

Purpose: To evaluate the clinical efficacy, safety, and biomechanical effects of Doughnut Refractive Lenticule Transplantation (DRLT) in patients with advanced keratoconus over 16 months.

Methods: This prospective interventional study included 41 eyes of 40 patients (ages 11–32) with advanced keratoconus. Donor stromal lenticules from SMILE (−6.00 to −10.00 D) were fashioned into doughnut-shaped grafts and implanted into femtosecond laser-created stromal pockets. Patients were followed for 16 months with assessments including DCVA, corneal tomography, and AS-OCT. Outcomes included keratometry, topographic astigmatism, pachymetry, corneal volume, Q value, and biomechanical parameters (ARTmax, PPI). Statistical analysis used paired t tests or Wilcoxon signed-rank tests, with significance at $p < 0.05$.

Results: DCVA improved from logMAR 1.00 ± 0.20 to 0.30 ± 0.15 ($p < 0.001$), with 30% achieving logMAR 0.18 or better. Mean K1 decreased from 52.19 ± 5.38 D to 50.98 ± 5.62 D, K2 from 60.46 ± 6.27 D to 55.29 ± 6.19

D ($p=0.0021$), and Kmax from 70.07 ± 9.72 D to 62.90 ± 7.76 D ($p<0.001$). Topographic astigmatism reduced from 8.27 ± 3.50 D to 4.81 ± 2.55 D ($p<0.001$). Thinnest corneal thickness increased from 410.33 ± 39.23 μ m to 443.33 ± 80.68 μ m. Posterior keratometry decreased significantly, and the Belin ABCD staging showed marked improvement (D value from 31.00 ± 4.51 to 14.52 ± 2.05 ; $p<0.0001$). Pachymetric indices and CTSP improved, while ARTmax decreased, reflecting biomechanical stabilization.

Conclusions: DRLT is a safe and effective option for advanced keratoconus, offering sustained visual, thickness, and biomechanical improvements.

Abstract No.: 206113

Duration-Dependent Ocular Surface and Systemic Changes Following Carbon Black Exposure: An In Vivo Rat Model

First Author: Woojin **KIM**

Co-Author(s): Yujiao **JIN**, Boram **KANG**, Junfeng **PIAO**, Jong Suk **SONG**

Purpose: The effects of carbon black (CB), a particulate pollutant, on ocular and systemic health remain poorly characterized. This study evaluated duration-dependent ocular surface damage and systemic immune responses following topical CB exposure in rats.

Methods: Male Sprague-Dawley rats (6 weeks, 250–300 g) received topical CB (Printex 35, 20 mg/mL, 10 μ L) into the right eye three times daily. Cohorts were exposed for 1 day, 5 days, or 4 weeks, with controls. Ocular surface changes were assessed by rose bengal, corneal fluorescein staining and conjunctival hyperemia scoring. Tears were collected under anesthesia to measure LDH, MMP-9, histamine, lactoferrin, and VEGF. At endpoint, blood was collected for IgE and IgG. Lacrimal glands were examined for LDH, MMP-9, histamine, lactoferrin, VEGF, and SIRT1, and the cornea and conjunctiva for IFN- γ , VEGF, MMP-9, SIRT1, and IL-4.

Results: CB exposure induced progressive ocular and systemic changes. Rose bengal, corneal fluorescein staining, and conjunctival hyperemia increased with duration, indicating cumulative epithelial injury. Tears and lacrimal glands showed increased LDH, MMP-9, and histamine, while SIRT1 declined significantly in lacrimal glands at 4 weeks, suggesting aging-like dysfunction. In ocular tissues, IFN- γ , VEGF, MMP-9, and IL-4 increased after exposure, whereas SIRT1 decreased. Serum IgE increased progressively, whereas IgG rose transiently then declined, indicating a Th2-skewed immune imbalance.

Conclusions: Topical CB exposure induced duration-dependent ocular surface damage, inflammatory activation, and lacrimal dysfunction. Findings included elevated pro-inflammatory mediators and a Th2-

skewed systemic response. Overall, chronic CB exposure leads to ocular injury, immune dysregulation, and aging-like lacrimal changes, underscoring public health relevance.

Abstract No.: 202094

Effect of Artificial Tear Therapy on Best-Corrected Visual Acuity in Patients With Aqueous-Deficient Dry Eye

First Author: Rastri **PARAMITA**

Co-Author(s): Fitri **RAHMANTIKA**, Atika **YASMIN**

Purpose: To evaluate the effect of artificial tear therapy on best-corrected visual acuity (BCVA) in patients with aqueous-deficient dry eye (ADDE).

Methods: A prospective, single-arm, pre-post intervention study was conducted involving 17 patients (aged >18 years) diagnosed with ADDE. Participants received artificial tears containing NaCl and KCl, administered six times daily for six weeks. BCVA was measured using the Snellen chart with corrective lenses at baseline (Day 1), Week 4, and Week 6, and was subsequently converted to logMAR units for analysis. Changes in BCVA over time were analyzed using the Wilcoxon signed-rank test, with statistical significance set at $p<0.05$.

Results: Seventeen patients (34 eyes) with ADDE were included. The mean BCVA in logMAR was 0.321 ± 0.303 at baseline (Day 1), 0.227 ± 0.170 at Week 4, and 0.211 ± 0.176 at Week 6. Compared to baseline, BCVA improved at both follow-up points. The change in BCVA at Week 4 was $\Delta\log\text{MAR} = -0.094$ ($p = 0.099$), while the change at Week 6 was statistically significant ($\Delta\log\text{MAR} = -0.110$; $p = 0.006$), based on the Wilcoxon signed-rank test.

Conclusions: Artificial tear therapy with a NaCl–KCl formulation produced a modest yet statistically significant BCVA improvement at six weeks in ADDE patients. For those requiring visual correction, initiating artificial tear therapy before prescribing spectacles may optimize outcomes. Larger studies with varied formulations are warranted.

Abstract No.: 202013

Effect of Topical Adapalene 0.1% and Benzoyl Peroxide 2.5% on Tear Film and Ocular Surface in Patients With Facial Acne Vulgaris

First Author: Theep **MAHASUWEERACHAI**

Co-Author(s): Chanat **KUMTORNRUT**, Vannarut **SATITPITAKUL**

Purpose: To evaluate the impact of a fixed combination of topical 0.1% adapalene and 2.5% benzoyl peroxide (Epiduo) on tear film stability and meibomian gland function in patients undergoing treatment for facial acne vulgaris.

Methods: This prospective observational study included 13 patients with facial acne vulgaris. All participants applied a fixed-dose combination of adapalene 0.1% and benzoyl peroxide 2.5% once daily at bedtime for one month. Ocular surface evaluations—including the Ocular Surface Disease Index (OSDI), noninvasive tear breakup time (NIBUT), tear film lipid layer thickness (TFLT), upper eyelid meibography, National Eye Institute (NEI) fluorescein staining scores, lid margin abnormalities, and assessments of meibum quality and expressibility—were performed before and after treatment. A p -value < 0.05 was considered statistically significant.

Results: No statistically significant changes were observed in OSDI scores (mean difference: 0.71; 95% CI: -8.24 to 9.65), NIBUT (mean difference: 0.08 seconds; 95% CI: -1.86 to 2.01), or TFLT (mean difference: 3.66 nm; 95% CI: -8.56 to 15.89). Similarly, there were no significant differences in meibum quality ($Z = -1.414$, $p = 0.157$), meibum expressibility ($Z = -1.414$, $p = 0.157$), lid margin abnormalities ($Z = -0.447$, $p = 0.655$), or NEI fluorescein staining scores ($Z = -1.635$, $p = 0.102$).

Conclusions: Short-term use of a fixed combination of adapalene 0.1% and benzoyl peroxide 2.5% for the treatment of facial acne vulgaris did not significantly affect the tear film or ocular surface.

Abstract No.: 206635

Effects of microRNA-16-5p and microRNA-142-3p on Inflammation and Autophagy In Vitro Dry Eye Model on Human Corneal Epithelium

First Author: Yu Jeong **KIM**

Co-Author(s): Min-ji **CHA**, Hyunsoo **CHO**, Yeji **YEON**

Purpose: We investigated the effects of microRNA(miR)-16-5p and miR-142-3p on inflammation and autophagy-related mechanisms in vitro dry eye model on human corneal epithelium.

Methods: A dry eye model was established by treating human corneal epithelial cells with 450mOsm NaCl for 24 hours. The expression levels of miR-16-5p and miR-142-3p were confirmed using quantitative polymerase chain reaction(qPCR). MiR-16-5p and miR-142-3p mimics were transfected into the dry eye model. Cell viability was assessed using CCK-8 solution, and changes in the expression of inflammatory cytokines and autophagy-related proteins were measured using western blot and qPCR.

Results: Under hyperosmotic stress, the expression of miR-16-5p and miR-142-3p was significantly lower compared to the control. The cell viability was increased in the groups transfected with miR-16-5p and miR-142-3p mimics. The group transfected with miR-16-5p mimic showed a decrease in the expression of IRAK, IL-6, IL-1 β , TNF- α , TGF- β , ATG5, ATG16L1, and Bax. The miR-142-3p mimic transfected groups showed

a decrease in the expression of IL-6, IL-1 β , TNF- α , TGF- β , and ATG5.

Conclusions: We confirmed that miR-16-5p and miR-142-3p maintain cell survival by regulating the expression of genes related to inflammation and autophagy. They are expected to contribute to understanding the pathogenesis of dry eye and developing new treatment strategies.

Abstract No.: 202740

Efficacy and Safety of Cross-Linked Acellular Porcine Corneal Stroma for Infectious Corneal Disease in China: A Multicenter Prospective Clinical Trial

First Author: Yunxiao **ZANG**

Co-Author(s): Ying **JIE**

Purpose: Acellular porcine corneal stroma (APCS) is a promising alternative to allografts; however, its potential requires verification. To evaluate the efficacy and safety of novel cross-linked APCS transplantation for the treatment of infectious corneal disease.

Methods: This prospective, multicenter, single-arm clinical trial was conducted from 2015 to 2019. Ninety patients with infectious corneal disease who had undergone anterior lamellar transplantation with an APCS across four centers in China were enrolled. All patients had previously received ineffective drug treatment and had a preoperative best-corrected visual acuity (BCVA) $< 20/400$. The primary outcome was the deblinding rate at 180 days compared to the target rate of 65%. The secondary outcomes included BCVA, corneal transparency, and epithelial healing. Safety endpoints included corneal graft rejection, blood count, liver and kidney function, immunoglobulin levels, concomitant medications, and additional treatments. Follow-up was performed for at least 6 months postoperatively.

Results: A total of 100% (90/90) and 88.9% (80/90) of the cases were included in the safety analysis and efficacy per protocol sets, respectively. Eighty percent (72/90) of patients completed 180 days of follow-up after APCS transplantation. The deblinding rate at 180 days was 90.3% (95% confidence interval 81%-96%), exceeding the target ($P < 0.001$). At 180 days, 55% of the grafts were completely transparent, and 82.5% of the epithelium had no defects. The log of the minimum angle of resolution vision improved from 2.19 ± 0.25 preoperatively to 1.10 ± 0.3 . No serious adverse events occurred.

Conclusions: APCS demonstrated excellent corneal transparency and epithelialization following keratoplasty, confirming its safety and efficacy. Six-month data suggest its potential as an alternative treatment for infectious corneal disease. Further long-term trials are necessary to establish its comparative

effectiveness and evaluate chronic complications, offering valuable insights for future clinical practice.

Abstract No.: 204927

Enhancing Eye Donation Awareness and Knowledge Among Palliative Care Clinical Staff: A Comparative Study

First Author: Maggie Wun-king WU

Co-Author(s): Vanissa Wing-see CHOW, Candy Suet-man WONG, Catherine Suet-man WONG

Purpose: Corneal availability relies heavily on voluntary, non-remunerated eye donations within a society that follows an opt-in system. However, limited knowledge and awareness about eye donation continue to hinder donation rates in Hong Kong. Clinical staff working in palliative care play a vital advocacy role in promoting eye donation. This study examined the impact of a structured eye donation talk on enhancing their awareness and knowledge. To evaluate the impact of a structured eye donation talk on clinical staff awareness and knowledge

Methods: A structured eye donation promotion talk was delivered to clinical staff supporting end-of-life care patients in one of the oncology wards at Pamela Youde Nethersole Eastern Hospital. A comparative study of identical pre-talk and post-talk questionnaires was evaluated to assess changes in awareness and knowledge.

Results: A total of 22 pre-talk and 16 post-talk questionnaires were submitted by clinical staff, including doctors, nurses, allied health professionals, chaplaincy, and support staff. The questionnaire comprised 15 questions and the majority results indicated an increase in awareness following the talk, with improvements ranging from 2.9–71.1%. Understanding of the age limitation for corneal donation rose significantly from 22.7% to 93.8%. Interestingly, support for corneal donation showed a slight decline, dropping from 100% to 93.8%.

Conclusions: The well-structured educational talk demonstrated a significant improvement in palliative care staff's knowledge and awareness regarding eye donation. Design of content should be carefully to engage staff and promote donation support.

Abstract No.: 206705

Erythema Multiforme Major With Suspected Herpes Simplex Virus Association Presenting With Conjunctivitis: A Case Report

First Author: Sahildeep Singh BALIAN

Co-Author(s): Aditi BANSAL, Gian Chand RAJPUT

Purpose: Erythema multiforme major (EMM) is a severe, immune-mediated mucocutaneous disorder characterized by mucosal erosions and systemic involvement. Herpes simplex virus (HSV) is one of the

most common infectious triggers. Clinical diagnosis, supported by cytological evidence, is critical for timely management.

Methods: A 45-year-old male patient with no history of recent drug exposure, presented with painful oral ulcers, genital ulcerations, and conjunctival congestion of acute onset. Ocular examination showed best corrected vision of 6/6 with intraocular pressure within normal limits in both eyes. Anterior segment showed matted eyelashes and severe diffuse conjunctival hyperemia bilaterally. Rest of the bilateral anterior and posterior segments were unremarkable on slit-lamp biomicroscopy. Clinical examination revealed erosive mucosal lesions of mouth and erythematous patches in the genital region.

Results: A Tzanck smear demonstrated multinucleated giant cells, suggestive of Herpes simplex virus (HSV) etiology. Laboratory investigations were reported with raised ESR (Erythrocyte Sedimentation Rate) levels and a positive result for CRP (C-reactive protein). The patient was managed with supportive care, topical lubricants, systemic antivirals, and corticosteroids. Gradual clinical improvement was observed with resolution of mucosal lesions.

Conclusions: Erythema multiforme major can present with extensive mucosal involvement, including oral, genital, and ocular lesions. A positive Tzanck smear supports Herpes simplex virus (HSV) association, although further confirmatory testing (e.g. PCR [polymerase chain reaction], serology) may be warranted. Prompt diagnosis and management with antivirals and supportive measures are crucial for favourable outcomes.

Abstract No.: 207057

Evaluation of Tear Film Parameters in Keratoconus Using the Non-Invasive Analyzer

First Author: Renako KOZAKI

Co-Author(s): Yoko HYAKUTAKE, Koji KITAZAWA, Hiroko NAKAI, Mari OSAWA, Chie SOTOZONO, Keiko YAMAGISHI

Purpose: To investigate tear film status in keratoconus (KC) using a non-invasive dry eye diagnostic device (idra®, SBM Sistemi, Italy).

Methods: Patients who visited the keratoconus clinic at Kyoto Prefectural University of Medicine between May 2024 and March 2025 and were diagnosed with KC or regular astigmatism, without prior rigid gas permeable lens wear, were included. Tear film parameters (NIBUT, LLT, tear meniscus height) were assessed using the idra®. Maximum keratometry (Kmax) was measured with anterior segment OCT, and tear secretion with Schirmer's test. Clinical background factors (age, sex, atopic dermatitis, allergic conjunctivitis, and eye rubbing) were also examined. Comparisons were made between the KC and astigmatism groups.

Results: Forty-two patients (80 eyes) were included: 35 with KC (66 eyes; mean age 24.4 ± 6.0 years) and 7 with astigmatism (14 eyes; mean age 21.9 ± 7.2 years). NIBUT was significantly shorter in the KC group than in the astigmatism group (8.30 ± 2.69 vs. 12.05 ± 2.91 sec, $p=0.003$). No significant differences were found in tear meniscus height, LLT, or Schirmer's test. NIBUT was not correlated with Kmax ($r = -0.12$, $p = 0.346$). Atopic dermatitis, allergic conjunctivitis, and eye rubbing did not significantly affect NIBUT in KC eyes.

Conclusions: Keratoconic eyes demonstrated reduced tear film stability while maintaining tear secretion volume.

Abstract No.: 204149

Exogenous Endophthalmitis Secondary to Infective Keratitis: Surgical Challenges and Poor Outcomes — a Case Series

First Author: Nurul Ain **RAHIM**

Co-Author(s): Jemaima **CHE HAMZAH**, Teck Chee **CHENG**, Mazaya **MAHMUD**, Wan Haslina **WAN ABDUL HALIM**

Purpose: To describe four cases of infective keratitis progressing to exogenous endophthalmitis, focusing on risk factors, causative organisms, management, and outcomes.

Methods: Case series.

Results: • Case 1: A 53-year-old man sustained a traumatic left eye injury complicated by *Pseudomonas aeruginosa* keratitis with exogenous endophthalmitis. He received intravitreal antibiotics but later required therapeutic penetrating keratoplasty (TPK) with lens extraction. The graft eventually failed due to persistent inflammation and uncontrolled intraocular pressure (IOP). • Case 2: A 60-year-old woman with diabetes mellitus and end-stage renal failure presented with severe keratitis and exogenous endophthalmitis. Corneal culture grew *Aspergillus flavus*. Despite multiple intravitreal injections and subsequent TPK, her postoperative course was complicated by secondary angle-closure glaucoma and failed graft. She was advised glaucoma surgery but defaulted follow-up. • Case 3: A 78-year-old man sustained traumatic right eye injury and developed polymicrobial keratitis (*Streptococcus pneumoniae* and *Aureobasidium pullulans*) with exogenous endophthalmitis. He underwent TPK combined with trans-pars plana vitrectomy (TPPV). Postoperatively, his vision remained counting fingers, and the graft failed due to poor compliance with medications. • Case 4: A 62-year-old man with diabetes mellitus clinically treated as left eye polymicrobial keratitis (bacteria, fungal and *Acanthamoeba*) with exogenous endophthalmitis. Corneal culture revealed no obvious organism. He underwent TPK and TPPV. His graft failed due to secondary angle-closure glaucoma.

Conclusions: This case series found elderly age, diabetes mellitus, and ocular trauma as risk factors for developing exogenous endophthalmitis from infective keratitis. Early TPK effectively controlled infection and able to preserved globe integrity. In spite all, patients in this case series have poor visual outcome.

Abstract No.: 210310

Exogenous NIR-II Light/Endogenous pH-Activatable Copper Single-Atom Nanozyme for Treatment of *Candida albicans* Keratitis

First Author: Qinxiang **ZHENG**

Co-Author(s): Jianliang **SHEN**, Haijing **YAN**

Purpose: To examine the efficacy and underlying mechanisms of copper-doped nanozyme (Cu-N-C) in combating *Candida albicans* and its therapeutic potential for treating fungal keratitis.

Methods: Characterization of the material was conducted using transmission electron microscopy (TEM), energy-dispersive X-ray spectroscopy (EDS), and X-ray photoelectron spectroscopy (XPS). Enzyme activities and photothermal properties were evaluated using spectrometric techniques. Antifungal efficacy was assessed through colony counting, live/dead staining, and biofilm assays. An in vivo murine keratitis model was developed for evaluation using slit-lamp examination, clinical scoring, and histopathological analysis. Molecular mechanisms were explored through multi-omics analysis, western blotting, and immunofluorescence. Biocompatibility was evaluated in both in vitro and in vivo settings.

Results: Cu-N-C was characterized by a nanosheet structure with uniform elemental distribution, exhibiting superior photothermal conversion efficiency and enzyme-mimetic activities. It effectively eradicated planktonic fungi (98.54%), inhibited hyphal transformation, and disrupted biofilms through combined thermal effects and reactive oxygen species (ROS) generation. In the keratitis model, Cu-N-C, activated by NIR-II irradiation and acidic pH, effectively reduced fungal load, promoted corneal healing, and alleviated inflammation. Multi-omics analysis showed that Cu-N-C disrupted fungal antioxidant defenses by downregulating CAT and SOD. Its anti-inflammatory effect involved suppressing the NLRP3/IL-1 β pathway, with no significant toxicity observed.

Conclusions: Cu-N-C exhibits strong antifungal effects through synergistic PTT/CDT, effectively disrupting biofilms and overcoming fungal antioxidant defenses. It is highly effective and biocompatible for treating fungal keratitis, offering a promising alternative to conventional therapies.

Abstract No.: 204638**Extending the Death-to-Preservation Time of Corneal Tissue: Impact on Tissue Recruitment and Workflow Efficiency***First Author: Catherine WONG**Co-Author(s): Vanessa CHOW, Maggie WU*

Purpose: To increase the availability of eligible cornea donors, Hospital Authority Eye Bank has sought evidence from literature and lengthened the death-to-preservation time (DTPT) from 12 hours to 24 hours since 11 June 2024. Its impact on eye tissue recruitment will be studied.

Methods: A retrospective study was conducted between 11 June 2024 and 10 June 2025 and compared with the same period in the previous year. Parameters assessed included number of families approached, consents obtained, tissues collected & distributed, consent rate, tissue quality & report of adverse reaction.

Results: A total of 187 consented cases were obtained between 11 June 2024 and 10 June 2025. The total number of cases reviewed increased by 22.8% and the number of families approached increased by 11% compared to the previous year. The consent rate, however, was reduced by 3.4%. The total number of grafts collected increased by 25.7%, but the overall number of tissues that could be distributed only increased by 13.8%. The number of adverse reactions reported during the two time periods was comparable.

Conclusions: Extending DTPT allowed Eye Bank to recruit more donors and facilitated coordination in tissue procurement and logistics. However, other factors, such as the willingness to donate and the quality of the tissue harvested, still remained as limiting factors that hampered the availability of transplantable tissue.

Abstract No.: 202407**Extracellular Vesicles in Mouse Tear Fluids: Evidence of Uptake and Proliferative Effects in Corneal Epithelial Cells***First Author: Shogo FUKUDA**Co-Author(s): Kazuhiro HARADA, Masatoshi HIRAYAMA, Taku MATSUMOTO, Ayumi OKA, Saya OYA, Hiroaki OZAKI, Tomoko TSUKAHARA-KAWAMURA, Tomohiro YASUTAKE*

Purpose: Extracellular vesicles (EVs), including exosomes, have been identified in various body fluids, but their presence and roles in tears remain unclear. This study aimed to demonstrate the existence of EVs in mouse tear fluids and evaluate their biological activity on corneal epithelial cells.

Methods: EVs were isolated from mouse tear fluids by ultracentrifugation. Morphological features were analyzed using transmission electron microscopy (TEM)

and nanoparticle tracking analysis (NTA). Exosomal markers were confirmed by immunoblotting for CD9 and TSG101. Uptake of tear EVs was assessed in cultured corneal epithelial cells (TKE2) using fluorescein-labeled RNA. Cell proliferation was examined by Ki67 and BrdU immunostaining.

Results: TEM revealed spherical vesicles consistent with exosomes. NTA showed an average concentration of $2.53 \pm 0.22 \times 10^{12}$ particles/mL with a mean diameter of 134 ± 7.0 nm. Western blotting confirmed CD9 and TSG101 expression in tear EVs. Fluorescence tracing demonstrated efficient uptake of EVs by TKE2 cells ($89 \pm 3.1\%$), whereas uptake was significantly lower in C2C12 cells ($28 \pm 1.9\%$). EV treatment markedly enhanced the proliferation of corneal epithelial cells: the proportion of Ki67-positive cells increased from $3.5 \pm 0.4\%$ to $45.4 \pm 6.4\%$ ($p = 0.020$), and BrdU-positive cells increased from $53.3 \pm 6.5\%$ to $88.7 \pm 0.5\%$ ($p = 0.028$).

Conclusions: This study provides the first direct evidence that mouse tear fluids contain exosome-like EVs. These vesicles are efficiently internalized by corneal epithelial cells and significantly promote their proliferation, suggesting that tear EVs play a critical role in ocular surface homeostasis and may represent novel therapeutic targets for ocular surface diseases such as dry eye.

Abstract No.: 201687**Eyestrain and Dry Eye After Photorefractive Keratectomy in a Sample of Iranian Patients***First Author: Nader NASSIRI**Co-Author(s): Sara KAVOUSNEZHAD, Kourosh SHEIBANI*

Purpose: To evaluate the medium-term postsurgical effects of photorefractive keratectomy (PRK) on patients' subjective perception of dry eye and eyestrain.

Methods: This prospective comparative pre-post study was performed at Vanak Eye Surgery Center, Tehran, Iran, from May 2020 to September 2021. The inclusion criteria were patients with mild to moderate myopia (less than -6 diopters) undergoing PRK. To evaluate the indirect subjective signs of eyestrain and its severity, we used a questionnaire including six questions regarding itching, foreign body sensation, excessive tearing, eye tiredness, blurring, and photophobia. We administered this questionnaire to each patient in face-to-face interviews pre-surgery as well as 1 and 6 months post-surgery. To evaluate post-surgical dry eye, we asked patients if their dry eye symptoms had increased or decreased compared to the pre-surgical period.

Results: A total of 40 patients were assessed in this study. The mean age of patients was 26 ± 8 years, with 16 (40 %) male patients and 24 (60 %) female patients. There was no statistically significant difference in mean

eyestrain scores one month ($P = 0.371$) and six months ($P = 0.939$) post-surgery compared to pre-surgery. There was a significant increase in dry eye symptoms at both 1 month ($P = 0.010$) and 6 months ($P = 0.004$) post-surgical follow-ups.

Conclusions: Our results indicate that PRK significantly increases dry eye symptoms compared to the pre-surgical period. There was no statistically significant difference in eyestrain symptoms among patients compared to the pre-surgical period.

Abstract No.: 205209

Fenofibrate Ameliorates Ocular Surface Inflammation in Patients With Diabetes

First Author: Hassan **MANSOOR**

Co-Author(s): Yu-chi **LIU**, Hong Chan **TAN**

Purpose: To investigate the potential effects of oral fenofibrate in the amelioration of diabetic ocular surface inflammation.

Methods: Forty-one participants with type 2 diabetes mellitus (DM) and 40 age-matched healthy controls were recruited. The DM group received oral fenofibrate for 30 days. Ocular surface assessment, in-vivo confocal microscopy (IVCM) imaging and quantification for corneal dendritic cells (DCs), epithelium and neuromas, tear neuromediator analysis for inflammatory markers, and proteomics were performed before and after treatment.

Results: Fenofibrate treatment significantly improved the tear breakup time (TBUT) ($p=0.004$) and National Eye Institute score ($p=0.005$). On IVCM, fenofibrate significantly reduced the DC area ($p=0.01$) and DC density ($p=0.02$) while increasing the DC elongation ($p=0.004$) and length ($p=0.01$), suggesting that fenofibrate treatment shifts the DC morphology's equilibrium towards a more immature phenotype. Fenofibrate also significantly increased corneal epithelial cell density ($p=0.04$). On tear analysis, fenofibrate significantly reduced the concentration of tumour necrosis factor- α ($p=0.04$) and nuclear factor kappa B ($p=0.03$). Additionally, the tear concentration of anti-inflammatory interleukin-1 receptor antagonist was significantly increased ($p=0.03$), and pro-inflammatory proteins, such as complement 4B, cytochrome B5 Type A and cytochrome B5 Type B were significantly down-regulated after fenofibrate treatment (all $p<0.05$) via regulation of tricarboxylic acid cycle, oxidative phosphorylation and liver X receptor/retinoid X receptor activation.

Conclusions: Oral fenofibrate reduces diabetic ocular surface inflammation, as evidenced by decreased DC infiltration and tear inflammatory cytokines; increased CECD and anti-inflammatory tear mediators; and improved TBUT and corneal staining, all of which aid to alleviate diabetic keratopathy.

Abstract No.: 200417

Five-Year Trend in Microbiological Characteristics of Bacterial Keratitis

First Author: Mai **NGUYEN THI TRUC**

Co-Author(s): Huong **DUONG**, Vinh **LAM**, Phuc **NGUYEN**, Huan **PHAM**, Huy **TRAN**

Purpose: To identify microbiological features and to describe a 5-year trend in antibiotic susceptibility patterns of bacterial keratitis.

Methods: The research was conducted in the Cornea Department of Ho Chi Minh City Eye Hospital between 2019 and 2023. This study was retrospective and involved the analysis of 240 cases diagnosed with bacterial keratitis.

Results: The most commonly isolated bacteria were coagulase-negative Staphylococcus (57.6%), Pseudomonas aeruginosa (21.2%), and Staphylococcus aureus (8.08%). Onset time of Pseudomonas aeruginosa corneal ulcer (2.76 ± 1.55 days) was significantly shorter than others ($p=0.001$). Pseudomonas aeruginosa keratitis was significantly associated with eyelid edema ($p=0.02$), conjunctival edema ($p<0.001$), central infiltration ($p=0.01$), deep stromal infiltration ($p<0.001$), stromal melting ($p<0.001$), ring infiltration ($p<0.001$), retrocorneal plaque ($p<0.001$), hypopyon $>1\text{mm}$ ($p<0.001$), and intracameral fibrin ($p=0.004$). Pseudomonas aeruginosa was sensitive to tobramycin (100%), levofloxacin (95.0%), and not to moxifloxacin (0.0%). Proportion of multidrug-resistant strains among coagulase-negative Staphylococcus and Pseudomonas aeruginosa were 68.4% and 72.0%. 5-year cumulative antibiotic susceptibility patterns of Pseudomonas aeruginosa: imipenem (96.6%), tobramycin (95.9%), ceftazidime (95.4%), ciprofloxacin (91.9%) and levofloxacin (91.9%) were been most susceptible, whereas moxifloxacin (20.0%), cefotaxime (14.6%), and cefuroxime (2.6%) were been least susceptible. Over a 5-year period, the resistance of Pseudomonas aeruginosa to moxifloxacin increased significantly, however the resistance of Pseudomonas aeruginosa to tobramycin slightly decreased.

Conclusions: Multidrug-resistant strains among coagulase-negative Staphylococcus and Pseudomonas aeruginosa were significantly high. Our study offers insights into bacterial keratitis' clinical and microbiological patterns which guide antibiotics choice and management.

Abstract No.: 202046

From Trauma to Recovery: Effective Management of Descemetocoele

First Author: Kristo Hadi Audric **SUGIAMAN**

Co-Author(s): Gede **PARDIANTO**, Givenchy Angela **WINARJO**

Purpose: To describe the clinical presentation, management, and short-term outcomes of a traumatic

descemetocoele treated with urgent cryotherapy, aiming to preserve the eyeball and restore visual function.

Methods: A 17-year-old male presented with decreased vision and pain in the left eye one month after blunt trauma from an iron hoe. Slit-lamp examination revealed a severe descemetocoele. Initial visual acuity was hand movement (1/300), and intraocular pressure was unmeasurable. Anterior segment structures were difficult to assess, while ocular ultrasound showed no posterior segment abnormalities. Emergency cryotherapy was performed, followed by cycloplegics, oral antibiotics, and analgesics. The patient was monitored postoperatively for visual recovery and IOP stabilization.

Results: One week after surgery, the descemetocoele showed clinical improvement with visual acuity of 2/60 and IOP of 23 mmHg. Two weeks post-treatment, the corneal contour improved, with VA reaching 20/400 and IOP reduced to 19 mmHg. No signs of corneal perforation or infection were noted.

Conclusions: Urgent cryotherapy may offer a viable and effective option in managing traumatic descemetocoele. It helps stabilize the cornea, prevents serious complications such as perforation and endophthalmitis, and preserves the integrity of the eyeball. Timely intervention is key to improving prognosis and planning further visual rehabilitation.

Abstract No.: 210282

Global Trends and Prospects of Endothelial Keratoplasty From 2004 to 2023: A Bibliometric Analysis

First Author: Shiwen **CHENG**

Purpose: Endothelial keratoplasty (EK) has revolutionized the treatment of corneal diseases by offering a less invasive alternative to traditional full-thickness keratoplasty. Over the past decades, EK techniques have evolved significantly, improving surgical outcomes, expediting recovery, and reducing postoperative complications. Nevertheless, challenges such as postoperative rejection and endothelial cell loss persist. This study utilizes bibliometric analysis to map the current research landscape of EK and identify future directions.

Methods: A systematic bibliometric analysis was conducted on publications spanning from 2004 to 2023, retrieved from the Web of Science Core Collection. Key metrics such as annual publication and citation counts, contributions by countries and institutions, influential journals, authors and cited authors, highly cited references, co-citation references, and keyword trends were extracted and analyzed using CiteSpace and VOSviewer, Microsoft Excel, Bibliometrix, Scimago Graphica, and Microsoft Excel.

Results: A total of 2676 relevant publications were identified from 2004 to 2023. While the first 5 years

saw a limited number of publications in this field, a marked increase in publications has occurred throughout these years. The United States, Germany, and England were leading contributors. Marianne O. Price emerged as the most prolific author, with Francis W. Price Jr. most frequently cited among the top contributors. Major publishing journals included Cornea, Ophthalmology, and the American Journal of Ophthalmology. Leading institutions included the Netherlands Institute for Innovative Ocular Surgery and the Legacy Devers Eye Institute. VOSviewer keyword clustering revealed 13 thematic clusters, with trending keywords such as “risk factors” and “tissue”, suggesting emerging focal points.

Conclusions: The bibliometric analysis highlights the dynamic evolution and key research areas of EK and ocular disease management. Leveraging these insights is crucial for advancing clinical practice and driving further innovation in the field.

Abstract No.: 205899

Going DEEP (Dry Eye Education & Prevention) Against Digital Dry Eye: A Novel Adolescent Eye Health Intervention From the Himalayas

First Author: Amit **SACHDEVA**

Purpose: Dry eye disease (DED) is an emerging ocular morbidity among adolescents, largely driven by increased digital screen use. Data from hilly northern states of India are limited. This study assessed the prevalence of DED, identified associated risk factors, and evaluated the impact of the DEEP Protocol (Dry Eye Education & Prevention)—a structured intervention combining counseling, reading material, ocular exercises, and digital hygiene education.

Methods: A cross-sectional study was conducted from August–October 2023 at IGMSC Shimla, enrolling 310 adolescents (mean age 14.55 years; 64.8% females). Schirmer’s test (<10 mm) was used for diagnosis. Data on screen exposure, demographics, and ocular/allergic history were collected. Adolescents with DED received the DEEP Protocol and were reassessed at 1, 3, and 6 months. Statistical analysis employed chi-square, t-test, and repeated measures ANOVA; $p < 0.05$ was considered significant.

Results: DED prevalence was 21.3% (66/310). Affected participants had significantly greater mean daily screen time (3.59 ± 0.98 hrs) compared to non-DED peers (2.27 ± 0.76 hrs; $p < 0.001$). Logistic regression revealed that every additional 30 minutes of screen use increased odds of DED nearly twofold (OR = 1.80, 95% CI: 1.32–2.45; $p = 0.001$). Females were more frequently affected (69.7% of DED cases; $p = 0.04$). A history of ocular allergy emerged as another independent risk factor (OR = 1.78, 95% CI: 1.10–2.89; $p = 0.02$). Other factors, such as contact lens use and smoking, were rare and statistically insignificant in this population. Post-intervention, Schirmer’s scores improved

markedly: 6.2 ± 1.1 mm at baseline $\rightarrow 9.1 \pm 1.3$ mm at 1 month $\rightarrow 11.3 \pm 1.6$ mm at 3 months $\rightarrow 13.7 \pm 1.4$ mm at 6 months ($p < 0.001$). Symptomatically, $>85\%$ reported a substantial reduction in dryness, burning, irritation, and eye strain. The frequency of eye-strain episodes dropped from a median of 4/week to ≤ 1 /week ($p < 0.001$). Compliance with digital hygiene and ocular exercises was strongly correlated with improved outcomes.

Conclusions: DED is common among adolescents in Himachal Pradesh, with screen time as the strongest modifiable risk. The DEEP Protocol demonstrated significant clinical and symptomatic improvement, offering a simple, scalable solution for adolescent dry eye prevention.

Abstract No.: 200867

Graphitic Carbon Nitride Quantum Dots for Enhanced Corneal Crosslinking

First Author: Jinhai HUANG

Co-Author(s): Mei YANG, Xingtao ZHOU

Purpose: To address the limitations (in-situ hypoxia) of accelerated corneal crosslinking (A-CXL) in the treatment of keratoconus, we propose the development of a novel, oxygen self-sufficient platform utilizing graphitic carbon nitride quantum dots (g-C₃N₄ QDs) to augment the treatment efficacy.

Methods: The study involved the synthesis of biocompatible g-C₃N₄ QDs and their composite with riboflavin (RF@g-C₃N₄ QDs), intended to serve as photocatalytic oxygen-generating nanomaterials during A-CXL. Detailed assessments were conducted to evaluate the oxygen generation capability, reactive oxygen species (ROS) yield, and biosafety of these materials. Furthermore, their A-CXL efficacy were evaluated on male New Zealand white rabbits and compared with the conventional epi-off RF A-CXL protocol.

Results: The g-C₃N₄ QDs and RF@g-C₃N₄ QDs composites exhibited excellent photocatalytic oxygen generation, elevated ROS yield, and outstanding biosafety. In the rabbit model, these materials proved to be significantly more effective in strengthening the cornea after A-CXL compared to the RF protocol, suggesting a more effective treatment.

Conclusions: The study concludes that g-C₃N₄ QDs-based platforms possess notable potential for application in A-CXL, offering a promising approach to enhance corneal strength and treat corneal diseases, such as keratoconus and corneal ectasias. These findings prompt us to propose the potential application of g-C₃N₄ QDs in A-CXL for the treatment of corneal ectasias and various other corneal diseases.

Abstract No.: 207282

Impact of Air Pollution on Eyes in a Metropolitan City of India

First Author: Ritik JAIN

Co-Author(s): Vishal KATIYAR, Sanjiv KUMAR GUPTA, Arun SHARMA

Purpose: To evaluate the impact of urban air pollution on ocular surface health by comparing individuals with high outdoor exposure to those with predominantly indoor lifestyles.

Methods: This cross-sectional study enrolled 150 participants divided into two groups: traffic policemen (outdoor-exposed) and housewives (indoor-exposed). All subjects underwent slit-lamp examination, Schirmer's test, and tear break-up time (TBUT) assessment. Ocular symptoms (redness, dryness, irritation, watering, blurred vision) and protective practices were recorded. Statistical analysis, including chi-square testing, was used to assess associations between exposure and ocular outcomes.

Results: Outdoor-exposed participants showed significantly higher rates of dry eye symptoms, conjunctival congestion, and reduced tear film stability compared to indoor participants ($p < 0.05$). Schirmer's scores and TBUT were consistently lower in policemen. Symptom prevalence, including redness, dryness, and irritation, was markedly higher in the outdoor group. Eye-care practices (use of sunglasses, masks, or lubricants) were significantly associated with reported symptoms ($\chi^2 = 326.1$, $p = 0.000$).

Conclusions: Air pollution exerts a measurable adverse effect on ocular surface health. Individuals with prolonged outdoor exposure, particularly traffic policemen, are at higher risk of developing dry eye disease and ocular discomfort compared to those with indoor lifestyles. The findings highlight the need for preventive strategies, occupational health interventions, and policy-level action to mitigate pollution-related ocular morbidity in urban India.

Abstract No.: 201981

Incidence of Post-Cataract Surgery Descemet's Membrane Detachment and Anatomic and Functional Outcome of Perfluoroethane Descemetopexy

First Author: Manish PANDEY

Co-Author(s): Mahesh DEV, Rajiv Ranjan KARN

Purpose: To determine the incidence of Descemet membrane detachment (DMD) following cataract surgery and evaluate the anatomic and functional outcomes of perfluoroethane (C₂F₆) descemetopexy.

Methods: This retrospective study was conducted at a tertiary eye hospital from January to December 2023. Medical records of 41,843 cataract surgeries were reviewed, and 68 cases of DMD treated with

C₂F₆ descemetopexy were included. Demographic data, cataract surgical techniques, and postoperative complications were recorded. Anatomical success was defined as complete reattachment of the Descemet membrane, and functional success as best corrected visual acuity (BCVA) $\geq 6/18$ at 1 month.

Results: Of 41,843 cataract surgeries, 68 patients (0.16%) developed DMD. The mean age was 64.9 ± 7.9 years; male-to-female ratio was 53:47. Incidence was higher following small-incision cataract surgery compared with phacoemulsification (0.25% vs 0.07%, $p = 0.000$) and among trainees compared with consultants (0.19% vs 0.06%, $p = 0.003$). At one month, 6 patients were lost to follow-up. Primary C₂F₆ descemetopexy achieved anatomical success in 48 of 62 patients (77.4%). Functional success was achieved in 40 of 62 patients (64.5%). Complications included persistent DMD (17.4%), pupillary block with elevated intraocular pressure (9.7%), corneal decompensation (4.8%), posterior chamber gas with raised intraocular pressure (3.2%), and hyphema (3.2%). Three patients underwent repeat descemetopexy, with 2 achieving successful reattachment.

Conclusions: This study suggests that C₂F₆ descemetopexy is an effective and successful procedure for treating DMD following cataract surgery, providing good anatomical and functional outcomes.

Abstract No.: 201817

Injectable Microcarriers Enhance Stem Cell Delivery and Promote Corneal Regeneration for Alkali Burn

First Author: Li JINMING

Co-Author(s): Feng YUN

Purpose: Corneal alkali burns represent severe ocular injuries characterized by acute inflammation and long-term stromal fibrosis, potentially causing irreversible vision loss. Stem cell therapy has emerged as a promising treatment due to its regenerative and immunomodulatory properties. However, conventional cell injection methods are limited by poor cell viability, low retention rates, and injection-induced mechanical trauma.

Methods: Here, we present collagen-modified chitosan porous microspheres (ColMS) as a cell-laden porous microcarrier system to enhance adipose-derived stem cells (ADSCs) delivery efficiency for corneal repair following alkali burns.

Results: The pore sizes and particle sizes can be easily adjusted by varying the concentration of chitosan and stirring speed. Through in vitro experiment, it was demonstrated that ColMS-ADSCs guarantee the capability for epithelial regeneration and immunomodulatory. Finally, we investigated ColMS-ADSCs healing corneal alkali burn ability via subconjunctival injection. It was found that the

microcarriers exhibit outstanding therapeutic efficacy, which effectively suppresses inflammation during the early acute inflammatory phase and prevents the development of corneal fibrosis during the later recovery phase.

Conclusions: Cell-laden microcarriers exhibited the capability of promoting epithelial cell proliferation and the ability of immunomodulation by reducing M1 polarization. We developed a subconjunctival injection based on ColMS-ADSCs for corneal alkali burn healing, and ColMS-ADSCs group exhibited improved corneal transparency and faster epithelial healing, indicating its ability of anti-inflammation and anti-fibrosis. The prepared microcarriers provides a promising approach for effective treatment of corneal chemical injuries.

Abstract No.: 202765

Innate Lymphoid Cells Mediate Lacrimal Gland Epithelial Dynamics in Thyroid Eye Disease-Associated Dry Eye: A Novel Therapeutic Target

First Author: Lianfei FANG

Co-Author(s): Huifang ZHOU

Purpose: Thyroid eye disease (TED) frequently leads to dry eye disease (DED), for which current therapies remain predominantly palliative and fail to address underlying mechanisms. This study aims to delineate the immune landscape of the lacrimal gland in TED, with a particular focus on the roles of innate lymphoid cell (ILC) subsets in mediating epithelial injury and tissue repair.

Methods: Lacrimal gland tissues and peripheral blood from active and stable TED patients, and healthy controls, were analyzed. Histology evaluated inflammation and acinar damage. ILC subsets were quantified by flow cytometry, spatially mapped via multiplex immunofluorescence, and transcriptomically profiled using Smart-seq2. Functional roles were assessed through co-culture and cytokine blockade experiments.

Results: Active TED patients exhibited reduced tear secretion and more severe corneal damage than stable TED patients, with lacrimal glands showing pronounced inflammation, acinar atrophy, and elevated histological scores. Peripheral ILCs showed increased ILC1/ILC3 in active and ILC2 in stable TED patients. Notably, ILCs were enriched within lacrimal glands relative to blood, suggesting tissue-specific recruitment or expansion. Similarly, active TED is dominated by ILC1 and stable TED by ILC2 in the lacrimal gland, reflecting an ILC1-to-ILC2 shift during the transition from active to stable TED. ILC1s localized at inflammatory infiltration margins, producing TNF- α and inducing epithelial apoptosis, whereas ILC2s expressed AREG, promoting epithelial proliferation and repair.

Conclusions: ILCs mediate distinct immunoregulatory programs in TED lacrimal pathology: ILC1s drive epithelial injury in active disease, while ILC2s facilitate repair in stable disease. These findings highlight ILCs as potential immunotherapeutic targets for TED-associated DED.

Abstract No.: 202762

Innovative Limbal Stem Cell Functional Reconstruction Surgery – SLET

First Author: Hua WANG

Co-Author(s): Fei YAO

Purpose: Corneal limbal stem cell dysfunction (LSCD) often leads to severe ocular surface lesions, including neovascularization of the entire cornea, persistent corneal epithelial defects and ulcers, abnormal conjunctival metaplasia of the cornea, and severe dry eye, often resulting in a significant decline in visual function. Reconstructing the normal structure and function of corneal limbal stem cells and restoring a healthy ocular microenvironment have become key issues in solving LSCD.

Methods: Simple limbal epithelial transplantation (SLET) surgery is an innovative treatment method to solve this problem. The working principle of SLET is to take small pieces of autologous normal corneal limbal stem cell tissue, cut them into small clusters of stem cells, and implant them in the affected corneal limbus.

Results: SLET could reconstruct the structure and function of normal corneal limbal stem cells, restore a healthy ocular microenvironment: reduce corneal neovascularization, promote the proliferation and differentiation of normal corneal epithelial cells, and improve severe dry eye.

Conclusions: SLET is expected to become a new ideal surgical method for treating LSCD.

Abstract No.: 201714

Innovative Use of Cellulase and Cellulose Biosynthesis Inhibitors (CBIs) as a Novel Therapeutic Treatment for Vision-Threatening Pythium Insidiosum Keratitis

First Author: Bharat GURNANI

Co-Author(s): Kirandeep KAUR, Radhika NATARAJAN

Purpose: This study explores the therapeutic potential of cellulose biosynthesis inhibitors (CBIs) and cellulase enzymes as novel agents for the management of Pythium insidiosum keratitis, a devastating ocular infection often resistant to conventional therapy.

Methods: An extensive literature review substantiates the hypothesis and validates the use of CBIs and cellulase enzymes in treating this keratitis. The concept also delves into the molecular action mechanisms of these agents on the Pythium cell wall, exploring procurement and administration strategies as potential

therapeutic options. A comprehensive literature review was conducted to evaluate current evidence supporting the role of CBIs and cellulases in disrupting the Pythium cell wall. The review also examined the molecular mechanisms of action, delivery strategies, and possible clinical applicability of these agents.

Results: Unlike fungi and animals, Pythium possesses a unique plant-like cell wall that contains cellulose, making it particularly susceptible to agents targeting cellulose synthesis and degradation. CBIs inhibit the polymerization of β -glucan chains, thereby weakening structural integrity, while cellulase enzymes degrade existing cellulose fibrils. Together, these mechanisms may compromise the organism's survival and pathogenicity. The findings suggest that CBIs and cellulases could potentially provide superior efficacy compared with the limited success of current antifungal and antimicrobial therapies. Furthermore, the review highlights procurement feasibility and the possibility of developing topical or intracorneal administration routes.

Conclusions: Addressing the high rates of therapeutic keratoplasty, the study highlights CBIs and cellulase enzymes as potential revolutionary treatments. Future clinical trials are required to confirm these findings.

Abstract No.: 206800

Investigating a Hidden Invader on the Eyelid: Beware of Pthirus Pubis Infestation

First Author: Fredric ZULKIFLY

Co-Author(s): Angga FAJRIANSYAH, Elfa Ali IDRUS, Patriotika MUSLIMA, Arief Akhdestira MUSTARAM

Purpose: Phthiasis palpebrarum is a rare eyelash infestation by Pthirus pubis which was initially misdiagnosed as blepharitis and thus mistreated. This infestation is nearly affecting low- to middle-income countries. The accurate diagnosis of phthiasis palpebrarum is crucial for effective treatment and the prevention of further complications.

Methods: This is a case report of a patient who presented with chronic itching of both eyelids. The patient had undergone a comprehensive examination, including microscopic examination of her eyelashes.

Results: A 19-year-old girl complained of chronic itching on both eyelids for a year. The symptom was accompanied by the presence of debris that stuck to her eyelashes. The ophthalmologic examination revealed the nits and lice on her eyelashes. Wet mount microscopic examination showed a short, broad, crab-like body resembling Pthirus pubis during digestion after a blood meal, and a small, oval, translucent structure firmly attached to the hair shaft. The patient was subsequently referred to the dermatovenereology department, where lice were found on the scalp and pubic hair. The patient was treated by cleansing her eyelashes with terpinen-4-ol 1% twice daily, removing

mechanically the remaining nits and lice, and applying permethrine 1% lotion as a single dose. After two weeks, both eyelashes were found to be free of nits and lice.

Conclusions: Clinical manifestation of phthiasis palpebrarum may be confused with symptoms of blepharitis. Establishing a diagnosis of phthiasis palpebrarum poses challenges in the early stages of disease. Topical application of tea tree oil has been reported as a potential treatment for phthiasis palpebrarum.

Abstract No.: 201118

Isolation, Identification, and Characterisation of Mesenchymal Stromal Cells in Posterior Corneoscleral Limbus

First Author: Yuting **XIAO**

Co-Author(s): Sandra **BARRE-NGUYEN**, Charles **MCGHEE**, Jie **ZHANG**

Purpose: Mesenchymal stromal cells (MSCs) in the anterior corneoscleral limbal stroma (anterior limbal mesenchymal stromal cells, A-LMSCs) have been extensively studied, while their presence in the posterior limbus remains poorly defined. We hypothesise that MSCs may also exist in the posterior limbus, tentatively named posterior limbal mesenchymal stromal cells (P-LMSCs). This investigation aimed to isolate and characterise P-LMSCs.

Methods: Immunohistochemistry of human limbal tissue was performed to identify P-LMSCs in situ. Human limbal stroma was processed for explant culture to isolate A-LMSCs and P-LMSCs. Cultured P-LMSCs were characterised and compared to A-LMSCs using flow cytometry, tri-lineage differentiation, and immunocytochemistry.

Results: MSC markers CD73, CD90, and CD105 were expressed in the human posterior limbal stroma. P-LMSCs were successfully isolated through explant culture of the posterior limbal stroma, and were plastic adherent. Flow cytometry analysis showed that cultured P-LMSCs co-expressed CD73, CD90, and CD105, and lacked expression of MSC-exclusion markers CD14, CD34, CD45, CD19, and HLA-DR. P-LMSCs demonstrated the ability to differentiate into adipogenic, osteogenic, and chondrogenic lineages in vitro, with differentiation efficiencies comparable to those of A-LMSCs. P-LMSCs expressed recognised A-LMSC markers, including vimentin, Nestin, TRA-1-60, Oct3/4, and N-cadherin in extended culture.

Conclusions: This study identified MSCs in the posterior limbal stroma, which can be isolated via explant culture. They expressed MSC markers and exhibited multipotent differentiation potential. These findings provide new insights into the structure of the corneoscleral limbus.

Abstract No.: 205846

Knowledge, Attitude and Practice on Corneal Donation and Transplant Amongst the Allied Ophthalmic Personnel in Community Eye Centers in Nepal

First Author: Sagar **RUIT**

Co-Author(s): Anupama **AMATYA**, Samira **BYANJANKAR**, Ashiyana **NARIANI**, Saksham **TAMANG**, Raba **THAPA**

Purpose: This study aims to assess the knowledge, attitude, and practices regarding corneal donation and transplantation among allied ophthalmic personnel in community eye centers under the Tilganga Institute of Ophthalmology.

Methods: A questionnaire-based, cross-sectional study was conducted among 44 ophthalmic assistants and eye health workers from 19 community eye centers. Data was analyzed using SPSS software.

Results: The majority of respondents (77.3%) understood corneal donation as posthumous, and 97.7% were aware of its benefits for corneal blindness patients. Regarding age of donors, 56.8% believed all age groups could donate, and 31.8% set an age limit (1-75 years). While 81.8% pledged to donate their eyes, 66.7% of those unwilling cited religious beliefs. Counseling experience was reported by 72.7%, but 60% of those who had not cited lack of training as a barrier. Referrals for corneal transplantation were made by 54.4%, mainly due to corneal scarring.

Conclusions: The results of this study reveal a solid foundation of knowledge and practices related to eye donation and transplantation in Nepal but also highlights critical gaps in knowledge and areas for improvement. Therefore, ongoing training for ophthalmic paramedical professionals to increase awareness of eye banking structure, donor cornea demand and supply, referral services could prove to be an impactful yet cost effective way to empower them to be better advocates for eye donation. These efforts could benefit both Nepal and the 33 countries reliant on corneas from Nepalese donors.

Abstract No.: 203830

Lacrimal Gland Ultrasonography of Primary Sjögren's Syndrome: What Can We Learn From?

First Author: Wenyan **ZHOU**

Co-Author(s): Haozhe **YU**, Yun **FENG**

Purpose: Primary sjögren's syndrome (pSS)-related dry eye is more severe than non-pSS dry eye, while early diagnosis is critical for disease control. This study evaluated lacrimal gland ultrasonography (LGUS) for early diagnosis of pSS-related dry eye.

Methods: LGUS was performed on 32 pSS-related dry eye patients and 15 non-pSS dry eye controls. Meanwhile, we recorded ocular parameters to evaluate

dry eye, as well as systemic symptoms and laboratory test results to assess the severity of pSS. A receiver operating characteristic (ROC) curve was utilized to illustrate the diagnostic value of LGUS.

Results: The ocular surface evaluation including tear break-up time (BUT), Schirmer test (ST), ocular staining score (OSS), and LGUS greyscale score of patients with pSS-related dry eye showed significant differences as compared with non-pSS patients, while no difference was found of Ocular Surface Disease Index (OSDI), corneal perception and morphology and color Doppler ultrasound score between two groups. A ROC curve of the right lacrimal gland greyscale score of pSS patients showed an area under the curve (AUC) of 0.80, a sensitivity of 90.6% and a specificity of 66.7%. Besides, a significant correlation was found between the LGUS greyscale score and salivary gland involved, SSA antibody, ST, OSS, and psychological symptoms of patients.

Conclusions: Early ocular changes in pSS-related dry eye patients involve the lacrimal gland. LGUS could be an alternative to OSS or Schirmer test to recognize pSS patients, offering a slight advantage of higher sensitivity and specificity.

Abstract No.: 201017

LipiFlow Improves Ocular Surface Conditions in Patients With Meibomian Gland Dysfunction

First Author: **Nathania NGO**

Co-Author(s): **Allie LEE**

Purpose: To evaluate the effectiveness of the LipiFlow Thermal Pulsation System (LipiFlow) in increasing lipid layer thickness (LLT). This may offer a clinically accessible and non-invasive option for improving ocular surface conditions in patients with dry eye disease (DED) due to meibomian gland dysfunction (MGD), helping vulnerable individuals with debilitating MGD.

Methods: Patients whose MGD affected their activities of daily living (ADLs) were recruited. Exclusion criteria were fibrotic palpebral fissures, inability to remain immobile throughout treatment and acute pain. LipiFlow treatment and LLT measurement was successfully done on 35 eyes of 18 patients. LLT was measured before and after LipiFlow treatment with the Lipiview Ocular Surface Interferometer (LipiView). Further analyses were conducted on the resulting differences in pre-post-treatment measurements.

Results: Among the 18 patients, 12 were men and 6 were women. The mean age was 69.0 (± 12.9) years. The mean LLT pre-treatment was 57.0 (± 22.8) nm, and that of the post-treatment was 78.8 (± 22.7) nm. The difference between them was statistically significant ($p=0.0008$). The difference between LLT increase in males and females ($p=0.407$), as well as difference in LLT increase in patients aged below 70, and that of

patients aged 70 and above ($p=0.160$) were statistically insignificant.

Conclusions: LipiFlow is a safe and effective treatment for MGD, increasing the LLT in patients of varying ages and both sexes, successfully alleviating their dry eye symptoms.

Abstract No.: 205134

Long-Term Efficacy of Topoguided Excimer Laser Ablation (ASA) Combined With Corneal Crosslinking (CXL) for Keratoconus

First Author: **Jayant SARWATE**

Co-Author(s): **Nikit SARWATE**

Purpose: To evaluate the results of keratoconus eyes treated with Topoguided excimer laser ablation (ASA) with Ultraviolet corneal crosslinking (CXL).

Methods: Thirty-two eyes of keratoconus were included in a retrospective study. Minimum pachymetry was 465 microns and the Kmax was in the central 6 mm zone. Maximum laser ablation was 30 mic. Preoperative and Postoperative parameters were recorded. Uncorrected visual acuity (UCVA) best spectacle corrected visual acuity (BCSCA), flat keratometry (K1), steep keratometry (K2), maximum Keratometry (K Max), Root mean Square (RMS) of Total corneal Aberrations and (RMS) of higher order aberrations were recorded at the end of 3 months minimum and 32 months maximum.

Results: Average visual improvement was 2 lines. In two eyes with extreme k max of 66.3 and 79, it was only one line. K max and K2 reduced by minimum 2 D. Mean Pre op HOA reduced from 1.67 to 1.22. Total RMS from mean 6.74 to 4.98 post op. Kmax mean preop 52.83 reduced to 50.10 post op. Preop Mean K2 of 48.57 decreased to 46.72 post op. Post Op K1 values remained almost same. These results were statistically significant and were consistent after 32 months.

Conclusions: Topoguided ASA with CXL can be used as an effective tool to treat keratoconus with relatively thicker corneas of 465 microns and above and when the cone apex (Kmax) lies more centrally in the central 6 mm zone. The topoguided ASA with CXL does not alter the flat K but flattens the steep K. It improves total corneal aberrations and (HOA) thereby improving visual acuity and quality in all eyes.

Abstract No.: 205478

Long-Term Outcomes of Therapeutic Corneal Grafts Using Artificial Intelligence

First Author: **Prabhjot SINGH**

Co-Author(s): **Gairik KUNDU, Yathish S**

Purpose: This study aimed to look at demographics, clinical characteristics, and long-term outcomes of Therapeutic Penetrating Keratoplasty (TPK) performed using Artificial intelligence (AI) in a tertiary eye care hospital.

Methods: Case records of 1,046 therapeutic transplants were retrospectively analyzed, and outcomes were measured until 3 years of follow-up. Information on demographics, presentation characteristics, keratoplasty indications, microorganisms, and secondary surgical interventions was studied. The final outcome was classified in terms of therapeutic, anatomical, and functional outcomes. An AI model was then built to look at these risk factors. The area under the curve (AUC), sensitivity (SE), specificity (SP), and accuracy (AC), along with other metrics, were evaluated.

Results: The median age of the recipients was 58 years, with 72% men. The most common indications for TPK were advanced microbial keratitis, including perforated infectious ulcer, nonhealing ulcers, and graft infections. AI model detected mixed infections with concomitant fungal and bacterial followed by fungal infections as important factors for adverse outcomes. Therapeutic success was achieved in 72% at the end of 6 months. At 3 years 15 % retained a clear graft. The clinical risk factors model had an AC, SE, and SP of, 82%, 73% and 86%, respectively.

Conclusions: Therapeutic keratoplasty although effective in eradicating infection and providing anatomical integrity, needs timely intervention, and can aid in achieving the best functional outcome. Understanding key factors including type of infection, socio-economic factors can play an effective role in optimising outcomes.

Abstract No.: 204803

Management of Chronic Corneal Hydrops With Double Lenticule Transplantation

First Author: Faruk SEMIZ

Co-Author(s): Fetih Furkan ARSLAN, Njomza HIMA-MUSA, Ceren Ece SEMIZ

Purpose: To evaluate the clinical outcomes of double lenticule transplantation in keratoconus patients with chronic corneal hydrops.

Methods: This study included 24 keratoconus eyes with chronic corneal hydrops after prior crosslinking, indicated for penetrating keratoplasty. The cohort consisted of 24 patients (mean age 21.2 ± 2.5 years; 13 males, 11 females). All underwent double lenticule transplantation with one full lenticule ($134.2 \pm 18.0 \mu\text{m}$, -6.70 ± 0.91 D) and one semi-moon lenticule ($149.4 \pm 14.6 \mu\text{m}$), customized to astigmatism. Lenticules were transplanted through a 130- μm intrastromal pocket, targeting a postoperative central corneal thickness of 460 μm . All patients were followed for at least 12 months.

Results: At 1 year, UDVA/CDVA improved from 1.73 ± 0.24 to 0.76 ± 0.17 and 0.42 ± 0.07 logMAR, respectively. Q value improved from -0.75 ± 0.05 to -0.62 ± 0.04 , K1/K2 decreased from 71.7/61.0 D to

66.8/61.0 D, and CCT increased from 348.0 ± 20.3 to $482.5 \pm 8.7 \mu\text{m}$, with no complications or rejection.

Conclusions: Double lenticule transplantation using one full and one semi-moon lenticule appears to be a safe and effective alternative to penetrating keratoplasty, providing stromal thickening and maintaining corneal clarity in keratoconus eyes with chronic hydrops.

Abstract No.: 200287

Management of Microbial Keratitis in a Case of Ichthyosis

First Author: Mariya DOCTOR

Purpose: To report the management of microbial keratitis in a case of Ichthyosis.

Methods: A 26-year-old gentleman, a known case of ichthyosis, presented with LE redness, pain, and watering for 1 week. General examination showed short stature, coarse brown scales, eclabium, palmoplantar keratoderma, and distorted toes. Ocular examination showed matted eyelashes, upper and lower lid ectropion with thickened lid margins, loss of meibomian glands and lid margin keratinisation in BE. LE cornea had dendritic epithelial defect, anterior to mid stromal infiltration with peripheral corneal vascularisation.

Results: A provisional diagnosis of HSV stromal keratitis with ulceration was made, and corneal scraping showed RT-PCR and immunofluorescence assay (IFA) testing for herpes simplex virus-1 (HSV) was positive. Treatment with oral acyclovir and topical steroids resulted in a significant reduction in size of the stromal infiltrate and epithelial defect. At the last follow-up 20 days later, his visual acuity improved to 20/80 as compared to counting fingers close to face as noted on the first visit.

Conclusions: With this case, we plan to discuss the various ocular manifestations in a patient with ichthyosis, and we highlight the challenges faced in the management of microbial keratitis in such patients.

Abstract No.: 200742

Meesmann Dystrophy: Multimodal Diagnostics and Therapeutic Heterogeneity

First Author: Xingli ZHOU

Co-Author(s): Qing WANG, Ximing ZHAO

Purpose: To report three sporadic cases of Meesmann corneal dystrophy (MCD), supplement their imaging features and clinical management data, and emphasize preoperative screening necessity for occult lesions.

Methods: Retrospective analysis of 3 sporadic female MCD patients (aged 23-56 years). Examinations included best-corrected visual acuity (BCVA), fluorescein/non-fluorescein biomicroscopy, funduscopy, Schirmer test I, non-invasive break-up time

(NiBUT), esthesiometry, in vivo confocal microscopy (IVCM) and anterior segment OCT (AS-OCT) .

Results: All patients lacked family history, presenting foreign body sensation or decreased vision. Slit-lamp revealed corneal epithelial microcysts at peripheral, pupil-area, or pan-corneal locations. One case was diagnosed 4 years post-refractive surgery; one had concurrent cataract. AS-OCT showed epithelial thickening (70-74 μm) at lesions. IVCM identified microcysts (diameter: 12-71 μm ; density: 50-281/ mm^2) containing high-reflective debris (density: 178-378/ mm^2). All received artificial tears; one underwent phacoemulsification with intraocular lens implantation (Phaco+IOL), another phototherapeutic keratectomy (PTK). At 3-6-month follow-up, all achieved symptom relief and vision satisfaction.

Conclusions: Sporadic MCD exhibits clinical heterogeneity, requiring multimodal imaging (AS-OCT/IVCM) for diagnosis. Personalized treatments (artificial tears/surgery) effectively improve vision and satisfaction. Corneal dystrophies must be ruled out before refractive surgery.

Abstract No.: 204069

Mendelian Randomization and Genetic Analyses Reveal Causal Roles of Immune Cells and Inflammatory Proteins in Keratoconus

First Author: Xiaolin QI

Purpose: Immunity and inflammation are implicated in the progression of keratoconus (KC), but the causal relationships between inflammatory immune phenotypes and the disease remain unclear.

Methods: We conducted a comprehensive Mendelian randomization (MR) analysis using GWAS data to investigate the causal effects of inflammatory and immune factors on KC. Multiple sensitivity analyses were performed to validate our findings, with significant results confirmed through meta-analyses using independent GWAS datasets. The Steiger test, LD score regression, and multivariate MR were applied to assess independent effects.

Results: Analysis of inflammatory proteins revealed that IL-12B (PIVW = 8.26×10^{-5}) and IL-13 (PIVW = 0.012) were associated with an increased risk of KC, whereas IL-17 A (PIVW = 0.049) was inversely associated with KC risk. After FDR adjustment, the results for IL-12B (PFDR = 0.007) remained significant. Twenty-two protective and eleven risk immune cells were identified. Meta-analysis supports CD20 on IgD-CD24-B cells and Central Memory CD8 + T cells %CD8 + T cells as protective factors against KC. Multivariable MR revealed independent heritability for seven inflammatory proteins and three immune cells.

Conclusions: These findings highlight the critical role of immune and inflammatory factors in KC pathogenesis,

suggesting possible targets for future investigation in KC prevention and treatment.

Abstract No.: 206135

Methodology of Analysis of Human Meibum in Meibomian Gland Dysfunction and Dry Eye Disease: A Scoping Review

First Author: Chak Ka LAW

Co-Author(s): Nicole Ka Ying CHENG, Kelvin Kam Lung CHONG, Zhichao HU, Elva Lau Yung WONG

Purpose: Alterations in meibum composition and physical properties are critical to understanding the pathophysiology of meibomian gland dysfunction (MGD) and dry eye disease (DED), in addition to meibomian gland morphology and expressivity. However, methodologies for the meibum collection and analysis lack standardization. This scoping review aims to provide an overview of the methodologies used in the meibum research.

Methods: A total of 23 articles were included in the review after a systematic search from three electronic databases, PubMed, Cochrane library and MEDLINE, until September 2025. Studies that involved the methodologies for the collection and analysis of meibum from human subjects with MGD were included.

Results: 6 meibum collection methods were identified. The most frequently reported method was a metal spatula (39.1%), followed by a cotton swab, microcapillary tube, and Sebutape® (each 13.0%). Most studies (82.6%) focused on analysing the lipid composition, while a minority (21.7%) investigated its physical properties, including secreted amount, thermodynamic behaviour, and surface tension. 7 analytical techniques were identified, with liquid chromatography-mass spectrometry (LC-MS) being the most common (34.8%), followed by nuclear magnetic resonance (NMR) spectroscopy (26.1%) and infrared spectrometry (21.7%).

Conclusions: Heterogeneity exists across the methodologies used to investigate human meibum in MGD and DED, potentially contributing to inconsistent results and hindering meaningful comparisons across studies. The development of standardized protocols for meibum collection and analysis are urgently needed to ensure consistent and clinically translatable outcomes.

Abstract No.: 202656**Microbial Influx During Early Postnatal Life Fortifies the Ocular Surface and Guards Against Allergic Eye Disease***First Author: Yanbo LIU**Co-Author(s): Xiezhou HE, Wei LI, Zuguo LIU, Shangkun OU, Andrew J. QUANTOCK, Shulin SONG, Hang SUN, Han WU, Huping WU*

Purpose: Host-microbiome interplay during development governs the homeostasis of various bodily surfaces and is considered to have lifelong consequences for health. Postnatal colonization of the eye's microbiome, however, its impact on the homeostasis of the ocular surface is still unclear.

Methods: The composition and diversity of the conjunctival microbiome in C57BL/6J mice were tracked in 1-week-old neonates through to 8-week-old adult mice. Furthermore, we evaluated the effect of early antibiotic application following eyelid-opening on the homeostasis of ocular surface and its impact on allergic eye disease.

Results: The changes in the conjunctival microbiome correlate with age, especially at the 2-week and 3-week time points, which, respectively, are accompanied by eyelid-opening and weaning. Antigen-presenting cells were also recruited to the conjunctival epithelium after eyelid-opening, whilst an inhibition of microbial colonization at 2-to-3 weeks of age led to a disruption of mucosal homeostasis and aggravated the development of allergic eye disease.

Conclusions: This study improves our understanding of the development of the conjunctival microbiome in mice and provides an indication that early microbial colonization is required for the establishment of mucosal ocular surface homeostasis, the perturbation of which leads to increased susceptibility to allergic eye disease.

Abstract No.: 201243**Microplastics Identified in Commercial Over-the-Counter Lubricant Eyedrops***First Author: Chris LIM**Co-Author(s): Matthew BURKE, Emily CURREN, Julia JAEGER, Sandric LEONG, Blanche LIM, Jodhbir MEHTA, Andri RIAU, Xinyi SU, Robert SYMONS, Duoduo WU*

Purpose: There is increasing evidence that microplastics exert harmful effects on human health and on the ocular surface. This pilot study aims to investigate if microplastic particles are present in commonly used eyedrops in single-use plastic vials.

Methods: Six commonly used commercial tear-replacement solutions available without a doctor's prescription were tested (Brands A-F). All brands of eyedrops were analysed visually using light microscopy, and the number of microplastic particles was manually

counted. These were further analysed using the Agilent 8700 Laser Direct Infrared (LDIR) chemical imaging system.

Results: All eyedrops analysed contained microplastics. The number of particles identified using light microscopy ranged between 15 (Brand E) to >18,000 (Brand F). In total, nine types of microplastics were identified with LDIR: polyethylene, polypropylene, polystyrene, polyvinylchloride, polyethylene terephthalate, polycarbonate, polymethylmethacrylate, polyamide, and polyurethane.

Conclusions: This study provides the most extensive quantification of microplastic contamination in commercial eyedrops to date, highlighting a major, under-recognised source of ocular exposure. These particles may arise from secondary degradation of the plastic vials during production, transportation, storage, or during instillation, or be introduced from other sources during production and represent a major source of exposure to the ocular surface, especially among patients who require chronic instillation of eyedrops.

Abstract No.: 200312**Monkeypox-Associated Keratitis and Glabellar Lesion Mimicking a Third Eye***First Author: Wei Chen (eric) LAI**Co-Author(s): Shih Chung LAI, Mei-hui LEE, Timothy LEE, Jeremy LIU*

Purpose: To report a unique case of monkeypox virus keratitis that resolved with topical acyclovir treatment.

Methods: Case report.

Results: A 32-year-old male with a history of AIDS, neurosyphilis, and previous retinal detachment in the left eye was admitted for 1 week of left eye purulent discharge, blurry vision, and disseminated skin lesions. Visual acuity was 20/100 in the left eye. Externally, there is a large, ulcerated lesion on the glabellar region appearing like a third eye. There was a diffuse, vesicular rash with ulceration along the left upper and lower eyelids, associated with margin thickening and lower eyelid skin erosion. On the anterior segment, there was diffuse injection, chemosis, and corneal edema with perilimbal subepithelial stromal haze. Posterior exam was unremarkable. The patient's skin lesion swabs were positive for Monkeypox virus PCR. Additionally, skin biopsy demonstrated immunoreactivities in epidermal keratinocytes at the ulcer margin positive for monkeypox antibody. The patient was diagnosed with monkeypox blepharoconjunctivitis and keratitis. He was started on systemic tecovirimat, as well as acyclovir ointment every 4 hours, tobradex four times a day, and topical levofloxacin drops every 2 hours in the left eye. One month later, the patient's vision improved to baseline vision of 20/25. The patient experienced significant improvement in periocular skin ulceration,

blepharoconjunctivitis, corneal infiltrates, as well as skin lesions and rectal abscesses. He was tapered off systemic and topical antivirals on discharge.

Conclusions: This report demonstrates the striking ocular manifestations of monkeypox virus in an immunocompromised patient that resolved with antiviral treatment.

Abstract No.: 209602

Myelinated Corneal Nerve Fibers: A Case Report

First Author: Yajie SUN

Purpose: We accurately characterized the patient's characteristic morphological features.

Methods: In this case, we employed multimodal in vivo imaging to accurately capture the characteristic morphological features of the condition.

Results: In a 70-year-old male patient, conspicuous grey-white, thickened nerve fiber bundles in the anterior two-thirds of the corneal stroma were detected incidentally during cataract examination. On in vivo confocal microscopy (IVCM), the outermost region of nerve fibers in the corneal stroma is not uniform but is interrupted by hyperreflective, sheath-like sheaths. Corneal topography, optical coherence tomography (OCT) of the anterior segment and corneal sensitivity testing revealed no significant abnormalities. The patient subsequently underwent cataract surgery and achieved a best corrected visual acuity (BCVA) of 20/20.

Conclusions: We have obtained high quality multimodal imaging data of myelinated corneal nerve fibers that have not only enriched the imaging atlas of this disease, but have also shown that these myelinated fibers do not significantly affect ocular surface health or corneal morphology, nor negatively impact the outcomes of cataract surgery.

Abstract No.: 204995

New Onset of Herpes Simplex Keratitis following Alkaline Chemical Burn—A Case Report

First Author: Yu-ling LIU

Purpose: To report the clinical presentation and management of a patient with a new onset of herpes simplex keratitis following an alkaline chemical burn.

Methods: Case report.

Results: A 41-year-old man sustained an alkaline chemical burn to his left eye from sodium hydroxide. Initial findings included corneal epithelial loosening, limbal ischemia, and conjunctival erosion, with a best-corrected visual acuity (BCVA) of 0.8. Treatment involved epithelial debridement, a bandage contact lens (BCL), topical corticosteroids, lubricants, and

oral doxycycline. Four days later, corneal edema and limbal ischemia worsened despite epithelial healing. A cryopreserved amniotic membrane (CAM) was applied due to progressing edema and conjunctival melting. After the CAM melted, a new epithelial defect developed. The patient declined further surgical intervention, and corneal deterioration continued, with BCVA dropping to 0.3. Autologous serum was added, but the patient was lost to follow-up and later received dexamethasone injections elsewhere. One week later, he returned with BCVA 0.2 and classic signs of herpes simplex keratitis (HSK), including dendritic and geographic epithelial defects and stromal erosion, despite no prior HSK history. Antiviral ointment was started, corticosteroids stopped, and the ulcer healed in 3 days, though edema and necrosis worsened. Steroids were cautiously reintroduced, leading to recovery with BCVA of 0.6. Eight weeks later, disciform corneal edema occurred but improved with oral acyclovir and steroids, stabilizing BCVA at 0.7.

Conclusions: This rare case highlights the potential for new-onset HSK following chemical burns, emphasizing the need for careful monitoring and tailored treatment strategies in such complex presentations.

Abstract No.: 204070

Niche Microenvironment Promotes the Growth of Limbal Stem Cells

First Author: Jixing CAO

Co-Author(s): Jiansu CHEN, Sihui CHEN

Purpose: Limbal epithelial stem cell (LSC) deficiency (LSCD) leads to pain, corneal opacity, and eventually blindness. LSC transplantation of ex vivo expanded human LSCs on a carrier with limbal niche structure helps better treat LSCD. Here, we study the collagen vitrigel (CV) membrane with biomimetic niche microtopography to construct the LSC layer and transplant it for LSCD treatment.

Methods: We fabricated the 3-dimensional (3D) niche microtopography mold on a silicon substrate by ultraviolet (UV) lithography with photoresist to mimic the natural limbal microenvironment. Type-I collagen and 10 × DMEM were mixed at 9:1 to prepare a collagen sol, and it was incubated at 37°C, which was then removed to the rigid polymer scaffolds with micropattern and dried in a clean air chamber at 10°C for micropatterned collagen gel membrane formation. Next, LSCs at passage one (P1) were seeded onto the membrane and incubated at 37°C. The morphology and cell phenotype were analyzed.

Results: LSCs at P1 were acquired from the primary rabbit LSCs and exhibited polygonal morphology. The microstructure of the rigid niche-like microtopography polymer mold and embossed CV membrane was validated by the SEM images. The mold has tens of discrete fan bulges to form a 3D ring-like microstructure, with a gradient height from the center

70µm to the edge 40µm. LSCs cultured on curved CV membrane with microenvironment grew well by viability assay. The cultured cells were positive expression of CK3 and p63 by immunofluorescence staining.

Conclusions: CV membrane with limbal niche microenvironment promotes LSC growth and maintains cell phenotype.

Abstract No.: 201839

Nitric Oxide Protects Corneal Endothelium: In Vivo Correlation and In Vitro Confirmation

First Author: Yu-ting **TSAO**

Co-Author(s): Hung-chi **CHEN**, Yi-jen **HSUEH**, Tsai-te **LU**

Purpose: This study aims to elucidate the relationship between physiological concentrations of nitric oxide (NO) in the aqueous humor and corneal endothelial cell density (ECD). In addition, it investigates the proliferative, cytoprotective, and therapeutic roles of NO in maintaining ECD using an in vitro model.

Methods: This prospective case series was conducted from April 1, 2019, to September 30, 2024. Aqueous humor samples were collected at the initiation of phacoemulsification surgery, and NO levels were quantified using a commercially available nitrate/nitrite colorimetric assay kit. For the in vitro model, the B4G12 corneal endothelial cell line was used to evaluate the proliferative, protective, and therapeutic effects of NO, in comparison with ascorbic acid and a control group. Hydrogen peroxide (H₂O₂) was employed as the injurious agent in both the protective and therapeutic models.

Results: Spearman's correlation analysis revealed a moderately significant positive correlation between aqueous humor NO levels and corneal ECD ($P = 0.004$), suggesting a physiological role of NO in maintaining endothelial integrity. In the in vitro model, NO exhibited superior protective and therapeutic effects against H₂O₂-induced damage when compared to both the ascorbic acid and control groups.

Conclusions: Physiological levels of aqueous humor NO are positively associated with corneal endothelial cell density, indicating a role in maintaining endothelial integrity. In vitro, NO exerts stronger protective and therapeutic effects against oxidative stress than ascorbic acid, underscoring its potential in preserving corneal endothelial function. These findings warrant further exploration of NO-based strategies to prevent or mitigate endothelial damage.

Abstract No.: 201773

OSDI & Nei-VFQ25 Evaluation in Chronic Glaucoma Patients With Long-Term Use of Latanoprost 0.005% and Timolol 0.5% Eye Drop: A Multicenter Prospective Longitudinal Study

First Author: Ferdian **RAMADHAN**

Co-Author(s): Ruth **ANASTASIA**, Andry **LUKANDY**

Purpose: This study aimed to compare the effects of timolol 0.5% and latanoprost 0.005% on ocular surface health and vision-related quality of life in patients with chronic glaucoma.

Methods: Seventy glaucoma patients without a prior history of dry eye were enrolled from January 2023 to July 2024 at three eye clinics in Indonesia. Participants were assigned to either the timolol ($n=32$) or latanoprost ($n=38$) treatment group. Ocular surface status was evaluated using Tear Break-Up Time (TBUT), Schirmer I and II tests, and the Ocular Surface Disease Index (OSDI). Vision-related quality of life was assessed using the National Eye Institute Visual Function Questionnaire-25 (NEI VFQ-25) at 1, 3, and 6 months.

Results: In the timolol group, TBUT and Schirmer test scores declined over six months, accompanied by a significant increase in OSDI scores, indicating worsening dry eye symptoms. The latanoprost group showed no significant changes in these parameters. NEI VFQ-25 composite scores remained stable in both groups at 1 and 3 months, but declined at 6 months in the timolol group, particularly in subscales related to ocular pain, role difficulty, dependency, and social functioning. The driving subscale was excluded due to lack of statistical significance.

Conclusions: Timolol 0.5% was associated with greater deterioration of the ocular surface compared to latanoprost 0.005%. However, its impact on overall vision-related quality of life was modest.

Abstract No.: 201361

Ocular Health and Digital Device Use: Dry Eye Symptoms in High School Children in a South Indian City

First Author: Vaishnavi

Co-Author(s): Meghana **REDDY**

Purpose: To assess the association between digital device usage and the prevalence and severity of dry eye symptoms in high school children in a South Indian city.

Methods: This cross-sectional study assessed 352 students (grades 6–9) in a Kanchipuram school to evaluate the association between screen time and ocular health. Dry eye symptoms were measured using the Ocular Surface Disease Index (OSDI), Schirmer's test, and tear film break-up time (TBUT).

Results: The mean OSDI score was 37.2 ± 11.8 , and 90.6% of students exhibited DED symptoms. A daily screen time of over 3–3.5 hours significantly increased DED risk. Each additional 30 minutes of computer use increased the odds of moderate to severe DED (OR 1.94, 95% CI: 1.2–3.1). Higher grade levels also had a greater risk (OR 1.30, 95% CI: 1.1–1.6).

Conclusions: Digital device usage exceeding 3 hours per day is significantly associated with moderate to severe dry eye in school-aged children. • Children with increased computer use for education are at the highest risk • Limiting cumulative screen exposure to <3 hours/day may help prevent DED. • Interventions such as regular breaks, blink training, and increased outdoor time are recommended Our findings underscore the need for awareness among parents, schools, and policymakers to regulate screen habits in children to preserve long-term ocular surface health

Abstract No.: 204687

Ocular Rosacea: A Rare Case Report & Literature Review

First Author: Faria Tilat TIMA

Co-Author(s): Tanvir AHMED, Mahmood MUJTABA

Purpose: To report a case of Blepharokeratoconjunctivitis secondary to ocular rosacea.

Methods: Ms. X, 16 years, female, came to OPD with complaints of pain, redness, watering, photophobia, and foreign body sensation for 2 weeks. The condition subsided but this is recurring for about last 5 years. She also gave H/O recurrent allergic attack for last 1 year which include rashes in different parts of body & in the face. There were H/O flare-ups while working outside. She used a topical steroid, an antihistamine, vitamin C, and artificial tears for her complaints. Visual acuity (V/A)-Un aided 6/9(B/E), Pinhole 6/6P(B/E), Near-N6, pupil showed normal reaction. Slit lamp Examination revealed eyelid redness, swelling, margin telangiectasia (B/E) with a Meibomian cyst- LLL. Circumferential Superficial corneal Vascularisation & conjunctival congestion on B/E. Fundoscopic examination was non-contributory. Examination of the face revealed Facial papules, erythema over cheeks, nose, forehead, and chin. Diagnosis is based on symptoms, medical history, and an examination of the eyes and the skin of the face. She was treated with steroid-topical E/D: Dexamethason-1 drop 4 times daily B/E, steroid Oint: Dexamethasone at HS B/E, Antibiotic-topical E/D: Moxifloxacin-1 drop 6 times daily B/E, antibiotic oint: Ciprofloxacin at HS both eyelid & artificial Tear. She was referred to a skin specialist & they also confirmed our diagnosis. They prescribed Doxycycline, DUAC gel (Clindamycin & benzyl peroxidase) & oral antihistamine. She was re-examined after 7 days & her condition had improved.

Results: Ocular rosacea is not a very uncommon disease involving the skin & eyes. The various spectrum of manifestation & complexion of our population makes the diagnosis difficult. Life-long follow-up & observation is needed

Conclusions: The diagnosis of ocular rosacea is clinical and relies on collaborative study of both ophthalmologists and dermatologists and careful observation and interpretation of skin and ocular manifestations. Patient must seek dermatologic consultation. Lifestyle modification is equally important alongside the treatment option. So, successful therapy requires a multidisciplinary approach.

Abstract No.: 204861

Ocular Saviour: Allogenic Simple Limbal Epithelial Transplantation

First Author: Madhuvanthi MOHAN

Co-Author(s): Sujatha MOHAN

Purpose: To report the effectiveness of bilateral Allogeneic Simple Limbal Epithelial Transplantation (AlloSLET) for rapid re-epithelisation and inflammation control in a case of bilateral chemical injury

Methods: A 32-year-old male labourer presented with bilateral ocular pain, photophobia, and lid swelling following accidental injury with cement while working. On examination, both eyes showed marked chemosis and lid edema, total corneal epithelial defects and significant damage to the conjunctival epithelium along with cement particles on the ocular surface. After a thorough irrigation was performed, both eyes were graded as grade V according to Dua's grading and L6C3K2P0I0X1 according to the E-PIX grading system. Bandage contact lenses were placed and hourly topical corticosteroids were initiated. Persistent inflammation after 48 hours prompted bilateral AlloSLET. During surgery, lid eversion permitted careful and meticulous removal of residual cement particles which were the source of inflammation. The left eye, being more severely affected, required a repeat AlloSLET 10 days later.

Results: Postoperatively, there was resolution of inflammation and progressive re-epithelisation of the surface in both eyes. Visual acuity improved gradually, with best-corrected visual acuity showing significant recovery at follow-up. The removal of residual cement was crucial in reducing the continued inflammation. The patient remains symptom-free with stable ocular surface.

Conclusions: Bilateral AlloSLET, combined with thorough removal of retained alkali, can successfully restore the ocular surface in severe cement-related chemical burns. Early surgical intervention in cases with persistent inflammation may speed up recovery, reduce complications, and improve visual prognosis

Abstract No.: 206289**Ocular Surface Disease in a Young Boy With Laryngo-Onycho-Cutaneous Syndrome: A Case Report***First Author: Hajra MALIK**Co-Author(s): Shehrbano ABBAS, Saman GULZAR, Najia UZAIR*

Purpose: To present a rare case of ocular surface disease associated with LaryngoOnychoCutaneous Syndrome (LOCS), to describe its clinical course, management, and implications for longterm ophthalmic care.

Methods: A descriptive case report of a young boy with known LOCS was conducted. Detailed ophthalmic examination, photographic documentation, and assessment of ocular surface findings (including conjunctival granulation, symblepharon, and corneal involvement) were performed. Therapeutic interventions (medical and surgical) were applied, with longitudinal followup to monitor outcomes and recurrence.

Results: The patient exhibited significant conjunctival granulation tissue, symblepharon formation, and ocular surface compromise. Topical anti-inflammatory therapy and surgical excision of granulation tissue provided temporary improvement. However, recurrence was observed, requiring repeated interventions and close monitoring. Visual prognosis was challenged by progressive surface scarring.

Conclusions: LOCS may present with severe and recurrent ocular surface disease, posing difficulties in achieving lasting control. Early recognition, aggressive management of granulation, and long-term follow-up are essential to prevent visionthreatening complications in such cases.

Abstract No.: 204130**One-Year Clinical Outcomes of Phase II Advanced Cellular Therapy for Keratoconus***First Author: Hao ZHANG**Co-Author(s): Jorge L. ALIÓ, Jorge L. ALIÓ DEL BARRIO, Alejandra E. RODRIGUEZ*

Purpose: To assess the one-year outcomes of a Phase II clinical trial evaluating autologous adipose-derived adult stem cells (ADASCs), with or without decellularized donor corneal lamina, for corneal stromal regeneration in keratoconus.

Methods: Eleven patients with advanced keratoconus were enrolled; ten were randomized into two experimental groups and one received ADASCs alone. Group 1: ADASCs only (n=1); Group 2: 120-µm decellularized lamina (n=5); Group 3: 120-µm lamina recellularized with 3×10^6 ADSCs (n=5). ADSCs were harvested via elective liposuction and implanted in a mid-stromal pocket. Uncorrected (UDVA) and corrected

distance visual acuity (CDVA) were primary endpoints, with secondary parameters assessed preoperatively and at 1, 3, 6, and 12 months.

Results: No adverse events, including inflammation or rejection, occurred during follow-up. In vivo confocal microscopy demonstrated ADASC differentiation into keratocyte-like cells with new collagen deposition and progressive transparency improvement from 3 months. Anterior segment OCT confirmed integration and recellularization of implanted lamina. Keratoconus remained stable in all eyes. Stromal thickening was evident in Groups 2 and 3 but not in Group 1. Visual acuity improved modestly in Group 1, and by 1–2 Snellen lines in Groups 2 and 3.

Conclusions: ADASC-based therapy, especially in combination with decellularized lamina, appears safe and effective for restoring stromal thickness, transparency, and visual function in advanced keratoconus.

Abstract No.: 203683**Ophthalmologic Manifestations of Xanthoma Disseminatum in a Young Filipino Female***First Author: Kent FLORENTINO**Co-Author(s): Kristine Joy IRAOLA-DAVOCO, Ruben LIM BON SIONG, George Michael SOSUAN, Vincent TE*

Purpose: To report the first documented case of Xanthoma Disseminatum with ophthalmologic manifestations in an adult Filipino female

Methods: Case report

Results: A 42-year-old Filipino woman presented with bilateral red-yellow conjunctival and upper eyelid masses, accompanied by ocular redness and foreign body sensation. She also developed persistent, pruritic, red-yellow papules and nodules over the axilla, forearms, wrists, and thighs, along with intermittent globus sensation and hoarseness four months prior. Dermatologic evaluation, including a skin biopsy, revealed xanthomas, which was initially managed with oral statin therapy. Ocular symptoms led to empirical treatments in different clinics for presumed keratoconjunctivitis and phlyctenulosis, without improvement. Ophthalmologic examination showed red-yellow nodular lesions on the conjunctiva and upper eyelids. Videostroboscopy also identified multiple nodular lesions in the pharynx. Excision biopsies of the conjunctival and eyelid lesions demonstrated round cell proliferation, strongly positive for CD68 and negative for pancytokeratin, consistent with xanthogranulomatous inflammation. This, combined with the mucocutaneous and ocular involvement, supported a final diagnosis of Xanthoma Disseminatum. She was prescribed topical lubricants for symptomatic relief and scheduled for excision of recurrent conjunctival lesions for cosmesis. A multidisciplinary work-up was initiated to assess the

involvement of other organ systems. Upon completion, systemic immunosuppressive therapy with Cladribine is planned.

Conclusions: Xanthoma disseminatum is a rare, non-Langerhans cell histiocytosis with multisystemic involvement that can initially present with ocular manifestations. Early recognition of such is pivotal, as they may precede systemic symptoms. Diagnosis relies on characteristic clinical and immunohistopathologic features. Due to the lack of standardized treatment protocols, effective management requires interdisciplinary collaboration.

Abstract No.: 200253

Optimizing Corneal Ulcer Treatment: Drape Technique Supersedes Corneal Button

First Author: Basitali LAKHANI

Purpose: This case series presents multiple instances where drape bandage contact lenses (BCL) were utilized as an emergency measure for corneal perforations in resource-limited settings. One notable case involved a patient with a 3.5 mm corneal perforation, treated at a secondary medical facility lacking access to corneal buttons. The intervention involved the application of drape BCL, chosen due to its cost-effectiveness and availability. Detailed clinical presentations, diagnostic procedures, and the rationale for selecting drape BCL are discussed. The procedural steps and post-operative care protocols are also outlined. These cases underscore the potential of drape BCL as a viable alternative in settings where traditional corneal buttons are not accessible, advocating for its broader adoption. This approach not only provides hope for patients but also alleviates the burden on healthcare systems by offering a practical and affordable solution for managing corneal perforations.

Methods: .

Results: .

Conclusions: By sharing this experience, we aim to encourage the adoption of this approach in similar clinical scenarios, offering hope to patients.

Abstract No.: 203886

Oral Calycosin Restores Ocular Surface Integrity in NOD Mice With Primary Sjögren's Syndrome via Th17 Cell Modulation

First Author: Hao CHEN

Co-Author(s): Yun FENG, Haozhe YU, Zhiyu ZHANG

Purpose: Primary Sjögren's syndrome (pSS) is an autoimmune disorder characterized by lacrimal gland dysfunction and dry eye, with limited therapeutic options. This study investigated whether oral Calycosin (Caly), an isoflavonoid derived from Astragalus, could improve ocular surface integrity in NOD mice

with pSS, and explored its underlying immunological mechanisms.

Methods: Age-matched NOD/ShiLtJ mice with similar body weights were randomly assigned to four groups: control, low-dose Caly (10 mg/kg, oral gavage), high-dose Caly (50 mg/kg, oral gavage), and dexamethasone (tail vein injection) (n = 4–5 per group, 4 weeks). Tear secretion, corneal fluorescein staining, lacrimal gland histology, and central corneal thickness were evaluated. Multiplex immunohistochemistry, quantitative real-time PCR (qPCR), Western blotting (WB), and flow cytometry were used to assess T cell subsets. Humanized mice were employed to evaluate the potential immunotoxicity of Caly by flow cytometry.

Results: High-dose Caly significantly improved tear secretion and reduced corneal fluorescein staining. Lacrimal gland histology showed decreased lymphocytic infiltration, consistent with immunohistochemistry, qPCR, and WB findings. Central corneal thickness demonstrated structural recovery. Flow cytometry revealed a marked reduction in Th17 cell populations, with unobvious changes in Th1 and Treg cells. No adverse effects on human immune cell development were observed in humanized mice.

Conclusions: Calycosin alleviates ocular surface damage associated with pSS, likely through selective modulation of Th17-mediated immune responses. These findings highlight Caly as a promising immunomodulatory therapy with translational potential for pSS-related dry eye.

Abstract No.: 205287

Pain, Proptosis, and a Surprise in the Sinus: A Case of Bulla Ethmoidalis Mucocele

First Author: Arjan DHILLON

Co-Author(s): Chee SHEW FEI

Purpose: To report a case of unilateral non-axial proptosis secondary to mucocele.

Methods: Case report.

Results: A 46-year-old with underlying hypertension presented to us with right eye (OD) throbbing pain for 1 week duration, with pain on movement temporally. On further history, the patient claims his OD was gradually bulging outwards. On examination, his best corrected visual acuity (BCVA) was 6/9 in both eyes with a negative relative afferent pupillary defect. Hirschberg test revealed OD exotropia. Hertel exophthalmometer revealed significant proptosis of the OD, which was 20 mm compared to the left eye (OS) which was only 15 mm. Extraocular movements of the OD were restricted superiorly and laterally, and otherwise full. The anterior segment and posterior segment of both eyes were unremarkable on slit lamp and fundus examination. A contrasted commuted topography (CECT) was performed which revealed a non-enhancing heterogeneous hypodense lesion within the right

anterior ethmoidal air cell, strongly suggestive of a mucocele. Patient underwent a functional endoscopic sinus surgery (FESS) where a right bulla ethmoidalis mucocele was marsupialized successfully. The final diagnosis was OD non-axial proptosis secondary to right bulla ethmoidalis mucocele. Post operation, the eye pain resolved, with Hirschberg being central and Hertel exophthalmometer repeated showing OD 16 mm and OS 15 mm respectively.

Conclusions: Sinonasal mucocèles may present with orbital features such as painful non-axial proptosis, ocular misalignment, and motility restriction, closely resembling primary orbital disease. Recognition of this entity with timely imaging and surgical intervention is vital to relieve symptoms, restore ocular function, and prevent long-term visual morbidity.

Abstract No.: 205783

Pathogenic Mechanisms and Targeted Therapy of Keratoconus Based on Tunable In Vitro Matrix Stiffness Models and Nrf2 Knockout Mice

First Author: Xiaoxue LI

Co-Author(s): Jiansu CHEN, Zekai CUI

Purpose: This study investigates keratoconus (KC) mechanisms by integrating patient clinical data, a tunable matrix-stiffness in vitro model, and Nrf2 knockout (Nfe2l2_ko) mice, and evaluates the therapeutic potential of RTA-408 in modulating oxidative stress, inflammation, and ECM remodeling.

Methods: Corneal topography and Corvis ST parameters were collected from KC patients. Human corneal stromal cells (hCSCs) from SMILE-derived non-KC lenticules were used to establish a standardized in vitro model. Low-stiffness collagen hydrogels mimicked the KC microenvironment, followed by CXL treatment and RTA-408 intervention. Gene and protein expression were analyzed via RNA-seq, qPCR, proteomics, immunofluorescence, and Western blotting. An Nfe2l2_ko mouse model was generated using CRISPR/Cas9, and corneal changes were assessed by slit-lamp, OCT, TEM, immunofluorescence, ROS detection, and single-cell sequencing.

Results: KC patients exhibited significant corneal morphological and biomechanical abnormalities. In vitro, low matrix stiffness reduced collagen density, increased ROS, and dysregulated inflammation, oxidative stress, and ECM-related factors, which were reversed by CXL and RTA-408. Nfe2l2_ko mice showed KC-like features, including central corneal thinning, decreased stromal collagen, and proteoglycans. Single-cell sequencing and immunofluorescence revealed that Nrf2 deficiency activated inflammatory and oxidative stress pathways while suppressing antioxidant defenses and ECM homeostasis.

Conclusions: We established a tunable matrix-stiffness in vitro model of KC and demonstrated that reduced stiffness and Nrf2 deficiency drive KC-like pathology via the oxidative stress–inflammation–ECM degradation axis. RTA-408 activation of Nrf2 alleviated these changes, offering a potential therapeutic strategy. The Nfe2l2_ko mouse model provides a reliable platform for mechanistic studies and drug development.

Abstract No.: 207148

Persistent Red Eye? Look Out for Conjunctival Ulcers; Eye Opener for Systemic Differential Diagnosis

First Author: Harshitha KANISSETTY

Co-Author(s): Naveena Reddy ASAM

Purpose: To alert young ophthalmologists that conjunctival lesions in acute red eye require thorough evaluation beyond ophthalmology, requiring detailed history and cross-referral.

Methods: A 32-year-old male presented to us with a history of persistent redness after completion of a course of topical antibiotic eye drops (Gatifloxacin eye drops 6 times a day for 5 days) prescribed in the out patient department of a tertiary care Medical college hospital.

Results: Multiple conjunctival ulcers in the bulbar, palpebral and inter marginal conjunctiva of both eyes were found. They were 2 to 3 mm in diameter with whitish necrotic floor and surrounding intense congestion. Rest of the anterior segment, visual acuity & fundus were normal. The patient was again quizzed in detail, when he revealed that he was actually attending the ENT out patient. His records revealed that he was under evaluation for laryngeal stricture and was scheduled for biopsy of a sub glottic nodule.

Conclusions: Although conjunctival ulcers are a rare association with Behcets disease, it is very important to keep the mind open for such associations.

Abstract No.: 202147

Phototherapeutic Keratectomy for Anterior Corneal Diseases

First Author: Amrin Fatema Afzal Hussain NAYANI

Purpose: To evaluate the role of photo therapeutic keratectomy for anterior corneal diseases and to determine the role of diagnostic modalities for planning and management of anterior corneal diseases.

Methods: This was a prospective, cross-sectional observational study conducted at a tertiary eye care centre in northern India. Preoperative patient selection and evaluation are done for systemic diseases as well as for assessment of the depth and size of stromal involvement. Detailed ophthalmological evaluation is done to evaluate the depth and amount of stromal involvement by Anterior segment OCT and epithelial

thickness mapping. Topographical evaluation was done for refractive planning. Excimer laser ablation was done to ablate the diseased Stromal ablation as per standard protocols with residual bed thickness >300 µm. Post-operative evaluation and visual rehabilitation is done with routine follow-up.

Results: Statistical evaluation was done by SPSS 23.0 software. Mean improvement in visual acuity was calculated for all participants. BCVA was >6/24 for all patients.

Conclusions: Anterior stromal diseases are amenable to PTK with good post-operative visual rehabilitation. Careful evaluation of stromal involvement with a multimodal approach is crucial for planning the ablation depth.

Abstract No.: 205233

Pierced by Nature: Study on Manifestations of Triangular Thorn Corneal Injuries

First Author: Rakhi P **DCRUZ**

Purpose: Triangular thorn injuries to the cornea present a unique diagnostic challenge due to their transparent, glass-like appearance, often making them invisible in routine examinations. These thorns typically lodge in the upper tarsus, leading to superior half corneal abrasions that may go unnoticed, even with fluorescein staining. Misdiagnosis or delayed detection can result in serious complications, necessitating meticulous examination techniques for accurate identification and timely intervention.

Methods: This prospective study examines a case series of 35 patients presenting with triangular thorn injuries. Patients were classified into early and late presentations, with late cases exhibiting advanced complications such as corneal ulcers, anterior uveitis, nodular abscess-like swelling in the upper tarsus, and granuloma formation engulfing the thorn. Primary ophthalmologists frequently missed the diagnosis, leading to disease progression. A «bud and feel» technique—gently swiping the tarsus to detect a gritty sensation—was evaluated as a crucial method for identifying the presence of the thorn.

Results: Early presentations were primarily characterized by isolated corneal abrasions, whereas late cases exhibited infectious and inflammatory complications requiring extensive management. Granuloma formation and abscess-like swellings developed around undetected thorns, reinforcing the importance of careful upper tarsus examination in suspected cases. Routine fluorescein staining often failed to highlight the embedded thorn, leading to diagnostic delays.

Conclusions: Triangular thorn injuries, due to their near-invisibility and deceptive nature, pose a diagnostic challenge. Timely identification and careful removal, coupled with bandage contact lens placement for

widespread abrasions, and frequent lubricant and antibiotic therapy, are essential for optimal patient recovery and prevention of progressive ocular damage.

Abstract No.: 203070

Post-Filtration Surgery Ocular Digital Massage Induced Acute Corneal Hydrops

First Author: Indra **AMARJARGAL**

Co-Author(s): Anudari **BATKHUU**

Purpose: To report a case of a juvenile open-angle glaucoma patient with long-term ocular massage following trabeculectomy, who developed an Acute Corneal Hydrops.

Methods: Case report and review of literature.

Results: Acute Corneal Hydrops induced by ocular massage following trabeculectomy surgery is a controversial and rare complication. The 21-year-old female patient was diagnosed with juvenile-onset glaucoma 6 years ago and went through filtration surgery to lower intraocular pressure with daily ocular massage. She had denied previous ocular trauma, allergic disease, and a family history of keratoconus. Slit lamp examination revealed a protrusion in the cornea mimicking corneal hydrops with epithelial microcysts, intrastromal cleft, and Descemet's membrane detachment in her right eye. She was diagnosed with acute corneal hydrops and received intracameral C3F8 gas tamponade injection with compression sutures on the cornea. On 1 1-week follow-up, the corneal edema was significantly improved.

Conclusions: The relationship between long-term post-trabeculectomy ocular massage and the development of acute corneal hydrops is not well studied and proven, but it can occur in a minority of patients who have predisposing factors. In this case, due to having poor vision since childhood, the patient didn't know whether her complaints arose from a newly acquired condition rather than glaucoma, which she's been dealing with for a long time. Therefore, she had been continuously massaging the globe, making her already existing keratoconus worse and resulting in corneal hydrops formation. When advising therapeutic massage to enhance aqueous outflow, doctors should rule out any other ocular condition and warn the patient about the complications.

Abstract No.: 200852

Prevalence and Clinical Associations of Demodex Infestation in Taiwanese Patients With Dry Eye Disease

First Author: Ming-hwei **TSAI**

Co-Author(s): Yi **WAN**

Purpose: To investigate the prevalence of Demodex infestation and its association with clinical symptoms

and ocular surface parameters in Taiwanese patients presenting with dry eye disease.

Methods: A cross-sectional study was conducted enrolling patients with dry eye symptoms. Symptom profiles were documented and patients completed the Ocular Surface Disease Index (OSDI) questionnaire. Ocular examinations were performed with recording of ocular surface parameters. Eight eyelashes were sampled per patient (two from each eyelid of both eyes), preferentially selecting lashes with cylindrical dandruff when present. Samples were examined microscopically for Demodex identification and quantification. Multivariate analyses were performed to evaluate associations between Demodex counts and clinical symptoms and parameters.

Results: Fifty patients were enrolled with a mean age of 69 years. Demodex infestation was detected in 72% of patients, with a mean count of 3.4 mites per patient. Higher Demodex counts demonstrated significant associations with symptoms of ocular itching and stickiness, as well as reduced tear break-up time. No significant correlation was observed between Demodex counts and OSDI questionnaire scores.

Conclusions: Demodex infestation exhibits a high prevalence (72%) among Taiwanese patients with dry eye symptoms. The significant association between elevated Demodex counts and specific symptoms (itching and stickiness) suggests these clinical features may serve as reliable indicators for Demodex-related ocular surface disease. The absence of correlation with standardized OSDI scores indicates that targeted symptom evaluation may provide superior diagnostic utility compared to general dry eye questionnaires for identifying Demodex-associated pathology in this patient population.

Abstract No.: 206105

Prevalence of Corneal Guttata in Patients Undergoing Cataract Surgery at a Tertiary Hospital in Thailand

First Author: Teeravee **HONGYOK**
Co-Author(s): Chanchanok **SAELIM**

Purpose: To assess the prevalence of corneal guttata and identify the associated risk factors among pre-operative cataract patients in a tertiary care hospital in Thailand.

Methods: The prospective observational study included 869 eyes from 566 cataract patients presenting at the ophthalmology clinic. All participants underwent routine eye examinations, followed by ocular biometry and corneal endothelial evaluation using the IOL Master and specular microscopy, respectively. Demographic and clinical data were recorded using a standardized data collection form. The diagnosis of corneal guttata was independently made by two

authors based on specular microscopy printout images and was graded from 2 to 4 depending on severity.

Results: The overall prevalence of corneal guttata among cataract patients was 29.1% (253/869). Of these 253 eyes, the majority demonstrated stage 2 severity at 19.2% (167), followed by stage 3 at 7.5% (65), stage 4 at 1.8% (16), and stage 5 at 0.6% (5). Logistic regression analysis indicated that female gender, daily sunlight exposure exceeding two hours, residence in southern provinces, lower endothelial cell density, reduced percentage of hexagonality, and higher central corneal thickness were associated with an increased risk of corneal guttata.

Conclusions: A high prevalence of corneal guttata was observed in cataract patients in Thailand, associated with female gender, southern province residents, daily sunlight exposure, and compromised corneal endothelial parameters. The findings highlight the value of routine corneal guttata screening in preoperative patients to reduce the risk of postoperative endothelial decompensation and its adverse outcomes.

Abstract No.: 203372

Prospective Study of Accelerated Transepithelial Corneal Cross-Linking in Young Indonesian Patients With Keratoconus

First Author: Rifa **WIDYANINGRUM**
Co-Author(s): Reny **SETYOWATI**, Supanji **SUPANJI**, Agus **SUPARTOTO**, Khadijah **ZAI**

Purpose: To evaluate the safety and efficacy of accelerated transepithelial corneal collagen cross-linking (ATE-CXL) using 9 mW/cm² ultraviolet-A (UVA) irradiation for 10 minutes in pediatric and adolescent patients with keratoconus.

Methods: In this single-arm prospective study, 36 eyes of 36 patients aged 8–25 years with keratoconus underwent ATE-CXL at Dr. Sardjito Tertiary Teaching Hospital, Indonesia. Visual acuity, refractive parameters, keratometry, central corneal thickness, and intraocular pressure were assessed at baseline, 2 weeks, 1.5 months, and 6 months postoperatively. Safety was evaluated based on slit-lamp findings and patient-reported symptoms.

Results: Mean best-corrected visual acuity (BCVA) improved from 1.158 ± 0.38 LogMAR preoperatively to 0.794 ± 0.35 LogMAR at 6 months ($p < 0.001$). Mean astigmatism decreased significantly from 5.49 ± 2.2 D to 4.81 ± 2.1 D ($p = 0.03$). Keratometric parameters (K1, K2, Kmean), central corneal thickness, and intraocular pressure remained stable throughout the follow-up. No serious adverse events occurred. Minor postoperative symptoms, including photophobia and dry eye, resolved spontaneously by 1.5 months. Subgroup analyses by age and keratoconus stage showed consistent trends in visual and refractive improvements.

Conclusions: ATE-CXL with 9 mW/cm² UVA for 10 minutes is a safe and effective intervention in young keratoconus patients, providing early improvements in visual acuity and astigmatism while maintaining corneal stability. These results support ATE-CXL as a minimally invasive option for managing progressive keratoconus in pediatric and adolescent populations. Further long-term, controlled studies are warranted to confirm these findings and determine the durability of clinical outcomes.

Abstract No.: 201124

Rapid Assembly of Corneal Layers With Bi-liquid/ Liquid-solid Interfaces

First Author: Noel **CHEONG**

Co-Author(s): Joseph Y.k. **CHAN**, Kendrick C. **SHIH**

Purpose: Existing tissue engineering approaches are frequently limited by being time-consuming and requiring specialized resources. While bi-liquid interphases offer a comparatively simple and rapid method for forming thin tissue constructs, the resulting cell structures suffer from fragility. To overcome this, we investigated a novel bi-liquid/liquid-solid interface system (BLSLS) designed to create stable, scaffold-supported tissue.

Methods: We investigated the construction of a corneal epithelial and endothelial tissue-like planar construct with BLSLS. Cell layers were assembled with a biocompatible and biodegradable scaffold within a few hours using a simple apparatus. The resulting constructs could be easily collected by removing the liquid phases for subsequent culturing. Cell viability was assessed with live-dead assays and apoptotic assays. Proliferation and attachment of cells beyond scaffold was investigated with Transwell chemical injury model.

Results: The engineered corneal constructs maintained high viability in vitro. Functionally, the tissue-like planar construct could transplant corneal epithelial and endothelial cells to a designated surface. Cells would attach to adjacent surfaces and proliferate beyond the scaffold. Wound healing rate is increased with tissue-like planar construct application in an in vitro corneal epithelial injury model. Furthermore, preliminary data illustrated the strength and elasticity the scaffold possesses for manipulation during intraocular insertion.

Conclusions: These results demonstrate the potential of bi-liquid/liquid-solid interfaces for the easy and rapid construction of corneal tissue-like structures. This strategy is envisioned as a foundational platform for developing transplantable tissue-engineered corneal epithelium and endothelium.

Abstract No.: 200696

Real-World Study of 3% Diquafosol Sodium Eye Drops in Dry Eye Patients (SPRING Study)

First Author: Yuqian **WANG**

Co-Author(s): Zuguo **LIU**

Purpose: To evaluate the efficacy and safety of the P2Y2 receptor agonist (3% diquafosol sodium eye drops) in the clinical application for dry eye patients in China and provide guidance for its clinical use in Chinese dry eye patients.

Methods: An open-label, single-arm, multicenter real-world observational study conducted in China. Patients meeting the dry eye diagnostic criteria from the «Chinese Consensus on Dry Eye: Examination and Diagnosis (2020)» were included in the study and received 3% diquafosol sodium eye drops (Santen Pharmaceutical) according to the physician's treatment strategy.

Results: A total of 3,677 patients were screened, and 3,641 patients (99.02%) were successfully enrolled, with 3,118 patients (85.64%) completing the trial. After 2 weeks, 1 month, and 3 months of 3% diquafosol sodium eye drop treatment, significant improvements were observed in the patient's FBUT, DEQS (Dry Eye Questionnaire Score) total score, overall symptom rating, corneal fluorescein staining score, and tear meniscus height. For MGD patients with dry eye, significant improvements were seen in the eyelid margin abnormality score, meibum quality, and gland opening blockage score, with a significant increase in lipid layer thickness in patients with lipid layer thickness less than 60 nm. No serious adverse events related to the study drug were reported.

Conclusions: The results of this real-world study conducted in China demonstrate that the P2Y2 receptor agonist (3% diquafosol sodium eye drops) is both effective and safe for treating dry eye, providing a new therapeutic option for dry eye patients in China.

Abstract No.: 204211

Remarkable Improvement of Symptoms and Signs of Severe Dry Eye Treated by Ocular Immersion Hydrotherapy

First Author: Haoran **CUI**

Co-Author(s): Yong **TAO**, Shuang **ZHANG**, Tao **ZHANG**

Purpose: To explore the safety and effectiveness of a novel therapy for dry eye disease.

Methods: A 35-year-old woman was referred to our service with a 16-month history of bilateral blurred vision, and dry, gritty, red and painful eyes secondary to a history of hematopoietic stem cell transplantation. Traditional treatment options such as eye drops or ointments have limited efficacy in this case. A pair of swimming goggles was sterilized with 75% medical alcohol, then both eye cups were filled with

commercial intraocular irrigating solutions. By securing the straps, the swimming goggles were fastened onto the head, ensuring that both eyes were immersed in the solutions. The patient underwent 8-hour-per-day treatment of OIH for both eyes in the daytime. Eye ointment was given at night.

Results: At 6 days post-treatment, her BCVA increased to bilateral 0.4, and it was 0.8 from the 9 days post-treatment on. She felt more comfortable, gradually, with wide-open eyes and alleviated photophobia and ocular pain. Sodium fluorescein staining of the cornea showed that corneal filaments disappeared after 8 days of consistent OIH treatment, with a few small punctate corneal staining with sodium fluorescein. After two weeks of OIH treatment, the inflammation of her right eye resolved remarkably, and corneal nerves could be detected again by in vivo confocal microscopy.

Conclusions: The remarkably improved short-term outcome of the present case showed that OIH swimming goggles may serve as a promising choice for the treatment of severe dry eye secondary to oGVHD, especially for patients who failed to get benefits from conventional treatments.

Abstract No.: 200909

Rho-Kinase Inhibitors in Corneal Disease: Mechanisms, Clinical Applications, and Future Directions

First Author: Elizabeth **LEONG**

Co-Author(s): Andrea **ANG**, Chris H.L. **LIM**, Jodhbir S. **MEHTA**, Nigel **MORLET**, Evan **WONG**

Purpose: This narrative review comprehensively examines the mechanisms of action, pharmacological properties, safety profile, and therapeutic applications of Rho-associated protein kinase inhibitors (ROCKI) in corneal disease. It integrates preclinical and clinical evidence, reviews ongoing and emerging clinical trials, and discusses novel approaches. Key evidence gaps are identified, and future research priorities are outlined.

Methods: A structured literature search of PubMed, EMBASE, and Clinical Trials Gov was conducted from inception to May 2025 in accordance with the Scale for the Assessment of Narrative Review Articles (SANRA) framework. Keywords included “Rho-kinase inhibitor,” “corneal endothelium,” “Fuchs endothelial corneal dystrophy,” and “corneal neovascularization.” Eligible studies included preclinical or clinical research on ROCKI in corneal pathology.

Results: ROCKI modulate cytoskeletal organization, cell proliferation, migration, inflammation, and fibrosis in the cornea. Evidence supports their role in promoting endothelial regeneration in Fuchs endothelial corneal dystrophy and reducing oedema in pseudophakic bullous keratopathy (particularly after Descemet stripping only). They demonstrate anti-fibrotic and anti-angiogenic effects, suppressing

corneal neovascularization and minimizing post-surgical fibrosis. ROCKI have a favourable safety profile, with conjunctival hyperaemia and mild, reversible corneal epithelial changes as the most common adverse effects. Sustained-release delivery systems and combination strategies with cell therapy are under active investigation.

Conclusions: ROCKI are a promising therapeutic class for corneal diseases, offering regenerative, anti-inflammatory, anti-fibrotic, and anti-angiogenic benefits. Large-scale randomized controlled trials and optimized delivery strategies are warranted to define their role in routine corneal care.

Abstract No.: 204614

Role of CD200R1 in Regulating Macrophage-Driven Inflammation and Corneal Neovascularization After Alkali Burn

First Author: Li **JIANG**

Co-Author(s): Fan **XU**, Yuchen **ZHOU**

Purpose: To investigate the role of CD200R1 in regulating macrophage infiltration and activation, and its potential to suppress inflammation and pathological corneal neovascularization (CoNV) following alkali burn.

Methods: A corneal alkali burn (CAB) model was established in C57BL/6J wild-type and CD200R1 knockout (CD200R1^{-/-}) mice. Corneal edema and structural changes were assessed using anterior segment optical coherence tomography and hematoxylin–eosin staining. The extent of CoNV was evaluated by slit-lamp biomicroscopy and whole-mount corneal immunofluorescence. Macrophage infiltration and activation were analyzed by F4/80 immunostaining staining. Expression levels of CD200R1, CD200, and phosphorylated STAT6 were also examined to explore the underlying signaling mechanisms.

Results: CAB induced a robust upregulation of CD200R1, CD200, and p-STAT6, with CD200R1 expression prominently colocalizing with infiltrating F4/80+ macrophages. Compared with wild-type controls, CD200R1^{-/-} mice exhibited significantly exacerbated corneal edema and morphological disorganization. This was accompanied by marked increases in macrophage accumulation and activation, leading to accelerated and more extensive CoNV. These findings indicate that CD200R1 plays a protective role in maintaining corneal immune balance by restraining macrophage-driven inflammatory responses and neovascularization after alkali injury.

Conclusions: This study revealed that CD200R1 is a critical immunoregulatory receptor in the corneal response to alkali burn. Its deficiency results in heightened inflammation, enhanced macrophage infiltration, and increased pathological angiogenesis. Modulation of the CD200–CD200R1 axis may provide a

promising therapeutic avenue for preventing or limiting inflammation-induced corneal neovascularization.

Abstract No.: 200634

Safety and Efficacy of Ripasudil (Rho-Kinase Inhibitor) for Treatment of Postoperative Striate Keratopathy

First Author: Keerti WALI

Co-Author(s): Vallabha K, Sneha L, Vivea NAGDEV

Purpose: To study the safety and efficacy of ripasudil in the treatment of postoperative striate keratopathy in terms of corneal clarity, visual improvement, and IOP control.

Methods: A randomised controlled trial was performed at a tertiary eye hospital. Striate keratopathy grading and IOP measurement were done for postoperative cataract surgery patients. Three hundred patients were randomly divided into 2 groups- GROUP A patients were prescribed Ripasudil, and GROUP B were treated with the standard regimen of hypertonic saline and antiglaucoma drugs.

Results: A total of 300 patients were enrolled in the study, with 150 patients in each group. The majority of patients (46%) presented with grade 2 edema, and the mean number of days to achieve corneal clarity was 4.5 days and 3.5 days in groups A and B, respectively. In grade 3, mean days to resolution were 11 days and 5.8 days, respectively, which is statistically significant.

Conclusions: Ripasudil appears to be a promising targeted therapy for post-cataract surgery striate keratopathy, especially in patients presenting with milder degrees of corneal edema. Further studies incorporating objective evaluation of the corneal endothelium, using higher doses of Ripasudil and standardized surgical technique with a single surgeon, are warranted.

Abstract No.: 200157

Seeing the Signs: Disseminated Tuberculosis Presenting As Scleral and Iris Granulomatous Nodules: A Case Report

First Author: Aera Veenice BRIOSO

Co-Author(s): Mary Ellaine DIAZ

Purpose: Ocular tuberculosis has varying clinical manifestations; however, careful assessment allows a small preview of a more severe, life-threatening disseminated disease.

Methods: This was a case of a 50-year-old housewife who presented with a perilimbal granulomatous conjunctival nodule that seemed to invade the anterior chamber of the right eye, associated with granulomatous uveitis with a rapid increase in the number of iris granulomas. She had multiple neck, axillary, and preauricular masses that had unremarkable biopsy findings previously. Clinical

impression was multiple extrapulmonary tuberculosis. Anterior segment Ocular Coherence Tomography (AS OCT) showed hyperechoic thickening of the sclera extending to the limbus and a hypoechoic lesion in the anterior chamber angle. Repeat biopsy of the neck mass identified acid-fast bacilli. During her admission, she exhibited progressive weakness, increased respiratory effort, and abdominal distension. Unfortunately, her condition deteriorated rapidly, leading her demise.

Results: Disseminated tuberculosis poses a life-threatening condition, which harbors a mortality rate of 34.9% which is 3.39 to 4.53 times greater than non-disseminated types. Spread from a primary site can be lymphatic or hematogenous. Extrapulmonary tuberculosis and other disseminated types are typically diagnosed late, but initiation of treatment at the first catch of signs is crucial in the prevention and can decrease further dissemination and complications by 65%.

Conclusions: Disseminated tuberculosis is an important cause of morbidity and mortality, particularly in the Philippines where it is endemic. This case emphasized that prompt holistic evaluation is important to prevent complications and untimely death.

Abstract No.: 204408

Sequential Superior and Inferior Shield Ulcers in Vernal Keratoconjunctivitis: A Rare Case in a Young Female

First Author: Chester Aldwin YAP

Co-Author(s): Sharlene NOGUERA

Purpose: To describe a rare case of sequential superior and inferior shield ulcers in a young female with vernal keratoconjunctivitis (VKC). Inferior shield ulcers are extremely uncommon, with only a few cases reported previously, highlighting this atypical presentation.

Methods: This is a case report of a 14-year-old female VKC patient with a history of asthma and multiple allergies who presented with pruritus, tearing, and a whitish corneal opacity in the right eye. Initial examination revealed a superior corneal shield ulcer associated with giant papillae on the tarsal conjunctiva.

Results: She was treated with topical Loteprednol etabonate 0.5% + Tobramycin 0.3% and Tacrolimus 0.03% ointment. Visual acuity and symptoms initially improved; however, the patient was lost to follow-up. On return, slit-lamp examination revealed a double shield ulcer, with a newly developed inferior shield ulcer in addition to the pre-existing superior ulcer scar. Intensive topical therapy was restarted, and over three weeks, the ulcer healed with mild subepithelial scarring and restoration of visual acuity to 20/25. Shield ulcers are a recognized complication of VKC, usually affecting the superior cornea, while inferior ulcers are quite rare. To date, superior-to-inferior progression has been

reported only once, in a young male, making this the first documented case in a female.

Conclusions: To the best of our knowledge, no previous case report has described a young female patient with VKC who developed sequential superior and inferior corneal shield ulcers. Given the rarity of such cases, our report adds valuable insight into the spectrum of VKC presentations.

Abstract No.: 201629

Shewanella Keratitis: An Emerging Cause of Gram-Negative Bacterial Keratitis

First Author: George Michael SOSUAN

Co-Author(s): Ruben LIM BON SIONG, Ino Paul VILLACASTIN

Purpose: To present an emerging cause of Gram-negative bacterial keratitis

Methods: Case report

Results: A man in his 50s without comorbidities consulted for a whitish opacity on the right eye. Twelve hours previously he had been chiseling dry cement in a pool of water when a piece of cement suddenly chipped off and went into his right eye. He immediately rinsed his right eye with running tap water. No medication was applied. Over the following hours, he developed a whitish corneal opacity associated with blurring of vision. On examination, best-corrected visual acuity was 20/50 and a 2 x 1.5-millimeter anterior corneal stromal infiltrate with brush-like border staining with fluorescein was located inferiorly. Gram stain of the corneal scraping of the ulcer showed multiple Gram-negative bacilli. The patient was managed as a case of Gram-negative bacterial keratitis presumed *Pseudomonas*. One week later, vision improved to 20/30. Examination showed a clear cornea with resolution of the stromal infiltrates. Culture of the corneal scraping grew *Shewanella* algae. All topical treatment was ceased after one week.

Conclusions: Human infections by *Shewanella* are usually associated with trauma while fishing in the sea. The case here was not associated with exposure to a marine environment and is the first case to be reported in Southeast Asia. Despite the virulent nature of *Shewanella* algae, the keratitis in this case was diagnosed early and timely treatment with appropriate topical antibiotic treatment directed against Gram-negative organisms was provided, thus preventing serious ocular and visual complications.

Abstract No.: 203809

Short-Term Temporal Effects of Particulate Matter on Quality of Life of Refractive Surgery Cases

First Author: Phit UPAPHONG

Co-Author(s): Janejit CHOOVUTHAYAKORN, Prangchanok SAWETWONG, Napaporn TANANUVAT

Purpose: To find the temporal causal relationship between ambient particulate matter (PM) exposure and vision-related quality of life in refractive surgery individuals.

Methods: This secondary analysis used data from a prospective cohort in Chiang Mai, Thailand, where participants completed the Refractive Surgery-Related Quality-of-Life Questionnaire (RES-Q) at baseline, 1 week later (preoperative), and 3 months postoperatively. Daily PM_{2.5} and PM₁₀ levels were obtained from regional monitoring stations, and exposures were estimated for the survey day and lag periods of 1, 3, 7, and 14 days.

Results: A total of 504 visits from 168 participants (mean age 33.4±7.8 years; 73.2% female; 78.6% LASIK, 21.4% PRK) were analyzed. Higher PM_{2.5} and PM₁₀ levels were significantly associated with worse RES-Q scores at multiple lags, indicating poorer quality of life. Preoperatively, both pollutants affected the summary score, vision, and IDL subscales, with PRK showing cumulative increases at most longer lags (all $p \leq 0.04$). PM_{2.5} significantly worsened the summary score at lag 0 (+0.71, 95% CI: 0.05–1.37), lag 1 (+0.88, 95% CI: 0.22–1.54), lag 3 (+0.63, 95% CI: 0.02–1.25), lag 7 (+1.03, 95% CI: 0.14–1.93), and lag 14 (+1.50, 95% CI: 0.45–2.55). Ocular symptoms were less consistently affected, except at later lags. PM affected scores in LASIK group but without clear patterns. Postoperatively, PRK paradoxically showed early improvements at lag 0 but increases thereafter, whereas LASIK showed adverse postoperative associations with rising summary and IDL scores from lag 1 through lag 7 (all $p \leq 0.03$).

Conclusions: Short-term PM exposure negatively impacts the quality of life of refractive surgery patients, especially after LASIK.

Abstract No.: 205243

Significant Corneal Flattening 7 Years After Accelerated Epithelium-Off Collagen Cross-Linking in Late-Onset Keratoconus: A Case Report

First Author: Lin ZHAO

Co-Author(s): Jie BAI, Zexia DOU, Ling LI, Shaowei LI, Chang LIU

Purpose: To document long-term curvature changes after accelerated epithelium-off corneal collagen cross-linking (CXL) in late-onset keratoconus diagnosed at age 37.

Methods: A male patient with progressive bilateral keratoconus underwent accelerated epithelium-off CXL and was followed for 7 years and 3 months (87 months). Best-corrected visual acuity (BCVA) and Pentacam Scheimpflug tomography were recorded pre-operatively and at 6 months, 1 year, 2 years, 3 years, and the final visit.

Results: Pre-operative BCVA was 0.6 in both eyes. Baseline Pentacam data: Right eye: K1 51.7 D, K2 53.8 D, Km 52.7 D, Kmax 59.6 D, thinnest corneal thickness (TCT) 405 µm. Left eye: K1 48.2 D, K2 51.1 D, Km 49.6 D, Kmax 58.0 D, TCT 427 µm. Km values at 6 months, 1 year, 2 years, 3 years and 7 years: OD 52.3 D, 51.0 D, 49.9 D, 49.6 D, 47.1 D; OS 48.6 D, 47.6 D, 47.1 D, 47.1 D, 45.1 D. Kmax at 7 years: OD 51.3 D (-8.3 D), OS 48.4 D (-9.6 D). TCT fluctuated within a narrow range: OD: 405, 373, 374, 375, 372, 356 µm; OS: 427, 405, 393, 402, 394, 386 µm. BCVA improved to 0.8 OD and 0.9 OS at final visit; no complications occurred.

Conclusions: Accelerated epithelium-off CXL produced sustained corneal flattening and functional gain in late-onset keratoconus. Early post-operative pachymetric fluctuations did not preclude long-term stabilization, supporting the efficacy of this protocol irrespective of age at treatment.

Abstract No.: 201664

Silent Ulcer Becomes a Loud Warning: Neurotrophic Keratitis Secondary to Cerebellopontine Angle Acoustic Neuroma

First Author: Delgerzul BAT

Co-Author(s): Indra AMARJARGAL, Byambadorj MUNKHBAYAR

Purpose: INTRODUCTION: Neurotrophic keratitis (NK) is a rare, vision-threatening corneal disease resulting from impairment of trigeminal nerve innervation, leading to reduced corneal sensation and poor epithelial healing. While cerebellopontine angle (CPA) acoustic neuromas most commonly cause hearing loss and facial weakness, corneal complications are uncommon and often overlooked. We present a case highlighting the importance of recognizing painless corneal ulceration as a sign of underlying trigeminal pathology.

Methods: CASE SUMMARY: A 59-year-old woman presented with six days of painless redness and tearing in the right eye. Examination revealed a 7×4 mm central stromal ulcer, 2 mm hypopyon, markedly reduced visual acuity (finger counting), and absent corneal sensation. Three months earlier, she had undergone stereotactic radiotherapy for a right CPA acoustic neuroma. Neuroophthalmic assessment confirmed decreased right trigeminal nerve function. Treatment included intensive topical fluoroquinolones, preservative-free lubricants, cycloplegics, and lateral tarsorrhaphy. By day 24, the ulcer had reduced by 80%, and by day 38, complete epithelialization was achieved with visual acuity improving to 6/12.

Results: DISCUSSION: NK secondary to CPA acoustic neuroma is rare but can result from direct nerve compression or postradiotherapy changes. Painless keratitis with corneal hypoesthesia should prompt detailed cranial nerve evaluation and neuroimaging to guide timely management.

Conclusions: CONCLUSION: Painless corneal ulcers should raise strong suspicion for neurotrophic causes. Early diagnosis, multidisciplinary collaboration, and prompt intervention are vital to prevent irreversible vision loss.

Abstract No.: 204334

Silent Yet Blinding: Case Series of Xerophthalmia in Autism

First Author: Cassandra QUEK

Co-Author(s): Hannie CH'NG, Xin Gen NG, Rohanah BINTI ALIAS, Norlina BINTI MOHD RAMLI

Purpose: To highlight the risk of vitamin A deficiency and xerophthalmia in autistic children with restrictive diet. To raise awareness of the spectrum of ocular complications that can lead to irreversible blindness.

Methods: Case series

Results: Xerophthalmia may occur in children with autism spectrum disorder (ASD) and avoidant/restrictive food intake disorder (ARFID). We present a case series of four boys (aged 5–11 years), diagnosed with ASD and ARFID: A 10-year-old boy, consuming mainly rice and snacks, presented with eyelid swelling. Examination showed conjunctival xerosis with keratinization and corneal xerosis with epithelial defect. He improved with lubrication, topical antibiotics, and vitamin A. A 5-year-old boy on a French fries-only diet presented with photophobia and redness. He had a sealed corneal perforation in the right eye and Bitot's spot with central scarring in the left. Vision stabilized at 6/6 bilaterally with conservative treatment and vitamin A. An 11-year-old on fries and burgers developed bilateral xerosis and left corneal perforation with iris prolapse. He underwent tectonic keratoplasty, amniotic membrane transplantation, and tarsorrhaphy, achieving 6/12 vision. A 6-year-old with ASD, epilepsy, and vitamin D deficiency presented with bilateral xerosis and corneal ulcers. He had a right corneal perforation with Streptococcus infection requiring urgent keratoplasty. Although both corneal ulcers healed, the right corneal graft ultimately failed.

Conclusions: This case series highlights the varying severity of xerophthalmia in children with ASD and ARFID, ranging from Bitot's spots to corneal perforation. Early recognition of ARFID, along with appropriate ocular management and timely vitamin A supplementation, is crucial to prevent irreversible blindness.

Abstract No.: 207121**Soft Contact Lens-Related Corneal Ulcers: Rapid Aggressive Treatment is a Must***First Author: Elisa YOPITASARI*

Purpose: To highlight the severe risk of extended cosmetic soft contact lens wear and its management in a limited medical facility in developing countries.

Methods: A case report of a 34-year-old woman with a severe corneal ulcer following overnight usage of a cosmetic soft contact lens.

Results: The patient came with a 6.5 millimeters central corneal ulcer, suppurative ulcer bed without impending perforation, 2.5 millimeters of hypopion and visual acuity of hand movement. Corneal scrapping followed by Gram and KOH staining revealed a negative gram bacillus and no fungi, but there was no culture examination done. She was hospitalized and treated with 1 gram intravenous Ceftriaxone twice daily, fortified Gentamycin in pulsed loading maintenance continued with an hourly administration, Levofloxacin every 2 hours, and strong cyclopegic. Debridement under topical anesthesia and documentation of ulcer and hypopion size were done daily. Reduced ulcer size to 4 millimeters, diminished hypopion, and reduced pain were clinical factors to decide an outpatient status. Weekly visit up to one-month period resulted in a central deep corneal scar with visual acuity of 1/60. The patient was then enrolled to have a penetrating keratoplasty in the future.

Conclusions: Incautious soft contact lens use is still one of the common risk factors of severe corneal ulcer, particularly in developing countries. Immediate aggressive empirical antibiotic treatment is mandatory based on clinical judgment and simple laboratory findings from corneal scrapping in limited medical facility.

Abstract No.: 206982**Squamous Papilloma Presenting as Primary Pterygium: A Case Report***First Author: Jamille TURINGAN**Co-Author(s): Steffani Krista CHUA*

Purpose: To report a case of squamous papilloma in the right eye initially suspected as a pterygium.

Methods: This is a case report.

Results: A 46-year old male was referred to our clinic from another institution for excision of a presumed nasal pterygium on the right eye. Slit-lamp examination showed an cylindrical elevated smooth, non-movable fleshy conjunctival mass on the nasal aspect of the right eye, measuring 10 mm x 4 mm x 2 mm. The patient underwent excision biopsy of the conjunctival mass on the right eye under local anesthesia. Histopathologic findings confirmed the diagnosis of squamous papilloma.

Conclusions: This case underscores the importance of a careful clinical evaluation in distinguishing pterygium from other conjunctival lesions. Although conjunctival squamous papilloma is rare, a high index of suspicion is essential for accurate diagnosis and appropriate management.

Abstract No.: 201711**Sympathetic Ophthalmia Following Corneal Patch Graft for Corneal Perforation Secondary to Pediatric Blepharokeratoconjunctivitis***First Author: Jan Louise CABRERA**Co-Author(s): Ruben LIM BON SIONG, Bryan Vincent MESINA, Bobbie Marie SANTOS, George Michael SOSUAN*

Purpose: This is the first reported case of sympathetic ophthalmia (SO) that developed following a corneal patch graft in the absence of overt postoperative uveal incarceration for a complication of severe pediatric blepharokeratoconjunctivitis (PBKC), a treatable condition that may result in visual morbidity and corneal blindness if not treated promptly and adequately.

Methods: A 14-year-old Asian male presented with recurrent eye redness, pruritus, and blurring of vision of the left eye and was diagnosed with corneal perforation from ruptured descemetocoele from PBKC of the left eye. He was treated with antibiotics, underwent a full-thickness corneal patch graft, and was discharged well with topical steroids, antibiotics, cycloplegics, and a lid scrub regimen with an antibiotic-steroid combination ointment. One month post-operation, his visual acuity worsened to hand movement with anterior chamber inflammation, optic disc edema, and retinal detachment of both eyes and was diagnosed with sympathetic ophthalmia. He was given intravenous corticosteroids, which was gradually tapered on subsequent follow-up consults, and was started on immunosuppressants.

Results: Visual acuity improved from hand movement to 20/80 for both eyes, with a decrease in anterior and posterior chamber inflammation. However, there was a recurrence of inflammation at ten months post-operation from poor adherence with the topical corticosteroids and lid scrub regimen.

Conclusions: PBKC is a chronic disease with a wide clinical spectrum. Prompt diagnosis and management are crucial to prevent severe presentations and visual and systemic morbidities such as SO.

Abstract No.: 206156

TREM2-Mediated Polarization of Adipose Tissue Macrophages Reverses Inflammation and Lipid Dysregulation in Thyroid-Associated Ophthalmopathy

First Author: Zhihui XU

Co-Author(s): Huasheng YANG, Huijing YE

Purpose: Thyroid-associated ophthalmopathy (TAO) is an autoimmune disorder characterized by orbital inflammation, fibrosis, and adipogenesis. The contribution of adipose tissue macrophages (ATMs) and their immune checkpoints to TAO pathogenesis remains unclear. This study aimed to investigate the role of triggering receptor expressed on myeloid cells 2 (TREM2) in ATM polarization and orbital tissue remodeling.

Methods: Orbital adipose tissues from TAO patients and healthy controls were profiled by flow cytometry and immunohistochemistry to evaluate ATM subpopulations, M1/M2 polarization, and TREM2 expression. In vitro, primary human orbital fibroblasts were co-cultured with ATMs to assess TREM2-dependent effects on inflammation and adipogenesis. In vivo, bone marrow-specific TREM2-deficient mice and TREM2 agonist treatments were used to examine therapeutic effects and downstream NF κ B/IL1 β signaling.

Results: TAO orbital tissues displayed increased ATM accumulation with M1-skewed polarization and reduced TREM2 expression compared to controls. TREM2 overexpression or agonist treatment reversed M1 polarization, decreased fibroblast pro-inflammatory and adipogenic responses, and mitigated tissue remodeling in vitro. In experimental models, TREM2 activation improved thyroid hormone dysregulation, orbital inflammation, and adipose expansion.

Conclusions: TREM2 acts as a novel immunometabolic regulator of orbital tissue remodeling in TAO. Modulating macrophage polarization through TREM2 represents a promising therapeutic strategy for autoimmune orbitopathies.

Abstract No.: 204411

Tacrolimus Prolongs Corneal Allograft Survival and Prevents Dendritic Cell Infiltration in a Myeloid-Derived Suppressor Cell-Dependent Manner

First Author: Yingyi LIU

Co-Author(s): Yan HE

Purpose: To clarify the cellular mechanism by which tacrolimus (FK506) suppresses immune activation and elongates allograft survival, with a focus on understanding its effects on immune regulation via myeloid-derived suppressor cells (MDSC).

Methods: A mouse model of corneal penetrating keratoplasty was utilized, with recipient mice receiving FK506 treatment and MDSC depletion using anti-Gr-1 antibody at different time points post-transplant. Flow cytometry was used to evaluate the proportion of MDSC and dendritic cells (DC) in immune organs. Single-cell RNA sequencing and immunofluorescence staining were performed on corneal graft to analyze immune cell populations within the graft microenvironment. Ex vivo-generated MDSCs were cocultured with immature DCs, and RNA sequencing was performed to determine how FK506 modulates MDSC immunosuppressive activity.

Results: Administration of FK506 led to increased expansion of MDSC in recipient mice and prolonged survival of corneal allografts. In contrast, antibody-mediated depletion of MDSC abolished the FK506-mediated beneficial effects, which were associated with increased DC activation and recruitment to the graft bed and allografts. Notably, unlike continuous depletion and temporary early depletion, delayed depletion beginning on day 8 post-transplant failed to disrupt the FK506-induced elongation of corneal allograft survival. Single-cell RNA sequencing analysis and immunofluorescence staining of corneal grafts revealed that FK506 reduced graft infiltration of immune cells, including DC and T cells, in an MDSC-dependent and temporal fashion. Moreover, depletion of MDSC reverted FK506's suppression of DC maturation in the draining lymph node on day 7.

Conclusions: These findings indicate that FK506 prolongs allograft survival through induction of MDSC-mediated suppression of early DC activation.

Abstract No.: 202194

Targeting DLK/MAPK/Necroptosis Pathway-Mediated Inflammation Enables Mesenchymal Stem Cell Secretome to Alleviate Dry Eye Disease

First Author: Yaqi CHENG

Co-Author(s): Jiayi LIN, Shiqi LING, Huan YU

Purpose: Dry eye disease (DED) is a chronic inflammatory disease with chronic condition and high occurrence. This study aimed to investigate the effectiveness and mechanism of MSC-S in DED treatment.

Methods: The murine DED model was established and then treated with 10mg/ml MSC-S. Tear secretion and corneal fluorescein staining scores were performed to evaluate DED severity. The inflammation state was detected by flow cytometry of DCs and RT-PCR analysis of inflammatory factors. The human corneal endothelial cell line (HCECs) was subjected to hyperosmotic stress (HS, 500 mOsm). Cell proliferation, reactive oxygen species (ROS), and mitochondrial membrane potential (MMP) were examined. RNA-sequencing was performed on different corneas to

clarify the mechanisms underlying MSC-S treatment. The expression of potential pathway was verified.

Results: MSC-S enhanced tear secretion, reduced the cornea defects and inflammation in DED mice and protected HCECs from necroptosis in HS model. Analysis of RNA-sequencing data revealed MAPK and necroptosis pathway were activated in DED corneas and were inhibited by MSC-S. The core genes of MAPK pathway, DLK were identified. Overexpression of DLK accentuated DED and impaired MSC-S' therapy effects, accompanied by upregulation of the JNK and p38 MAPK pathway, necroptosis pathway, and inflammation factors.

Conclusions: This study demonstrates that the application of MSC-S exerts significant therapeutic effects on DED by inhibiting the DLK-mediated MAPK/ necroptosis pathway and inflammatory response. The findings of this research could provide an effective strategy for treating DED and propose new therapeutic targets.

Abstract No.: 200190

The Effect of Pterygium on Corneal Biomechanical Properties

First Author: Kosol **KAMPITAK**

Co-Author(s): Tararat **HOOPHOLERB**, Thanat **KAMPITAK**

Purpose: To evaluate the effect of pterygium on corneal biomechanical parameters using the Corvis ST®.

Methods: This prospective study included 27 participants (mean age: 59.7+/-12.1 years) with unilateral primary pterygium. The Corvis ST® was used to measure corneal biomechanical properties. Pterygium size was measured in the horizontal axis. A paired t-test was used to compare corneal biomechanical parameters between the pterygium eyes and the contralateral normal eyes. Pearson correlation analysis was performed to evaluate the correlations between corneal biomechanical parameters and pterygium size. A p-value of less than 0.05 was considered statistically significant.

Results: Significant differences were observed in the following corneal biomechanical parameters between the pterygium and fellow eyes: Ambrósio Relational Thickness horizontal ($p = 0.016$), Deformation Amplitude ($p = 0.049$), Deformation Amplitude Ratio ($p = 0.006$), and Deflection Amplitude ($p = 0.030$). However, no significant differences ($p > 0.05$) were found in the parameters of Integrated Radius, Peak Distance at Highest Concavity, Radius at Highest Concavity, Stiffness Parameter at First Applanation, or Stress-Strain Index. A significant correlation was identified between the horizontal Ambrósio Relational Thickness and the horizontal size of the pterygium ($p =$

0.002), while no significant correlations ($p > 0.05$) were observed with other biomechanical parameters.

Conclusions: Pterygium can affect corneal biomechanical properties as measured by the Corvis ST®. Therefore, the presence of pterygium should be considered when interpreting Corvis ST® measurements in clinical assessments.

Abstract No.: 201852

The Impact of Diabetes Mellitus on Corneal Endothelial Cells

First Author: Bayasgalan **PUREVDORJ**

Co-Author(s): Uranchimeg **DUGARSUREN**, Bayarmaa **KHUYAG**, Bayarmagnai **LKHAGVASUREN**, Bayarsukh **NARMANDAKH**

Purpose: This study aimed to compare corneal endothelial morphology and thickness in patients with type 2 diabetes mellitus and age-matched nondiabetic controls.

Methods: A cross-sectional study included 160 diabetic patients and 160 healthy individuals selected through random sampling. All underwent comprehensive ophthalmic examinations. Specular microscopy was used to assess central corneal thickness and endothelial morphological parameters.

Results: The mean endothelial cell density (ECD) in the diabetic group was 2599.75 ± 242.53 cells/mm², significantly lower than that in controls 2768.12 ± 263.21 cells/mm² ($P < 0.001$). The coefficient of variation was 0.32 ± 0.04 in controls and 0.35 ± 0.04 in diabetics, a significant difference ($P < 0.001$). Central corneal thickness was higher in diabetics 547.27 ± 28.78 μ m than in controls 523.24 ± 32.7 μ m ($P < 0.001$). Among patients with diabetes >10 years, the CV in cell size increased and hexagonality decreased ($P < 0.05$). The percentage of hexagonal cells was $59.70 \pm 4.63\%$ in the good glycemic control group and $55.58 \pm 3.75\%$ in the poor control group (HbA1c >7.5%) ($P = 0.003$).

Conclusions: Diabetes mellitus leads to a decrease in corneal endothelial cell density and induces morphological abnormalities, including polymegathism and pleomorphism. Therefore, in patients with diabetes, it is essential to conduct a detailed corneal assessment prior to intraocular surgery to select the most appropriate surgical approach and technique.

Abstract No.: 206030

The Impact of Second-Hand Smoking on Dry Eye Prevalence and Severity: A Population-Based Study in Hong Kong

First Author: Shue Hei **WONG**

Purpose: Smoking is an eye irritant that may cause dry eye in patients, but only a few studies highlight the impacts of passive smoking (second-hand smoking) on

dry eye. This study aims to investigate the impacts of passive smoking on dry eye prevalence and severity.

Methods: This is a cross-sectional, random population-based study on Chinese subjects aged 50 and above between the 1st of September 2021 and the 31st of August 2022. Patients underwent comprehensive dry eye assessment in order from least invasive to most invasive, including dry eye questionnaire (OSDI score), Non-invasive keratographic tear breakup time, tear meniscus height, tear breakup pattern, SMTube, and NEI cornea staining score. The definition of dry eye was adopted from the Asia Dry Eye Society.

Results: Of 578 patients recruited, 88 had dry eye disease (15.2%), and second-hand smoking exposure was documented in 44 participants (7.61%). The average age was 62.8, and 209 were male (36.2%). OSDI score was found to be significantly higher in participants affected by passive smoking in both univariate (OR=4.75, CI95=1.20-8.29, $p=0.009$) and multivariate logistic regression (OR=7.21, CI95=2.59-11.84, $p=0.002$). The odds of developing dry eye disease were also significantly higher in participants with passive smoking in both univariate (OR=1.07, CI95=0.36-1.73, $p=0.002$) and multivariate analysis (OR=1.45, CI95=0.60-2.28, $p<0.001$). Linear regression did not show any correlation between the risk of dry eye and the duration of second-hand smoke exposure.

Conclusions: Our study showed that individuals with frequent second-hand smoke exposure were more likely to have dry eye disease.

Abstract No.: 201810

The Netarsudil Paradox: Worsening Corneal Edema — a Case Report

First Author: Apurva **BAGLA**

Co-Author(s): Arti **SINGH**

Purpose: To report a rare case of netarsudil-associated reticular epithelial edema in a patient with persistent corneal edema following cataract surgery.

Methods: A 60-year-old female with postsurgical corneal edema was prescribed netarsudil ophthalmic solution, a Rho kinase (ROCK) inhibitor FDA-approved for primary open-angle glaucoma and ocular hypertension, but also explored for enhancing corneal endothelial function.

Results: Shortly after initiation of netarsudil, the patient developed worsening corneal edema and reticular epithelial bullae. The epithelial changes resolved completely upon discontinuation of the drug.

Conclusions: This case highlights a paradoxical epithelial response to netarsudil in the setting of compromised corneal endothelium. While ROCK inhibitors may support endothelial healing, clinicians should be aware of potential keratopathy and closely monitor patients with preexisting corneal conditions.

Further research is needed to clarify the mechanisms underlying netarsudil-induced epithelial changes.

Abstract No.: 204222

The Pediatric Ocular Surface Microbiome in Pet-Owning Households

First Author: Xiangtian **LING**

Co-Author(s): Li Jia **CHEN**, Jason C. **YAM**, Charlene C. **YIM**, Yuzhou **ZHANG**

Purpose: The influence of pet exposure on the pediatric ocular surface microbiome (OSM), a potential mediator of ocular immunity, remains uncharacterized. This study investigates OSM alterations in children with household pet contact.

Methods: In this cross-sectional study, conjunctival swabs from 347 children (aged 5–15 years) in the CUHK Hong Kong Children Eye Study were analyzed. 16S rRNA sequencing (V3–V4 region) was performed, followed by bioinformatic analysis (QIIME2, DADA2, SILVA 138) and functional prediction (PICRUSt2). Alpha/beta diversity, taxonomic composition, and KEGG pathways were compared.

Results: Pet-exposed children had higher alpha diversity (Shannon/Simpson/Observed indexes; $P<0.05$) with positive dose-response to contact time. Compositionally, these children showed distinct beta diversity (Bray-Curtis Distance, $P=0.015$) and enriched genera (Streptococcus, Actinomyces, Neisseria; LDA Score>2.0). NF- κ B signaling and VEGF signaling were predicted to enrich in pet-exposed children while non-exposed children showed increased macrolide biosynthesis pathways.

Conclusions: Pet exposure associates with increased diversity, animal-related taxa enrichment, and NF- κ B/VEGF pathway activation in the pediatric OSM. This suggests OSM as a novel mechanism for pet-related immune modulation, potentially influencing ocular surface health and allergy susceptibility.

Abstract No.: 206667

The Role of Diquafosol Sodium 3% Eye Drops in Managing Dry Eye in Thyroid Eye Disease: A Case Series

First Author: Fathia **AZZAHRA**

Co-Author(s): Rosy **ALDINA**, Zendy **SAGITA**

Purpose: Thyroid Eye Disease (TED) is an autoimmune disorder frequently complicated by Dry Eye Disease (DED) resulting from eyelid retraction and proptosis-related exposure, lacrimal gland dysfunction, and meibomian gland disease. This case series aims to describe the clinical heterogeneity of TED-related DED and evaluate the adjunctive role of diquafosol sodium 3% eye drops.

Methods: Four TED patients with DED underwent a comprehensive assessment, including Ocular Surface

Disease Index (OSDI), fluorescein tear break-up time (TBUT), ocular surface staining, tear meniscus height, tear break-up pattern, and meibomian gland evaluation. Subtypes were classified as aqueous-deficient or evaporative DED. All patients received lifestyle modification guidance, the same preservative-free artificial tears, and adjunctive diquafosol sodium 3% eye drops, administered according to subtype and severity.

Results: Two patients presented with aqueous-deficient DED and two with evaporative DED. After four weeks of diquafosol therapy, all patients reported symptomatic improvement. Objective parameters, especially TBUT, showed improvement across both subtypes. Recognizing the subtype of Dry Eye is essential for effective management of TED. Diquafosol, a P2Y₂ receptor agonist, stimulates both aqueous and mucin secretion, making it suitable for diverse presentations. Integration of ocular surface assessment into TED care, combined with multidisciplinary collaboration involving endocrinology and oculoplastics, further enhances patient outcomes.

Conclusions: Dry Eye associated with TED is clinically heterogeneous and requires individualized treatment. Adjunctive diquafosol sodium 3% may improve symptoms and ocular surface stability across both aqueous-deficient and evaporative subtypes.

Abstract No.: 205929

Therapeutic Deep Lamellar Keratoplasty in a Case of Fungal Keratitis

First Author: Inderjeet KAUR

Purpose: To highlight the therapeutic potential of Deep Lamellar Keratoplasty in refractory infective keratitis.

Methods: A 24-year-old male presented with redness and watering in the left eye for last 20 days, with a possible history of insect fall. On the basis of clinical features, a provisional diagnosis of infective keratitis was made, and was started on antifungals. Microbiology evaluation confirmed fungal infective etiology. Initial improvement was noted; however, due to subsequent non-responsiveness, the patient received two doses of intracameral and intrastromal antifungals. As the keratitis remained refractory to medical therapy, surgical intervention was planned. Anterior segment optical coherence tomography revealed infiltrates extending up to two-thirds of corneal depth. Based on this, a therapeutic Deep Lamellar Keratoplasty with interface wash with antifungal was performed. Postoperatively, the graft-host interface was well opposed, and no recurrence was observed during the longest follow-up period.

Results: Postoperatively, the graft-host interface was well opposed, and no recurrence was observed during the longest follow-up period.

Conclusions: This case highlights the role of anterior segment optical coherence tomography in surgical planning & therapeutic potential of Deep Lamellar Keratoplasty in refractory infective keratitis, with the added advantage of avoiding complications associated with open-sky procedures.

Abstract No.: 205778

Therapeutic Effects of Topical Nerve Growth Factor in a Mouse Model of Sjögren Syndrome

First Author: Chang Ho YOON

Co-Author(s): Suil JEON, So Hyun KANG, Kyoung Woo KIM, Mee Kum KIM, Ki Hean KIM, Yunjin LEE, Noseong PARK, Jin Suk RYU

Purpose: To evaluate the therapeutic effects of topical nerve growth factor (NGF) on the ocular surface and lacrimal gland (LG) in the NOD.B10-H2b (NOD) mouse model of Sjögren syndrome (SS).

Methods: Age-dependent changes in the ocular surface staining (OSS) and corneal subbasal nerve plexus (SBNP) were analyzed. Based on these results, eleven-week-old male NOD mice received topical NGF or balanced salt solution (BSS) three times daily for seven weeks. OSS, tear secretion, and corneal sensation were assessed before and after treatment. The corneal SBNP was evaluated using confocal microscopy of corneal whole mounts. Cytokine expression in the cornea and LG was analyzed by RT-qPCR, and LG focus scores were graded histologically.

Results: After seven weeks of treatment, the NGF group exhibited significant clinical improvements in OSS and tear secretion compared to baseline (both $p < 0.01$), with greater improvement than the BSS group (both $p < 0.001$). Corneal sensation remained stable in the NGF group but significantly declined in the BSS group ($p = 0.0222$), resulting in significantly better sensation in NGF group ($p < 0.0001$). Additionally, the number and length of central and peripheral SBNP were greater in the NGF group. Expression levels of IL-1 β , IL-6, and CGRP in the cornea, as well as IL-6 in the LG, were significantly reduced in the NGF group compared to the BSS group. LG focus scores were also lower in the NGF group.

Conclusions: Topical NGF demonstrated excellent therapeutic efficacy in a mouse model of SS by preserving the SBNP, enhancing sensory reflex tearing, and suppressing corneal and LG inflammation.

Abstract No.: 206650

Therapeutic Efficacy and Safety of Non-Invasive Radiofrequency Treatment in Patients With Refractory Meibomian Gland Dysfunction: A Randomized Controlled Trial

First Author: Sam In Kirsty LEE

Co-Author(s): Kendrick Co SHIH

Purpose: Determine clinical efficacy and safety of radiofrequency treatment (RF), followed by meibomian gland expression (MGX), in reducing the number and severity of symptoms and signs of dry eye disease secondary to refractory meibomian gland dysfunction.

Methods: A prospective, 24-week, double-masked, randomized, sham-controlled clinical trial comparing clinical efficacy and safety of RF and MGX with MGX alone in patients with MGD-related dry eye disease. It also investigates longitudinal changes in meibum quality and expressibility, including tear cytokines, after RF, and correlates these with changes in dry eye symptoms and tear film metrics. During the treatment period, all subjects will receive polyethylene glycol eye drops (Systane ULTRA, Alcon Company, Fort Worth, Texas, USA) four times a day in both eyes until 6 months post-treatment.

Results: Conducted preliminary analysis of 26 subjects. Average age was 62.5 years. All subjects underwent RF followed by MGX. 80 shots were made with energy level between 2.5-3.5. Each eyelid was treated with 20 shots; 2 passes of 10 shots. Compared to baseline, SPEED score (413.12 ± 5.472 vs 9.35 ± 4.804), NIKBUT (7.0356 ± 6.249 vs 10.4665 ± 6.804), ocular redness score (1.468 ± 0.664 vs 1.240 ± 0.578) and meibum expressibility score (2.8 ± 0.422 vs 1.75 ± 0.957) showed statistically significant improvements 3 months post-treatment. No significant differences in tear meniscus height and meibum quality score 3 months post-treatment. Patients experienced erythema post-treatment, which resolved within seconds.

Conclusions: Non-invasive RF of the eyelid is a safe and potentially effective treatment for refractory MGD-related dry eye disease.

Abstract No.: 201420

Three Years of Endothelial Cell Loss in Patients After Phakic Intra-Ocular Lens Implantation (Artisan, Artiflex, and ICL)

First Author: Seoyoon KIM

Purpose: To investigate the rate of corneal endothelial cell (CEC) loss after removal of phakic intraocular lens (pIOLs), and to compare CEC loss among pIOL types.

Methods: This was a prospective, non-randomised, comparative study including 160 eyes of 110 patients who underwent pIOL explantation, who committed to follow-up in 6-month intervals for at least 3 years. CEC densities at 5 different directions, anterior chamber

depth (ACD), and axial length (AL) were measured at each visit and were compared among pIOL types. To determine the pre-operative factors which affect surgical outcomes, linear mixed-model analysis was performed to evaluate the rate of CEC loss after explantation.

Results: There were no significant differences in patient demographics among pIOL types. The mean ACD was 3.385 ± 0.350 mm. The mean AL was 27.601 ± 1.603 mm. It is noteworthy that patients with a lower ACD (3.278 ± 0.332 mm) had a relatively lower CEC (<1000 cells/mm²), and exhibited a greater rate of CEC depletion over time (median [IQR] age, 40.5 [37-44] years; 135 [84.38%] female and 25 [15.63%] male). There were no significant differences observed in the pattern, trend, or slope of CEC loss among pIOL types. The model predicted that a critical threshold of 500 cells/mm² would be reached in approximately 8.56 years following pIOL explantation (95% CI, -159.98 to -127.87; $P < .0001$).

Conclusions: CEC loss was notably upregulated without significant differences between pIOL types. The model may imply that some patients require corneal transplantation following such within the next 9 years.

Abstract No.: 200547

Three-Year Results of Fresh Lenticule Transplantation for Herpetic Scarring

First Author: Faruk SEMIZ

Co-Author(s): Fetih Furkan ARSLAN, Njomza HIMA-MUSA, Ceren Ece SEMIZ

Purpose: To evaluate the long-term outcomes of customized fresh lenticule transplantation as an alternative surgical method for corneal reorganization and stability in patients with herpetic keratitis scarring.

Methods: This study included 23 eyes from 23 patients (aged 21-46 years) with multifocal or unifocal herpetic stromal scarring. Scar thickness was measured in microns using anterior segment optical coherence tomography (AS-OCT). Scar tissue was excised using femtosecond laser-assisted small incision lenticule extraction (SMILE), followed by transplantation of a SMILE-derived fresh lenticule from myopic donors. Lenticules averaged $66.74 \mu\text{m}$ in thickness (range, 30-140 μm) with a mean refractive power of -3.34 ± 1.40 diopters (range, -7.00 to -1.50 D), matched to recipient corneal topography. All patients were followed for a minimum of 3 years. Follow-up evaluations included uncorrected and corrected distance visual acuity (UDVA, CDVA), slit-lamp biomicroscopy, corneal topography, pachymetry, and AS-OCT imaging.

Results: No cases of recurrent herpetic keratitis or graft rejection were observed, while significant improvements were achieved in UDVA (0.91 ± 0.14 to 0.31 ± 0.06 logMAR, $p < 0.001$), CDVA (0.58 ± 0.09 to 0.16 ± 0.05 logMAR, $p < 0.001$), CCT (444.13 ± 16.55

μm to $508.35 \pm 7.09 \mu\text{m}$, $p < 0.001$), K1 (39.01 ± 2.36 D to 42.61 ± 1.17 D, $p < 0.001$), K2 (43.50 ± 2.52 D to 44.09 ± 1.17 D, $p < 0.001$), and Q-value (-0.47 ± 0.07 to -0.73 ± 0.08 , $p < 0.001$) at 3 years.

Conclusions: At 3 years, customized fresh stromal lenticule transplantation effective in strengthening the cornea, restoring clarity, and sustaining visual gains in herpetic scarring.

Abstract No.: 204025

Tissue-Localized and Systemic Immune Dysregulation in the Autoimmune Etiology of Mooren's Ulcer

First Author: Shengqian **DOU**

Co-Author(s): Weiyun **SHI**, Qingjun **ZHOU**

Purpose: Mooren's ulcer (MU) is a rapidly progressive, severely painful peripheral corneal ulcer with high aggressiveness and frequent recurrence. Despite its clinical distinctiveness, the underlying pathogenesis and effective therapeutic strategies remain elusive.

Methods: We conducted single-cell RNA sequencing (scRNA-seq) analysis on limbal tissues and peripheral blood mononuclear cells (PBMCs) from MU patients and healthy controls, followed by validations with immunohistochemical staining and immunofluorescence. Corneal epithelial cells and immune cells were subclustered and altered transcriptional signals were comprehensively dissected between conditions. Altered cell-cell communications in MU and comparisons of the PBMC atlas across various autoimmune diseases were also deciphered.

Results: We compiled the first single-cell atlas of limbus and PBMCs in MU patients and healthy subjects, revealing distinct cellular compositions. Limbal epithelial cells exhibited pronounced pro-inflammatory signatures and disrupted differentiation trajectories in MU samples, while tissue-invaded B cells and activated circulating B cells were prominently observed. Subcluster analysis and cell-cell communication networks further implicated the involvement of T cells, monocytes, and macrophages in MU progression. Finally, comparative analysis with other autoimmune diseases demonstrated shared immune activation patterns, particularly in T and B cell responses.

Conclusions: In summary, our study advances the understanding of MU pathogenesis by uncovering dysregulated limbal niche homeostasis and aberrant immune cell crosstalk, reinforcing its autoimmune nature. These findings not only elucidate key molecular mechanisms underlying MU but also provide a foundation for developing targeted therapeutic strategies. Furthermore, the shared immunological signatures between MU and other autoimmune disorders suggest potential avenues for repurposing existing immunomodulatory therapies in MU management.

Abstract No.: 207481

Topical Insulin's Use in Various Etiologies of Persistent Epithelial Defects: A Case Series

First Author: Raj Shekhar **PAUL**

Purpose: To report the efficacy of topical insulin under various case scenarios.

Methods: The topical insulin 16 IU/ml drops were prepared by mixing 6 parts of artificial tears with 4 parts of regular insulin. They were administered in cases presenting with persistent epithelial defects (PEDs), following neurotrophic keratitis, following surgeries like therapeutic penetrating keratoplasty, deep anterior lamellar keratoplasty, collagen cross-linking for ectasia, recurrent corneal erosions, and corneal decompensation after retinal surgeries such as buckle procedures and vitrectomy. Additional indications included recurrent corneal erosions, congenital hereditary endothelial dystrophy (CHED), epithelial defects due to Stevens-Johnson syndrome with PROSE lens misfit, and an additive role in exposure keratopathy from Bell's palsy.

Results: The patients ranged in age from 6 to 66 years, with a median of 30.5 years. The duration of topical insulin treatment for epithelial healing ranged from 15 days to 3 months, with a mean of approximately 57 ± 27 days. Out of 10 cases, 8 achieved complete epithelial closure (80% success rate, comparable with other studies). One case of CHED remains under treatment, while another case involving Stevens-Johnson syndrome with PROSE-related PED did not respond. All the patients had more than 8 months of follow-up after cessation of insulin eyedrops.

Conclusions: Overall, due to the ease of preparation and convenient administration technique, as simple as eyedrops, topical insulin is a preferred choice over other modalities of treatment like amniotic membrane graft, autologous serum, for non-healing epithelial defects.

Abstract No.: 200870

Transepithelial Corneal Cross-Linking Advancement With Novel Hibiscus-Inspired RF/ZIF-8 Composites

First Author: Jinhai **HUANG**

Co-Author(s): Mei **YANG**, Xingtao **ZHOU**

Purpose: Hibiscus-like RF@ZIF-8NF composites were developed to enhance TE-CXL efficacy while preserving the epithelium, offering an innovative approach for keratoconus treatment.

Methods: The RF@ZIF-8 composites were synthesized using 5-phosphoric acid-riboflavin (RF), 2-methylimi, and zinc nitrate as precursors, through the optimization of reaction conditions. Detailed material characterization, alongside in vitro and in

vivo biological evaluations, was conducted for the synthesized RF@ZIF-8 composites.

Results: The doping of RF in appropriate range has little effect on the phase structure of ZIF-8, while the morphology and size of the composites can be adjusted by changing reaction factors. Under identical conditions, various experimental outcomes demonstrated that the synthesized RF@ZIF-8 composites exhibit superior corneal permeability, with increased RF concentration within the stroma compared to other groups. Biocompatibility assessments revealed that the RF@ZIF-8 NF nanocomposites possess outstanding biocompatibility without causing discernible damage to the cornea. In vivo studies showed that the TE-CXL efficacy of the RF@ZIF-8 composite matched or slightly surpassed that of standard CXL (SCXL).

Conclusions: The engineered hibiscus-like RF@ZIF-8NF composites demonstrated superior TE-CXL performance with epithelial preservation, rivaling or even exceeding that of SCXL. This novel TE-CXL nanotherapy heralds a promising strategy for keratoconus treatment, offering significant research potential and pioneering a new avenue in CXL development.

Abstract No.: 205767

Uncommon Fungal Keratitis: Clinical Presentations and Prognoses of Uncommon Corneal Pathogens

First Author: Ahyan **ILMAN QUDSI**
Co-Author(s): Qingfeng **LIANG**

Purpose: While fungal keratitis (FK) is commonly caused by *Fusarium*, *Aspergillus*, *Alternaria* and *Candida*, uncommon FK pathogens remain poorly characterized. This study aims to describe the clinical features, microbiological diversity, and treatment outcomes of uncommon FK.

Methods: Retrospective analysis of uncommon fungal keratitis cases identified by MALDI-TOF MS at a tertiary referral center (2008–2023). Data on demographics, predisposing factors, clinical signs, microbiological findings, and outcomes were analyzed.

Results: 63 cases (69.8% male, mean age 56.1±9.8 years) were identified. Trauma was predominated risk factors (66.7%) primarily from plant-related injuries (31.7%). Patients presented after 31.1±24.8 days of symptoms. Slit-lamp findings included dry texture (71.4%), dense infiltrates (50.8%) and feathery margins (38.1%) as predominant features. Prolonged treatment was observed (median 189 days; IQR 54-237), with 11 cases (17.5%) required surgery. Pathogens from Eurotiomycetes class comprised the longest treatment duration (median 242.5 days; IQR 197-272), with 27.3% of surgical cases, and exhibited the most severe manifestations, with frequent severe ulcers (>5mm) 50.0%, multifocal lesions (66.7%, P=0.001),

neovascularization (58.3%, P=0.035), and hypopyon (50.0%). Triazoles (ISA and VRC) showed the lowest MICs in vitro across all fungal classes.

Conclusions: Uncommon FK pathogens collectively demonstrate aggressive features and prolonged treatment courses owing to delayed diagnosis and virulence of the species. Eurotiomycetes were associated with severe presentations and poor outcomes, while all classes showed favorable in vitro response to newer triazoles. These observations highlight the need for heightened suspicion, early identification, and tailored antifungal selection for uncommon FK.

Abstract No.: 204416

Unmasking Coogan-Reese Syndrome: A Rare Yet Vision-Threatening Mimic of Glaucoma

First Author: Sean **TAY**
Co-Author(s): Qiu Yip **LIM**, Benjamin **LIM CHING HOW**, Henry **NGOO QI ZHE**

Purpose: To review the clinical features, diagnostic approach, and management strategies of Coogan-Reese syndrome.

Methods: Case Report

Results: A 25-year-old female presented with a 6-month history of progressive blurred vision of left eye. Her visual acuity was 6/12 (right eye) and 6/36 (Left eye). She reported no prior ocular trauma or systemic illness. On examination, multiple pigmented, nodular lesions were observed on the iris surface, primarily near the pupillary margin, with irregular pupil shape (corectopia). Gonioscopy revealed shallow anterior chambers and secondary angle closure due to peripheral anterior synechiae. Detailed imaging and slit-lamp examination confirmed the diagnosis of Coogan-Reese syndrome, distinguished by the pigmented iris nodules, corectopia, and secondary angle-closure. Humphrey Visual field (24-2) was conducted and noted superior arcuate scotoma. Notably, the nodules appeared to migrate slightly with eye movements, indicating active endothelial cell proliferation. Her initial intraocular pressure was 14 (RE), 24 (LE) respectively. The patient was started on combination anti-glaucoma medications, but IOP remained suboptimal. Surgical options included trabeculotomy and potential endothelial cell removal were considered. In her case, trabeculectomy was done and her IOP was subsequently optimized.

Conclusions: Coogan-Reese syndrome, though uncommon, represents a clinically significant cause of secondary glaucoma. Patients typically present with progressive glaucoma, corectopia, and pigmented nodules on the anterior iris surface. Endothelial abnormalities lead to angle closure and trabecular dysfunction. Intraocular pressure control is challenging especially with medical therapy alone, hence surgical

approaches are frequently required. With that in mind, awareness and timely intervention are essential for preserving vision.

Abstract No.: 205910

Unmasking Microsporoidal Keratitis—The Great Deceiver

First Author: Sagar RUIT

Co-Author(s): Leena BAJRACHARYA, Bandana KHANAL, Rachana SINGH RANA

Purpose: This case report outlines a very rare clinical presentation of Microsporoidal Keratitis, in an immunocompetent adult in Nepal, highlighting diagnostic challenges and therapeutic outcomes, who was initially diagnosed as a case of Vortex Keratopathy.

Methods: A 58-year-old female presented with unilateral painful keratitis with recurrent redness. Detailed slit-lamp examination, corneal scrapings, and microbiological staining were performed. The patient was managed initially with topical Chlorhexidine 0.02% 1 Hourly, Topical Moxifloxacin 0.5% 2 Hourly, but eventually was subjected to therapeutic keratoplasty.

Results: Microsporidia spores were confirmed on staining. The ulcer in the left eye progressed to stromal keratitis and was refractory to medical management and eventually underwent a therapeutic keratoplasty.

Conclusions: Microsporoidal Keratitis although rare is difficult to diagnose as it does not grow on culture and is not responsive to medical treatment. There are very limited cases noted of which most Stromal Microsporidiosis ends up in Therapeutic Keratoplasty. Early suspicion, appropriate laboratory work up, and timely initiation of anti-microsporidial agents can prevent irreversible visual loss.

Abstract No.: 200641

Unmasking the Invisible Threat: Penetrating Keratoplasty Graft Rejection Following COVID-19 Vaccination

First Author: Clara VALENTINA

Co-Author(s): Siska, I Made Agus KUSUMADAJA

Purpose: To report a rare case of acute graft rejection and progressive corneal melting following COVID-19 vaccination in a patient with prior penetrating keratoplasty (PK), and to explore the potential immunological implications.

Methods: a 37-year-old female who presented with ocular inflammation and profound visual deterioration in the right eye, three weeks post-AstraZeneca COVID-19 vaccination. The patient had a history of PK and cataract extraction for keratoconus, along with prior intrastromal corticosteroid therapy for corneal neovascularization. A previous history of immune disorders was denied. Treatment included intensive topical corticosteroids, topical antibiotic prophylaxis,

and lubricants. Systemic immunosuppressive therapy with intravenous methylprednisolone was initiated to suppress the immune response and prevent further graft damage.

Results: A 37-year-old female with prior keratoplasty and cataract extraction for keratoconus developed fulminant graft rejection after COVID-19 vaccination. Despite intensive immunosuppression, progressive corneal melting ensued, requiring another attempt at PK. Re-PK was performed; however, graft rejection persisted in the absence of systemic autoimmune evidence.

Conclusions: This case underscores a potential correlation between COVID-19 vaccination and immunologically mediated graft rejection in corneal transplant recipients. While causality remains unconfirmed, the temporal association suggests vaccine-induced immune dysregulation may compromise corneal immune privilege. Possible mechanisms include molecular mimicry, elevated systemic cytokine response, or disruption of local immune tolerance. Clinicians should maintain a high index of suspicion for graft rejection in recently vaccinated PK patients and initiate prompt, aggressive management to avert irreversible damage. In refractory cases, Keratoprosthesis is considered a viable therapeutic alternative.

Abstract No.: 205153

Unraveling the Role of the Sympathetic Nerve-Macrophage Axis in Mediating Mitochondrial Damage in Dry Eye Disease Corneal Epitheliopathy

First Author: Zhang JINYU

Purpose: Dry eye disease (DED) is a prevalent ocular surface disorder whose hallmark is corneal epithelial damage. While corneal inflammation is a key driver of this damage, the specific pathways activating macrophages remain unclear. This study investigates whether corneal sympathetic overactivation, via neuropeptide Y (NPY), regulates macrophage function and elucidates the downstream mechanism leading to epithelial injury.

Methods: A classic mouse dry eye model was employed. Techniques including RNA sequence, immunofluorescence, Western blot, ELISA, and qRT-PCR were used to assess corneal sympathetic nerve activity, NPY expression, macrophage activation (markers F4/80/CD68), and levels of the effector lipocalin-2 (LCN2). Transmission electron microscopy (TEM) evaluated mitochondrial ultrastructure in epithelial cells. In vitro assays confirmed NPY's direct effect on macrophages and LCN2's impact on epithelial mitochondria.

Results: Dry eye corneas exhibited significant sympathetic overactivation and elevated NPY levels.

This was accompanied by increased macrophage infiltration and activation, alongside markedly raised LCN2 protein and mRNA expression. In vitro, NPY directly induced macrophage activation and LCN2 secretion. Crucially, TEM revealed severe mitochondrial damage in the corneal epithelium, including cristae loss and vacuolization. Mechanistically, macrophage-derived LCN2 was identified as the key factor directly causing this mitochondrial injury.

Conclusions: This study defines a novel «sympathetic nerve-macrophage-epithelial cell» axis in DED: sympathetic overactivation releases NPY, which recruits and activates corneal macrophages. These activated macrophages secrete LCN2, which directly triggers mitochondrial damage in epithelial cells, ultimately disrupting the epithelial barrier. These findings provide a new neuroimmunological mechanism for DED pathogenesis and identify potential therapeutic targets, such as blocking the NPY receptor or neutralizing LCN2.

Abstract No.: 202546

Unraveling the Unknown: Inverse Keratoconus Following Deep Anterior Lamellar Keratoplasty

First Author: Pravallika PAMULAPATI

Co-Author(s): Jagadheesh Kumar Reddy, Vandhana SUNDARAM

Purpose: To describe and analyze a novel topographic pattern of inverse keratoconus, defined by central corneal flattening as a late complication in keratoconus patients following deep anterior lamellar keratoplasty (DALK).

Methods: A retrospective case series of 25 eyes from 25 patients with keratoconus who underwent DALK was reviewed. Patients presented with progressive visual deterioration during long-term follow-up. Corneal topography and tomography were analyzed to assess curvature changes and pachymetry. Clinical data, including slit-lamp findings, visual acuity, and refraction, were analyzed.

Results: All eyes exhibited a distinct topographic pattern of central corneal flattening, contrasting with the classic keratoconus cone. A central stromal haze of variable density was clinically observed, correlating with areas of flattening and thinning (central pachymetry ranging 406–499 μm). Haze onset occurred at a mean of 4.5 ± 3 years post-DALK, progressively worsening over time. Visual acuity declined accordingly, without signs of epithelial defects, graft rejection, or active inflammation.

Conclusions: Inverse keratoconus represents a novel and previously undocumented topographic pattern, characterized by central corneal flattening developing as a late complication following DALK. This atypical presentation challenges conventional expectations of postoperative corneal remodeling contributing to

progressive visual decline. This central flattening island correlating with stromal haze, thinning, and decreased visual acuity raises important questions regarding its etiology, including the possibilities of chronic stromal rejection, subclinical interface pathology, a delayed manifestation of keratoconus progression in residual host tissue, or donor pathology. Recognizing this pattern is critical, as it may have direct implications for postoperative monitoring, diagnosis, and visual rehabilitation.

Abstract No.: 204333

Urrets-Zavalía Syndrome Following Penetrating Keratoplasty: A Rare Case Report

First Author: Cassandra QUEK

Co-Author(s): Hannie CH'NG, Rohanah BINTI ALIAS, Norlina BINTI MOHD RAMLI

Purpose: to highlight urrets-zavalía syndrome in post penetrating keratoplasty

Methods: case report

Results: A 65-year-old woman with hypertension and bronchial asthma presented with progressive bilateral visual loss over 20 years. She had a strong family history of corneal stromal dystrophy. Examination revealed visual acuity of counting fingers in the right eye and 6/120 in the left. Both corneas showed central stromal opacification with epithelial defects. Anterior chambers were formed, but pupil and iris details were obscured. Intraocular pressures (IOP) were normal. Fundus view was obscured; B-scan showed flat retinas without vitreous opacities. She underwent right eye penetrating keratoplasty. Intraoperatively, repeated iris prolapse occurred despite intravenous mannitol given and optimised general anaesthesia. The procedure was otherwise uneventful, with a round, undilated 3 mm pupil at closure. On postoperative day one, the graft was clear with Descemet's striae, epithelial defects and intact sutures. Anterior chamber was moderately shallow, the pupil fixed and dilated at 6 mm, and IOP was 40 mmHg. IOP reduced to 30 mmHg with oral acetazolamide and topical timolol, and to 18 mmHg with intravenous mannitol, accompanied by deepening of the anterior chamber. At two months, the graft remained clear with no intraocular inflammation observed and IOP normal. Visual acuity improved to 6/18 though the pupil remained 5 mm and sluggish to light.

Conclusions: This case illustrates Urrets-Zavalía syndrome, where repeated iris prolapse, transient acute postoperative IOP elevation, and subsequent ischemic sphincter damage likely contributed to the persistent dilated pupil following penetrating keratoplasty.

Abstract No.: 200793**Use of Phakic Implant As Piggy Back Lens in Post RK Pseudophakic Eyes: Efficacy and Safety***First Author: Bhupesh SINGH**Co-Author(s): Neha BHARTI***Purpose:** To know the safety and efficacy of phakic implants as piggy back lens in operated eyes.**Methods:** This is retrospective chart review of 12 eyes of 12 patients operated for cataract surgery in radial keratotomy eyes were included in the study. Phakic Toric implants were used to correct the residual refractive error post cataract surgery in these eyes. Patients were followed up for 12 months.**Results:** All patients achieved UCVA of 20/30. Good vault height 656 + 230 micron was noted in all eyes. No intraocular pressure rise was seen in any of these eyes. Pigment dispersion was noted in 1 eye.**Conclusions:** This is a safe and effective modality to correct residual refractive error in post RK pseudophakic eyes.**Abstract No.: 204811****When Edema Persists: Descemet's Membrane Detachment Masquerading as Pseudophakic Bullous Keratopathy***First Author: Riskha PANGESTIKA***Purpose:** Descemet's membrane detachment (DMD) is a rare but serious complication of cataract surgery, with an incidence of about 0.5%. It may present with persistent corneal edema and be mistaken for pseudophakic bullous keratopathy. This report highlights the diagnostic approach and management of DMD**Methods:** A 72-year-old man presented with blurred vision in the right eye one month after uneventful phacoemulsification. Visual acuity was 1/60. The condition was initially considered pseudophakic bullous keratopathy due to persistent corneal edema. Slit-lamp biomicroscopy with a narrow beam demonstrated localized stromal edema, microcystic bullae, Descemet's membrane folds, and a "double anterior chamber" appearance, confirming extensive DMD. Medical therapy with preservative-free prednisolone acetate 8 times daily and 3% hypertonic saline hourly was initiated but showed no improvement after one week. Descemetotomy with sulfur hexafluoride (SF6) was then performed under topical anesthesia**Results:** Two weeks postoperatively, the Descemet's membrane was successfully reattached, the cornea was clear, and visual acuity improved to 0.2 logMAR**Conclusions:** Early recognition of DMD and timely surgical intervention can restore corneal clarity and

improve vision, preventing progression to irreversible corneal decompensation and the need for keratoplasty

Abstract No.: 204258**When Tears Run Dry – Unveiling Dry Eye Disease in Type 2 Diabetes Mellitus***First Author: Prem SAI.T**Co-Author(s): Krithika M, Ragul VR***Purpose:** Type 2 Diabetes Mellitus is a global concern in the present and future; there are various complications of T2DM, the most underestimated one is Dry Eye disease, which can affect the quality of life.**Methods:** A total of 150 patients were included. Vision refraction, history, especially duration, type of treatment, overall control of diabetes by recent FBS, PPBS & HbA1c values were noted, anterior segment, and level of DR status assessed by dilated fundus examination. The following are the diagnostic criteria to diagnose DED: Ocular surface disease index, which is considered with 1 or more positive clinical findings as follows: Tear meniscus height, Tear breakup time, Ocular surface staining score, Schirmer's test, Fluorescein staining of cornea, conjunctiva & Meibomian gland dysfunction.**Results:** Prevalence of DED in type 2 DM was 46.6% (140/300 eyes).**Conclusions:** DED was more prevalent & statistically significant ($p < 0.0001$) among patients having high HbA1c, not on regular medication, longer duration of DM & in the proliferative stage of DM 68.5% (96/140 eyes).**Abstract No.: 204766****When Topography Isn't There: Unmasking Hidden Corneal Irregularity As the Amblyopia Mimic***First Author: Prasthiti Dewi HASDINI**Co-Author(s): Sagung Gede INDRAWATI***Purpose:** To highlight a practical and innovative approach for accurate diagnosis of suspected corneal irregularities in a hospital setting lacking corneal topography.**Methods:** A retrospective case series was conducted from June to July 2025 on astigmatism patients with suspected corneal irregularities. They underwent keratometry measurements and best-corrected visual acuity (BCVA) assessment.**Results:** Four patients reported discomfort and poor vision with previous spectacles prescribed only with spherical correction, lacking cylindrical components. Examination of six eyes from these patients showed the estimated refractive error (ERE) from current uncorrected visual acuity (UCVA) required less power than previous prescriptions, indicating possible overcorrection. Compound myopic astigmatism was

identified in the current spectacle prescriptions, yet BCVA remained suboptimal at 20/40 to 20/100 despite maximal refractive correction. Two patients also demonstrated anisometropia, with interocular differences of 1 and 6 diopters. Anterior and posterior segment examinations were unremarkable, suggesting amblyopia. Keratometry showed mild corneal toricity between 0.25 and 1.25 diopters, with no evidence of corneal irregularity. Guided by this finding, spherical rigid gas permeable (RGP) lenses with power of -4.00 to -6.00 diopters were applied as a diagnostic tool. This clarified the true refractive status and restored crisp 20/20 acuity in all patients. They experienced complete symptom resolution, and the lenses demonstrated excellent stability.

Conclusions: The importance of recognizing subtle corneal irregularities that may masquerade as amblyopia cannot be overstated. Keratometry-guided diagnostic RGP lens trials offer a reliable method to detect such irregularities even in the absence of corneal topography, thereby facilitating accurate refraction and optimal visual outcomes, particularly in resource-limited settings.

Abstract No.: 204253

mTOR Signaling Promotes PPAR γ /SREBP-Driven Lipid Production in Human Meibomian Gland Epithelial Cells

First Author: Ikhyun JUN

Purpose: The mechanistic target of rapamycin (mTOR) pathway is increasingly recognized as a central regulator of cellular metabolism, but its contribution to lipid homeostasis in the meibomian gland remains unclear. This study aimed to define how mTOR activity influences lipid synthesis and differentiation in human meibomian gland epithelial cells (HMGECS).

Methods: Cultured HMGECS were exposed to rapamycin to inhibit mTOR signaling, and lipid accumulation was assessed through lipid-specific staining and quantitative assays. The expression of transcriptional regulators PPAR γ and SREBP-1 was examined by immunoblotting and real-time PCR. Phosphorylation of downstream effectors, including p70S6 kinase and AKT, was analyzed as indicators of mTOR complex activity. Additional knockdown experiments targeting both mTORC1 and mTORC2 with siRNA were performed to validate their roles in lipid regulation.

Results: Rapamycin exposure led to a pronounced decline in lipid accumulation as well as reduced expression of PPAR γ and SREBP-1. In parallel, phosphorylation of p70S6 kinase and AKT was significantly diminished. Dual inhibition of mTORC1 and mTORC2 further suppressed PPAR γ /SREBP-1 expression and markedly lowered lipid synthesis, indicating that both complexes are required for proper lipid metabolism and differentiation in HMGECS.

Conclusions: These findings demonstrate that mTOR signaling is essential for lipid biosynthesis and maturation of meibomian gland epithelial cells. Both mTOR complexes contribute to PPAR γ /SREBP-driven lipogenesis, highlighting this pathway as a potential therapeutic target for conditions associated with meibomian gland dysfunction and ocular surface disease.

Glaucoma

Abstract No.: 203543

A Case Report of Late-Onset Lens Particle Glaucoma After Pars Plana Vitrectomy

First Author: Yanin SUWAN

Co-Author(s): Boonsita SRISAMARN, Siripa TIPPAPUT, Siripa TIPPAPUT

Purpose: To describe an atypical late-onset presentation of lens particle glaucoma after pars plana vitrectomy.

Methods: Case report.

Results: A 36-year-old male presented to the hospital complaining of acute, painful, blurred vision in the left eye with a history of pars plana vitrectomy. Examination revealed whitish material in the anterior chamber and a mature cataract with an intact anterior capsule, with intraocular pressure (IOP) of 50 mmHg. The lens particle glaucoma was highly suspected according to the history of pars plana vitrectomy. Therefore, Anterior Segment Optical Coherence Tomography (AS-OCT) was sent to confirm the diagnosis and revealed evidence of posterior capsule rupture. After failure of medical management to control IOP, lens aspiration with pars plana vitrectomy was done, and IOP was regained to 14 without any ocular-hypotensive medications.

Conclusions: After several months of pars plana vitrectomy with traumatic posterior capsular rupture, lens particle glaucoma may lead to elevated intraocular pressure (IOP). Initially, lens particles are released into the posterior chamber and vitreous cavity, then gradually migrate into the anterior chamber through weakened zonules.

Abstract No.: 205434

A Case of Sympathetic Ophthalmia Following Preserflo MicroShunt Implantation

First Author: Disheng WU

Co-Author(s): Keisuke ADACHI, Sayuri MANO, Shintaro NAKAO, Kousei TOMITA

Purpose: Sympathetic ophthalmia (SO) is an autoimmune disease triggered by penetrating ocular trauma or intraocular surgery. We report a case

of presumed SO following Preserflo MicroShunt implantation.

Methods: A 69-year-old man had a history of partial scleral buckling for retinal detachment in the right eye 30 years earlier. He underwent trabeculectomy in the right eye for bilateral open-angle glaucoma 5 years ago, followed by cataract extraction with intraocular lens implantation in the left eye 4 years ago and in the right eye 3 years ago. Due to progressive glaucoma in the left eye, Preserflo MicroShunt implantation was performed. Postoperative intraocular pressure was well controlled; however, 4 weeks later, the patient developed bilateral blurred vision. Optical coherence tomography revealed dome-shaped serous retinal detachments with septa in both eyes. As HLA-DR4 positivity was also detected, SO was suspected, and steroid semi-pulse therapy was administered. Retinal findings and subjective symptoms improved after treatment.

Results: SO is considered to develop after penetrating trauma involving the uvea or following intraocular procedures. Reported cases include those after vitrectomy, scleral buckling, cataract surgery, strabismus surgery, and cyclodestructive procedures. In this case, although the surgical procedure was performed according to standard technique, inadvertent ciliary body injury during scleral penetration with a double-step knife or scleral suturing cannot be excluded.

Conclusions: This represents a rare case of SO following Preserflo MicroShunt implantation and serves as an important reminder of this potential complication.

Abstract No.: 203340

A Comparison of the Utility and Reliability Indices Between Different Humphrey Visual Field Testing Strategies in a Tertiary Care Centre

First Author: Soumya PODURY

Purpose: This study evaluates and compares the utility of different testing strategies available within the Zeiss Humphrey Field Analyzer 3 among patients with various ocular conditions at a tertiary care center. We assessed test parameters—mean deviation (MD), pattern standard deviation (PSD), visual field index (VFI), and test duration—as well as reliability indices including fixation losses, false positives, and false negatives. Patient comfort and confidence were also evaluated via a post-test survey.

Methods: Participants scheduled for HVF testing at the University of Ottawa Eye Institute underwent an additional HVF test using a different strategy. A questionnaire was administered after both tests.

Results: Data from 67 eyes of 34 patients showed statistically significant differences in VFI and test duration, with SFR 24-2C yielding a 2% higher VFI and being 161 seconds faster than SS 24-2. MD and

PSD differences were not statistically significant. SFR 24-2C had 1.9% more false positives; fixation losses were similar. Survey results showed no difference in confidence or discomfort, though patients perceived SS 24-2 as longer and more error-prone.

Conclusions: Overall, SFR 24-2C consistently produced shorter test durations and slightly overestimated VFI compared to SS 24-2. Patients reported greater reliability and comfort with the SFR 24-2C

Abstract No.: 204347

A Novel Deployable Microstent for the Treatment of Glaucoma

First Author: Weijia ZHANG

Co-Author(s): Jared CHING, Chun ZHANG

Purpose: Minimally invasive glaucoma surgery (MIGS) has experienced a surge in popularity in recent years. Glaucoma drainage devices aimed at subconjunctival space keeping updated. In order to optimise the shortcomings of commercially available minimally invasive surgical approaches targeting the subconjunctival space for glaucoma, we developed a novel deployable microstent fabricated with nickle titanium.

Methods: We undertook a 6-month head-to-head experiment with the commercially available XEN® gel stent without subconjunctival fibrosis augmentation in vivo implantation in rabbit models. Eighteen New Zealand white rabbits were randomly assigned to three groups: Xen implant group (6 right eyes), Microstent implant group (6 right eyes), Microstent implant with mitomycin C (MMC) group (6 right eyes). Intraocular pressure (IOP), anterior and posterior segment photos, anterior segment optical coherence tomography (AS-OCT), outflow test and histology were assessed to measure the safety and efficacy of the microstent.

Results: Microstent demonstrated intraocular pressure (IOP) lowering over the course of 6 months both with MMC or without MMC, while IOP did not change significantly after 14 days with Xen®. All eyes developed blebs over the implant, and sodium fluorescein still drained from the anterior chamber to the subconjunctiva 6 months after microstent implantation. Microstent was well tolerated and little displacement. Histopathology at 6 months showed minimal tissue response and no obvious inflammation, fibrosis, or necrosis around the microstent.

Conclusions: To date, this is the first deployable microstructure designed to treat glaucoma, demonstrating the safety and efficacy of microstent in controlling IOP after implantation into the anterior in normal IOP rabbit model.

Abstract No.: 207413

A Rare Presentation of Maroteaux-Lamy (MPS VI) Syndrome With Secondary Glaucoma

First Author: Dewang **ANGMO**

Co-Author(s): Ramneek Kaur **MAHAL**, Anuja **PATIL**

Purpose: The purpose of this case is to report an unusual manifestation of type MPS VI (Manteaux-Lamy syndrome) presenting with secondary glaucoma.

Methods: An eight-year-old boy presented with bilateral cloudy cornea, coarse facies, large tongue, chest deformities, abdominal hernia, and skeletal deformities. On examination, anterior and posterior segment details were not visible due to corneal haze. IOP in RE was 24 mmHg and LE 30 mmHg. The patient was started on anti-glaucoma medications and planned for examination under anaesthesia (EUA). BE USG was anechoic. AS-OCT and UBM were done during EUA. Blood tests were done for lysosomal enzymes and showed the absence of serum arylsulfatase B. Clinical and paraclinical findings confirmed the diagnosis of MPS 6 with secondary glaucoma. Echocardiography, audiometry, and radiography for chest, back, hip, and hand were performed to investigate the presence of other systemic associations.

Results: During EUA, IOP in RE was 12 mmHg and 22 mmHg in LE with Perkins' tonometer. Therefore, LE trabeculectomy with trabeculotomy with MMC for 2 minutes was done. Anaesthetists found difficulty during the intubation of the patient due to his systemic comorbidities. Therefore, more time was required to intubate and extubate the patient. At 3 months follow-up, IOP was 14 mmHg in RE and 10 mmHg in the LE.

Conclusions: MPS VI is associated with multiple systemic comorbidities, along with corneal clouding as the most common ocular presentation. Though less common, glaucoma is difficult to diagnose and manage due to inappropriate IOP recording and poor visualization of the ONH changes.

Abstract No.: 201861

A Review of Psychosomatic Interactions and Management Strategies in Glaucoma: Integrating Evidence From a Neuro-Endocrine-Behavioral Perspective

First Author: Liyang **ZHANG**

Purpose: Synthesize epidemiology, mechanisms and interventions linking depression/anxiety/sleep disturbance with glaucoma to guide a bio-psycho-social pathway.

Methods: Systematic search (inception–Aug 2024, PubMed/Embase/Web of Science/CNKI) identified 128 studies; PRISMA selection, AHA grading; data on prevalence, stress–IOP axis and intervention effect sizes (Hedges g).

Results: Pooled prevalence: depression 28.9%, anxiety 31.5%, sleep disorders 46.2%. Risk factors: female sex, living alone, low education, severe field loss. Acute stress elevates IOP 3–7 mmHg within 15 min; chronic stress index $\uparrow$ 1 point $\rightarrow$ annual RNFL loss $+0.15 \mu\text{m}$. Eight-week mindfulness lowers IOP 2.3 mmHg; CBT plus motivational interviewing $\uparrow$ adherence 23 % and slows MD loss by 0.6 dB/year. SSRIs/TCAs may raise IOP 1–3 mmHg and angle-closure risk 1.7-fold.

Conclusions: Glaucoma is psychosomatic: negative emotions drive IOP fluctuation and optic nerve damage via sympathetic–HPA activation and circadian disruption, while visual loss worsens mental health. Integrate brief mood/sleep screening into routine follow-up; offer mindfulness or CBT first-line. Large multicentre trials are needed to validate personalized psychosomatic management.

Abstract No.: 202012

A Silver Lining With Kahook Dual Blade: Transforming Outcomes in Traumatic Angle Recession Glaucoma Management Following Blunt Injury

First Author: Prasanna Vekatesh **RAMESH**

Purpose: Blunt ocular trauma can cause persistent IOP elevation and angle recession glaucoma. Minimally Invasive Glaucoma Surgeries (MIGS), such as Kahook Dual Blade goniotomy, expand treatment options. This is the first reported adult case of traumatic glaucoma unresponsive to medical therapy managed with combined cataract extraction and KDB goniotomy.

Methods: A 25-year-old male with a 10-year history of blunt trauma presented with pain, reduced vision, secondary glaucoma, and traumatic cataract. Antiglaucoma medications (AGMs) failed to control IOP, so he underwent combined cataract surgery and KDB goniotomy, with follow-ups at 1 week and 1 month.

Results: The combined surgical approach yielded promising outcomes, achieving both visual rehabilitation and IOP control. KDB goniotomy was selected due to its safety, cost-effectiveness, and ability to restore aqueous drainage by removing obstructive trabecular tissue. The procedure resulted in an approximate 50% reduction in IOP. Additionally, KDBs goniotomy avoided the astigmatic changes often associated with filtering surgeries like trabeculectomy, thus minimizing visual distortion. By preserving the conjunctiva, the procedure also maintained the option for future trabeculectomy if needed. Compared to bleb-based procedures, KDB reduced the risks of complications such as corneal edema, bleb leaks, and hypotony maculopathy.

Conclusions: KDB goniotomy effectively manages traumatic glaucoma, improving vision and controlling IOP in a single procedure. By targeting the trabecular meshwork, it offers excellent IOP control with minimal

complications, highlighting MIGS' potential in complex glaucoma cases.

Abstract No.: 200338

A Translational Mathematical Model for Normal Tension Glaucoma: Advancing Explainable, Personalized Management

First Author: Aik Kah TAN

Purpose: To enhance understanding and management of normal tension glaucoma (NTG), I developed a translational mathematical model that captures the dynamic interactions among intraocular pressure (IOP), radial peripapillary capillary (RPC) density, retinal ganglion cell (RGC) density, and visual field (VF) sensitivity. The model aims to enable explainable, individualized treatment planning.

Methods: Guided by a representative NTG clinical scenario, hypotheses describing key biological relationships were formulated as differential equations and numerically simulated using the fourth-order Runge-Kutta method across IOP levels of 12–20 mmHg (IOP burden: 2–10 mmHg) over 20 years.

Results: Simulated trajectories revealed IOP-dependent patterns in RPC, RGC, and VF loss. From these, five mechanistic conjectures were derived, bridging microvascular and neurodegenerative dynamics to clinical outcomes: - Exponential vulnerability: VF loss accelerates nonlinearly with IOP; - Threshold compression: higher IOP shortens time to critical VF decline; - Temporal divergence: delayed IOP control causes irreversible outcome separation; - Integrated damage burden: area under dVF/dt quantifies cumulative functional loss; and - Critical deceleration: minimum d^2VF/dt^2 identifies optimal intervention window. The “functional reserve exhaustion point” explains advanced VF loss despite residual RNFL, likely due to non-functional axons or glial remodeling. A simplified conceptual expression, $VF \propto e^{-\text{(relative pressure burden)}}$, is also introduced.

Conclusions: This model provides a new toolkit to simulate NTG progression and optimize treatment timing. Its modular design supports integration with future AI systems, enabling precision glaucoma care through patient-specific explainable strategies. This may inform when to escalate therapy or predict irreversible decline.

Abstract No.: 205073

Advancing MIGS: Clinical Outcomes of Hydrus Microstent Implantation With Phacoemulsification

First Author: Woan Shian SEE

Co-Author(s): Haireen KAMARUDDIN, Zhi Yiu Hiang Weang LIM, Chai Keong TAN

Purpose: Hydrus Microstent, a microinvasive glaucoma surgery (MIGS) device, lowers intraocular pressure (IOP) by serving as an intracanalicular scaffold. This case series presents outcomes of primary open-angle glaucoma patients undergoing combined phacoemulsification and Hydrus implantation.

Methods: This retrospective, non-comparative, single-center case series included six phakic eyes with mild to moderate glaucoma that underwent phacoemulsification and Hydrus Microstent implantation. The primary endpoint was IOP reduction, assessed by comparing preoperative values with one-year postoperative measurements. Secondary observations included adjunctive medication use, best-corrected visual acuity (BCVA), visual field stability, and safety outcomes.

Results: Five of six patients (83%) achieved a reduction in mean IOP, with 83% reaching ≤ 15 mmHg, the target for mild to moderate glaucoma. Five patients discontinued all glaucoma medications postoperatively. All patients maintained BCVA of 6/9 or better. Visual fields remained stable in 83% of cases. However, progression in one patient, despite an IOP of 14 mmHg, highlights the role of non-IOP-related risk factors. No postoperative complications were observed.

Conclusions: Phacoemulsification combined with Hydrus Microstent implantation appears to be a safe and effective approach for lowering IOP and reducing the need for glaucoma medications in mild to moderate glaucoma. The findings support the growing role of MIGS in glaucoma management, though continued studies are needed to refine patient selection and long-term outcomes.

Abstract No.: 203958

An Unpleasant Surprise

First Author: Nabila RAHMAN

Co-Author(s): Mostafa HOSSAIN, Tasnima RAHMAN

Purpose: Reporting on 6 patients coming to OPD just for a regular eye checkup, eventually turned out to be a case of glaucoma or glaucoma suspect.

Methods: Commonly, their vision was 6/6 in both eyes, and retinoscopy findings were PLANO for both eyes. An undilated fundus revealed disc changes in all the cases. Among them, 2 patients had almost full cupping of discs, and others had suspected discs. None of them had a positive family history. Needful investigations and observation confirmed the diagnoses.

Results: Two patients had to take anti-glaucoma drugs and be kept under close observation. One of them was planned for filtration surgery as he had raised IOP of 31 mm (right eye) and 33 mm (left eye).

Conclusions: Regular checkups might not always be normal, but rather a very disappointing conclusion. A detailed evaluation is needed for every patient, even with 6/6 vision and no complaints.

Abstract No.: 206544

Analysis of Aldosterone Concentrations in Aqueous Humor and Serum of Patients With Posner-Schlossman Syndrome

First Author: Yifan JIN

Purpose: Analysis of variations in aldosterone concentrations in aqueous humor and serum among patients with posner-schlossman syndrome (PSS).

Methods: Prospective case-control study. Untreated patients with PSS exacerbation or patients with PSS remission were designated as the PSS exacerbation group and the PSS remission group, respectively. The aqueous humor and serum samples of the PSS exacerbation group and the serum samples of the PSS remission group were collected. The concentrations of aldosterone in these samples were measured by liquid chromatography-mass spectrometry (LC-MS). Control groups include: Cataract group, AACG group, CACG group, and POAG group.

Results: The aqueous humor aldosterone concentration of PSS exacerbation group, cataract group, AACG group, CACG group, and POAG group were 22.15 (18.14, 28.64), 16.02 (0.01, 21.82), 0.01 (0.01, 16.45), 15.37 (0.01, 18.84) and 15.27 (0.01, 17.94) pg/ml, respectively, with the overall difference of the aqueous humor aldosterone concentration among the 5 groups was statistically significant ($H=17.48$, $P=0.002$). And further comparisons revealed that the aqueous humor aldosterone concentration was increased in the PSS exacerbation group, and the differences were statistically significant with those in the cataract group, AACG group, CACG group, and POAG group (all $P<0.05$). A positive correlation between the concentration of aldosterone in the aqueous humor and that in the serum ($r=0.76$, $P<0.001$), and a negative correlation between the concentration of aldosterone in the aqueous humor and intraocular pressure ($r=-0.53$, $P=0.023$) in PSS exacerbation group were observed.

Conclusions: Compared with the cataract, AACG, CACG, and POAG, elevated aqueous humor aldosterone is observed in patients with PSS exacerbation group, suggesting that ocular aldosterone may be involved in the elevation of IOP and the development of localized inflammation in PSS.

Abstract No.: 201020

Analysis of Choroidal Thickness and Choroidal Vascularity Index in Early Primary Angle-Closure Glaucoma by Swept Source Optical Coherence Tomography Angiography

First Author: Hui LIU

Co-Author(s): Danyan LIU

Purpose: To investigate changes of choroidal thickness (CT) and choroidal vascularity index (CVI) in eyes with early primary angle-closure glaucoma (PACG) based on swept source optical coherence tomography angiography (SS-OCTA).

Methods: A total of 86 early PACG patients (86 eyes) and 79 healthy individuals (79 eyes) were enrolled. All subjects underwent 12×12 mm macular scan and 6×6 mm optic disc scan to analyze and compare CT and CVI. Univariate and multivariate linear regression analyses were used to evaluate the relevance of CT and CVI to related factors.

Results: In all macular regions, early PACG patients exhibited thicker CT and higher CVI as compared with controls (all $P<0.05$). Multivariate linear regression analysis showed that increased subfoveal CT and CVI were associated with younger age, PACG diagnosis, and/or shorter axial length (all $P<0.05$). After adjusting for the compound factors of age and/or axial length, subfoveal CT and CVI remained significantly higher in early PACG patients than in controls (both $P<0.01$).

Conclusions: Early PACG patients are usually associated with thicker CT and higher CVI in 1-12 mm annular regions of macula. The changes in CT and CVI were independent of age and axial length, indicating that alterations in choroidal characteristics may be involved in the pathogenesis of PACG.

Abstract No.: 202601

Analysis of Intraocular Pressure After Myopic Laser Refractive Surgery

First Author: Zainul Abideen AREAKAT

Co-Author(s): Yasmin MOHAMED

Purpose: The objective of this study was to analyze the intraocular pressure (IOP) after laser refractive surgery PRK patients with myopia.

Methods: Fifty-six patients who underwent PRK intervention to treat myopia. In total, 112 eyes were treated. Before the intervention, all patients underwent a complete ophthalmologic examination, including the measurement of central corneal thickness (CCT) and measurement of IOP with a non-contact tonometer. The IOP was also measured on days 3, 7 and 30 after the surgery. The mean IOP was taken for statistical analysis.

Results: One hundred and twelve eyes of 56 patients (mean age 24.6) underwent PRK to treat myopia. The average spherical equivalent was -4.1 diopters. Mean

CCT before the intervention was $521.9 \pm 31.9 \mu\text{m}$, while mean postoperative CCT was $439.8 \pm 45.3 \mu\text{m}$ ($p < 0.0001$). Mean preoperative IOP was 15.4 mmHg while mean postoperative IOP was 11.4 mmHg ($p < 0.0001$).

Conclusions: The reduction of IOP after laser refractive surgery PRK is significant. This reduction is about 1 mmHg per 1 diopter. This should be taken into account in the future in these patients because, due to the underestimation of the IOP and this can lead to later detection of glaucoma.

Abstract No.: 202157

Angle Closure Glaucoma in a Patient With Nanophthalmos Eye: Does Clear Lens Extraction Matter? A Case Report

First Author: Ravidhar BHANDARI

Purpose: To determine the reduction of intraocular pressure after clear lens extraction in a patient with nanophthalmos.

Methods: In this case report, we treated the two eyes of one patient with nanophthalmos and glaucoma with clear lens extraction and posterior intraocular lens (IOL) implantation.

Results: A thirty-four-year-old male previously diagnosed with Nanophthalmos with angle-closure glaucoma was using maximum glaucoma medications in both eyes for 5 years. Patient had visual acuity of 6/60 in the right eye (RE) and 5/60 in the left eye (LE), with intraocular pressure (IOP) in RE 42 mmHg and LE 38 mmHg. Patient underwent clear lens extraction with IOL implantation (Phaco aspiration with Foldable IOL implantation) in RE under topical anesthesia under I/V mannitol. On 1st POD, RE- visual acuity improved to 6/24. After a month, the patient was operated on for the other eye (LE- Phaco aspiration with Foldable IOL implantation) under topical anesthesia under I/V mannitol. On the 1st postoperative day (POD), LE-visual acuity improved to 6/24.

Conclusions: Clear lens extraction with IOL implantation helps in deepening the anterior chamber, which results in opening of the angle, due to which there is an increased outflow of fluid from the anterior chamber and thereby reducing IOP and saving sight of the patient with fewer complications.

Abstract No.: 205785

Angle-Closure Glaucoma and Albinism

First Author: Weiwei WANG

Purpose: To explore the association between angle-closure glaucoma and albinism.

Methods: Clinical data of two patients with albinism complicated by angle-closure glaucoma and cataract were analyzed before and after surgical treatment.

Results: Patient 1: A 58-year-old female presented with blurred vision in the right eye, accompanied by ocular pain and headache for one week. Examination revealed white hair and eyebrows, with IOP > 40 mmHg and iris hypopigmentation in both eyes. The right eye exhibited an acute angle-closure attack with a white, opacified lens, precluding fundus view. The left eye had cataracts, obscuring the posterior pole, though choroidal vessels and white sclera were visible in the periphery. Ocular biometry indicated short AXL of 21.1 mm and 20.9 mm, respectively. Both eyes underwent combined glaucoma and cataract surgery, resulting in stable postoperative IOP control. Patient 2: A 53-year-old male presented with a six-month history of progressive visual decline in both eyes. Of his six siblings, one sister also has albinism. He was found to have elevated IOP in both eyes. The right eye had a shallow anterior chamber and a white, opacified lens, preventing fundus examination. Following cataract surgery in the right eye, IOP normalized. Genetic analysis of the pedigree revealed that both the patient and her sister harbored compound heterozygous variants c.230G $>$ A (p.Arg77Gln) and c. 832G $>$ A (p. Arg278*) in the TYR gene.

Conclusions: Angle-closure glaucoma and albinism share embryologic and anatomic features, increasing glaucoma risk in affected individuals. Accurate diagnosis and timely surgical intervention can significantly improve the quality of life for these individuals.

Abstract No.: 206414

Aqueous Humor Insulin/GLP-1 Axis as a Stage-Linked Biomarker of Glaucoma Independent of IOP

First Author: Muneeb FAIQ

Co-Author(s): Rima DADA, Tanuj DADA, Daman SALUJA, Himanshu SINGH

Purpose: To evaluate whether aqueous humor (AH) insulin/GLP-1 signaling markers provide stage-linked molecular readouts of glaucoma independent of IOP, and whether they couple to mitochondrial injury and neurotrophic loss.

Methods: AH (0.5 mL) from cataract controls ($n=30$), early POAG (MD -6 to -12 dB; $n=30$), and advanced POAG (MD < -20 dB; $n=30$) underwent LC-MS proteomics (Orbitrap, MaxQuant) and untargeted metabolomics (Compound Discoverer; MetaboAnalyst 5.0). A curated panel captured insulin/GLP-1 pathway (INSR, IRS1, PIK3CA, AKT1, MTOR, RICTOR; GLP-1, IGF-1, IGFBP6), mitochondrial/TCA indices (IDH3A, ATP5F1A, citrate, α -ketoglutarate, cardiolipin), and neurotrophic/stress markers (BDNF, β -endorphin, cortisol). Group differences used LIMMA with Benjamini-Hochberg FDR. Linear models tested MD as a function of IOP with and without an insulin/GLP-1 composite (z-scored). Elastic-net (nested CV) evaluated stage classification.

Results: Compared to cataract, early POAG already showed insulin axis suppression (e.g., INSR, IGFBP6, GLP-1; all $FDR < 0.05$) with parallel TCA depletion; advanced POAG intensified these patterns and added higher cortisol and kynurenine. Adding the insulin/GLP-1 composite to IOP significantly improved MD prediction ($\Delta R^2 \approx 0.18-0.25$; $\Delta AIC < -10$). Mediation suggested insulin-axis deficits partially act through mitochondrial compromise (indirect effect $p < 0.01$). An 8-feature panel (INSR, IGFBP6, GLP-1, citrate, α -ketoglutarate, ATP5F1A, BDNF, cortisol) classified early vs advanced POAG with AUC 0.86–0.90 (nested CV).

Conclusions: AH insulin/GLP-1 signaling captures glaucoma severity beyond IOP, linking endocrine-metabolic failure to mitochondrial injury and neurotrophic loss. These findings support a translational biomarker panel for risk stratification and trial enrichment targeting insulin sensitization or GLP-1 pathways.

Abstract No.: 203157

Association Between Anterior Chamber Angle Configuration and Corneal Endothelial Cell Health in Angle Closure Disease

First Author: Maharani Kartika **ANGGRAENI**

Co-Author(s): Muhammad **FIRMANSJAH**, Dicky **HERMAWAN**, Evelyn **KOMARATIH**, Yulia **PRIMITASARI**

Purpose: This study aimed to evaluate the relationship between anterior chamber angle parameters, particularly the trabecular iris space area at 750 μm (TISA750) and the angle opening distance at 750 μm (AOD750), relates to the health of corneal endothelial cells in patients diagnosed with angle closure disease.

Methods: A cross-sectional observational study was conducted on 35 eyes diagnosed with angle closure disease. Measurements of TISA750 and AOD750 were obtained using anterior segment optical coherence tomography (AS-OCT), focusing on the nasal and temporal quadrants. Corneal endothelial cell density (ECD) was assessed using non-contact specular microscopy. Clinical histories of prior intraocular interventions—such as laser peripheral iridotomy, surgical iridectomy, and lens extraction—were also reviewed. Correlations between angle parameters and ECD were analyzed using Spearman's test.

Results: Eyes with narrower angles and prior intraocular procedures tended to have lower ECD. There was a statistically significant positive correlation between TISA750 and ECD ($r = 0.585$, $p = < 0.05$), as well as between AOD750 and ECD ($r = 0.717$, $p = < 0.05$). Wider angle measurements were associated with better preservation of endothelial cells.

Conclusions: Findings suggest that a more open anterior chamber angle, as reflected by TISA750 and AOD750 values, may be linked to healthier corneal

endothelium in patients with angle closure. These parameters could potentially serve as noninvasive indicators of endothelial vulnerability, particularly in eyes at risk of progressive angle narrowing or requiring intervention.

Abstract No.: 201611

Association Between Corneal Biomechanics and Tonometric Intraocular Pressure Across Five Devices

First Author: Shuichiro **AOKI**

Co-Author(s): Ryo **ASAOKA**, Yuri **FUJINO**, Yoshiaki **KIUCHI**, Hiroshi **MURATA**, Shunsuke **NAKAKURA**

Purpose: To quantify the associations between corneal biomechanical and morphologic parameters and intraocular pressure (IOP) measured by five tonometers in open-angle glaucoma.

Methods: Cross-sectional analysis of 483 right eyes. IOP was measured by Goldmann applanation tonometry (GAT), rebound tonometry (RT), non-contact tonometry (NCT), Ocular Response Analyzer (ORA; corneal-compensated IOP [IOPcc]), and Corvis ST (biomechanically corrected IOP [bIOP]). Corneal parameters included central corneal thickness (CCT), corneal hysteresis (CH; an index of viscoelastic damping), stress-strain index (SSI; an index of corneal stiffness), corneal radius, and pachyslope. Multivariable linear regression modeled device-specific IOP and differences from GAT.

Results: Devices correlated with GAT ($r = 0.59-0.71$; intraclass correlation = $0.50-0.69$) yet showed significant mean differences (all $p < 0.0001$). Models accounted for 14–55% of the variance in absolute IOP and 17–29% of the differences versus GAT. Greater SSI was associated with higher GAT, RT, and NCT values; higher CH was associated with lower IOPcc. bIOP showed the weakest associations with the measured corneal parameters. Across devices, CH showed the largest association with disagreement versus GAT.

Conclusions: Tonometric IOP readings varied with corneal stiffness and viscoelastic damping. bIOP exhibited the least dependence on the measured corneal parameters, suggesting relative robustness to corneal-property differences.

Abstract No.: 201044

Associations of Diabetes Mellitus With Primary Open Angle Glaucoma and Alzheimer's Disease: A Large Cohort Study in UK Biobank

First Author: Xinyue **HE**

Purpose: We analysis to explore the associations between diabetes mellitus (DM) and POAG and AD by considering depression and diabetic retinopathy (DR) as intermediate factors.

Methods: Data on diagnosis of glaucoma, diabetes, depression, Alzheimer's disease, diabetic retinopathy, apolipoprotein E (APOE) E4 genotypes and data from ophthalmologic examinations were gathered. We further collect the prevalence of DM, DR, depression, POAG and AD, gender, APOE E4 genotypes, C-reactive protein (CRP) levels to analysis.

Results: Depression, AD, and POAG were more prevalent in participants with DM compared with non-DM participants, and if DM patients had DR, the prevalence of those comorbidities was even higher than those without DR (all $p < 0.05$). DM, DR, AD, and POAG were more prevalent in participants with depression compared with non-depression participants. Specifically, if DM patients had depression, the prevalence of DR and AD were even higher than those without depression (all $p < 0.05$). In addition, using age-adjusted multivariable general linear model (GLM), we found DM and depression were associated with a higher prevalence of POAG in females while DM and APOE E4 negative status were associated with a higher prevalence of POAG in males. DM, APOE E4, and depression were all associated with higher prevalence of AD in both univariable and multivariable GLM adjusted by age (all $p < 0.05$). DM and depression with APOE E4 was associated with lower CRP levels in both univariable and multivariable GLM (all $p < 0.001$) in all populations.

Conclusions: DR and depression may play pivotal roles in the development of POAG and AD among DM patients.

Abstract No.: 205628

Axenveld-Rieger Syndrome With Secondary Glaucoma in a Filipino Pediatric Patient: A Case Report

First Author: Lilibeth **DY**

Co-Author(s): George **SOSUAN**

Purpose: We present a rare case involving a Filipino pediatric patient diagnosed with Axenveld-Rieger Syndrome (ARS) and secondary glaucoma. This report emphasizes the importance of early diagnosis, particularly in resource-constrained settings.

Methods: This report presents the clinical findings in a pediatric patient with progressive, bilateral blurring of vision, ocular pain, and exotropia in the left eye. Key findings included anterior segment dysgenesis, as indicated by posterior embryotoxon, iris hypoplasia, and adhesion to Schwalbe's line. These anterior and iridocorneal changes caused glaucoma with significant morbidity. Additionally, craniofacial and dental anomalies were noted.

Results: Visual acuity was 10/200 in the right eye and hand motion with good light perception in the left eye. Intraocular pressure was slightly elevated. Slit-lamp examination showed an opacified ring at both

corneal margins, along with a thin, irregular, dilated pupil and iris hypoplasia. Gonioscopy revealed closed angles with peripheral anterior synechiae and anterior angle insertion. Fundus examination indicated optic nerve damage. Systemic findings included microdontia, flattening of the midface and nasal bridge, and a redundant periumbilical skin fold. The patient's family had no reported inherited disorders. The diagnosis was Axenveld-Rieger syndrome with secondary glaucoma. Surgery with a glaucoma drainage device and genetic testing were planned.

Conclusions: This case demonstrates the importance of early detection for inherited disorders that present with both ocular and systemic symptoms. Glaucoma resulting from iridocorneal dysgenesis often requires treatment with glaucoma drainage devices to control intraocular pressure. Management should involve a multidisciplinary team.

Abstract No.: 205178

Bilateral Iridoschisis Without Glaucoma: Challenges During Cataract Surgery

First Author: Deekshya **MALLA**

Purpose: To report a case of bilateral iridoschisis with cataract in a 64-year-old male, highlighting the absence of glaucoma and the surgical challenges encountered during phacoemulsification.

Methods: A 64-year-old male presented with progressive decrease in vision in both eyes. Comprehensive ocular examination was performed. Anterior segment evaluation revealed bilateral nuclear sclerosis grade 2 cataract with iridoschisis. Gonioscopy showed open angles, intraocular pressure was within normal limits, and no glaucomatous features were noted. Posterior segment examination revealed normal fundi. The patient underwent phacoemulsification with posterior chamber intraocular lens implantation in both eyes. Intraoperative and postoperative outcomes were documented.

Results: During cataract surgery, floating iris fibrils intermittently disturbed the surgical field, complicating nucleus removal. Careful surgical maneuvers with the aid of viscoelastic devices allowed safe phacoemulsification and intraocular lens implantation. There were no intraoperative complications. Postoperatively, the patient achieved good visual recovery with stable intraocular lenses and no evidence of iris or glaucoma-related complications.

Conclusions: Iridoschisis is a rare degenerative disorder of the iris commonly associated with angle-closure glaucoma. This case demonstrates that it may present without glaucomatous changes, with gonioscopy showing open angles. Cataract surgery in such cases can be challenging due to iris fibrils interfering with visualization and surgical maneuvers. With meticulous planning and technique, favorable surgical and visual

outcomes can be achieved. Long-term follow-up remains essential, as glaucoma may still develop later in the disease course.

Abstract No.: 203895

Born to Pressure: The Glaucoma Burden in Axenfeld-Rieger Syndrome

First Author: Wen Jin KOW

Co-Author(s): Ee Ling ANG, Siu Wan FOO, Qiu Yip LIM, Julieana MUHAMMED

Purpose: To present a case of Axenfeld-Rieger Syndrome (ARS) with advanced secondary glaucoma, emphasizing early diagnosis and surgical consideration.

Methods: Case report.

Results: A 19-year-old Chinese male with intellectual disability presented with progressive bilateral blurred vision over one year on a background of longstanding high myopia. Best corrected visual acuity was 5/60 (right) and 4/60 (left). The anterior segment examination revealed posterior embryotoxon, polycoria, corectopia, ectropion uveae, and iris hypoplasia. Intraocular pressures were 40 mmHg (right) and 38 mmHg (left). Gonioscopy showed high iris insertion with peripheral anterior synechiae in all quadrants. The fundus examination revealed pale optic discs with a cup-disc ratio of 0.9 bilaterally. Humphrey visual field demonstrated tunnel vision with macular splitting. Systemic features included craniofacial dysmorphism and dental anomalies. A diagnosis of ARS with secondary glaucoma was made. Despite maximal topical therapy, intraocular pressures remain uncontrolled, necessitating trabeculectomy in both eyes. At one-month follow-up, intraocular pressure was controlled at 12mmHg bilaterally.

Conclusions: Glaucoma associated with Axenfeld-Rieger Syndrome is frequently severe and resistant to medical management. Although glaucoma may be present in early infancy, most cases occur during adolescence or early adulthood. Delayed recognition may lead to irreversible visual loss. This case underscored the importance of early diagnosis, vigilant monitoring, and timely surgical intervention to preserve vision in ARS patients.

Abstract No.: 205557

Case Report: Traumatic Aniridia Following Blunt Injury in a Pseudophakic Patient

First Author: Chi-hsin HSU

Purpose: We report a case of total iris loss (traumatic aniridia) in a pseudophakic patient following blunt ocular trauma.

Methods: A case report.

Results: A 73-year-old woman presented with right eye vision loss after blunt trauma from a forward fall. She had undergone uncomplicated bilateral

phacoemulsification with PCIOL implantation 7 years earlier. On examination, the right eye's visual acuity (VA) was hand motion at 15 cm, with intraocular pressure (IOP) elevated to 48 mmHg. Slit-lamp evaluation showed corneal edema and near-total hyphema filling the anterior chamber, obscuring the iris. The PCIOL was well-centered and stable within the capsular bag. B-scan ultrasonography revealed no vitreous hemorrhage or retinal detachment. The patient was started on full anti-glaucoma therapy and topical anti-inflammatory treatment. At the 2-week follow-up, IOP had normalized, and the hyphema had resolved. Complete aniridia was observed, with the PCIOL remaining well-positioned within an intact capsular bag. From 1 month post-injury through 6 years of follow-up, the patient's visual acuity remained stable at approximately 20/25, and IOP was consistently maintained around 15 mmHg without the need for ongoing anti-glaucoma medication.

Conclusions: This case demonstrates that clear corneal incisions can remain vulnerable to blunt trauma long after cataract surgery, potentially causing wound dehiscence. A stable, in-the-bag IOL and intact capsular bag may absorb some of the impact, minimizing intraocular damage. When traumatic aniridia occurs in isolation, the visual prognosis is generally favorable, and IOP can remain stable without medication, even if some angle structures are damaged.

Abstract No.: 203294

Changes in 24-Hour Intraocular Pressure Fluctuations Before and After Preserflo® MicroShunt Surgery Monitored with Triggerfish®

First Author: Takashi MATSUSHIMA

Co-Author(s): Kei SHINODA, Takahiro SUZUKI, Yuji YOSHIKAWA

Purpose: To describe the effect of Preserflo® MicroShunt surgery on diurnal intraocular pressure (IOP) fluctuations in glaucoma patients, assessed with a contact lens sensor, using a case series approach.

Methods: Three patients with glaucoma (two with primary open-angle glaucoma and one with normal-tension glaucoma; two males and one female; mean age 74 years) underwent Preserflo® implantation. Continuous 24-hour IOP-related profiles were recorded preoperatively and again 3–6 months after surgery using the Triggerfish® sensor. Measurements were expressed in millivolt equivalents (mVeq).

Results: Mean IOP decreased from 15.8 mmHg preoperatively to 7.5 mmHg postoperatively, with all patients achieving medication-free control. All three cases demonstrated consistent reductions in amplitude and overall fluctuation (approximately 30–45%). Prominent nocturnal peaks observed preoperatively were attenuated in two cases. In one case, nocturnal fluctuation appeared increased; however, this

was likely attributable to partial signal loss during the night, possibly related to sensor–antenna misalignment during sleep. Representative 24-hour profiles demonstrated smoother, more stable patterns postoperatively.

Conclusions: This case series suggests that Preserflo® MicroShunt surgery may stabilize diurnal IOP dynamics beyond lowering mean IOP alone. Though factors like nocturnal signal loss should be considered, the consistent reductions observed suggest these findings may have clinical significance. Larger studies are warranted to validate these preliminary observations.

Abstract No.: 203253

Choroidal Detachment as a Delayed Complication of Trabeculectomy: A Case Report and Literature Review

First Author: Chi-jeui **JENG**

Co-Author(s): Chi-hsin **HSU**

Purpose: To report a case showing choroidal detachment 5 years after non-complicated trabeculectomy.

Methods: Interventional case report.

Results: A 91-year-old man with a history of cataract surgery and trabeculectomy in the right eye five years ago presented with a sudden onset of painless visual loss in the right eye. He had not required glaucoma medications since surgery. Baseline BCVA was 0.3 (OD), 0.8 (OS); IOP was 9 mmHg (OD), 10 mmHg (OS). On presentation, vision in the right eye declined to hand motion at 10 cm; IOP was 6 mmHg. Examination revealed a functioning bleb (60–90°), mild IOL decentration, no inflammation, and 360° choroidal detachment with kissing choroids obscuring the macula and disc. Due to systemic limitations, oral steroids were contraindicated. Topical steroids, atropine, subtenon triamcinolone, and therapeutic lens were ineffective. OVD injection temporarily raised IOP and improved detachment, but it recurred. A compression suture of the bleb was performed, stabilizing IOP at 9 mmHg. Choroidal detachment resolved within a week, and vision recovered to 0.3.

Conclusions: Choroidal detachment occurs years later after smooth trabeculectomy. A compression suture is an ideal treatment option.

Abstract No.: 204500

Clinical Outcomes of Ahmed ClearPath® Implantation in Thai Glaucoma Patients

First Author: Chayanit **JUNSANGSRI**

Co-Author(s): Anuwat **JIRAVARNSIRIKUL**, Naris **KITNARONG**, Sakaorat **PETCHYIM**, Ngamkae **RUANGVARAVATE**, Darin **SAKIYALAK**

Purpose: To evaluate the efficacy and safety of the Ahmed ClearPath® implantation in Thai glaucoma patients.

Methods: This was a retrospective chart review of glaucoma patients who underwent Ahmed ClearPath® implantation between January 2023 and December 2024 in Thailand. Collected data included demographics, best-corrected visual acuity (BCVA), intraocular pressure (IOP), number of antiglaucoma medications (AGMs), and postoperative complications. Patients were evaluated at baseline and at 1 day, 1 week, and 1, 3, and 6 months postoperatively.

Results: Twenty eyes of 20 patients were included. The mean (SD) age was 66.50 (18.08) years. All patients were pseudophakic, and 50% had primary open-angle glaucoma. Baseline mean (SD) logMAR BCVA, IOP and number of AGMs were 0.30 (0.34), 16.75 (4.83) mmHg and 3.70 (1.17), respectively. At 6 months, the mean (SD) BCVA was 0.29 (0.29), with no significant change from baseline (Δ -0.16, $P=0.74$). In contrast, significant reductions were observed in mean (SD) IOP (12.20 (4.28) mmHg; Δ -4.55, $P<0.01$) and in the mean (SD) number of AGMs (1.10 (1.21); Δ -2.60, $P<0.01$). Postoperative complications included IOP elevation (45%), hypotony (25%) and conjunctival wound leak (15%).

Conclusions: Ahmed ClearPath® implantation led to significant reductions in IOP and the number of AGMs, while maintaining stable visual acuity over 6 months. However, complications were observed, and long-term careful monitoring is required.

Abstract No.: 208421

Coding Region Mutation Screening in Optineurin in Chinese Normal-Tension Glaucoma Patients

First Author: Jing Na **HE**

Co-Author(s): Li Jia **CHEN**, Wai Kit **CHU**, Chi Pui **PANG**, Clement C. **THAM**

Purpose: To study the roles of sequence alterations in the optineurin (OPTN) gene-coding region in normal-tension glaucoma (NTG) among Chinese patients.

Methods: Genomic DNA was extracted from 190 NTG patients and 201 control subjects. The thirteen exons of OPTN were amplified by polymerase chain reaction and analyzed by direct sequencing. Detected sequence changes were compared between NTG patients and control subjects.

Results: Seven sequence changes in OPTN were identified in both NTG patients and control subjects. Among them, c.464G>A (T34 T), c.509C>T (T49T), c.806G>A (V148V), and c.959T>C (P199P) were synonymous codon changes, whilst c.655T>A (M98K), c.1996G>A (R545Q), and c.1582T>C (I407T) were missense changes. Two previously reported heterozygous mutations, c.458G>A (E50K) in exon 4 and c.691_692insAG in exon 6, were not found in this study. Out of these seven OPTN sequence variants, c.464G>A (T34T) was significantly associated with NTG in both the allelic and genotypic association analyses (allelic association: $p = 0.0001$, OR = 2.20, 95% CI: 1.46-3.31; genotypic association: $p = 0.0001$), whereas the association of other variants with NTG did not reach statistical significance ($p > 0.05$). Variants c.1582 T>C (I407T) and c.806G>A (V148V) were identified in one and two NTG patients, respectively, but not in the control subjects.

Conclusions: This study confirmed the association of the OPTN T34T variant with NTG, suggesting that OPTN is a susceptibility gene for NTG in Chinese. Moreover, a variant with amino acid change (I407T) was identified in NTG but not in controls. Further studies are warranted to assess whether this variant is a causative mutation for NTG.

Abstract No.: 204789

Comparative Evaluation of Functional Aqueous Humor Outflow in Primary Open Angle Glaucoma Versus Primary Angle Closure Glaucoma Using Aqueous Angiography

First Author: Anuja PATIL

Co-Author(s): Nitika BERI, Tanuj DADA, Namrata SHARMA

Purpose: To quantitatively compare the circumferential, perilimbal aqueous humor outflow (AHO) pathways in patients of primary open-angle glaucoma (POAG) and primary angle-closure glaucoma (PACG) using Aqueous Angiography (AA).

Methods: Thirty-two eyes of 32 patients were included (16 patients of POAG and 16 PACG patients) presenting with age-related cataract and planned for phacoemulsification surgery. All patients underwent AA with 0.1% indocyanine green dye injected into the anterior chamber prior to the capsulorhexis step, followed by capture of images using the flex module of the OCT machine. Images at 60 seconds were exported for image analysis to Image J software, where angiographic signal intensity along the limbus into eight sectors, four quadrants, and overall flow for POAG & PACG was calculated.

Results: The mean age (years) was 58.8 ± 5.8 (POAG) and 59.8 ± 8.6 (PACG) [$P=0.704$]. There was no significant difference in the visual field defect with MD (db) in POAG and PACG; [$P=0.904$] and VFI in POAG

and PACG; [$P=0.777$]. The overall flow was decreased in PACG compared to POAG [$P=0.029$]. On quadrant analysis, all quadrants showed lower flow in PACG compared to POAG; however, this difference was statistically significant in the superior quadrant and inferior quadrant only. A statistically significant positive correlation of MD ($r=0.515$, $P=0.044$) and VFI ($r=0.581$, $P=0.020$) with overall flow was seen in PACG and not in POAG patients.

Conclusions: PACG eyes had lower functional AHO compared to POAG, which correlated with disease severity. This study has implications for trabecular MIGS in PACG and may predict worse outcomes in PACG compared to POAG.

Abstract No.: 205267

Comparative Outcomes of NPDS and GATT in Advanced Open Angle Glaucoma: A 12-Month Prospective Study

First Author: Madhavi PILLAI

Co-Author(s): Devendra MAHESHWARI, Nimrita NAGDEV

Purpose: To compare the 12-month surgical outcomes of Non-Penetrating Deep Sclerectomy (NPDS) and Gonioscopy-Assisted Transluminal Trabeculotomy (GATT) in advanced open-angle glaucoma

Methods: This prospective study included 92 eyes with advanced primary open-angle or pseudoexfoliation glaucoma (42 NPDS, 50 GATT). Baseline demographics, IOP, anti-glaucoma medication (AGM) use, and best-corrected visual acuity (BCVA) were recorded. Post-operative IOP, AGM, and BCVA were assessed at week 2 and months 1, 3, 6, and 12. Success was defined by three IOP-based criteria: ≤ 21 mmHg with $\geq 20\%$ reduction (criteria 1), ≤ 18 mmHg with $\geq 25\%$ reduction (criteria 2), and ≤ 15 mmHg with $\geq 30\%$ reduction (criteria 3), with or without AGMs. Mixed-effects regression, Kaplan-Meier survival, and Cox regression analyses were used.

Results: Mean baseline IOP was higher in NPDS (29.5 ± 10.9 mmHg) than GATT (20.8 ± 5.5 mmHg, $p<0.001$). Both groups showed significant IOP reduction at all follow-ups ($p<0.001$). At 12 months, mean IOP was comparable (NPDS 13.5 ± 3.2 mmHg vs GATT 12.6 ± 3.4 mmHg, $p=0.179$). The percentage IOP reduction was significantly more in the NPDS group (46.8% versus 36.8%, $p=0.004$). GATT achieved significantly lower AGM use (0.1 ± 0.4 vs 1.6 ± 1.0 , $p<0.001$). Complete success under criteria 1 was markedly higher with GATT (82% vs 14%, $p<0.001$). BCVA improved more in GATT at all visits ($p<0.001$). Kaplan-Meier analysis showed similar cumulative success rates across groups ($p>0.7$). No major sight-threatening complications were observed in both groups.

Conclusions: NPDS and GATT both provided significant IOP reduction in advanced glaucoma, but GATT

achieved greater medication independence and visual recovery with a comparable safety profile.

Abstract No.: 205923

Comparison of AS-OCT Biometric Changes After Laser Peripheral Iridotomy in Primary Angle-Closure Disease With and Without Visible Ciliary Body Processes on Gonioscopy

First Author: Pawinee **BOONYOT**

Co-Author(s): Purit **PETPIROON**, Wasu **SUPAKONTANASAN**, Yanin **SUWAN**

Purpose: To evaluate anterior segment optical coherence tomography (AS-OCT) changes after laser peripheral iridotomy (LPI) in Thai patients with primary angle-closure disease (PACD), comparing eyes with and without visible ciliary body processes (CBP) on gonioscopy.

Methods: Forty-eight eyes of 25 Thai PACD patients scheduled for LPI were prospectively enrolled and stratified by CBP visibility on gonioscopy. ANTERION AS-OCT imaging was performed before and 2 weeks after LPI. Parameters measured included anterior chamber depth (ACD), anterior chamber volume, pupil diameter, lens vault (LV), horizontal angle opening distance at 500 μm and 750 μm (AOD500, AOD750), and trabecular-iris space area at 500 μm and 750 μm (TISA500, TISA750). The primary outcome was the change in AOD750.

Results: Axial length was significantly shorter in eyes with visible CBP ($P = 0.02$). AOD750 increased significantly after LPI in both CBP-positive eyes (nasal: $\Delta = 0.11$ mm, $P < 0.01$; temporal: $\Delta = 0.11$ mm, $P < 0.01$) and CBP-negative eyes (nasal: $\Delta = 0.12$ mm, $P < 0.01$; temporal: $\Delta = 0.13$ mm, $P < 0.01$), with no significant differences between groups (nasal: $\Delta = 0.01$ mm, $P = 0.65$; temporal: $\Delta = 0.03$ mm, $P = 0.11$). Similar trends were observed for anterior chamber volume, AOD500, TISA500, and TISA750. LV changes were not significant.

Conclusions: AS-OCT demonstrated significant angle widening after LPI in PACD eyes. CBP visibility on gonioscopy did not significantly alter biometric outcomes but may serve as a practical gonioscopic marker for identifying anatomical variation in angle closure.

Abstract No.: 204522

Comparison of Central Corneal Thickness (CCT), Anterior Chamber Depth (ACD), Lens Thickness (LT) and Retinal Nerve Fibre Layer (RNFL) Thickness in Pseudoexfoliation Syndrome (PXS) and Pseudoexfoliative Glaucoma (PXG)

First Author: Faradatul Aisyah **ABDUL AZIZ**

Co-Author(s): Norfarizal Ashikin **ABDULLAH**, Jemaima **CHE HAMZAH**, Nor Idahriani **MUHD NOR**

Purpose: To compare anterior and posterior segment parameters among patients with pseudoexfoliation syndrome (PXS), pseudoexfoliative glaucoma (PXG), and normal subjects.

Methods: A total of 120 subjects were recruited and divided equally into three groups: PXG, PXS, and control. Central corneal thickness (CCT), anterior chamber depth (ACD), lens thickness (LT), and retinal nerve fiber layer (RNFL) thickness measurement were obtained using anterior segment optical coherence tomography (OCT). Data were analysed to identify significant differences between groups.

Results: A total of 120 subjects were included in this study, with 56 females (46.7%) and 64 males (53.37%). The mean ages of patients with PXG, PXS, and control were 69.85 ± 6.78 , 73.28 ± 6.38 , and 61.60 ± 8.38 years, respectively. The mean CCT and ACD in PXG were (494.55 ± 20.31 μm), (3.07 ± 0.28 mm), and PXS were (507.13 ± 22.28 μm), (2.99 ± 0.29 mm), which were statistically significantly less than control (530.42 ± 30.82 μm), (3.18 ± 0.11 mm). The mean LT showed the thickest in PXG (4.53 ± 0.16 mm), followed by PXS (4.08 ± 0.38 mm) and control (3.78 ± 0.24 mm). The mean average RNFL was significantly lower in the PXG (96.28 ± 13.29 μm) and PXS (126.25 ± 12.40 μm) groups as compared to the control group (133.82 ± 14.76 μm).

Conclusions: Patients with pseudoexfoliation glaucoma (PXG) and pseudoexfoliation syndrome (PXS) exhibit significant alterations in both anterior and posterior segment parameters compared with control group. These findings emphasize the importance of comprehensive ocular assessment in pseudoexfoliation-related disorders to aid in early diagnosis and management.

Abstract No.: 202148

Comparison of Microinvasive Glaucoma Surgery (MIGS) With Trabeculectomy in Glaucoma: A Systematic Review

First Author: Angel Lim

Co-Author(s): I Gusti Ayu Stiti Sadvika

Purpose: Glaucoma is one of the leading causes of blindness worldwide. Several studies considered Trabeculectomy to be the gold standard for Glaucoma. Recently, microinvasive Glaucoma Surgery (MIGS) has

been considered one of the eye interventions that can be applied in glaucoma patients. It has provided a shorter surgical time and tends to be less invasive compared to Trabeculectomy. The aim of the study is to compare the efficacy of MIGS and Trabeculectomy in Glaucoma.

Methods: A systematic review was conducted through PubMed, ScienceDirect, and Cochrane Library to obtain the studies relevant to the topic. The inclusion criteria were the studies that compared both MIGS and Trabeculectomy without concurrent cataract surgery. Our study assessed IOP at baseline and postoperative with certain follow-up periods, visual acuity at baseline and postoperative, and the use of medications at baseline and postoperative.

Results: We included three articles in the review. Two studies were retrospective studies, and one study was a case-control. The mean IOP was found to be significantly reduced in both groups (MIGS and Trabeculectomy) compared to the baseline. The visual acuity showed similar results between MIGS and Trabeculectomy. In addition, the use of medications was found decreased in both interventions postoperatively.

Conclusions: Both MIGS and Trabeculectomy can significantly reduce the mean IOP and the use of medication in Glaucoma patients. This study showed MIGS can be a potential eye intervention that offers comparable efficacy with Trabeculectomy.

Abstract No.: 206336

Comparison of RNFL Bundle Defect Detection Using En Face Image Slab: RNFL Slab and Fixed 52 μ m ILM Slab in Myopic Eyes

First Author: Po-han YEH

Co-Author(s): Chu-yen HUANG, Yung-sung LEE, Xiao Chun LING

Purpose: To compare the detection rates of retinal nerve fiber layer (RNFL) bundle defects in myopic eyes using two en face reflectance imaging slabs: the RNFL slab and a fixed-depth slab extending 52 μ m below the internal limiting membrane (ILM).

Methods: This cross-sectional study included 89 eyes from participants aged >20 years with spherical equivalent (SE) < -3.0 diopters or axial length (AXL) > 24.5 mm. Exclusion criteria included prior intraocular surgery (except uncomplicated cataract or refractive surgery), retinal laser treatment, diabetic retinopathy, epiretinal membrane, optic neuropathies (e.g., optic neuritis, NAION), and OCT image quality <5. Collected data included age, sex, SE, AXL, intraocular pressure (IOP), central corneal thickness (CCT), fundus photography, OCT (optic disc and macular scans, 12 $\times$ 12 mm OCTA), and Humphrey visual field testing. En face reflectance slabs were generated from ILM to the nerve fiber layer/ ganglion cell layer boundary (RNFL slab)

and from ILM to a fixed depth of 52 μ m (ILM-52 slab). RNFL bundle defects were defined as arcuate low-reflectance areas extending from the peripheral retina to the optic disc. Defect detection rates were compared in eyes with peripapillary RNFL abnormalities using the McNemar test.

Results: The study included 89 eyes with a mean spherical equivalent (SE) of -6.2 ± 2.7 diopters, axial length (AXL) of 26.7 ± 1.7 mm, and age of 48.8 ± 11.9 years. The mean baseline intraocular pressure (IOP) was 18.74 ± 9.8 mmHg. RNFL bundle defects were identified in 28 eyes (31.4%) using the RNFL slab and in 30 eyes (33.7%) using the ILM-52 slab. The difference in detection rates between the two slabs was not statistically significant (McNemar test, $p = 0.72$).

Conclusions: The RNFL en face slab and ILM-52 en face slab showed similar detection of RNFL defect. Both slab types can be applied for detecting RNFL bundle defects in myopic eyes.

Abstract No.: 201187

Comparison of Short-Term Outcomes Between Different Probes in Micropulse Transscleral Cyclophotocoagulation

First Author: Sachi KOJIMA

Co-Author(s): Toshihiro INOUE, Tomoyo MATSUMURA, Natsumi MURATA, Yuji TAKIHARA, Riku YUKINO

Purpose: To investigate whether the type of P3 probe (Rev1/Rev2) used for micropulse transscleral cyclophotocoagulation (MPCPC) with the CYCLO G6 affects treatment outcomes.

Methods: We evaluated intraocular pressure (IOP, mmHg) reduction in patients who underwent MPCPC at Kumamoto University Hospital between March 2018 and December 2024 with a follow-up of at least three months retrospectively. The cumulative survival rates for the Rev1 and Rev2 groups were compared using the Kaplan-Meier method with two primary endpoints: Criterion A (IOP less than the pre-treatment mean) and Criterion B (IOP reduction of 20% or more).

Results: 201 eyes and 48 eyes were included in the Rev1 and Rev2 groups, respectively. The diagnoses included primary open-angle glaucoma, pseudoexfoliation glaucoma, neovascular glaucoma, secondary glaucoma, and other types. Pre-treatment IOP (mean $\pm$ standard deviation, mmHg) was 30.6 ± 10.6 and 25.8 ± 7.6 for the Rev1 and Rev2 groups, respectively. At 1-week post-treatment, IOP was 16.3 ± 8.6 and 14.3 ± 7.4 . At 1 month, 18.4 ± 9.2 and 18.4 ± 10.0 . At 3 months, was 20.5 ± 10.0 and 19.9 ± 10.0 . At 6 months, 19.5 ± 8.6 and 20.7 ± 10.1 . At 12 months, 18.1 ± 9.4 and 16.5 ± 6.8 . A significant IOP reduction was observed at all follow-up time points ($P < 0.005$, t-test). There was no significant difference in the cumulative survival rates between the two groups (A: $P=0.6636$, B: $P=0.6320$, log-rank test).

Conclusions: MPCPC provided effective IOP reduction. The IOP-lowering effect was equivalent between the different types of probes.

Abstract No.: 201197

Corneal Endothelial Cell Loss After Baerveldt Glaucoma Implantation in Pseudophakic Eyes

First Author: Hiro KOSHIYAMA

Co-Author(s): Toshihiro INOUE, Sachi KOJIMA, Natsumi MURATA, Eri TAKAHASHI, Yuji TAKIHARA

Purpose: To evaluate corneal endothelial cell density (ECD) changes after Baerveldt glaucoma implantation (BGI) and examine associated risk factors for ECD loss.

Methods: This was a single-center retrospective study of pseudophakic eyes without prior filtering surgery that underwent BGI. Eyes with tube placement in anterior chamber (AC) or ciliary sulcus (CS) were included. The primary outcome was the 1-year change in ECD. Paired t-tests, multivariable linear regression, and ANCOVA were used to assess risk factors, with a specific subgroup analysis in exfoliation glaucoma (EXG) eyes.

Results: We analyzed 79 eyes from 75 patients. Mean ECD decreased significantly at 1 year ($p < 0.001$). The loss was significant in the EXG group ($n = 44$; from 1907.18 to 1678.22 cells/mm², $p < 0.001$, paired t-test), but not in the non-EXG group ($n = 35$; from 2015.08 to 1941.28 cells/mm², $p = 0.153$). In multivariable linear regression, EXG was the only independent factor associated with a greater ECD reduction rate (fractional change) ($p = 0.009$). In the EXG subgroup, CS tube placement was associated with a greater ECD reduction rate ($p = 0.040$). An ANCOVA of 1-year ECD, adjusted for baseline ECD, age, and preoperative IOP, also showed lower final ECD with CS placement ($p = 0.047$).

Conclusions: EXG was an independent risk factor for 1-year ECD loss after BGI. In EXG eyes, CS tube placement was associated with greater ECD loss. These findings suggest that glaucoma subtype and tube placement should be considered when planning BGI to minimize ECD loss.

Abstract No.: 201855

Correlation Between Retinal Nerve Fiber Layer and Ganglion Cell Complex Layer Thickness in Patients With Various Non-Glaucomatous Optic Neuropathies Including Lesions in the Anterior Visual Pathway

First Author: Stephen SUDHAKAR

Purpose: To analyse the correlation of RNFLT and GCCT in patients presenting with various non-GON, including lesions in the anterior visual pathway, and to differentiate the OCT measures with associated factors.

Methods: It is a cross-sectional study with 55 subjects who were clinically diagnosed with optic neuropathy.

Patients with macular disorders, diabetic retinopathy, or hypertensive retinopathy were excluded. All subjects underwent a complete clinical assessment and OCT imaging. RNFLT and CCT were measured and compared with variables such as age, gender, diagnosis, and cause.

Results: The mean age among study subjects was 41.05±15.431um. Age shows a non-linear relationship with RNFLT. Most of the subjects were diagnosed with CON (15), followed by papilledema (12) and RBON (12). Common causes are IHTN, TED, CVST, and pituitary tumors. The mean RNFLT was significantly higher (304.0000±29.18261) in papilledema patients. The maximum thinning of RNFLT was noted in ION individuals. Subjects with CVST measured; 50 microns. VA and Avg.RNFLT has shown a correlation with a decrease in RNFLT, which is attributed to reduced visual acuity. Trauma and infiltration aetiologies showed poor VA (<6/60).

Conclusions: Optic neuropathy is a conspicuous disorder; timely detection and intervention might be beneficial in terms of visual prognosis and mitigating severity. SD-OCT is increasingly becoming a crucial screening technique.

Abstract No.: 203754

Correlation of Functional and Structural Parameters With Glaucoma-Specific GQL-15 Questionnaire

First Author: Kavita BHATNAGAR

Purpose: To evaluate the correlation of functional and structural parameters with Quality of life assessed by the glaucoma-specific GQL-15 questionnaire in glaucoma patients.

Methods: A prospective observational study was conducted on 54 eyes of 46 open-angle glaucoma patients who underwent trabeculectomy between October 2022 and December 2023. Parameters studied were BCVA (Best Corrected Visual Acuity), refraction, IOP, Perimetry {MD (Mean Deviation), VFI (Visual Field Index)}, number of anti-glaucoma medications, Peripapillary Retinal Nerve Fibre Layer (RNFL) OCT, ONH (Optic Nerve Head) OCT comprising rim area, rim volume & cup area, OCT Macula comprising RNFL, GCL+ {Ganglion cell layer (GCL) + Inner Plexiform Layer (IPL)} & GCL++ (GCL + Inner Plexiform Layer + RNFL). All patients filled GQL-15 questionnaire. The follow-up period was 6 months. Correlation of duration of glaucoma, number of anti-glaucoma medications, Peripapillary RNFL, and OCT macula was done with GQL-15 scores.

Results: Functional parameters showed a significant positive correlation between GQL-15 scores and both duration of glaucoma ($r=0.844$, $p<0.001$) and number of medications ($r=0.298$, $p=0.045$). Structural parameters showed significant negative correlations

between GQL-15 score and inferior peripapillary RNFL (pre-operative $r: -0.339$, $p=0.01$; post-operative $r: -0.305$, $p=0.03$), Macular RNFL (pre-operative $r: -0.35$, $p=0.01$; post-operative $r: -0.382$, $p=0.01$), GCL+ (pre-operative $r: -0.345$, $p=0.01$; post-operative $r: -0.466$, $p=0.00$) and GCL++ (pre-operative $r: -0.431$, $p=0.00$; post-operative $r: -0.458$, $p=0.00$).

Conclusions: GQL-15 scores significantly correlated with both functional and structural parameters, suggesting that disease progression and retinal structural deterioration are associated with reduced quality of life in glaucoma patients.

Abstract No.: 202138

Cost-Related Non-Adherence to Glaucoma Medication in Glaucoma Patients Attending an Eye Hospital in Western Nepal

First Author: Ravidhar **BHANDARI**

Purpose: To assess and estimate the frequency and factors associated with cost-related non-adherence to glaucoma medication. To determine the factors associated with CRNA.

Methods: The study included all patients aged 18 and above, attending our hospital with a diagnosis of glaucoma, and who were undergoing glaucoma therapy for at least six months. A complete eye examination was done along with a face-to-face interview to record the socio-demographic details of the participants and to assess non-adherence to therapy. CRNA was considered if, in the last six months, the patient: a) reduced, or skipped medication dosage to save money b) delayed filling prescription because of cost issues, c) reverted to alternative therapies because of costs.

Results: The mean duration of glaucoma was 4.2 years, and the mean duration of medication was 4 years. More than one glaucoma medicine bottles were prescribed in 37.1%: 2 bottles in 28.8% and three bottles in 8.3% of included participants. At least one CRNA behavior was observed in 14 (10.6%; 95% CI 6.1 -17.5) patients. Associated systemic disease(s) increased the risk of non-adherence by nearly 22 times, while prescribing more than one medicine for glaucoma increased the risk by nearly 7-fold due to the high cost of medicine.

Conclusions: The results of this study showed that cost-related non-adherence was present in 1 in 10 individuals with glaucoma. Gender, presence of systemic disease(s) or co-morbidity, and number of glaucoma medicines prescribed were significant risk factors for cost-related non-adherence.

Abstract No.: 201918

Detection of Retinal Nerve Fiber Layer Bundle Defects in Myopic Eyes: A Comparison Between Thickness and En Face Reflectance Maps Using OCT

First Author: Chu-yen **HUANG**

Co-Author(s): Po-han **YEH**

Purpose: To compare the detection rates of retinal nerve fiber layer (RNFL) bundle defects in myopic eyes using en face reflectance maps versus thickness maps derived from optical coherence tomography (OCT).

Methods: This cross-sectional study included 86 eyes from participants aged over 20 years with a spherical equivalent (SE) less than -3.0 diopters or an axial length (AXL) greater than 24.5 mm. Eyes with a history of intraocular surgery, retinal laser treatment, or retinal diseases were excluded. All subjects underwent comprehensive ophthalmic examinations, including refraction, AXL, intraocular pressure (IOP), fundus photography, 12×12 mm wide-field OCT scans (optic disc and macula), and Humphrey visual field testing. RNFL bundle defects were assessed using two OCT-derived modalities: the en face reflectance map (Ganglion cell complex (GCC) slab) and the GCC thickness map. Detection rates were compared using McNemar's test.

Results: Among the 86 eyes analyzed (mean age: 51.3 ± 13.7 years; mean SE: -5.85 ± 3.38 D; mean AXL: 26.41 ± 1.36 mm; mean IOP: 16.63 ± 4.42 mmHg), RNFL bundle defects were identified in 37 eyes (43.0%) using the en face reflectance map, compared to 21 eyes (24.4%) using the thickness map. The difference in detection rates was statistically significant ($p < 0.05$, McNemar's test).

Conclusions: En face reflectance maps demonstrated a significantly higher detection rate of RNFL bundle defects in myopic eyes compared to thickness maps. Reflectance-based imaging may provide improved sensitivity for detecting early glaucomatous changes in highly myopic eyes.

Abstract No.: 206348

Different Retinal Microvascular Response to Flicker Light Between Normal-Tension Glaucoma and High-Tension Primary Open-Angle Glaucoma Detected With Optical Coherence Tomography Angiography

First Author: Shaodan **ZHANG**

Co-Author(s): Ruirong **YOU**, Daokuan **YU**

Purpose: To compare the visual task-evoked microvascular response in the macula between normal-tension glaucoma (NTG) and high-tension primary open-angle glaucoma (HTG) by using optical coherence tomography angiography (OCTA).

Methods: In this case-control observational study, ten eyes of 10 patients with HTG, twelve eyes of 12 patients with NTG, and eleven eyes of 11 healthy participants were included. All glaucoma eyes had a preserved central visual field of at least 10° and best corrected visual acuity of 20/40 or better. Macular superficial vessel density (VD) was measured by OCTA at baseline and then immediately after a 12.5 Hz white light flicker stimulation.

Results: Flicker light stimulation evoked a significant increase in macular superficial VD of HTG (baseline vs. poststimulation: $35.31\% \pm 4.31\%$ vs. $36.07\% \pm 4.35\%$, $P=0.048$) and control eyes ($46.21\% \pm 2.94\%$ vs. $47.09\% \pm 2.68\%$, $P=0.028$) but not the eyes with NTG ($37.98\% \pm 5.99\%$ vs. $37.44\% \pm 5.69\%$, $P=0.622$). The absolute change in VD (Δ VD) was significantly smaller in NTG eyes compared to control eyes ($-0.54\% \pm 1.40\%$ vs. $0.88\% \pm 1.14\%$, $P=0.026$). NTG eyes also had a lower VD change percentage in the temporal macula than that in HTG eyes ($-1.17\% \pm 5.53\%$ vs. $4.01\% \pm 4.73\%$, $P=0.042$).

Conclusions: Visual task-evoked vasoreactivity changes provide additional information in the understanding and assessment of the pathophysiological mechanisms of glaucoma. Discrepancies in the retinal vasoreactivity between HTG and NTG imply that vascular factors may play different roles in the onset and progression of these diseases.

Abstract No.: 204513

Direct Surgical Gonioscopy Without Microscope Tilt: A Novel Technique Using Patient Head Rotation and Disposable Gonioprisms

First Author: Nilesh KUMAR

Purpose: To describe a simplified technique for direct surgical gonioscopy that eliminates the need for microscope tilt by employing enhanced patient head rotation with disposable gonioprisms, thereby facilitating minimally invasive glaucoma surgery (MIGS) in resource-limited settings.

Methods: Traditional gonioscopy requires ~30–40° patient head rotation combined with ~30–40° microscope tilt for optimal angle visualization. In this modification, the microscope is kept upright while the patient's head is rotated ~60° away from the surgeon. The surgeon operates from the temporal position, using a disposable gonioprism in a steeper "diving" orientation to visualize the opposite angle. The technique was applied in MIGS procedures including trabecular bypass, goniotomy, and trabeculotomy.

Results: Clear angle visualization was consistently achieved without microscope tilt. Patient comfort and airway safety were preserved despite increased head rotation. Disposable gonioprisms provided superior optical clarity, eliminated sterilization needs,

and reduced infection risks. The technique simplified surgical setup, maintained ergonomic comfort for the surgeon, and was compatible with basic microscopes lacking tilt functionality. Limitations included a short learning curve for altered geometry and restricted working space in certain cases.

Conclusions: Direct surgical gonioscopy without microscope tilt is a safe, efficient, and cost-effective alternative for MIGS. By removing dependence on advanced equipment, this approach expands surgical feasibility in low-resource environments. Adoption may help democratize access to MIGS globally, supporting equitable glaucoma care delivery.

Abstract No.: 208316

Double Glaucoma Xen Implant for Difficult Glaucoma

First Author: Nancy Shi Yin YUEN

Purpose: To report a case of Double Glaucoma Xen implant for treatment of secondary glaucoma with high Peripheral Anterior synechia after retinal detachment surgery.

Methods: Retrospective case report.

Results: The immediate and long-term outcome of the eye pressure control after double Xen implant was reported. Morphology of the drainage bleb was shown.

Conclusions: Xen implant may be considered in cases with distorted anatomy in difficult secondary glaucoma cases. The selection of the site for implant may be planned pre-operatively.

Abstract No.: 203427

Dynamic Mechanism of Primary Angle Closure Based on Anterior Segment Video: An Exploratory Study

First Author: Qiaona YE

Co-Author(s): Zidong CHEN, Yu-tzu PING, Kezheng XU, Yangfan YANG, Minbin YU, Songfu ZOU

Purpose: To explore the dynamic risk factors and mechanisms of primary angle closure under fixed force based on anterior segment video.

Methods: The dynamic anterior segment videos of the subjects with shallow anterior chamber (central anterior chamber depth ≤ 2.2 mm) were collected using Corvis ST, and the dynamic Lens parameters were established.

Results: A total of 148 eyes (118 subjects) were recruited: 67 eyes in PACS group, 45 eyes in PAC group, and 36 eyes in PACG group. There were no statistically significant differences in age, central anterior chamber depth (ACD), lens thickness (LT), axial length or pupil diameter (PD) among the three groups. The intraocular pressure (IOP) in PACG group was significantly higher than the other group. The dynamic Lens changes

under external force mainly divided into two stages: the deformation period and the displacement period. There were statistically significant differences in the deformation amplitude (LensDA), speed (LensDS), initial deformation time, and maximum deformation time during the deformation period among the three groups. There were no statistically significant differences in the backward and forward distance during the displacement period. The LensDA was positively related to ACD, AL and PD, while negatively correlated with LT. The LensDS was positively correlated with age and ACD, while negatively correlated with IOP.

Conclusions: This exploratory study indicated the differences in the dynamic Lens changes in subjects with shallow anterior chamber, suggesting that the deformation of the Lens might be a potential risk factor for the dynamic mechanism of PAC.

Abstract No.: 202847

ELIOS Excimer Laser Trabeculostomy – Early UK Experience: 12 Months, 4 Centres, 138 Eyes

First Author: Adnan **ABDUL-AZIZ**

Co-Author(s): Chrys **DIMITRIOU**, Dan **LINDFIELD**, Claudia **QUIJANO**, Gok **RATNARAJAN**, Neeru **VALLABH**

Purpose: «Phaco plus» is becoming the treatment of choice for patients with concurrent cataract surgery and glaucoma in the UK. ELIOS adds 2-4 minutes to a cataract procedure and creates 10 x 210um channels through the trabecular meshwork. This conduit between the anterior chamber and Schlemm's Canal appears to safely reduce IOP and medication requirement.

Methods: Retrospective case series of the first 138 consecutive cases performed in the UK. This includes the learning curve cases. Real-world data across 4 UK sites (Guildford, East Grinstead, Liverpool, and Colchester).

Results: A total of 138 eyes completed a 12-month follow-up. Baseline IOP 18.56mmHg on 1.78 medications. 12-month IOP 14.37mmHg on 0.95 medications. No serious complications were noted. Microhyphaema was noted in 12% of eyes and always resolved by 1 month. 47% of eyes were medication-free at 12 months.

Conclusions: ELIOS appears to provide safe and reproducible reduction in IOP and medication usage for glaucoma patients undergoing cataract surgery.

Abstract No.: 201631

Effect of Selective Laser Trabeculoplasty (SLT) on the Fellow Eyes in Patients With Normal Tension Glaucoma: The First-Line or Second-Line Selective Laser Trabeculoplasty (FSS) Study

First Author: Hiroaki **OZAKI**

Co-Author(s): Tomoko **NAITO**, Akiko **NARITA**, Koji **NITTA**, Kae **SUGIHARA**, Fss Study Group

Purpose: Selective laser trabeculoplasty (SLT) is established as a first-line treatment for glaucoma patients. SLT treatment also produces intraocular pressure (IOP) reduction in the fellow eyes of patients with primary open-angle glaucoma. This study was designed to investigate the IOP-lowering effect on the fellow eyes in patients with normal tension glaucoma (NTG).

Methods: The study included 137 patients with NTG from 26 institutions in Japan. Patients were treated with SLT on one eye and IOP reduction on both eyes, which was measured for 1 year. The correlation of the IOP-lowering effect between the treated eyes and the untreated fellow eyes was examined. The success category was defined as a reduction in IOP of 20% or more.

Results: The mean preoperative IOP in the SLT-treated eye was 16.0 ± 2.0 mmHg. It lowered to 13.3 ± 2.2 mmHg at 12 months after SLT. The mean preoperative IOP in the untreated fellow eye was 15.5 ± 2.2 mmHg. It also lowered to 14.6 ± 2.5 mmHg at 12 months. The mean reduction in IOP in the fellow eye was 0.8 ± 2.2 mmHg (5.2%). The success rate was 35.8% in SLT-treated eyes and 11.2% in the fellow eyes. Linear regression analysis demonstrated that patients with greater IOP reduction on the treated eyes showed greater IOP reduction on the fellow eyes after SLT ($R = 0.5696$).

Conclusions: IOP reduction is observed in the untreated fellow eye after SLT, it is also more effective in the fellow eye when SLT is effective in the operated eye.

Abstract No.: 206493

Effectiveness of Resorption Drainage Implant in Non-Penetrating Surgery for Open-Angle Glaucoma

First Author: Natalia **POSTUPAEVA**

Co-Author(s): Alexei **POSTUPAEV**

Purpose: To explore the clinical effectiveness of slow resorption drainage implant (RDI) in non-penetrating deep sclerectomy (NPDS) in patients with primary open-angle glaucoma (POAG).

Methods: One hundred and six patients (106 eyes) with POAG, the intraocular pressure (IOP) level was 27.8 ± 3.6 mm Hg. Patients were divided into an

observation group (53 eyes, NPDS with RDI hyaluronic acid 22.5 mg/ml) and a control group (53 eyes, NPDS alone). After 1 month, all patients were subjected to Nd:YAG laser goniopuncture.

Results: On the 1st day after surgery, the IOP was 9.3 ± 1.8 mm Hg in the 1st group, 9.6 ± 1.7 mm Hg in the 2nd group. After 3 months, the IOP level was 12.6 ± 1.4 mm Hg in the 1st group, 16.4 ± 1.6 mm Hg in the 2nd group. After two years, the IOP level in the 1st group was 17.3 ± 1.7 mm Hg (IOP normalization achieved in 93% of eyes, which had developed functional filtration blebs), 67% of patients did not use hypotensive therapy. In the 2nd group — 18.0 ± 1.8 mm Hg (IOP normalization achieved in 80% of eyes), 36% of patients did not use hypotensive therapy. Over the 2 years of follow-up, reoperations were required in 7% of eyes in the 1st group and in 20% of eyes in the 2nd group.

Conclusions: The use of resorption drainage implant in NPDS allowed normalization of IOP in 93% of patients with POAG within 2 years of follow-up.

Abstract No.: 204239

Efficacy and Safety of Switching to Preservative-Free Tafluprost and Timolol in Patients With Primary Open-Angle Glaucoma and Ocular Hypertension with Latanoprost Monotherapy

First Author: Jin Wook **JEOUNG**

Co-Author(s): Jong Chul **HAN**, Joon Mo **KIM**, Do Young **PARK**, Kyung Rim **SUNG**

Purpose: To evaluate the efficacy and safety of switching from preserved latanoprost monotherapy to preservative-free tafluprost/timolol fixed-combination therapy in patients with primary open-angle glaucoma (POAG) or ocular hypertension (OHT) with insufficient intraocular pressure (IOP) control.

Methods: This prospective, single-arm, open-label, multicenter trial included 32 patients aged 19–80 years. Following a 4-week washout period, patients were treated with preservative-free tafluprost (0.015 mg) and timolol (5 mg) once daily for 12 weeks. IOP was measured at baseline, 4 weeks, and 12 weeks. Safety assessments and subgroup analyses were also performed.

Results: Mean IOP decreased from 17.06 ± 3.76 mmHg at baseline to 14.61 ± 2.94 mmHg at week 12 ($p < 0.0001$). The mean reduction was -2.45 ± 2.66 mmHg, which was statistically significant ($p < 0.0001$). A $\geq 20\%$ IOP reduction was achieved in 34.4% of patients. Mild adverse events, including glare and dry eye, were reported in 21.9% of patients, while no serious adverse events occurred.

Conclusions: Switching to preservative-free tafluprost/timolol resulted in significant IOP reduction and was well tolerated. This fixed-combination therapy may represent an effective alternative for patients with

POAG or OHT inadequately controlled on latanoprost monotherapy.

Abstract No.: 204790

Efficacy of the Novel MIGS Implant Wistend Compared to Kahook Dual Blade in the Treatment of Experimental Ocular Hypertension in Rabbits

First Author: Yingfan **WANG**

Co-Author(s): Manman **HUANG**, Changgeng **LIU**, Qian **LIU**, Yu **ZHANG**

Purpose: To evaluate and compare the efficacy of novel microinvasive glaucoma surgery (MIGS) device implants Wistend and Kahook Dual Blade (KDB) in an experimental ocular hypertension model.

Methods: Twelve New Zealand white rabbits were randomized into four groups (blank, sham-operated, Wistend and KDB groups) after establishment of an ocular hypertension animal model. Intraocular pressure (IOP) was observed over three months. Eaton and Draize scores, Swept-source optical coherence tomography (SS-OCT), fundus photography were used to evaluate ocular health and confirm microstent placement.

Results: Both the Wistend and the KDB significantly lowered IOP over the three-month follow-up. At 7, 10, 20, and 30 days post-operation, there were significant differences in IOP reduction between the Wistend and the KDB groups ($P < 0.05$). Postoperative assessments showed that the anterior and posterior segments of the eyes remained healthy, with no notable adverse events.

Conclusions: Wistend and KDB both effectively reduced IOP in experimental ocular hypertension, and a stable and significant IOP reduction was maintained throughout the 3-month postoperative follow-up period. The findings may provide potentially experimental rationale for the selection of the MIGS devices Wistend and KDB for glaucoma patients.

Abstract No.: 205100

Evaluating the Impact of Anxiety on Visual Field Test Reliability: An Observational Study

First Author: Nattana **HARN SOMVONG**

Co-Author(s): Raveewan **CHOONTANOM**, Panrapee **FUNARUNART**, Napat **MANEECHAEYE**, Issaraporn **TREESIT**, Panhathai **YAISIRI**

Purpose: To evaluate the impact of anxiety levels on the reliability of visual field tests in patients with diagnosed or suspected glaucoma.

Methods: This cross-sectional observational study included patients with diagnosed or suspected glaucoma aged 20–80 years scheduled for standard automated perimetry. Participants completed the State-Trait Anxiety Inventory (STAI Y1, Y2) and

knowledge questionnaires before visual field testing, followed by a post-test questionnaire. Anxiety scores were analyzed in relation to the VF test unreliability. The association between the glaucoma and VF testing knowledge and anxiety levels, as well as the reliability of VF results, was analyzed. Factors and obstacles affecting test unreliability were identified.

Results: A total of 173 participants (mean age 64.3 ± 10.8 years; 58.4% female) were enrolled, including 121 glaucoma patients (69.9%) and 52 suspects (30.1%). Low anxiety was reported in 65.3% (trait) and 62.4% (state). Anxiety showed no association with visual field unreliability ($p=0.999$), but trait anxiety correlated negatively with glaucoma knowledge ($r=-0.152$, $p=0.047$) and visual field test knowledge ($r=-0.261$, $p<0.001$). Multivariable regression indicated a higher C:D ratio reduced odds of unreliability (OR=0.03, 95% CI 0.002–0.61), whereas prior unreliable tests increased odds (OR=7.67, 95% CI 2.55–23.01).

Conclusions: Most participants demonstrated low anxiety, which was not associated with visual field reliability. Trait anxiety correlated inversely with glaucoma and visual field test knowledge. Previous unreliable VF performance strongly predicted subsequent unreliability, while C:D ratio was a protective factor against unreliability.

Abstract No.: 205196

Evaluation of Antiglaucoma Eyedrop Administration Techniques Among Patients Diagnosed With Glaucoma in Mongolia Japan Hospital

First Author: Bulganchimeg **BUYANDUUREN**

Co-Author(s): Amarsanaa **DELGERJAV**, Bolormaa **GANBAATAR**, Bayasgalan **PUREVDORI**

Purpose: Glaucoma is a multifactorial disease characterized by optic nerve damage due to the loss of retinal ganglion cells. Globally, approximately 70 million people are affected. As the disease progresses, the economic burden on patients increases, largely influenced by the number of intraocular pressure-lowering medications required. Treatment efficacy depends not only on pharmacological properties but also on correct administration techniques, including timing, dosage, and method. Hence, this study focused on how to instill antiglaucoma eyedrops in patients with glaucoma at Mongolia Japan Hospital.

Methods: A cross-sectional, hospital-based observational study was conducted at the Department of Ophthalmology, Mongolian National University of Medical Sciences, from January to March 2025. Ethical approval was obtained, and informed consent was secured from all participants. Inclusion criteria were patients aged ≥ 35 years, diagnosed with primary open-angle glaucoma or primary angle-closure glaucoma post-laser iridotomy, who had been self-administering eye drops for over six months. Patients with secondary

glaucoma, tremors, or physical disabilities preventing self-administration were excluded.

Results: Among the participants, 64.7% ($n=22$) demonstrated adequate instillation technique. However, a significant proportion had not fully mastered the correct method, highlighting the need for improved patient education.

Conclusions: From this study, it can be seen that the majority of participants (64.70%, $n=22$) had an adequate technique for administering eye drops. Teaching the proper method to patients who are using drops incorrectly can help reduce surface damage to the eye, prevent infections transmitted by the drops, minimize ineffective medication use and unnecessary expenses, and reduce both local and systemic side effects on the eye.

Abstract No.: 207659

Excimer Laser Trabeculostomy (ELIOS) on Intraocular Pressure (IOP) and Outflow Facility in Eyes With Primary Open-Angle Glaucoma (POAG)

First Author: Kin Sheng **LIM**

Purpose: To assess the short-term effects of excimer laser trabeculostomy (ELIOS) on intraocular pressure (IOP) and outflow facility in eyes with primary open-angle glaucoma (POAG) at 3 months.

Methods: Thirty pseudophakic patients with mild to moderate POAG and suboptimal IOP control on topical therapy underwent standalone ELIOS at St Thomas' Hospital between August 2024 and March 2025. Following a four-week medication washout, baseline assessments included IOP, tonographic outflow facility (C), endothelial cell density (ECD), and laser flare photometry. These parameters were reassessed three months post-procedure. Primary outcomes were changes in IOP and outflow facility; secondary outcomes included changes in medication, ECD, flare values, and adverse events. Paired two-tailed t-tests were used for statistical comparisons.

Results: The mean patient age was 71 years; 67% were male. Ethnicity was 53% Afro-Caribbean and 47% White. At 3 months, mean IOP reduced from 26.06 ± 6.40 mmHg to 23.68 ± 5.37 mmHg (-9.1% , $p=0.06$). A $\geq 20\%$ IOP reduction was achieved in 33% of eyes, with complete success ($\geq 20\%$ IOP reduction, IOP < 21 mmHg, medication-free) in 13%. Tonographic outflow facility increased from 0.15 ± 0.09 to 0.19 ± 0.07 $\mu\text{L}/\text{min}/\text{mmHg}$ ($p=0.65$). The number of medications decreased from 1.93 ± 1.2 to 0.83 ± 0.70 ($p<0.0001$). ECD remained stable (2039 ± 338 vs. 1971 ± 361 cells/ mm^2 , $p=0.21$), and flare values showed no significant change (12.06 ± 6.23 to 14.89 ± 10.01 ph/ms, $p=0.06$). Adverse events included transient IOP spikes in four eyes and one case of toxic anterior segment syndrome (TASS).

Conclusions: This is the first prospective interventional washout study evaluating the standalone effect of ELIOS. Preliminary findings suggest a modest reduction in IOP with a favourable safety profile and minimal impact on trabecular outflow facility. Longer-term follow-up is necessary to assess sustained efficacy and durability of response.

Abstract No.: 200360

Exploring the Association of Arterial Stiffness in the Pathophysiology of Glaucoma: A Meta-analysis

First Author: Rukesh YADAV

Purpose: Studies implicating arterial stiffness in the pathophysiology of glaucoma have produced conflicting results. Our aim was to investigate whether glaucoma is associated with arterial stiffness and endothelial dysfunction. Accordingly, we compared the carotid intimal media thickness (CIMT) value among the patients of glaucoma with healthy controls (HC).

Methods: PubMed, Google Scholar, and Embase were searched for studies that assessed CIMT and arterial stiffness parameters in glaucoma patients and the healthy controls. Results comprised the standardized mean difference (SMD) in the CIMT value of the two groups with a 95% Confidence Interval (CI). According to the heterogeneity, the CIMT values were analyzed using the Revman 5.1 program using either a fixed or random effect.

Results: In this meta-analysis, six studies were included. 277 had glaucoma and 247 were HC. The analysis revealed a higher CIMT in glaucoma patients as compared to HC (SMD: 0.19, CI: -0.10-0.48, I²=54%, P value =0.20). However, the difference was not statistically significant. The study by Rogosic et al.2023 found that the flow mediated dilation was significantly lower in glaucoma patients as compared to the HC. Whereas, a study by Bossuyt et al 2015 did not find significant difference in carotid-femoral pulse wave velocity among the glaucoma and controls.

Conclusions: Though, this study could not show a significant association of glaucoma with altered CIMT and arterial stiffness, glaucoma patients are likely to exhibit signs of subclinical vascular abnormalities. Further studies are needed to better understand the microcirculation and microcirculation associated with glaucoma pathogenesis.

Abstract No.: 203562

Exploring the Therapeutic Potential of Exercise in Glaucoma

First Author: Kai GAO

Purpose: This study reviews current evidence from basic and clinical research on the role of exercise in glaucoma management, explores underlying

physiological and molecular mechanisms, evaluates different exercise modalities, and identifies future research priorities.

Methods: A comprehensive search of scientific databases focused on peer-reviewed English articles using keywords such as "exercise," "glaucoma," "intraocular pressure," "neuroprotection," "ocular blood flow," and "retinal ganglion cells." Relevant findings were synthesized across study designs to assess mechanistic insights and clinical outcomes.

Results: Aerobic exercise consistently induces acute, and in some cases sustained, reductions in intraocular pressure (IOP), mediated by altered aqueous humor dynamics, sympathetic activation, and enhanced ocular blood flow. Experimental studies highlight neuroprotective effects, particularly via upregulation of brain-derived neurotrophic factor (BDNF), supporting retinal ganglion cell survival. Resistance training can transiently elevate IOP, especially with high-intensity loads or Valsalva maneuvers, while its long-term influence on glaucoma progression remains uncertain. Inverted yoga poses are associated with marked, short-term IOP elevations. Clinical evidence suggests that higher overall physical activity correlates with slower visual field deterioration, although long-term randomized controlled trials (RCTs) assessing functional outcomes and quality of life are limited.

Conclusions: Moderate aerobic exercise emerges as a promising adjunctive approach in glaucoma management, exerting both IOP-lowering and neuroprotective effects through multifactorial mechanisms. However, optimal exercise guidelines remain undefined, particularly regarding resistance training and inverted positions. Future studies should delineate molecular pathways underlying exercise-induced ocular changes and conduct long-term RCTs to determine the impact of tailored exercise regimens on disease progression and patient quality of life.

Abstract No.: 201125

Factors Associated with Postoperative Tissue Thickness Covering Baerveldt Glaucoma Implant Tubes

First Author: Natsumi MURATA

Co-Author(s): Toshihiro INOUE, Sachi KOJIMA, Eri TAKAHASHI, Yuji TAKIHARA

Purpose: Tube exposure is a serious complication following Baerveldt glaucoma implantation (BGI), often linked to patch graft thinning. Evaluating the thickness of the patch graft is key to understanding the underlying mechanisms of tube exposure. Therefore, this study aimed to identify factors associated with postoperative tissue thickness over the BGI tube using anterior segment optical coherence tomography (AS-OCT).

Methods: This retrospective study included 200 eyes of 178 patients who underwent BGI (BG101-350 with a preserved scleral patch graft) at a single academic institution. Using AS-OCT (CASIA2) approximately one year postoperatively, tissue thickness was measured from the conjunctival surface to the outer tube edge. Associations with clinical variables were evaluated using multivariable linear regression.

Results: Multivariable analysis revealed that anterior chamber (AC) tube insertion was independently associated with significantly thinner tissue compared to sulcus insertion (estimate 0.074; $p = 0.019$) and pars plana insertion (estimate 0.178; $p < 0.001$). In the subgroup of AC insertion cases, prior micropulse transscleral cyclophotocoagulation (MP-CPC) was independently associated with greater tissue thickness (estimate 0.170; $p = 0.031$).

Conclusions: AC tube insertion is an independent risk factor for postoperative tissue thinning over the tube. Prior MP-CPC may have a protective effect on tissue preservation in eyes with AC tubes. These factors should be considered during surgical planning for tube exposure.

Abstract No.: 201630

From X-Y Plane to X-Y-Z Space: Transforming Visual Field Reports Into Engaging 3D Learning Tools

First Author: Prasanna Vekatesh **RAMESH**

Purpose: Practical sessions enhance understanding of ophthalmic concepts and promote critical thinking, especially among medical students, glaucoma residents, and allied ophthalmic personnel. With the increasing use of virtual and augmented reality in ophthalmic education, this study explores the creation of three-dimensional (3D) printed models representing visual field reports for better comprehension of visual field defects.

Methods: This project utilizes data from real patient perimetry reports to develop 3D-printed models of various visual field patterns. The models include both normal fields and complex defects such as isopter contraction, arcuate scotomas, and quadrantanopias. Through tactile interaction with these 3D puzzles, learners gain insights into neuro-ophthalmic conditions like glaucoma, optic neuropathies, and chiasmal syndromes, enhancing their understanding of both normal and pathological visual fields.

Results: 3D printing offers precision and affordability, making it ideal for rapid prototyping of patient-specific models. Traditional ophthalmic learning tools rely on diagrams and digital platforms, but these tactile 3D models provide a hands-on experience that promotes active learning. By converting clinical data into physical models, students and trainees engage more effectively, and patients better understand visual field changes.

This is the first known attempt to develop 3D-printed visual field report models directly from clinical data, filling a gap in ophthalmic education.

Conclusions: This novel pedagogical approach offers valuable tools for ophthalmic education and patient care. The 3D-printed visual field models provide students with a multisensory learning experience and help ophthalmologists communicate more effectively with patients about disease progression, such as glaucomatous visual field loss.

Abstract No.: 203667

GUIDE: A Machine Learning-Based Decision Support System for Glaucoma Long-Term Management

First Author: Qianyu **ZHAN**

Co-Author(s): Zidong **CHEN**, Kezheng **XU**, Yangfan **YANG**, Minbin **YU**

Purpose: This study focuses on open-angle glaucoma and aims to develop clinical decision-making algorithms for the critical treatment escalation during long-term follow-up leveraging advanced machine learning, to provide insights and improve capabilities in the long-term management of open-angle glaucoma.

Methods: This study included newly diagnosed patients with open-angle glaucoma and ocular hypertension from a large trial, the Laser in Glaucoma and Ocular Hypertension Trial in China (LiGHT China). At first, we utilized a guideline-based decision system to assess whether treatment escalation was needed during patient follow-ups. Glaucoma specialists will reviewed these initial recommendations and their final decisions were taken as ground-truth labels to train machine learning-based decision support system using CatBoost algorithms.

Results: This study included a total of 771 patients, 1,376 trial eyes, and 6,889 follow-up records from 2015 to 2023. Based on guideline-based decision system, 765 visits in 6889 were labelled as requiring treatment escalation. Glaucoma specialists reviewed these initial decisions and modified 192 treatment escalation (25%) to continuing monitoring. We then further taken these decision as ground-truth labels to train machine learning-based decision support algorithms, and the model achieved an AUROC of 0.86 (0.02) and an F1 score of 0.73 (0.04) under 10-time 3-fold cross-validation. SHapley Additive exPlanations showed the appropriate and robust reasoning of characteristics of the algorithms on decision-making of treatment escalation, and mainly based on real-time intraocular pressure.

Conclusions: This study develops rigorously validated algorithms leveraging advancements in computational modelling to achieve automated, robust and explainable decision-making which potentially relieve

the heavy burdens of glaucoma management in the future.

Abstract No.: 201461

Gazing Into the Angle: Is Anterior Segment Optical Coherence Tomography the New Gonioscopy?

First Author: Nehal KAPOOR

Purpose: To prospectively compare the diagnostic efficacy of Anterior Segment Optical Coherence Tomography (AS-OCT) with gonioscopy in evaluating anterior chamber angles for glaucoma patients, and to assess whether AS-OCT can serve as a reliable, non-contact alternative to the current gold standard.

Methods: This prospective, observational, cross-sectional study was conducted over 15 months at a tertiary eye care center. Patients diagnosed with or suspected of having glaucoma were recruited after informed consent. Exclusion criteria included history of intraocular surgery, corneal opacities, angle abnormalities due to trauma or neovascularization, and poor fixation preventing reliable imaging. Each subject underwent gonioscopy with a Goldmann two-mirror lens under standard illumination and anterior chamber angle imaging with AS-OCT in dark conditions. Gonioscopy findings were graded using Shaffer's system, while AS-OCT angle parameters such as angle opening distance and trabecular-iris angle were documented. The primary outcome was the agreement between gonioscopic angle grading and AS-OCT measurements, with secondary analysis of sensitivity, specificity, and diagnostic efficacy.

Results: Overall diagnostic performance of AS-OCT compared to gonioscopy showed sensitivity of 97.98%, specificity 74.29%, positive predictive value 78.23%, negative predictive value 97.50%, and diagnostic accuracy 85.78%. The high sensitivity and negative predictive value highlight the reliability of AS-OCT in ruling out angle closure, though specificity was moderately lower due to overestimation of narrow angles.

Conclusions: While gonioscopy remains the gold standard for angle evaluation, AS-OCT offers reproducible, and patient-friendly imaging, making it a strong adjunct in diagnosis and large-scale screening.

Abstract No.: 208400

Genetic Association of ANGPT2 With Primary Open-Angle Glaucoma

First Author: Jing Na HE

Co-Author(s): Li Jia CHEN, Wai Kit CHU, Chi Pui PANG, Clement C. THAM

Purpose: To determine the association of the ANGPT2 gene with primary open-angle glaucoma (POAG) in Chinese.

Methods: Six single-nucleotide polymorphisms (SNPs) in ANGPT2 (rs2515487, rs2922869, rs13255574, rs4455855, rs13269021, and rs11775442) were genotyped in a total of 2601 study subjects from two cohorts. One is a Hong Kong Chinese cohort of 484 high tension glaucoma (HTG) and 537 normal tension glaucoma (NTG) patients, and 496 non-glaucoma control subjects. Another cohort is a Shantou Chinese cohort of 403 HTG and 135 NTG patients, and 543 non-glaucoma control subjects. Subgroup analysis by sex was conducted. Outcomes from different cohorts were combined for meta-analysis.

Results: The association of SNP rs11775442 with NTG in the Hong Kong cohort [$P = 0.0498$, OR = 1.24, 95% confidence interval (CI) 1.00–1.55] after adjusting for age and sex did not reach statistical significance after Bonferroni correction. Other SNPs were not significantly associated with NTG, HTG and POAG in individual cohort or in the combined analyses ($P > 0.05$). In the subgroup analysis by sex, SNP rs13269021 in the Shantou cohort, but not in the Hong Kong cohort, was significantly associated with NTG in males ($P = 0.0081$, OR = 1.67, 95% CI: 1.14–2.43) but not in females ($P = 0.874$).

Conclusions: In the subgroup analysis by sex, a significant association was shown in SNP rs13269021 with NTG in Shantou males, but not in Hong Kong males. Further studies are needed to verify the association between ANGPT2 locus (rs13269021) and NTG in Chinese males.

Abstract No.: 208190

H486R Mutation in OPTN Affected Autophagy Level in TM-1 Cells Through Ubiquitin-Binding

First Author: Jing Na HE

Co-Author(s): Wai Kit CHU, Jian LI, Yan TONG, Jiaxin ZHANG

Purpose: Investigate the consequences of the H486R OPTN mutation in TM cells.

Methods: The oxidative stress levels, numbers of damaged mitochondria, apoptosis levels, and OPTN-Ubiquitin binding of TM-1 cells stably expressing these OPTN mutant proteins were investigated.

Results: In our study, H486R-4 cells had higher endogenous and induced oxidative stress levels than WT-4 cells. More damaged mitochondria and higher apoptosis levels have also been found in H486R-2 cells compared to WT-4 cells.

Conclusions: All these results indicated that the H486R mutation in OPTN affected the cellular responses to oxidative stress damage in TM-1 cells. Further studies are needed to confirm what molecular functions of OPTN are impaired in the H486R OPTN-expressing cells.

Abstract No.: 204355

High Myopia Normative Database of Peripapillary Retinal Nerve Fiber Layer Thickness to Detect Myopic Glaucoma in a Chinese Population

First Author: Fei LI

Purpose: To develop and validate the performance of a high myopia (HM)-specific normative database of peripapillary retinal nerve fiber layer (pRNFL) thickness in differentiating HM from highly myopic glaucoma (HMG).

Methods: A total of 1,108 eyes from 694 participants with HM were included in the normative database; 459 eyes from 408 participants and 322 eyes from 197 participants were included in the internal and external validation sets, respectively. The pRNFL thickness was measured with swept-source OCT. Four strategies of pRNFL-specified values were examined, including global and quadrant pRNFL thickness below the lowest fifth or the lowest first percentile of the normative database. The accuracy, sensitivity, and specificity of the HM-specific normative database for detecting HMG.

Results: Setting the fifth percentile of the global pRNFL thickness as the threshold, using the HM-specific normative database, we achieved an accuracy of 0.93 (95% confidence interval [CI], 0.90–0.95) and 0.85 (95% CI, 0.81–0.89), and, using the first percentile as the threshold, we achieved an accuracy of 0.85 (95% CI, 0.81–0.88) and 0.70 (95% CI, 0.65–0.75) in detecting HMG in the internal and external validation sets, respectively. Compared with the built-in database of the OCT device, the HM-specific normative database showed a higher sensitivity and specificity than the corresponding pRNFL thickness below the fifth or first percentile ($P < 0.001$ for all).

Conclusions: The HM-specific normative database is more capable of detecting HMG eyes than the built-in database, which may be an effective tool for differential diagnosis between HMG and HM.

Abstract No.: 202165

Immediate Change of Intraocular Pressure and Choroidal Thickness After Laser Panretinal Photocoagulation (PRP)

First Author: Thanida POMSUNAN

Co-Author(s): Noppakhun PANYAYINGYONG

Purpose: To evaluate intraocular pressure (IOP) and choroidal thickness changes following the first session of panretinal photocoagulation (PRP) in the early period.

Methods: This prospective cohort study included 40 eyes from 40 patients, comprising 31 eyes with proliferative diabetic retinopathy (PDR), and 9 eyes with severe non-proliferative diabetic retinopathy

(severe NPDR). All patients underwent the first session of PRP. IOP was measured with a rebound tonometer (i-Care), while subfoveal choroidal thickness (SFCT) and anterior chamber angle width were assessed using EDI-OCT and AS-OCT, respectively, before PRP and at 1 hour post-PRP.

Results: The mean IOP at the first hour after PRP (17.90 ± 4.82 mmHg) was significantly higher than pre-PRP (15.58 ± 3.94 mmHg) IOP values ($p < 0.01$). The pressure elevation in these eyes averaged 2.32 ± 4.39 mmHg. Mean SFCT before PRP was 307.75 ± 60.56 μ m, which increased to 308.63 ± 58.78 μ m after PRP ($p = 0.37$). Mean anterior chamber angle width did not reduce after PRP (25.87 ± 10.00 before PRP, 26.10 ± 12.28 at the first hour after PRP; $p = 0.85$). Although both mean IOP and SFCT increased after PRP, there was no significant correlation between their changes. A negative correlation was observed between IOP-angle and SFCT-angle changes.

Conclusions: The elevation of IOP was observed at the first hour after PRP. Further monitoring and prophylaxis treatment may be considered in patients with borderline or high IOP with a vulnerable optic nerve head sensitive to IOP intensification. However, the mechanism of IOP elevation could not be identified clearly.

Abstract No.: 201770

Impact of Selective Laser Trabeculoplasty on Diurnal IOP Dynamics Assessed by Home Monitoring

First Author: Rongrui LIU

Co-Author(s): Ping HUANG, Jonathan MYERS, Reza RAZEGHINEJAD

Purpose: To evaluate the impact of selective laser trabeculoplasty (SLT) on diurnal intraocular pressure (IOP) using home rebound tonometry

Methods: Patients with open-angle glaucoma were prospectively enrolled in a home monitoring program and trained to perform IOP self-measurements with a rebound tonometer. They obtained IOP readings three times daily for seven consecutive days every 3 months. Eyes that underwent SLT were analyzed. Diurnal IOP parameters and number of glaucoma medications were compared before SLT and at 3 and 6 months after treatment.

Results: Thirteen patients (16 eyes; 6 men, 7 women) were included: normal-tension glaucoma ($n = 7$), primary open-angle glaucoma ($n = 8$), and pigmentary glaucoma ($n = 1$). Mean age was 58.6 ± 13.0 years. At baseline ($n = 16$), mean IOP was 14.62 ± 4.16 mmHg, peak IOP 19.31 ± 5.57 mmHg, fluctuation 8.62 ± 3.69 mmHg, and medications 3.12 ± 1.15 . At 3 months ($n = 14$), mean IOP was 13.89 ± 4.60 mmHg ($p = 0.368$), peak 18.85 ± 6.66 mmHg ($p = 0.669$), and fluctuation 9.31 ± 4.71 mmHg ($p = 0.625$). At 6 months ($n = 12$ for IOP, $n = 16$

for medications), mean IOP declined significantly to 13.16 ± 4.04 mmHg ($p=0.005$), while peak (17.80 ± 5.41 mmHg, $p=0.107$) and fluctuation (8.10 ± 3.54 mmHg, $p=0.864$) were unchanged. Medications decreased to 2.85 ± 1.68 ($p=0.219$).

Conclusions: SLT resulted in a significant reduction in mean IOP at 6 months. In this cohort of medicated eyes with relatively low baseline IOP, treatment may be less effective than in higher-IOP eyes treated primarily. Home monitoring proved feasible for assessing IOP dynamics after SLT.

Abstract No.: 201743

Implantation Intraocular Lens With an Extended Depth of Focus in Glaucoma Patients With Only Seeing Eye

First Author: Nadezhda **GORBUNOVA**

Co-Author(s): Nadezhda **POZDEYEVA**, Diana **YAMBROVSKAYA**

Purpose: The purpose of this study is to determine the opportunity and appropriateness of implantation of an intraocular lens with an extended depth of focus (EDOF) in the surgical treatment of cataracts in glaucoma patients with only one seeing eye. The criteria under study: visual acuity in far, near, and intermediate (66 cm) distances, indicators of retinal photosensitivity, and patients' satisfaction with the quality of life after surgery.

Methods: The study included 22 patients. An IOL with an expanded depth of focus (Lentis Comfort, Teleon Surgical BV, Netherlands) was implanted in the glaucoma patients. Sixteen patients had angle-closure glaucoma, and 6 had open-angle glaucoma. The patients were divided into stages: 13 patients at the initial stage, 4 at the moderate stage, and 5 at an advanced stage of glaucoma. In addition to measuring visual acuity at different distances evaluated computer perimetry with photosensitivity analysis and assessment of vision quality using the questionnaire VF-14.

Results: IOL implantation with an extended depth of focus is a safe and effective cataract treatment for glaucoma patients with an only seeing eye, providing the benefits of an extended range of visual acuity without a significant increase in the risk of complications and deterioration in retinal light sensitivity.

Conclusions: Implantation of an EDOF IOL increases visual acuity at all distances in glaucoma patients with an only seeing eye. Implantation of an EDOF IOL does not affect the retinal photosensitivity. Glaucoma patients with EDOF IOL were satisfied with the quality of vision in daily life.

Abstract No.: 202051

Insertion of Preserflo MicroShunt Under OCT Guidance in a Case of Congenital Glaucoma With Aniridia and Corneal Opacity

First Author: Shohei **MORIKAWA**

Co-Author(s): Tetsuro **OSHIKA**, Yuta **UENO**

Purpose: To report a case of congenital glaucoma with aniridia and corneal opacity treated with Preserflo MicroShunt (PMS) implantation under intraoperative optical coherence tomography (OCT) guidance.

Methods: A 5-year-old girl with bilateral aniridia, elevated intraocular pressure (IOP) since birth, and a maternal family history of congenital glaucoma underwent PMS implantation in the left eye. Multiple trabeculotomies had been performed in both eyes, and micropulse transscleral cyclophotocoagulation in the right eye had resulted in phthisis bulbi. PMS implantation was selected because the left eye was the only seeing eye, and trabeculectomy carried a high risk of complications. Severe aniridia and corneal opacity markedly impaired intraoperative visualization through the surgical microscope. Real-time intraoperative OCT was used to determine scleral tunnel depth and anterior chamber entry angle.

Results: OCT guidance allowed accurate PMS placement despite poor microscopic visibility. The IOP decreased from 38 mmHg (on two topical agents) to 17 mmHg postoperatively without complications.

Conclusions: In congenital glaucoma with aniridia and corneal opacity, intraoperative visualization may be severely limited, making conventional techniques risky. Intraoperative OCT provided real-time anatomical feedback, enabling precise PMS placement and contributing to a safe and effective surgical outcome. This approach may be particularly beneficial in complex pediatric glaucoma with anterior segment opacities.

Abstract No.: 202090

Inter-Device Agreement of Nidek Mirante and Heidelberg Spectralis OCT for Glaucoma Monitoring: A Comparative Analysis Across Disease Severity

First Author: Norlina **RAMLI**

Co-Author(s): Muhammad Syafiq **AHMAD MUSTHAFA**, Nurul Ilham **HUSSAIN**, Monisha **NONGPIUR**

Purpose: Evaluation of the agreement in retinal nerve fiber layer (RNFL) and macular thickness measurements between the Nidek Mirante and Heidelberg Spectralis optical coherence tomography (OCT) devices in glaucoma patients of varying severities.

Methods: In this cross-sectional study, 146 eyes from 73 subjects (66 glaucoma patients, 7 normal controls) underwent a comprehensive ophthalmic examination. Peripapillary RNFL and macular thickness were measured with both devices. Correlation, Bland-Altman

analysis for agreement, and regression for influencing factors were assessed.

Results: RNFL thickness showed strong correlations across all sectors, strongest in the inferior quadrant ($r=0.947$). The mean inter-device bias for average RNFL thickness was $-1.10 \mu\text{m}$. Macular thickness also correlated strongly ($r>0.82$ in central/inner sectors), though the outer superior sector showed wider limits of agreement. Fixed and proportional biases were present in most sectors. Regression analysis revealed that age, axial length, anterior chamber depth, glaucoma stage, spherical equivalent, and lens status did not significantly influence the measurement differences.

Conclusions: While measurements from the Spectralis and Mirante show strong correlation and acceptable agreement, the presence of consistent biases indicates that their measurements are not directly interchangeable in clinical practice.

Abstract No.: 205691

Interim One-Year Results of the Comparison Ahmed–Paul Glaucoma Implant Study (CAPS): A Multicenter Randomized Controlled Trial

First Author: Katherine LUN

Co-Author(s): Victor KOH, Dawn LIM, Karl MERCECA, Sirisha SENTHIL

Purpose: To compare the safety and efficacy of the PAUL® Glaucoma Implant (PGI) and Ahmed Glaucoma Valve (AGV) in patients undergoing aqueous shunt surgery for refractory primary and secondary glaucoma.

Methods: CAPS is a prospective, multicenter randomized controlled trial conducted at three international sites (Singapore, Bonn, India). Eligible patients aged 21–85 years with inadequately controlled glaucoma were randomized 1:1 to PGI or AGV implantation. The primary outcome was surgical success, defined as intraocular pressure (IOP) between 6–21 mmHg with $\geq 20\%$ reduction from baseline on two consecutive visits beyond 3 months, with or without IOP-lowering medication. Failure was defined as IOP outside this range, $<20\%$ reduction, need for reoperation, implant removal, or loss of light perception. Secondary outcomes included visual acuity, number of glaucoma medications, endothelial cell count, and postoperative complications.

Results: A total of 44 patients were included in the analysis. Baseline demographics and ocular characteristics were balanced between groups. At 1 year, both PGI and AGV achieved substantial IOP reduction. Rates of complete and qualified success, medication reduction, and endothelial cell density change were analyzed. No patient required reoperation, implant removal, or lost light perception. Complications were limited and manageable; no sight-threatening adverse events occurred.

Conclusions: Preliminary 1-year results suggest that both PGI and AGV provide effective IOP control with acceptable safety profiles in refractory glaucoma. The PGI may offer comparable success rates relative to AGV, with low rates of serious complications. Longer-term follow-up in the full cohort ($n=88$) will clarify comparative efficacy and safety.

Abstract No.: 202247

Introduction of a Micro-Incision Scleral Tunnel Technique for Glaucoma Tube Shunt Surgery

First Author: Masaki TANITO

Co-Author(s): Akiko HARANO, Chisako IDA, Mizuki IIDA, Sachiko KAIJZU, Kana MURAKAMI, Hinako OHTANI, Kazunobu SUGIHARA, Keigo TAKAGI

Purpose: To introduce the micro-incision scleral tunnel (MIST) technique, a novel sutureless and allograft-free method for Ahmed glaucoma valve (AGV) tube implantation, by presenting three illustrative cases.

Methods: Three patients with refractory glaucoma underwent AGV implantation using the MIST approach. A 1-mm crescent blade was used to create a short scleral tunnel for tube insertion into the anterior chamber, ciliary sulcus, or vitreous cavity. Intraocular pressure (IOP), medication use, and postoperative anterior segment status were evaluated.

Results: Case 1: A man in his seventies with primary angle-closure glaucoma underwent pars plana insertion combined with vitrectomy; IOP was 6 mmHg without medication at three months. Case 2: A man in his seventies with secondary angle-closure glaucoma due to iridocyclitis underwent ciliary sulcus insertion; IOP was 7 mmHg without medication at three months. Case 3: A teenage male with Axenfeld-Rieger syndrome-related glaucoma received anterior chamber insertion; IOP was 8 mmHg with two medications at eight months. Anterior segment findings were stable in all cases.

Conclusions: The MIST approach allows AGV tube placement without sutures or donor grafts while providing effective IOP reduction. The absence of serious complications, including hypotony and tube exposure, together with its adaptability across insertion sites, suggests that MIST may be a useful alternative technique for glaucoma tube implantation.

Abstract No.: 200484**Juvenile Rheumatoid Arthritis-Associated Uveitic Glaucoma: Clinical Characteristics and Long-Term Outcomes***First Author: Chaehyun SONG**Co-Author(s): Jin Wook JEOUNG, Young Kook KIM, Ki Ho PARK*

Purpose: To investigate the clinical characteristics and long-term prognosis of juvenile rheumatoid arthritis-associated uveitis, with a particular focus on secondary glaucoma, in a Korean pediatric population.

Methods: This study reviewed the medical records of patients who were diagnosed with both juvenile rheumatoid arthritis and uveitis at Seoul National University Hospital between August 2021 and July 2024. Demographic data, clinical findings, treatment modalities, ocular complications, surgical outcomes, and long-term visual prognosis were analyzed.

Results: A total of 48 juvenile rheumatoid arthritis-associated uveitis patients were included, of whom 23 (47.9%) developed glaucoma, and 17 (35.4%) underwent glaucoma surgery. HLA-B27 positivity was significantly more prevalent in the glaucoma group (48.0% vs. 17.4%, $p=0.025$). The common ocular complications in glaucoma patients were cataract (68.4%), corneal band keratopathy or opacity (42.1%), and posterior synechiae (36.8%). Glaucoma surgeries included trabeculectomy (59.1%) and Ahmed valve implantation (54.6%). IOP was significantly reduced postoperatively (mean reduction 44.06%). Long-term follow-up (≥ 10 years) of 32 eyes showed that 59.4% maintained normal visual acuity and 43.8% of patients had no significant bilateral visual deterioration.

Conclusions: Nearly half of the juvenile rheumatoid arthritis-associated uveitis patients developed secondary glaucoma, with many requiring surgical intervention. Despite the severity of disease, appropriate and timely management, including immunosuppression and surgery, enabled preservation of visual function in a significant proportion of patients over long-term follow-up. This research shows a step forward in understanding the juvenile rheumatoid arthritis-associated uveitis with glaucoma, providing information to clinicians for predicting outcomes and tailoring management strategies.

Abstract No.: 207497**Knockdown of PTEN Promotes RGC Axon Growth***First Author: Baoyuan QU**Co-Author(s): Shaohong CHEN, Wang LI, Jing QIAO, Fan ZHANG*

Purpose: Currently available glaucoma treatments focusing on lowering intraocular pressure only slow the progression of glaucoma, rather than halt or reverse it. Once treatment is discontinued due to poor patient

compliance or when the surgical efficacy declines, intraocular pressure will rise again and cause optic nerve damage. Furthermore, IOP-lowering methods are inapplicable to patients with normal-tension glaucoma. This research aims to develop a universal gene therapy for glaucoma that can reverse the course of glaucoma.

Methods: Screening shRNAs efficiently knockdown PTEN, and then constructed to AAV vector, and proceed AAV production. Purified viral vectors were administered to C57 mice via subretinal injection, followed by optic nerve crush surgery two weeks later. One month post-surgery, CTB was injected to the vitreous to assess optic nerve regeneration. Visual cliff testing was performed to evaluate mouse behavioral responses, and visual evoked potentials (VEP) were recorded to examine RGC electrophysiological function.

Results: PTEN was efficiently knock down in AAV-shRNA treated retina. The optic nerve was regenerated strongly in AAV-shRNA treated mice compared with control treated mice, and the treated mice spent more times in shadow side of the cliff in Visual cliff testing, the VEP showed a trend of increasing in AAV-shRNA treated mice compared with control.

Conclusions: Knock down PTEN can induce the regeneration of RGC axons and recovery the function of damaged RGC.

Abstract No.: 200597**Knowledge and Awareness of Glaucoma Among Rural and Urban Patients in Northern Bangladesh***First Author: Habiba SULTANA**Co-Author(s): Shajeda AZIZI, Khairul ISLAM*

Purpose: To assess and compare the level of knowledge and awareness of glaucoma among rural and urban patients in northern Bangladesh.

Methods: This comparative cross-sectional study was conducted on 706 respondents in total, with an equal number of 353 participants selected from both urban and rural regions in northern Bangladesh. Informed consent was obtained from eligible participants over 18 years. The questionnaire, available in both English and Bengali, collected demographic data and included questions on glaucoma awareness and knowledge. Data were analysed using SPSS 26, and the chi-square test was applied to determine statistical significance.

Results: The mean ages were 39.31 ± 14.1 years for urban and 52.01 ± 14.2 years for rural participants. Awareness of glaucoma was low, with only 20.8% of participants familiar with the term, slightly higher in urban areas (22.7% vs. 19%). A notable 81.6% of urban and 81.3% of rural respondents were unaware or unsure about glaucoma. Additionally, 51.2% of urban respondents recognized that age increases glaucoma risk, while only 16.4% of rural participants did. A statistically significant association ($p < 0.001$)

was observed between residence and knowledge level, with excellent knowledge found in 31.3% of urban participants versus 9% in rural areas. Overall, only 15% of all participants demonstrated «good» knowledge of glaucoma.

Conclusions: The study reveals a rural-urban gap in glaucoma awareness, with rural populations having less knowledge. The findings emphasize the need for targeted rural eye health programs to enhance early detection, timely treatment, and reduce preventable blindness.

Abstract No.: 204697

Latanoprost-Dependent Pulsatile Aqueous Discharge to the Episcleral Veins

First Author: Chen XIN

Purpose: To explore the mechanism of immediate IOP reduction after a single dose of latanoprost.

Methods: One-factor repeated-measures design, observational study. Intraocular pressure (IOP) and video imaging of aqueous vein were captured before and 10-min, 30-min, 45-min, 60-min, 120-min, 240-min after instillation of latanoprost. Aqueous stratum diameter (ASD) and aqueous velocity (AV) were measured.

Results: Before medication instillation, IOP was 28.3 ± 4.2 mmHg. It started to dramatically decrease to 24.3 ± 2.3 mmHg after 120 minutes ($F=10.203$, $P=0.006$). Before medication instillation, ASD was 0.019 ± 0.010 μm . It started to dramatically increase to 0.034 ± 0.007 μm after 45 minutes ($F=26.187$, $P<0.001$), which kept increasing to 0.050 ± 0.012 μm until 60 minutes afterwards ($F=20.723$, $P<0.001$). Before medication instillation, AV was 2.1 ± 0.5 $\mu\text{l/s}$. It started to dramatically increase to 2.6 ± 0.6 $\mu\text{l/s}$ after 30 minutes ($F=5.757$, $P=0.031$), which kept increasing to 4.3 ± 0.9 $\mu\text{l/s}$ at 45 minutes and 4.3 ± 0.9 $\mu\text{l/s}$ at 60 minutes ($F_{30-45}=8.512$, $P_{30-45}=0.011$; $F_{45-60}=8.512$, $P_{45-60}=0.021$).

Conclusions: Latanoprost increases aqueous humor through the trabecular meshwork pathway, resulting in immediate IOP reduction.

Abstract No.: 204299

Leaky Bleb With Multiple Revisions and an Inferior Glaucoma Drainage Device Implantation: A Case Report

First Author: Jon Denzel YU

Co-Author(s): Maria Catherina NASOL, Cathleen Joyce VILLAFUERTE

Purpose: To report a case of a 40-year old female who had a leaking bleb and underwent three bleb revisions and a glaucoma drainage device (GDD) implantation at the inferonasal area and to discuss its effectiveness.

Methods: A retrospective case report was done followed by review of related literature and case correlation.

Results: A 40-year-old Filipino female with juvenile open-angle glaucoma presented with left eye pain 10 years after initial trabeculectomy. Examination revealed a cystic, avascular bleb with a positive Seidel's test. She underwent three bleb revisions: (1) scleral patch with conjunctival advancement, (2) horizontal mattress suture with bandage contact lens, and (3) Tenon's flap with scleral patch. On day 16 after the third repair, intraocular pressure (IOP) increased to 36 mmHg. A Paul Glaucoma Implant (PGI) was placed inferonasally. Her IOP stabilized in the mid-teens with Brimonidine + Timolol 2x a day and Dorzolamide 3x a day, and remained in the low-teens after ripcord removal, maintained on Brimonidine + Timolol.

Conclusions: The aim of management of a leaking bleb is to prevent future leaks and maintain a low IOP. After three revisions, the initial goal of leak prevention was achieved, however, there was subsequent elevation of IOP. An inferiorly-placed GDD implant was deemed necessary to achieve both leak prevention and IOP lowering. Inferior placement has been demonstrated to be safe and effective. In addition, it offers advantages in eyes with significant conjunctival scarring or anatomic abnormalities at the superior limbus.

Abstract No.: 201341

Long-Term Clinical Course of Primary Angle Closure in Korean Patients

First Author: Wool SUH

Co-Author(s): Kyung Eun HAN, Roo Min JUN

Purpose: To assess the long-term clinical course of primary angle-closure suspect (PACS), primary angle closure (PAC), and primary angle-closure glaucoma (PACG) in Korean patients.

Methods: This retrospective study reviewed eyes classified as PAC/PACG or PACS that presented at a tertiary hospital between 1994 and 2022. The eyes were categorized as having PAC/PACG or PACS. Presenting features, management, and subsequent long-term IOP outcomes measured with optical coherence tomography (OCT) were included.

Results: The study included 305 eyes : 84 eyes with PAC/PACG and 221 eyes with PACS. The mean follow-up period was 11.1 ± 6.6 years. In 48 eyes with PAC/PACG treated with laser peripheral iridotomy (LPI), 97.9% achieved controlled IOP, with 2.1% undergoing cataract surgery. Of the 185 eyes with PACS treated with LPI, 46.5% required no further surgery and 50.8% underwent cataract surgery. In 107 eyes, OCT revealed significant retinal nerve fiber layer thinning in the PAC/PACG in the superior and average sectors and in PACS in the superior, inferior, and average sectors (all $P < 0.001$) and temporal sector ($P = 0.039$), with PACS

showing a significant increase in the cup-to-disc ratio ($P = 0.033$).

Conclusions: LPI effectively controlled IOP in most patients with PAC and PACS, although some required surgery. Prolonged follow-up revealed progressive retinal nerve fiber layer thinning and increased cup-to-disc ratio in eyes with PACS, indicating structural changes despite IOP control. Regular OCT-based monitoring is crucial for detecting and managing disease progression in patients with angle-closure diseases.

Abstract No.: 204718

Long-Term Course of Primary Congenital Glaucoma After Trabeculotomy: Emphasizing Lifelong Follow-Up and Timely Escalation to Glaucoma Drainage Device

First Author: Brandon Willis **SING**

Co-Author(s): Manuel Jr. **DELFIN**, Mara Augustine **GALANG-LU**

Purpose: To describe the clinical course and surgical management of a patient with primary congenital glaucoma (PCG) from infancy through childhood, highlighting the importance of long-term follow-up.

Methods: This is a case report.

Results: An otherwise healthy 21-day-old female, born term with unremarkable birth history, presented with bilateral corneal enlargement (13.5 mm), left corneal opacity, and markedly elevated intraocular pressures (IOP) OD:55, OS:86. Examination under anesthesia showed right disc finding of CDR 0.2, while B-scan of the left eye revealed attached retina. Bilateral trabeculotomy was performed due to poor corneal visualization with no untoward postoperative course. IOP was lowered to 18mmHg. Pressures were maintained in the 20s on timolol/dorzolamide and latanoprost, with one spike to 34. Visual acuity was age-appropriate at OU: 20/40 at 3 years. Patient followed up at age 7 with complaints of frontal headache and tearing. Examination revealed worsened VA of 20/80 OU with IOPs of 24 OD and 34 OS. revealed bilaterally closed angles, except for the inferior angles open to the Ciliary body band. Fundoscopy showed optic disc cupping of OD 0.3 and OS 0.7. A glaucoma drainage device (ClearPath 250) was implanted, resulting in a stable IOP of 20s mmHg in both eyes post-operatively. Ripcord removal at 3 months further lowered OS IOP to 15 mmHg, with uneventful follow-up, eliminating the need for any anti-glaucoma medications.

Conclusions: Primary congenital glaucoma may progress despite initial surgical success. This case emphasizes lifelong monitoring, timely surgical escalation, and patient education as essential to preserve vision and prevent irreversible optic nerve damage in children.

Abstract No.: 205651

Long-Term Outcomes of PreserFlo MicroShunt Implantation in a UK Tertiary Centre: A Nine-Year Retrospective Series

First Author: Yunzi **CHEN**

Co-Author(s): Hari **JAYARAM**

Purpose: To evaluate long-term outcomes of PreserFlo MicroShunt implantation for glaucoma at a UK tertiary centre, with follow-up of up to nine years.

Methods: Retrospective case series of the first 50 consecutive patients undergoing PreserFlo implantation; 49 eyes met inclusion criteria (no prior glaucoma surgery, ≥ 12 months follow-up). Surgical success was defined as intraocular pressure (IOP) 6–21 mmHg with $\geq 20\%$ reduction from baseline, with (qualified) or without (complete) medication, without loss of light perception or further glaucoma surgery. Follow-up was censored when eyes failed to meet success criteria.

Results: Mean age was 67 years; 80% had primary open-angle glaucoma. Mitomycin-C concentration ranged 0.1–1.0 mg/ml (49% received 0.2 mg/ml); 10% received adjunctive beta radiation and 10% intracameral bevacizumab. Combined phacoemulsification was performed in 12%. Median follow-up was 36 months (IQR 18–60, maximum 108), with 25% of eyes followed beyond 5 years. At last follow-up, 33% achieved success (18% complete, 14% qualified). Kaplan–Meier analysis showed cumulative success of 61% at 1 year, declining to 33% at 5 years, remaining stable to 9 years. Postoperative rescue interventions were required in 55% (41% needling, 37% open revision, some underwent both). Further glaucoma surgery was required in 10% (8% tube, 2% diode). Complications occurred in 16%, mostly self-limiting; 4% required reoperation.

Conclusions: PreserFlo implantation provided sustained IOP reduction with long-term success rates comparable to published series. Complication rates were low, though many eyes required revision procedures. Larger studies are needed to evaluate the surgical learning curve and the effect of adjunctive measures, such as mitomycin-C dosage, on long-term outcomes.

Abstract No.: 206147

Long-Term Outcomes of Trabecular Micro-Bypass iStent Implantation in Malaysia

First Author: Norjeehan **MAARIS**

Co-Author(s): Zulhilmi **ABDUL RAZAK**, Norshamsiah **MD DIN**, Kah-hie **WONG**, Mimiwati **ZAHARI**

Purpose: To evaluate the long-term efficacy and safety of iStent trabecular micro-bypass implantation, performed as a standalone procedure or combined with phacoemulsification, in three tertiary centres in Malaysia.

Methods: This retrospective multicentre study included 90 eyes from 63 patients who underwent iStent implantation between January 2020 and November 2023 in three tertiary centres. Intraocular pressure (IOP), number of antiglaucoma medications, and postoperative outcomes were analysed. Surgical success was defined using World Glaucoma Association (WGA) criteria.

Results: After a mean duration of four years, IOP reduced from 18.4 ± 3.3 to 14.6 ± 2.8 mmHg ($p < 0.001$). In subgroup analysis, IOP decreased from 19.6 ± 4.0 to 16.2 ± 4.3 mmHg in the standalone group and from 18.0 ± 3.1 to 14.1 ± 2.1 mmHg in the combined group, with no significant between-group difference. Medications declined from 3.0 ± 1.0 to 2.0 ± 1.0 , with eyes on ≥ 3 drops decreasing from 67.8% to 26.3%. At four years, qualified success was 31.6% and complete success 10.5%. Safety outcomes were favourable, with 89% of eyes free of intraoperative complications, and postoperative events were mostly minor and self-limiting.

Conclusions: Standalone or combined iStent implantation achieved sustained IOP and medication reductions over four years, with a high safety margin. These findings support MIGS as an effective long-term treatment option for open-angle glaucoma in the Malaysian population

Abstract No.: 205944

Long-Term Update on Deep Sclerectomy vs. Combined Trabeculotomy Trabeculectomy in Cases With Congenital Glaucoma

First Author: Saleh **AL OBEIDAN**

Co-Author(s): Abdulaziz **AL AREFI**, Ehab **AL SIRHY**, Faisal **ALMOBARAK**, Abdulsalam **ALTURJOMAN**, Philippe **KESTELYN**, Ahmed **MOUSA**, Essam **OSMAN**

Purpose: To compare the efficacy and safety of Deep Sclerectomy Vs. Combined Trabeculotomy Trabeculectomy on the long-term.

Methods: A clinical trial design. Bilateral cases were recruited, where OD was conducted as DS and OS as CTT. Clinical indices were evaluated preoperatively and at 3, 6, 12, 24 months & the last follow-up visit. The change in clinical glaucoma indices was monitored, and two main comparisons were done: to compare pre- to post-intervention in each arm, as well as to compare findings from both arms.

Results: A total of 140 eyes of 70 patients were recruited. Subjects were in the mean (SD) age of 1.6 (2.3), months, 29 (41.4%) males, and 41 (58.6%) females. In both groups, the IOP was significantly reduced ($p < 0.0001$). The complete success rate was 49 (71%) in the DS eyes, while it was 35 (51.5%) in the CTT eyes ($p=0.016$). The overall success rate was 58 (82.9%) and 41 (58.6%) in the DS and CTT eyes, respectively ($p=0.001$). The intraoperative complication rate was 3

(4.3%) in the DS, while it was 17(24.3%) in the CTT eyes ($p=0.002$). The postoperative complication rate was 6 (8.6%) in the DS eyes, while it was 21(30.0%) in the CTT eyes ($p=0.005$).

Conclusions: Deep sclerectomy is superior to the combined trabeculotomy/trabeculectomy in terms of both efficacy and safety, as assessed by the increased success rate and the lower rate of complications.

Abstract No.: 205927

Long-Term Visual Acuity Outcomes of Deep Sclerectomy in Paediatric Glaucoma

First Author: Saleh **AL OBEIDAN**

Co-Author(s): Muhannad **ALKHALIFAH**, Ahmed **MOUSA**

Purpose: To evaluate the long-term outcomes of deep sclerectomy in paediatric glaucoma.

Methods: Retrospective review of all patients who underwent deep sclerectomy at King Abdulaziz University Hospital from 2001 to 2016. All patients had valid visual acuity testing. The preoperative indices, long-term visual acuity, and intraocular pressure outcomes were analyzed. The primary outcome of interest was the improvement in vision as well as the other glaucoma indices.

Results: A total of 83 eyes of 68 patients were included. The mean age of participants was 11.1, [5-25] years. The mean age at surgery was 5.9 months, and the mean follow-up period was 10.75 years. The visual acuity was $\geq 20/40$ in 56.6%, between 20/40 and 20/200 in 18.1%, and $\leq 20/200$ in 25.3% of the operated eyes. A complete success rate after one surgery was achieved in 53 eyes (63.86%), qualified success was achieved in 8 eyes (9.6%), while 22 eyes (26.5%) failed. Nine eyes (10.74%) had post-operative complications.

Conclusions: Deep sclerectomy is a reasonable option for paediatric glaucoma that can provide good long-term visual outcomes and IOP control with a lower risk of surgical complications.

Abstract No.: 202254

Malignant Glaucoma Versus Pupil Block: Comparative Case Series of Secondary Angle Closure Glaucoma After Cataract Surgery

First Author: Ardiella **YUNARD**

Co-Author(s): Virna Dwi Oktariana **ASRORY**, Yulinda Arty **LAKSMITA**, Astrianda **SURYONO**

Purpose: To highlight how similar clinical presentations of secondary angle closure glaucoma (ACG) after cataract surgery can mask distinct underlying mechanisms, leading to different therapeutic strategies.

Methods: We describe two postoperative cases of secondary ACG presented with similar complaints and clinical features following cataract surgery. Both patients underwent comprehensive ophthalmic

evaluation to confirm the underlying pathophysiology, thus individualized treatment strategies were implemented for each case.

Results: Both patients presented with eye pain, blurred vision, and nausea after cataract surgery. The first case occurred three weeks postoperatively, while the second case occurred five days postoperatively. Both patients had markedly elevated IOP (56 mmHg and 66 mmHg, respectively), decreased visual acuity (VA), ciliary injection, and microcystic corneal edema, and shallow anterior chamber (AC), raising suspicion of secondary ACG. Further evaluation, however, revealed different mechanisms. In Case 1, iris bombe and 360° posterior synechiae signifying a pupil block mechanism, while in Case 2, a uniformly flat AC indicating malignant glaucoma. The patients were managed in accordance with the underlying mechanisms: Case 1 underwent peripheral iridectomy, while Case 2 underwent iridozonulo-hyaloido-anterior vitrectomy. Both patients showed significant IOP reduction, VA improvement, and favorable clinical recovery following appropriate intervention.

Conclusions: Secondary ACG after cataract surgery may present with overlapping clinical symptoms and signs, yet arise from distinct mechanisms. Careful clinical evaluation is essential to differentiate pupillary block from malignant glaucoma, as each requires a different therapeutic approach. Early recognition of the underlying pathophysiology and tailored management are critical to achieve IOP control, visual recovery, and favorable outcomes.

Abstract No.: 200599

Micropulse Cyclophotocoagulation in Patients Affected by Primary Glaucoma: 2-Year Follow-Up

First Author: Michele **LANZA**

Co-Author(s): Francesco **ABBATE**, Francesca **AGRICOLA**, Salvatore **AMBROSIO**, Rosa **BOCCIA**, Teresa **CANGIANO**, Italo **FATTORE**, Luigi **SERRA**, Francesca **SIMONELLI**

Purpose: To evaluate the efficacy and safety of micropulse transscleral laser therapy (MP-TLT), in eyes affected by primary glaucoma.

Methods: In this study, 84 eyes of 53 patients, with a mean age of 67.14 ± 11.39 years, affected by progressive primary open-angle glaucoma (POAG) and primary angle closure glaucoma (PACG), were included. Before treatment, patients had a mean best visual acuity with correction of 0.26 ± 0.36 LogMAR, a mean intraocular pressure (IOP) of 22.32 ± 6.64 mmHg, and they assumed a mean of 2.96 ± 0.75 topical IOP-lowering molecules. Every MP-TLT treatment was performed under peribulbar anaesthesia. Patients were checked at day 1, week 1 and at 1, 3, 6, 12, 18 and 24 months of follow-up.

Results: No adverse reactions or vision loss were recorded in every eye treated. At 1-month follow-up, a significant ($p < 0.001$) reduction of mean IOP was detected both in POAG (-7.16 ± 2.92 mmHg) and PACG (-6.89 ± 3.12 mmHg) eyes that remained stable at the last follow-up. A significant ($p < 0.01$) reduction in the number of drugs was observed at 3 months follow-up, both in POAG (-0.59 ± 0.32) and PACG (-1.06 ± 0.42 mmHg) eyes that stayed stable during further follow-up.

Conclusions: Even if the data observed in this study need to be confirmed in further studies with a larger population and longer follow-up, the obtained results suggest that MP-TLT could be an effective and safe option to manage patients with progressive POAG and PACG.

Abstract No.: 202154

Micropulse Transscleral Diode Cyclophotocoagulation (MP-TSCPC Laser): An Effective Non-Surgical Non-Invasive Alternative for Treating Glaucoma

First Author: Dr M Afzal **BODLA**

Co-Author(s): Arfa **AHSAN**

Purpose: Glaucoma is a leading cause of blindness. Micro-pulse transscleral diode photocoagulation Laser (MP-TSCPC) is the latest non-invasive non-surgical laser procedure for the treatment of refractory open-angle glaucoma. This study aimed to assess the efficacy of MP-TSCPC in seeing eyes with the extent of lowering of intraocular pressure and reduction in the number of topical anti-glaucoma medications.

Methods: A prospective, interventional, non-comparative case series was conducted in the Eye Department, CMH Institute of Medical Sciences, and Bodla Eye Care, Multan, Pakistan, on 40 eyes of 40 patients with various types of glaucoma, ranging from mild to moderate and advanced. A paired-t sample test was used to analyze results. Best-corrected visual acuity, intraocular pressure (IOP), and number of anti-glaucoma medications were recorded before and after treatment. Success rates, number of treatment sessions, and postoperative complications were also recorded. The follow-up period was from Oct 2022 to November 2024.

Results: Out of 40 eyes of 40 patients average IOP reduction rate was 47.66 % in 24 weeks of follow up. A reduction in number of required topical medications was noted improving patient compliance. Visual acuity also remained stable in most of the cases. No serious complications were observed, mild inflammation was managed conservatively.

Conclusions: MP-TSCPC is safe and effective in lowering IOP in refractory glaucoma with different severity. Keeping in view of results we can safely recommend this procedure to be adopted in cases of

mild to moderate refractory POAG in seeing eyes, failed Trabeculectomy and eyes with cataractous changes.

Abstract No.: 200941

Navigating Challenges in Neovascular Glaucoma: Treatment Strategies for Refractory Cases

First Author: Divya KOTCHARLAKOTA

Co-Author(s): Gazella BRUCE

Purpose: A case of Neovascular glaucoma (NVG) post central retinal artery occlusion (CRAO) with central retinal vein occlusion (CRVO) and the challenges associated with its treatment.

Methods: A 34-year-old male presented with pain in the right eye (OD) and was diagnosed with OD Neovascular glaucoma, with a history of OD CRVO with CRAO due to uncontrolled hypertension. BCVA was OD 6/18 and 6/6 in the left eye (OS). 270-degree neovascularization of the iris (NVI) was noted at the pupillary margin in OD, and gonioscopy revealed 360° closed angles. Fundus OD had disc pallor with old PRP marks and no macular oedema with severely depressed visual fields. OS normal. Trabeculectomy with mitomycin C (MMC) was performed after a dose of intravitreal anti-VEGF. After 3 weeks, bleb had features of early failure and bleb needling with MMC was performed. IOP was controlled with the subsequent addition of topical AGM (Anti-Glaucoma Medications). Limited inferior 180° transscleral cyclophotocoagulation (TSCPC) was performed. 5 months later, multiple neovascularization of the disc (NVD) and NVI developed with FFA (Fundus Fluorescein Angiography) showing multiple capillary non-perfusion (CNP) areas. PRP augmentation with subsequent AGV was performed.

Results: BCVA is 6/24 OD 6/6 OS and is currently in the hypertensive phase of AGV with IOP being controlled with oral Acetazolamide.

Conclusions: First report in literature of the management of NVG post CRVO and CRAO. Recurring NVI/NVD are an indication for repeat FFA. This glaucoma is recalcitrant with the need for aggressive treatment.

Abstract No.: 208447

Neuroimaging Findings in Patients With Presumed Normal Tension Glaucoma: A Retrospective Review

First Author: Thomas Chi-ho LAM

Co-Author(s): Leo CHAN

Purpose: To evaluate the prevalence of pathologies identified on computed tomography (CT) scans, and atypical features identified on glaucoma investigations in patients with normal tension glaucoma (NTG).

Methods: A retrospective review of the results of CT scans in 1975 consecutive patients performed at a tertiary eye institute in Hong Kong from April 2021 to March 2024.

Results: Among the 1,975 patients, 977 (49.5%) had presumed NTG and underwent CT scans to exclude compressive optic neuropathy. In this group, 179 patients (18.3%) had positive findings. Notably, 9 patients (0.92%) had SOLs that directly compromised the optic pathway, including 5 retrobulbar masses, 2 suprasellar masses, and 2 cavernous sinus masses. Other significant findings included small vessel disease in 106 patients (10.8%) and incidental SOLs, such as meningiomas, subarachnoid cysts and osteomas, in 70 patients (7.16%). Among the 9 patients with SOLs impacting the optic pathway, their average intraocular pressure (IOP) at presentation was 15.9 mmHg (standard deviation 2.58). Clinical features that point against the diagnosis of glaucoma included atypical visual field (VF) loss, unilateral or highly asymmetrical presentation, lack of structural-function correlation, absence of neuroretinal rim thinning or presence of optic disc pallor, and drop in central visual acuity.

Conclusions: The low incidence of optic pathway SOLs in NTG suggests that neuroimaging should be prioritized for patients with clinical presentations atypical of glaucoma. Our study provides insights into how we can better utilize neuroimaging to optimize resources in resource-constrained area.

Abstract No.: 208444

Neurotrophic Keratopathy After Transcleral Cyclophotocoagulation – a Retrospective Cohort Study Assessing Its Incidence and Risk Factors

First Author: Thomas Chi-ho LAM

Co-Author(s): Venice LI, Annie LING, Emma RAN, Clement THAM, William WONG

Purpose: To determine the incidence and risk factors for corneal epithelial defects (ED), a manifestation of neurotrophic keratopathy, following micropulse cyclophotocoagulation (MPCPC) and slow coagulation G-probe (G-probe).

Methods: This retrospective cohort study examined consecutive patients aged 18 or older who received MPCPC and G-probe at a single tertiary eye center (Hong Kong Eye Hospital) from January 2023 to July 2024.

Results: A total of 368 eyes from 255 patients were included in the study. Of these, 310 eyes (84.2%) underwent MPCPC, while 58 eyes (15.8%) received G-probe. The mean pre-operative and post-operative (1 month) intraocular pressures were 27.43 mmHg and 17.51 mmHg. The overall incidence of epithelial defects (ED) was 10.1% (n=37), with no significant difference between MPCPC and G-probe (9.7% vs. 12.1%,

$p=0.58$). Among disease categories, NVG had the highest incidence of ED at 19.5%, significantly higher than other diagnoses ($p=0.007$). Persistent epithelial defects (≥ 2 weeks) occurred in 23 patients (62.2% of ED cases), with a mean healing time of 27.4 days. All affected eyes received topical antibiotics; 54.1% used bandage contact lenses, and 32.4% received antiviral treatment (acyclovir or ganciclovir). Two cases required amniotic membrane transplantation. Complications included one case of infectious keratitis, one case of endophthalmitis, and two cases of residual dense corneal scars. Univariate logistic regression identified male gender ($p=0.015$), diabetes mellitus (DM) ($p=0.014$), history of ED ($p<0.001$), neovascular glaucoma ($p=0.004$), and higher pre-operative IOP ($p=0.015$) as predictors of ED occurrence in the MPCPC group, while history of ED ($p=0.036$) was significant in the G-probe group. Multivariate analysis confirmed history of ED ($p<0.001$) and neovascular glaucoma ($p=0.045$) as significant predictors in the MPCPC group, further validated using generalized estimating equations to account for inter-eye correlation and repeat treatments (history of ED ($p<0.001$), neovascular glaucoma ($p=0.005$)).

Conclusions: Neurotrophic keratopathy is a notable complication after TSCPC. Pre-operative identification of risk factors—especially a history of ED and NVG—is crucial for prevention and proper management to avoid sight-threatening outcomes.

Abstract No.: 208493

Novel Phenotype of MYO7A-Associated Usher Syndrome: Pigmentary Glaucoma

First Author: Zhou LIN

Purpose: This study investigated a Chinese consanguineous family with Usher syndrome (USH) and identified a pathogenic MYO7A mutation. We also describe a novel ophthalmic phenotype: pigmentary glaucoma.

Methods: Clinical data were collected from the proband. Examinations included best-corrected visual acuity, intraocular pressure, fundus imaging, optical coherence tomography, and visual field testing. Genomic DNA was extracted from peripheral blood. Whole-exome sequencing (WES) was performed, and candidate variants were validated by Sanger sequencing.

Results: The proband was a 53-year-old female with congenital deafness, nyctalopia, and advanced retinitis pigmentosa. She developed pigmentary glaucoma with ocular pain, iris concavity, heavy trabecular pigmentation, and glaucomatous optic neuropathy. Intraocular pressure remained uncontrolled despite maximal topical therapy, requiring trabeculectomy. WES revealed a homozygous missense variant in MYO7A (c.3728C>T, p.Pro1243Leu), previously reported

as pathogenic in USH. No other glaucoma-related mutations were identified.

Conclusions: We report pigmentary glaucoma as a novel phenotype associated with MYO7A-related Usher syndrome. This expands the known genotype-phenotype spectrum and highlights the need for careful glaucoma surveillance in patients with USH.

Abstract No.: 207447

On the Edge of Vision: A Glaucoma Tale With Twists and Turns

First Author: Nagalekshmi GANESH

Purpose: To illustrate the management strategies of tackling the highs and lows of dealing with multifactorial, advanced glaucoma. This case highlights the role of an interdisciplinary and step-wise approach in solving complex cases and restoring vision.

Methods: This is a case of a 72-year-old lady with advanced POAG and tunnel vision. She had a stormy phase with NVG secondary to PDR and infective keratitis simultaneously in the right eye, and the vision dropped to only PL, while the left eye was rapidly progressing due to uncontrolled glaucoma on maximum topical antiglaucoma medications.

Results: She was first treated for infective keratitis, as surgery would not be possible in the presence of an active infection, keeping her on oral acetazolamide to control her IOP, and aggressive PRP for the bilateral PDR. With this, her vision in the right eye improved marginally. She then underwent trabeculectomy in the left eye, after which IOP in the left eye stabilized. IOP in the right eye at this juncture increased due to PAS, NVG, for which a subsequent AGV was performed. Post-op op she had hypopyon, which was also treated as sterile hypopyon with intense steroids, and finally, her vision in the right eye improved to 6/18 from PL after 4 months of a staged multidisciplinary approach.

Conclusions: In advanced and complex glaucoma cases, when treated with patience, perseverance, and a polydisciplinary staged approach, useful vision can be restored. Do not give up in such cases.

Abstract No.: 201533

Outcomes of XEN Gel Stent Versus Trabeculectomy in Advanced Glaucoma: A Multi-Center Retrospective Cohort Study

First Author: Xiao Chun LING

Co-Author(s): Henry Shen-lih CHEN, Yu-chun CHENG, Lan-hsin CHUANG, Chu-yen HUANG, Yung-sung LEE, Po-han YEH

Purpose: To compare the efficacy and safety of XEN Gel Stent implantation versus trabeculectomy in patients with advanced glaucoma and persistently elevated intraocular pressure (IOP) on maximal medical therapy.

Methods: We conducted a multi-center retrospective cohort study including advanced glaucoma patients who underwent either XEN Gel Stent implantation or trabeculectomy. Outcomes at 6 months postoperatively were analyzed. The primary outcome was reduction in mean IOP from baseline, and secondary outcomes included the frequency of bleb revisions (needling procedures), complication rates, and changes in visual field mean deviation on Humphrey visual field (HVF) testing. Paired t-tests and regression models were used to compare outcomes between the two groups.

Results: Both surgeries significantly lowered IOP at 6 months. The XEN group achieved ~40% IOP reduction (from 30.5 to 18.3 mmHg, $p < 0.05$), whereas the trabeculectomy group achieved ~55% reduction (from 29.8 to 13.4 mmHg, $p < 0.05$). This reflects a greater absolute mean IOP drop with trabeculectomy (-15.8 vs -12.4 mmHg, $p < 0.05$). The XEN group required more frequent bleb revisions (i.e. needling) by 6 months compared to the trabeculectomy group (30.1% vs 7.9%, $p < 0.05$). Fewer serious complications were observed in the XEN group compared to trabeculectomy. No cases of hypotony maculopathy or persistent bleb leak occurred in the XEN cohort. There was no statistically significant difference in visual field outcomes between the two groups at 6 months.

Conclusions: In advanced glaucoma patients with uncontrolled IOP, trabeculectomy achieved a greater reduction in IOP than the XEN Gel Stent, reaching lower absolute pressure levels. However, the minimally invasive XEN Gel Stent is a valuable alternative for patients at higher risk of complications or those who prioritize safety. Further long-term studies are needed to confirm the durability of XEN's outcomes and to refine patient selection criteria for each surgical approach.

Abstract No.: 202974

Pattern of Emergency and Inter-Departmental Ophthalmology Referral Calls and Their Impact on Postgraduate Training in a Tertiary Care Hospital in Central India

First Author: Saroj GUPTA

Co-Author(s): Samendra KARKHUR, Priti SINGH, Vidhya VERMA

Purpose: To evaluate the pattern of emergency referrals and interdepartmental ophthalmology referrals in a tertiary care hospital and assess their impact on postgraduate residents' training.

Methods: A hospital-based prospective observational study was conducted over 18 months. Data from 1061 ophthalmology referral calls were analyzed, including patient demographics, referring departments, reasons for referral, the timing of referral, ocular findings, interventions done, and postgraduate residents' competency in attending referral calls.

Results: The study included referrals for patients aged 4 months to 92 years (mean age 39.76 ± 22.26 years) with a predominance of male patients ($n = 650$, 61.26%). The majority of calls were received on weekdays ($n = 782$, 73.7%), particularly between 8:00 am and 4:00 pm ($n = 672$, 63.34%). Referrals were predominantly from the Medicine department ($n = 377$, 35.53%) and the Trauma and Emergency department ($n = 251$, 23.66%). The most common reason for referral was for aid in diagnosis ($n = 333$, 31.39%). No ocular abnormalities were found in 648 cases (61.07%). Among those with positive findings, the most frequent were ocular trauma ($n = 148$, 13.95%) and diabetic retinopathy ($n = 83$, 7.83%). Postgraduate residents managed 221 cases (62.96%) independently with only minor corrections during the first six months of the study period, and their clinical competency improved significantly over time, as reflected in the reduction of discrepancies from 130 cases (37.01%) to 30 cases (8.77%).

Conclusions: The study highlighted the pattern of referral calls in ophthalmology and the importance of referral calls in enhancing postgraduate residents' learning process.

Abstract No.: 202611

Pigment Dispersion Syndrome Misdiagnosed As Uveitis

First Author: Leyla ALI ALJASIM

Purpose: Pigment dispersion syndrome (PDS) is a rare condition where pigmentary cells are released from the iris pigmented epithelium, leading to deposition on intraocular structures. While it commonly causes pigmentary glaucoma, it may also mimic uveitis due to overlapping symptoms and signs, such as recurrent intermittent blurring of vision with anterior chamber pigment cells that can be mistaken for inflammatory cells

Methods: Case review.

Results: This case involves a patient who initially presented with symptoms suggestive of uveitis, with blurring of vision, +3 cells in the anterior chamber, and increased intraocular pressure (IOP), and was managed accordingly with steroids by a general ophthalmologist. Then he was referred to a glaucoma specialist as secondary uveitic glaucoma, where the patient was diagnosed as PDS, due to iris posterior bowing, pathognomonic iris atrophy, hyperpigmented trabecular meshwork, and the cells were pigment cells. The patient experienced recurrent episodes of anterior chamber pigment release, particularly after pupillary dilation for fundus examination and exercise, which caused blurring of vision to HM (drop from 20/40), mimicking recurrent uveitis attacks. The corticosteroid treatment worsened the patient's condition by elevating IOP and exacerbating glaucoma. The correct diagnosis of PDS was eventually made, the patient was

cleared from the uveitis side, and the management was adjusted accordingly. The patient has been stable for many years now.

Conclusions: This case highlights the diagnostic challenges of differentiating some cases of PDS from uveitis and emphasizes the importance of accurate diagnosis to avoid inappropriate treatment and complications.

Abstract No.: 207780

Polyunsaturated Fatty Acids and Glaucoma Risk: A Convergent Meta-Analysis and Mendelian Randomization Study

First Author: Li Jia **CHEN**

Co-Author(s): Yuelan **GAO**, Jianming **XU**, Jason **YAM**, Jun **YU**, Mingzhi **ZHANG**

Purpose: To unravel the association between plasma polyunsaturated fatty acids (PUFAs) levels and risk of glaucoma.

Methods: The meta-analysis protocol was preregistered (PROSPERO; CRD42024589427). Two reviewers independently screened eligible articles (up to December 2024) from five databases (PubMed, Cochrane, Embase, Web of Science, Science Direct) and assessed quality using Newcastle-Ottawa Scale (NOS). Case-control metabolomics studies quantifying plasma total PUFAs, Linoleic acid (LA), α -Linolenic acid (ALA), Eicosapentaenoic acid (EPA), and Docosahexaenoic acid (DHA) were included. Standardized mean differences (SMD) with 95% confidence intervals (CI) were pooled for continuous PUFA levels. Causal relationships were assessed using Mendelian Randomization (MR) analysis with genome-wide association data.

Results: Among a total of 835 studies, seven comprising 6,440 participants were included in the meta-analysis, which revealed significantly lower levels of total PUFAs (SMD: -0.17, 95% CI: -0.28 – -0.06, $P=0.003$), and DHA (SMD: -0.28, 95% CI: -0.41 – -0.16, $P<0.001$) in glaucoma cases compared to controls. Subgroup analysis revealed significantly lower DHA levels in both POAG (SMD: -0.20, 95% CI: -0.39 – -0.10, $P=0.04$) and PACG (SMD: -0.34, 95% CI: -0.51 – -0.18, $P<0.001$). MR analysis supported causal relationship by total PUFA (Glaucoma: OR=0.95, 95% CI: 0.90 – 0.99, $P=0.035$; POAG: OR=0.94, 95% CI: 0.89 – 0.98, $P=0.011$) and DHA (Glaucoma: OR=0.89, 95% CI: 0.83 – 0.95, $P=0.002$, POAG: OR=0.91, 95% CI: 0.84 – 0.98, $P=0.022$) for glaucoma and POAG. No causal effects were observed for PUFAs components on PACG.

Conclusions: Integrated evidence identified association of PUFAs against glaucoma. These findings highlight PUFAs as modifiable targets for potential glaucoma prevention and intervention.

Abstract No.: 210333

Potential Mechanisms of Intraocular Pressure Reduction Following Micropulse Transscleral Laser Therapy in Normotensive Rabbit Eyes

First Author: Yanyan **WU**

Co-Author(s): Yutong **CHE**, Yangfan **YANG**, Minbin **YU**, Xiaofeng **ZHU**

Purpose: To evaluate histological changes and potential mechanisms underlying mid-term intraocular pressure (IOP) reduction following Micropulse Transscleral Laser Therapy (mTLT) in normotensive rabbit eyes.

Methods: mTLT was performed on the right eyes of Chinchilla rabbits, with left eyes serving as controls. Laser power was set at 2000 mW with durations of 100 seconds and 160 seconds, respectively. IOP and uveoscleral outflow—assessed using a fluorescent tracer—were measured at 1 day, 1 week, 2 weeks, 1 month, and 3 months post-treatment. Morphological and protein expression changes in the ciliary body, outflow tissues, and sclera were also evaluated.

Results: Preoperative IOP was 12.3 ± 1.6 mmHg (100s group) and 12.5 ± 1.5 mmHg (160s group). IOP decreased significantly at 1 day post-mTLT to 6.9 ± 2.1 mmHg (100s group) and 6.3 ± 2.3 mmHg (160s group). By 3 months, IOP measured 10.1 ± 1.4 mmHg in the 100s group and 9.4 ± 1.9 mmHg in the 160s group. Ciliary processes exhibited acute inflammation and stromal edema in both groups at 1 day post-mTLT. Partial destruction of the ciliary epithelium in the pars plicata was observed in the 160s group. mTLT significantly increased uveoscleral outflow initially, which then gradually decreased, whereas the outflow facility remained unchanged. Na-K-ATPase expression in the pars plicata decreased after mTLT, while AQP1/AQP4 expression in the ciliary body increased in the early postoperative period. MMP1, collagen, and fibronectin were significantly upregulated in the ciliary body and sclera.

Conclusions: The IOP reduction following mTLT in pigmented rabbit eyes may be attributed to early increases in uveoscleral outflow associated with MMP1 upregulation and Na-K-ATPase downregulation. However, reactive fibrotic responses observed in the outflow tract and sclera may contribute to subsequent IOP rebound.

Abstract No.: 208213

Protective Effects of Epigallocatechin-3-Gallate on Trabecular Meshwork Cells From Endoplasmic Reticulum Stress

First Author: Linbin **ZHOU**

Co-Author(s): Wai Kit **CHU**, Jing Na **HE**, Jiahui **LI**, Chi Pui **PANG**, Chee Yung **THAM**

Purpose: Primary open-angle glaucoma (POAG) is the most common form of glaucoma, for which elevated intraocular pressure (IOP) is a major risk factor.

Dysfunctions of TM cells due to endoplasmic reticulum (ER) stress have been demonstrated to increase the resistance of aqueous humor (AH) outflow, resulting in IOP elevation. Epigallocatechin-3-gallate (EGCG) has been shown to alleviate ER stress in several diseases, while its potential roles in alleviating ER stress in TM cells have not been determined. This study investigates the mitigation of tunicamycin-induced ER stress in TM cells by EGCG.

Methods: The primary PTM cells isolated from porcine TM tissues were characterized by immunostaining. MTT assay was used to measure the cell viability of human TM (HTM) cells and primary porcine TM (PTM) cells. ER stress levels in both HTM cells and primary PTM cells were detected by quantitative real-time PCR.

Results: 40 μ M and 80 μ M EGCG pretreatment substantially promoted HTM cell survival under 3 μ M tunicamycin-induced ER stress (n=3-4, P<0.05). Pretreatment of 40 μ M EGCG markedly reduced the expression of ER stress markers ATF4, HSPA5, and DDIT3 evoked by 3 μ M tunicamycin in HTM cells (n=3-4, P<0.05). Furthermore, 40 μ M EGCG pretreatment significantly decreased the expressions of ATF4, HSPA5, and DDIT3 at the mRNA level induced by 3 μ M tunicamycin and improved cell viability in primary PTM cells (n=3-4, P<0.05).

Conclusions: EGCG can protect TM cells from ER stress.

Abstract No.: 200644

Pseudoexfoliative Glaucoma or Neovascular Glaucoma: a Dilemma

First Author: Drishti KAUSHAL

Co-Author(s): Arti GUPTA, Sakshi KAPILA

Purpose: To identify if the secondary glaucoma is due to pseudoexfoliation or retinal ischemia.

Methods: A single case of this kind was evaluated in a tertiary care centre of North India for glaucoma. A thorough ophthalmic examination was carried out following ophthalmic investigations, including perimetry and OCT, after which a diagnosis of secondary glaucoma was made, and treatment was started. The patient is still on follow-up.

Results: A diagnosis of pseudoexfoliative glaucoma of the left eye was more likely, as there is no NVA on gonioscopy. PXF may be an independent risk factor of NVI; however, the possibility of CRVO-induced NVI cannot be ruled out.

Conclusions: A diagnosis of pseudoexfoliative glaucoma of the left eye is more likely, as there is no NVA on gonioscopy. PXF may be an independent risk factor of NVI; however, the possibility of CRVO-induced NVI cannot be ruled out. There are studies supporting that pseudoexfoliation may be a cause for neovascularisation, but in our case, we have evidence

of retinal ischemia that supports the subsequent neovascularisation.

Abstract No.: 203170

Public Perception of Glaucoma Screening

First Author: Kah Long AW

Co-Author(s): Andrew TATHAM, Sarah VEZ

Purpose: Primary open-angle glaucoma (POAG) is a major cause of irreversible blindness, yet more than half of cases remain undiagnosed, especially in low-resource settings. Population-wide glaucoma screening is not currently recommended in the United Kingdom due to low prevalence and the risk of false positives, but advances in artificial intelligence (AI) and genomics may enable more targeted strategies. The effectiveness of such programs depends on public engagement.

Methods: This systematic review, registered with PROSPERO (CRD42025626696) and conducted in accordance with PRISMA guidelines, examined factors influencing participation in glaucoma screening.

Results: Searches of CENTRAL, MEDLINE, and Embase identified 6,501 articles, of which seven studies (n=4,079) met inclusion criteria. Studies from the United States, Thailand, India, Poland, and the United Kingdom reported that participation was improved by personalised nurse-led counselling, direct invitations, reminder phone calls, and community-based outreach. Barriers included poor knowledge of glaucoma, low perceived risk, logistical and financial obstacles, cultural attitudes, and socioeconomic deprivation. Uptake was higher among older individuals, those with higher educational attainment, and first-degree relatives of glaucoma patients, particularly when family members had experienced vision loss. Nurse-led interventions significantly increased attendance, while neighbourhood-level deprivation strongly predicted non-attendance.

Conclusions: No included study directly assessed public attitudes to AI- or genomics-based screening; however, evidence suggests that trust, education, and accessibility will be essential for their future implementation. Effective strategies should therefore combine technological advances with culturally sensitive and community-engaged approaches to enhance equity and maximise impact.

Abstract No.: 208418

Rapamycin Removes Damaged Mitochondria and Protects Human Trabecular Meshwork (TM-1) Cells from Chronic Oxidative Stress

First Author: Jing Na HE

Co-Author(s): Wai Kit CHU, Chi Pui PANG, Clement C. THAM

Purpose: To study autophagy in response to chronic oxidative stress in TM cells

Methods: We induced chronic oxidative stress in human trabecular meshwork (TM-1) cells with 1 μ M rotenone and investigated the levels of reactive oxygen species (ROS), autophagy, and mitochondrial functions. Protective effects of rapamycin, an inducer of autophagy, were also investigated.

Results: Our data indicated that rotenone significantly increased oxidative stress, but not autophagy, in TM-1 cells. Rapamycin at 10 nM effectively suppressed the rotenone-induced cell apoptosis, as well as the ROS elevation. The protective effects of rapamycin could be associated to the induction of autophagy and removal of damaged mitochondria in TM-1 cells.

Conclusions: Our results suggest autophagy has important roles in protecting TM-1 cells from oxidative stress, which could be further developed into a novel treatment to POAG.

Abstract No.: 202109

Rapid Progression of Steroid-Induced Cataract: A Case Report

First Author: Yong **GIN YEN**

Co-Author(s): Awis Qarni **BIN FADIL**, Chew **CHANG FENG**

Purpose: To highlight a rare case of rapid progression of steroid-induced cataract culminating in phacomorphic glaucoma

Methods: Case report

Results: A 22-year-old female with underlying atopic eczema, on long-term oral and topical corticosteroids, was referred for gradual, progressive, painless blurring of vision over 2 months. Initial examination revealed best-corrected visual acuity (VA) of 6/18 (pinhole 6/9) in the right eye (RE) and 6/12 (pinhole 6/9) in the left eye (LE), with normal intraocular pressures (IOP) bilaterally. Periorbital examination showed multiple erythematous, scaly plaques consistent with eczema. Anterior segments were unremarkable, except for minimal anterior and posterior subcapsular cataracts in both eyes. One week later, the patient returned with worsening blurring in the RE (VA 3/60, pinhole 4/60). Examination revealed rapid progression to intumescent white cataract, which subsequently led to acute angle closure the following day with IOP of 50 mmHg. The acute attack was promptly managed and early lens extraction was performed, with satisfactory postoperative outcome

Conclusions: Although steroid-induced cataracts are generally considered to develop gradually, this case demonstrates that rapid progression can occur, with potential sight-threatening complications such as phacomorphic glaucoma. Clinicians should maintain high vigilance when monitoring young patients on chronic corticosteroid therapy, particularly when even minimal lens changes are present. Early recognition

and timely surgical intervention are crucial to prevent irreversible visual loss.

Abstract No.: 200308

Real-World Data Analysis of CPAP Usage and Leakage on Dry Eye Disease and Glaucoma in Patients With Obstructive Sleep Apnea Syndrome: A Cross-Sectional Study

First Author: Yun-hsiang **YANG**

Co-Author(s): Elizabeth P. **SHEN**

Purpose: To investigate the association between continuous positive airway pressure (CPAP) usage, mask leakage, and the prevalence or severity of dry eye disease (DED) and glaucoma in patients with obstructive sleep apnea (OSA).

Methods: This cross-sectional study included 57 adults with polysomnography-confirmed OSA (2010–2023) at Taipei Tzu Chi Hospital, grouped into CPAP users (n=40) and non-users (n=17). Ocular assessments included tear film break-up time, Schirmer's test, Oxford staining, meibomian gland evaluation, intraocular pressure (IOP), cup-to-disc (C/D) ratio, and retinal nerve fiber layer thickness. CPAP usage and leakage data were recorded. Chi-square, t-tests, and regression analyses evaluated associations.

Results: CPAP users showed trends toward higher glaucoma (HR=0.83) and DED risk (HR=0.69), but differences were not significant. CPAP+ patients had worse OSA severity (prolonged N1 sleep, p=0.0005; higher AHI, p=0.0001). CPAP leakage (mean=25.84 L/min, 95% exceeding 24 L/min) was linked to lower Schirmer test values (p=0.0307) and higher C/D ratio (p=0.0402).

Conclusions: CPAP leakage is associated with worsened dry eye and potential optic nerve changes in OSA patients. Optimizing mask fit may reduce ocular complications, as OSA-related hypoxia and IOP fluctuations may contribute to long-term eye risks.

Abstract No.: 202814

Refractive Error After Phacoemulsification Combined With Intraocular Lens Implantation in Primary Angle-Closure Glaucoma: A Multifactorial Analysis of Biometric Parameters and Surgical Strategies

First Author: Yong **LIU**

Co-Author(s): Jiantao **WANG**

Purpose: This study aims to explore the factors influencing refractive error following phacoemulsification combined with intraocular lens implantation (PE+IOL) in patients with primary angle-closure glaucoma (PACG), providing a theoretical basis for preoperative consultation and IOL power selection in clinical practice.

Methods: A retrospective analysis was conducted on 404 PACG patients from Shenzhen Eye Hospital between 2019 and 2024. Preoperative ocular biometric parameters and combined surgical approaches were evaluated using Spearman correlation, multinomial logistic regression, and receiver operating characteristic (ROC) curve analysis.

Results: Axial length (AL), lens thickness (LT), and white-to-white distance (WTW) were key predictive factors for prediction error and postoperative refractive outcomes. AL > 22.56 mm (AUC = 0.692) and LT > 5.055 mm (AUC = 0.633) increased the risk of myopic shift (MS), while AL < 22.25 mm (AUC = 0.604) and WTW < 11.55 mm (OR = 2.209, P = 0.001) were associated with hyperopic shift (HS). The axial length/corneal radius (AL/CR) ratio > 2.986 further indicated a higher risk of MS (AUC = 0.639) postoperatively. Among patients who underwent PE+IOL combined with a capsular tension ring, the proportion of HS was significantly higher (Z value = +2.95).

Conclusions: The unique anatomical characteristics of PACG patients are key contributors to postoperative refractive instability. Preoperative assessment for PE+IOL surgery should comprehensively evaluate AL, LT, WTW, and AL/CR ratio. When combined with other surgical approaches to control intraocular pressure, IOL power should be adjusted according to these thresholds to ensure postoperative refractive stability.

Abstract No.: 205203

Relationship Among Standard Vision Tests, Quality of Life, and Ability to Perform Daily Activities in Glaucoma Patients

First Author: Neethu **PRADEEP**

Co-Author(s): Smita **NARAYAN**

Purpose: 1. To assess the Quality of Life by subjective (Visual Functioning Questionnaire) and objective (ADREV) tests. 2. To find out the relationship between glaucoma stages and Quality of Life (QoL).

Methods: A cross-sectional study of 50 glaucoma patients was done. Best corrected visual acuity, IOP, slit lamp and fundus examination, gonioscopy, and visual field examination were carried out. Patients were categorised as early, moderate, and advanced on the basis of the disc damage likelihood scale (DDLS) and Modified Hodapp-Parrish-Anderson criteria. Quality of life was assessed subjectively using the Visual Functioning Questionnaire-25 (VFQ-25) and objectively by the Assessment of Disability Related to Vision (ADREV test) by assessing the ability to perform activities of daily living. Contrast sensitivity and stereopsis were the other parameters assessed.

Results: Of the 50 patients, 25 (50%) had POAG, 23 (46%) had PACG, and 2 had secondary glaucoma. Based on DDLS and Anderson criteria, there were 15(30%) early, 19 (38%) moderate and 16(32%) advanced

glaucoma cases. Mean ADREV/ VFQ scores were early 58.5/82.5, moderate 55.5/75.4, and advanced 48.4/54.5. In ADREV tasks, the lowest score was for motion detection (mean-5.2) and the maximum score was for ambulation (6.2). Advanced glaucoma patients have difficulty in detecting motion(4.6), recognising street signs. Contrast sensitivity also reduced with glaucoma progression.

Conclusions: ADREV scores correlate significantly with VFQ scores in all glaucoma categories. With respect to Quality of Life, patients faced difficulty in performing fine tasks. However, even advanced glaucoma cases were able to carry out their daily activities without much help. It was seen that as glaucoma progresses, stereopsis and contrast sensitivity decline rapidly.

Abstract No.: 201352

Repair of Exposed Glaucoma Drainage Device Tube in Uveitic Glaucoma With Autologous Conjunctival Graft

First Author: Rika **AGUSTANTI**

Purpose: To report a case of late tube exposure following glaucoma drainage device (GDD) implantation in a patient with uveitic glaucoma, and its surgical repair using an autologous conjunctival graft.

Methods: Case report of a 61-year-old woman with uveitic glaucoma in the left eye who underwent non-valved GDD implantation three years earlier. She presented with ocular pain after eye rubbing one week prior. Ophthalmic examination included visual acuity and intraocular pressure (IOP) measurement.

Results: Best corrected visual acuity was 6/15 in the right eye and hand movement in the left. IOP in the left eye was elevated, and tube exposure was noted in the superotemporal quadrant. Surgical repair was performed using a pericardial patch graft over the exposed tube, covered by an autologous conjunctival graft. The postoperative course was stable, with good graft integration and no recurrence of exposure.

Conclusions: Tube exposure is a potentially sight-threatening complication of GDD surgery and may occur even years after implantation. Lifelong monitoring and early surgical repair with adequate tissue reinforcement are essential to preserve ocular integrity and prevent severe complications.

Abstract No.: 203047

Retinal Nerve Fiber Layer Thickness Correlates With Regional Brain Volume in Psychiatric Disorders

First Author: Chi-hsin **HSU**

Purpose: To sort out the relationships between retinal nerve fiber layer (RNFL) thickness and specific brain region volume in patients with psychiatric disorders.

Methods: Participants with bipolar disorder were recruited in the study. All individuals underwent whole-brain MRI as well as spectral-domain OCT. The RNFL was segmented into 4 quadrants, and the average thickness for each quadrant in both eyes was automatically computed. The mean value of the RNFL thickness in both eyes of every participant was calculated for analysis. To account for inter-individual variability in overall brain size, the volume of each brain region was normalized to the individual's total intracranial volume, yielding region-specific volume proportions.

Results: A total of 30 patients with were enrolled. The RNFL had significantly positive correlations with the volumes of the bilateral insula, hippocampus, fusiform, left anterior cingulate cortex, and left amygdala. After adjustment for the effects of BMI and age, multiple regression analyses showed that thinner average RNFL remained associated with reduction of the total insula, anterior cingulum, and hippocampus volumes; the left anterior cingulum and left hippocampus volumes; and the volumes of insula in each hemisphere.

Conclusions: The present study suggests a potential link between glaucoma and psychiatric disorder through a biological association between RNFL thickness and region-specific structural alterations in the brains of individuals with bipolar disorder. The observed inconsistencies in gray matter alterations within the amygdala, hippocampus, and thalamus—despite the well-documented involvement of these regions in emotional processing—may be attributable to the clinical heterogeneity characteristic in patients of psychiatric disorders.

Abstract No.: 201678

SUOER SW-500 Rebound Tonometer Versus Goldmann Applanation Tonometer: Agreement and Impact of Corneal Thickness

First Author: Tengku Nuramiriah Fatishah **TENGKU AMIR**

Co-Author(s): Norlina **BINTI MOHD RAMLI**, Noor Sarah Khor **BINTI MUHAMMAD AZMI KHOR**

Purpose: To evaluate the agreement of intraocular pressure (IOP) taken with SUOER SW-500 rebound tonometer (RBT) and Goldmann applanation tonometer (GAT), and to compare their correlation with central corneal thickness (CCT).

Methods: This prospective, cross-sectional study included 334 eyes from 169 patients from glaucoma and general ophthalmology clinics. IOP was measured using both devices in sequence (RBT followed by GAT). Agreement was analyzed using the Bland–Altman plots, and correlation was assessed using Pearson's coefficient. The influence of CCT was evaluated by linear regression analysis.

Results: The mean age was 67.5 years; 52.1% of participants were male. Mean IOP was 15.70 ± 3.84 mmHg with RBT and 15.02 ± 4.58 mmHg with GAT. RBT consistently overestimated IOP by 0.69 mmHg across all CCT groups. A strong correlation was found between devices ($r = 0.77$, $p < 0.01$). IOP increased with CCT for both tonometers. In eyes with CCT $> 560 \mu\text{m}$, mean IOP was 17.02 ± 5.33 mmHg (RBT) and 16.35 ± 5.79 mmHg (GAT)—the highest among all groups. Both devices showed significant correlation with CCT ($p < 0.01$).

Conclusions: RBT and GAT show strong correlation, though RBT systematically overestimates IOP regardless of CCT. GAT remains the gold standard; RBT is a useful alternative in specific settings, though values should be interpreted cautiously, especially in thick corneas.

Abstract No.: 202570

Safety and Efficacy of Goniotomy following Failed Surgery for Glaucoma

First Author: Jiaxuan **JIANG**

Co-Author(s): Fengbin **LIN**, Xiulan **ZHANG**

Purpose: To evaluate the efficacy and safety of GT in patients with prior failed surgery for glaucoma.

Methods: A prospective, observational multicentered study was performed for patients who underwent GT with prior single or multiple surgery for glaucoma. Outcome measures included intraocular pressure (IOP) change, best-corrected visual acuity change, ocular hypotensive medication use, and occurrence of adverse events through 12 months. Complete success was defined as a postoperative IOP within 6–18 mmHg and a 20% reduction from baseline without ocular hypotensive medications. Qualified success was the same as the definition of complete success, except for postoperative use of medication. Logistic regression models were used to investigate the potential factors for surgical success.

Results: A total of 38 eyes of 34 patients were included. Twenty-three eyes had only 1 prior surgery, 13 eyes had 2 prior surgeries, 1 eye had 3 prior surgeries, and 1 eye had 4 prior surgeries. At month 12, there was complete success in 42.1% of the eyes and qualified success in 78.9% of the eyes. Preoperatively, the mean IOP was 29.4 ± 6.9 mmHg, and the median number of glaucoma medications used was 3.0 (2.0, 4.0); this decreased to 16.7 ± 3.6 mmHg (43.2% reduction; $P < 0.001$) and 2.0 (0.0, 3.0) ($P < 0.001$) at month 12, respectively. The most common complications included hyphema (13.2%), IOP spike (7.9%), and corneal edema (5.2%). Older age significantly contributed to surgical success.

Conclusions: GT seems to be a safe and effective procedure for patients with prior failed surgery for glaucoma.

Abstract No.: 200598

Safety and Efficacy of a 63 μ m Gel Stent Implant in Pseudophakic Patients Affected by Open Angle Glaucoma: 1 Year Follow Up

First Author: Rosa **BOCCIA**

Co-Author(s): Francesco **ABBATE**, Francesca **AGRICOLA**, Teresa **CANGIANO**, Italo **FATTORE**, Michele **LANZA**, Luigi **SERRA**, Francesca **SIMONELLI**

Purpose: To evaluate the safety and efficacy of a 63 μ m gel stent implant in pseudophakic patients affected by primary open-angle glaucoma (POAG) after 1 year of surgery.

Methods: In this retrospective study, 13 pseudophakic eyes of 11 patients (mean age: 70.81 ± 11.63 years) affected by glaucoma, not compensated with only medical therapy, were included. Every patient underwent a complete eye visit before surgery and at 1, 2, 6, 12 months follow up. Only standalone procedures with an ab-interno approach were included, aiming to reduce bias in evaluating the intraocular pressure (IOP) lowering effect of the device. Baseline mean best corrected visual acuity (BCVA) was 0.32 ± 0.46 logMAR, IOP was 22.08 ± 3.17 mmHg, and topical IOP-lowering drugs assumed were 3.23 ± 0.61 , and 4 patients were assuming oral acetazolamide (OA) too.

Results: After 1 month of surgery, a significant ($p < 0.01$) decrease in IOP (mean: 11.57 ± 2.23 mmHg) was observed without topical and oral therapy. After 1 year, IOP was stable (mean 10.81 ± 1.64 mmHg) without both topical and oral therapy; 2 eyes had undergone manual subconjunctival mobilization of the device, no visual acuity loss, and no other complications were detected.

Conclusions: Even if data of this study need to be confirmed in further ones with larger population and longer follow up, the observed results suggest that the standalone, ab-interno 63 μ m gel stent implant is a safe procedure and it is able to provide a consistent IOP lowering effect on eyes affected by POAG.

Abstract No.: 202356

Secondary Glaucoma With Calcium Crystal Precipitation in the Anterior Chamber of a Long-Term Hemodialysis Patient

First Author: Muneyuki **INOSAKA**

Co-Author(s): Takashi **MATSUSHIMA**, Yoshihiro **NAKAGAWA**, Takahiro **SUZUKI**, Yuji **YOSHIKAWA**

Purpose: To report a rare case of secondary glaucoma associated with calcium crystal precipitation in the anterior chamber in a patient undergoing long-term hemodialysis with renal hyperparathyroidism.

Methods: A 72-year-old man with a history of hemodialysis for diabetic nephropathy presented with uncontrolled intraocular pressure (IOP) in his only functional eye, as the right eye had been blinded by

diabetic retinopathy. At presentation, best-corrected visual acuity in the left eye was 20/32, and IOP was 32 mmHg without anterior chamber inflammation. Gonioscopy revealed scattered whitish crystalline deposits in the inferior angle. Surgical removal of the crystals combined with Preserflo® MicroShunt implantation was performed. The excised material and aqueous humor underwent compositional analysis.

Results: Elemental analysis confirmed calcium phosphate crystals. Laboratory testing demonstrated elevated parathyroid hormone (117 pg/mL), consistent with renal hyperparathyroidism. Following surgery, IOP was successfully reduced and remained stable without recurrence of inflammation or severe complications.

Conclusions: Calcium crystal precipitation in the anterior chamber has been described in patients with renal hyperparathyroidism. In this case, such crystals were associated with secondary glaucoma in a long-term dialysis patient. Surgical removal combined with microshunt implantation effectively controlled IOP. Recognition of this rare presentation may aid in the diagnosis and management of refractory glaucoma in patients with chronic kidney disease.

Abstract No.: 205821

Short-Term Clinical Outcomes of Phacoemulsification Combined With Goniotomy Versus Phacoemulsification Alone for Primary Angle Closure Disease

First Author: Jose Maria **MARTINEZ**

Co-Author(s): John Mark **DE LEON**, James Michael **SUAREZ**, Daryle Jason **YU**

Purpose: To compare the short-term clinical outcomes of Phacoemulsification (PHACO) versus Phacoemulsification with Goniotomy (PHACO-GT) in the treatment of Primary Angle Closure Disease (PACD).

Methods: This is a retrospective cohort study on outcomes of consecutive surgeries performed on PACD patients using standard techniques. Visual acuity, intraocular pressure, and number of glaucoma medications were collected pre-operatively and 1 month, 3 months, and 6 months post-operatively. Cases were matched with propensity scoring according to pertinent demographic characteristics.

Results: After matching, 86 surgeries (PHACO $n=59$, PHACO-GT $n=27$) were analyzed. Mean pre-operative IOP was 29.25 ± 13.56 mmHg for PHACO and 23.26 ± 11.98 mmHg for PHACO-GT. Mean IOP at 1 month, 3 months, and 6 months post-operatively significantly decreased from baseline at all time points to 15.73 ± 6.15 mmHg, 15.00 ± 6.09 mmHg, and 14.33 ± 5.18 mmHg for PHACO ($P < 0.001$) and 14.41 ± 5.47 mmHg, 12.93 ± 2.87 mmHg, and 14.37 ± 3.14 mmHg for PHACO-GT ($P < 0.001$). The number of glaucoma medications significantly decreased from 2.46 ± 1.02 for PHACO and 2.57 ± 0.94 for PHACO-GT pre-

operatively to 0.42 ± 0.91 for PHACO ($P < 0.001$) and 0.37 ± 0.84 for PHACO-GT ($P < 0.001$) after 6 months. The most common complications observed were corneal edema ($n=3$) for PHACO and transient hyphema ($n=7$) for PHACO-GT. There were no significant differences in visual acuity, IOP, and the number of glaucoma medications at all post-operative time points between the two groups. Mean survival time was not significantly different at 19.46 ± 1.07 weeks for PHACO and 20.89 ± 1.30 weeks for PHACO-GT. Cumulative success rates at 6 months were 71.20 % for PHACO and 81.50 % for PHACO-GT.

Conclusions: The efficacy of PHACO alone is similar to PHACO-GT in Primary Angle Closure Disease. There were no significant safety issues in performing angle surgery in addition to phacoemulsification.

Abstract No.: 203801

Silicone Oil, the Culprit Who Loves To Pressurize

First Author: Devina Bunga **MAWARNI**

Co-Author(s): Yulinda Arty **LAKSMITA**

Purpose: To show how a challenging case of silicone oil-induced glaucoma can be complicated and require long-term management.

Methods: A case report. A 19-year-old male with traumatic retinal detachment of the right eye (RE) underwent vitrectomy with silicone oil (SO) tamponade. Despite SO evacuation, intraocular pressure (IOP) was very high (46 mmHg). Visual acuity was 6/20, the lens was hazy, and the cup-to-disc ratio was 0.9. Gonioscopically, the superior anterior chamber angle was obscured by SO, while the other quadrants were open. The left eye (LE) was normal, with the IOP of 17 mmHg. He was diagnosed with SO-induced glaucoma and posterior subcapsular cataract of the RE. Ahmed glaucoma valve implantation was chosen to lower the IOP while minimizing the risk of postoperative hypotony.

Results: Post-op day 1, RE was 5 mmHg with a deep anterior chamber and an attached retina. After 1 week, the RE IOP was 18 mmHg, but the LE IOP increased to 37 mmHg, suspected to be due to steroid. Four months later, IOP rose and the bleb was high, thus he underwent aspiration and subconjunctival 5-fluorouracil (5FU). The patient received 3x repeated flushing with 5FU injections over 7 months, resulting in well-controlled IOP (10-16 mmHg).

Conclusions: SO can lead to secondary, often refractory glaucoma because residual emulsified droplets are difficult to eliminate and chronically obstruct outflow. With meticulous monitoring and multiple treatment modalities, intraocular pressure can be controlled. Glaucoma drainage device (GDD) implantation, commonly recommended for vitrectomized-eyes,

offers favorable outcomes, though it presents its own challenges.

Abstract No.: 206243

Standard "1 Port" vs Novel 2 Port "Wide" ELIOS Excimer Laser Trabecular MIGS for Glaucoma

First Author: Adnan **ADBUL-AZIZ**

Co-Author(s): Dan **LINDFIELD**, Claudia **QUIJANO**

Purpose: ELIOS is an MIGS procedure that uses an excimer laser to create 10 channels (210um) through the trabecular meshwork. Classically, this is performed through a single temporally-placed corneal incision, and 10 trabecular channels are created in the nasal quadrant. We have evolved the procedure to be performed through two corneal incisions. 5 shots through the main temporal incision aimed at the nasal angle, plus 5 shots delivered through the superior phaco sideport incision, allowing 5 channels to be created inferiorly. This doubles the area of treatment. We postulate that this «wide» treatment allows greater access to collector channels.

Methods: Retrospective analysis of the first 138 procedures performed in the UK of Phaco plus ELIOS. The data was collected by 4 UK centres. 3 centres performed standard 1-port treatment, 1 centre (Guildford, UK) performed 19 cases with the «wide» 2-port protocol. All eyes had 12 12-month follow-up.

Results: 1 Port: Baseline 18.6mmHg on 1.78 meds 12 months: 14.37mmHg on 0.95 meds 47% patients achieved eyedrop freedom (0 medications) 2 port «wide» Baseline: 18.7mmHg on 2.10 meds 12 months: 14.7mmHg on 0.70 meds 61% patients achieved eyedrop freedom (0 medications) 0% of patients required an increase in glaucoma medication at any timepoint in the «wide» protocol.

Conclusions: Both groups achieved similar IOP outcomes, 2-port «wide» protocol appears to show: - increased ability to achieve eye drop freedom at 12months - greater reduction in mean medication usage at 12months «Wide» protocol shows promise but requires prospective data with larger cohort and greater baseline homogeneity for true validation.

Abstract No.: 207427

Statin Therapy and Glaucoma: Hidden Risk in Hyperlipidemic Eyes

First Author: Rohith Reddy **YEDDULA VENKATA**

Co-Author(s): Sreedeeep **AMARAVADI**, Rahul M, Sanjana **MARIAM JIJI VARGHESE**, Sasankadhar Reddy **MUDUMALA**, Nishitha **NARUKULLA**

Purpose: To investigate the relationship between statin therapy and glaucoma prevalence in hyperlipidemic patients and determine whether treatment duration

independently predicts structural and functional optic nerve damage.

Methods: This hospital-based cross-sectional study included 200 hyperlipidemic adults (mean age 57.2 ± 8.6 years), categorized into statin users and non-users. Detailed history of statin type, dose, and duration was obtained. All participants underwent comprehensive ophthalmic evaluation including Goldmann applanation tonometry, dilated fundus examination, spectral-domain OCT for RNFL thickness, and 24-2 Humphrey visual field testing. Multivariate logistic regression was used to adjust for age, sex, systemic hypertension, and diabetes.

Results: Glaucoma prevalence was significantly higher in statin users compared with non-users (33.5% vs. 9.5%, $p < 0.001$). Long-term statin therapy (>3 years) conferred the highest risk (58.0%, $p < 0.001$). Mean IOP was elevated among users (17.9 ± 3.0 mmHg vs. 15.5 ± 2.6 mmHg, $p < 0.001$), with significant superior and inferior RNFL thinning and corresponding visual field defects. Logistic regression confirmed long-term statin use as an independent predictor of glaucoma (OR 4.1; 95% CI: 2.0–8.3; $p < 0.001$).

Conclusions: Chronic statin therapy is independently associated with increased risk of glaucomatous optic neuropathy in hyperlipidemic patients. Routine glaucoma screening, OCT-based RNFL monitoring, and early intervention should be considered integral to the care of long-term statin users. Large-scale prospective studies are warranted to clarify causal mechanisms and explore risk variation across statin subtypes and dosages.

Abstract No.: 206546

Sturge Weber Syndrome Management: Clinical Profile and Outcomes of Combined Trabeculectomy and Trabeculotomy Surgery

First Author: Shivam GUPTA

Co-Author(s): Devendra MAHESHWARI, Nimrita NAGDEV, Madhavi PILLAI

Purpose: To study the clinical profile of glaucoma in Sturge-Weber syndrome and outcomes of combined Trabeculectomy and Trabeculotomy surgery.

Methods: Observational study. To study the management and clinical course of Sturge-Weber patients, the clinical profile and Glaucoma management (surgical/medical) were assessed for 3 years.

Results: Twenty-six patients (26 eyes), of which 65% (17) were Female & 34% (9) were male, with a presenting age from 32 days to 68 years. 26.9% (8) had epilepsy. 3 patients had Ocular melanosis naevi. 65.3% (17) left, 30.7% (8) Right & 1 patient both side face involvement. Blood in Schelms Canal in (19.2%) (5), and Choroidal Hemangioma in 42.3% (11), 88.4% (23) had Glaucoma. 34.7% (8) medically managed with mean 2 AGM (18.5mmHg). 65.2% (15) were

surgically managed & majority underwent Combined Trabeculectomy + Trabeculectomy (14). The mean preop IOP was 31.1 mmHg, which reduced to 14, 11.2, 10.1 & 9.5 mmHg at 2 weeks, 1 month, 3 months, and 6 months, respectively. The number of AGMs has been reduced from 1 to 0.5.

Conclusions: Glaucoma in SWS patients requires Surgical intervention with combined Trabeculectomy and Trabeculotomy, giving promising surgical results

Abstract No.: 206292

Sturge-Weber Syndrome With Iridocorneal Endothelial Syndrome: Unravelling a Rare Ophthalmic Overlap

First Author: Srinidhi N

Co-Author(s): Shreya BHADANI, Manisha CHOUDHARY, Shrutakirti PARIDA, Nibedita SAHOO, Aanchal SINGHAL

Purpose: To describe a rare case of coexisting Sturge-Weber syndrome (SWS) and Iridocorneal endothelial syndrome (ICE) with secondary angle closure glaucoma.

Methods: A 52-year-old female presented with diminished vision associated with pain and redness of RE for one week and bluish pigmentation over the right side of the face since birth, progressed recently. Best corrected visual acuity in right eye (RE)- 6/60, N36; left eye (LE)- 6/6p, N6. Intraocular pressure (IOP) by Goldmann applanation tonometry (GAT) was 30mmHg in RE and 10mmHg in LE. There was hyperpigmentation of skin over the right side of the forehead, eyelid and malar area. Ocular evaluation of RE showed pigmentation of the conjunctiva and sclera with corkscrew episcleral vessels, diffuse corneal edema, shallow anterior chamber, iris atrophy with corectopia. Gonioscopy of RE showed closed angles in all quadrants. Anterior segment of the LE was within normal limits, open angles, and an unremarkable fundus.

Results: Characteristic features of cutaneous and ocular pigmentation, episcleral vascular congestion, suggest Sturge-Weber syndrome. In addition, corneal endothelial abnormalities, iris atrophy, peripheral anterior synechiae, and corectopia with secondary glaucoma indicate ICE syndrome. Overlapping features indicate a complex aetiology leading to secondary glaucoma in the RE. The patient was managed with medical therapy and may need future glaucoma and corneal surgical interventions.

Conclusions: To the best of our knowledge, this is the first reported case of coexisting SWS and ICE syndrome. Overlapping mechanisms of such dual pathologies may exacerbate ocular morbidity and complicate the management. Reporting rare associations enhances awareness amongst clinicians and contributes to clinical decision-making in complex glaucoma cases.

Abstract No.: 206028**Successful Trabeculectomy With Mitomycin-C Following Failed Glaucoma Drainage Device: A Case Report***First Author: Banupriyah M ELANGO VAN**Co-Author(s): Hayati ABDUL AZIZ, Nurulhuda ARIFFIN, Shatriah ISMAIL, Li Mun TAN*

Purpose: Refractory glaucoma after a failed glaucoma drainage device (GDD) remains difficult to manage. We report a case where trabeculectomy with Mitomycin-C (MMC) successfully restored long-term intraocular pressure (IOP) control after Ahmed valve failure.

Methods: Case report.

Results: A patient with childhood glaucoma, high myopia, and bilateral lens subluxation first presented 18 years ago with right eye (RE) retinal detachment. The RE underwent vitrectomy, scleral buckle, silicone oil tamponade, and cyclodiode, resulting in vision of 6/45 with IOP 22 mmHg on topical therapy. Three years later, the left eye (LE) developed retinal detachment, treated with vitrectomy, scleral buckle, and silicone oil. Postoperatively, LE vision was 6/24 but IOP rose to 40–65 mmHg. LE Ahmed valve implantation achieved IOP control (16–18 mmHg) for 9 years. After nearly a decade, LE vision declined to counting fingers, and IOP rose again (23–38 mmHg) despite maximal topical therapy, indicating GDD failure. LE trabeculectomy with MMC was then performed. Postoperatively, vision improved to 6/20, and IOP was maintained at 8–10 mmHg without topical therapy.

Conclusions: This case demonstrates that trabeculectomy with MMC can remain effective even after failed GDD, providing sustained IOP control and improved vision. In carefully selected patients with refractory glaucoma, trabeculectomy remains a valuable salvage option after drainage device failure.

Abstract No.: 202698**Surgical Outcomes and Prognostic Factors for Baerveldt Glaucoma Implantation in Open-Angle Glaucoma Without Prior Filtration Surgery***First Author: Takehiro KIYAMA**Co-Author(s): Toshihiro INOUE, Sachi KOJIMA, Natsumi MURATA, Eri TAKAHASHI, Yuji TAKIHARA*

Purpose: To evaluate outcomes and identify prognostic factors for primary Baerveldt glaucoma implantation (BGI) in open-angle glaucoma eyes without prior filtration surgery.

Methods: This retrospective study included 95 eyes with primary open-angle glaucoma or exfoliation glaucoma without prior filtration surgery. Surgical success was defined based on IOP criteria: ≥ 6 mmHg, $\geq 20\%$ reduction from baseline, and upper limits of 21 mmHg (Criterion A), 18 mmHg (B), and 15 mmHg (C).

Failure included not meeting IOP targets, requiring reoperation for glaucoma, or loss of light perception. Eyes were censored at the last follow-up or two years. Linear mixed-effects models, Kaplan–Meier analysis, log-rank tests, and Cox proportional-hazards models were used.

Results: Mean follow-up was 568.0 ± 384.4 days. Mean IOP decreased from 28.3 ± 7.5 mmHg to 12.3 ± 4.2 mmHg at two years, and mean medication score decreased from 4.4 ± 0.8 to 1.5 ± 1.6 (both $p < 0.001$). The 2-year success rate for IOP ≤ 15 mmHg (Criterion C) was 64.0%. Multivariate analysis for Criterion C identified two independent predictors of failure: preoperative bimatoprost use (HR 2.89; 95% CI 1.30–6.43; $p = 0.01$) and younger age (HR 0.97 per year; 95% CI 0.94–1.00; $p = 0.02$). Survival curves for Criterion C differed significantly by prostaglandin analog regimen (log-rank $p = 0.039$), with the bimatoprost group having the lowest success.

Conclusions: Preoperative bimatoprost use and younger age may be adverse prognostic factors for achieving an IOP ≤ 15 mmHg after primary BGI in open-angle glaucoma.

Abstract No.: 205706**Surgical Outcomes of Ahmed Valve Implantation in Patients With and Without Prior Trabeculectomy***First Author: Aroocha TECHAKOSOL**Co-Author(s): Sukhumal THANAPAISAL*

Purpose: To evaluate the efficacy and safety of Ahmed glaucoma valve (AGV) implantation in patients with and without prior trabeculectomy.

Methods: This retrospective comparative cohort study included 112 eyes from 112 patients who underwent AGV implantation (60 with previous failed trabeculectomy, 52 without). Primary outcome was the intraocular pressure (IOP) at 1, 3, 6 and 12 months. Secondary outcomes were the number of glaucoma medications, complication rates, and cumulative proportion failure (defined as IOP > 21 or < 6 mmHg, $< 20\%$ reduction from baseline after 3 months, reoperation or loss of light perception). The generalized estimating equation was used for the analysis.

Results: 107 patients completed the 12-month follow-up. Postoperative IOP was 0.12 (95%CI: -4.2 to 5.8), -2.02 (-4.88 to 0.85), -0.94 (-3.19 to 1.31), and -1.07 (-3.29 to 1.14) mmHg at 1, 3, 6, and 12 months, respectively. There was no difference in the number of glaucoma medications between two groups at any follow-up visits ($P > 0.99$). Early and late complications were not different between the two groups ($P = 0.15$). The cumulative failure probability at 12 months was 13.33% and 11.54% in patients with and without prior trabeculectomy ($P = 0.79$).

Conclusions: AGV Implantations in patients with and without prior trabeculectomy showed no difference in IOP reduction, medications, complications and failure rate at 12 months follow-up. These findings suggested that prior trabeculectomy did not diminish the efficacy and safety profile of AGV implantation.

Abstract No.: 205943

Surgical Outcomes of Phaco-GATT in Mild-Moderate vs Severe Open-Angle Glaucoma: A Comparative Analysis

First Author: Nimrita **NAGDEV**

Co-Author(s): Devendra **MAHESHWARI**, Madhavi **PILLAI**

Purpose: To study efficacy and safety of gonioscopy-assisted transluminal trabeculotomy combined with phacoemulsification in mild-moderate and severe primary open-angle glaucoma

Methods: A prospective, interventional study included 240 primary open-angle glaucoma patients (265 eyes), classified into mild-moderate (144) and severe (121) eyes. Patients evaluated at 2 weeks, 1, 3, 6, and 12 months. Primary outcomes included intraocular pressure (IOP), antiglaucoma medications (AGMs), best-corrected visual acuity (BCVA), and surgical success. Surgical success was determined for IOP <18 and <15 with at least 25% and 30% IOP reduction from baseline respectively by 1 year. Secondary outcomes included complications and secondary interventions, and p-value <0.05 was considered statistically significant

Results: Mean IOP (mmHg) reduced from 20.4±4.47 and 21.5±6.45 to 12.4±2.9 and 12.5±2.9 mmHg in mild-moderate (37.1%) and severe (38.5%) groups at 1 year (p=0.625). AGM decreased from 1.35±0.36 and 2.0±0.9 to 0.08±0.30 and 0.13±0.38, with 92.3% and 89.0% AGM-free eyes in both groups respectively (p=0.468). BCVA improved from 0.29±0.28 to 0.02±0.06 in mild-moderate and from 0.36±0.36 to 0.02±0.06 in severe cases. Complete success was 81.2%, eyes: in mild-moderate and 77.7%, 67.7% in severe group by criteria 1 and 2. Macrohyphema occurred in 12 eyes (5 mild-moderate, 7 severe group), 15 patients (7 mild-moderate, 8 severe group) had IOP spike. 5 (2 mild-moderate, 3 severe) required AC wash.

Conclusions: Gonioscopy assisted-transluminal trabeculotomy combined with phacoemulsification is a safe and efficacious option for open-angle glaucoma irrespective of its severity

Abstract No.: 201089

Surgically Managed Vogt-Koyanagi-Harada Disease Associated Refractory Glaucoma and Complicated Cataract in A Young Female: A Case Report From Bangladesh

First Author: Md Iftekher **IQBAL**

Co-Author(s): Fariah **OSMAN**

Purpose: To report a case of bilateral refractory glaucoma due to pupillary block and angle closure and complicated cataracts in a young patient with Vogt-Koyanagi-Harada (VKH) disease, managed successfully with combined glaucoma drainage device (GDD) implantation and cataract surgery.

Methods: A 35-year-old female presented with bilateral decreased vision and ocular pain. She was diagnosed with chronic recurrent VKH syndrome complicated by combined pupillary block and secondary angle-closure glaucoma, along with visually significant cataracts. Despite maximal medical therapy, intraocular pressure (IOP) remained uncontrolled. The patient underwent combined Aurolab Aqueous Drainage Implant (AADI) and cataract extraction.

Results: Preoperative visual acuity was perception of light (PL) in the right eye and 6/24 in the left eye, with IOP spikes up to 50 mmHg bilaterally. Following surgery, vision improved to 6/60 in the left eye and stabilized at 14-16 mmHg with single-agent topical therapy over an 18-month follow-up. Anterior chambers were deep, intraocular lenses were well-positioned, and no inflammation or implant-related complications were observed.

Conclusions: Patients with Vogt-Koyanagi-Harada syndrome may develop both refractory glaucoma and a visually significant cataract. If this happens, combining a glaucoma drainage device with cataract surgery after the settlement of active ocular inflammation can be very helpful in the long term.

Abstract No.: 200615

TASS in Secondary Glaucoma After Uneventful Filtering Surgery: A Case Report

First Author: Devi Putri **SWADAYANI**

Co-Author(s): Muhammad **YOSERIZAL**

Purpose: The purpose of this case report is to alert surgeons to the possibility of this complication following any anterior segment surgery, including trabeculectomy, and to highlight the possible etiologies and measures to prevent it.

Methods: A 55-year-old Female was initially managed medically for secondary glaucoma after iris claw lens implantation with antiglaucoma medications. There was rapidly progressive glaucomatous optic nerve damage and uncontrolled of IOP in her right eye within the following months, despite the use of antiglaucoma

medications, hence the need for trabeculectomy with mitomycin C.

Results: Postoperative condition, day 1, there were bleb elevated, midmidriatic pupil, hypopyon 1mm, minimal corneal edema limbus to limbus, posterior segment within normal limits, among other features of TASS, with associated deteriorating visual acuity. We gave oral fluoroquinolone antibiotic, steroid, both oral and eyedrop. On the 4th day after surgery, the condition improved, and the hypopyon disappeared.

Conclusions: Although there have been no documented reports of TASS following trabeculectomy with mitomycin C, surgeons should be aware of this possibility. Preventive measures include taking extreme care to avoid errors when preparing and administering diluted solutions, particularly those administered into the intracameral space.

Abstract No.: 203678

Targeting the Integrin $\alpha\beta3$ -ROCK/CLAN Pathway Attenuates Trabecular Meshwork Fibrosis and Reduces Ocular Hypertension in a Mouse Model

First Author: Yutong **CHE**

Co-Author(s): Yufan **JIANG**, Yangfan **YANG**, Yuqing **ZHANG**

Purpose: Trabecular meshwork (TM) hypercontractility and fibrosis contribute to elevated IOP in POAG. The specific pathway linking TGF β 2, a key driver of this pathology, to TM dysfunction remains unclear despite implicating integrin. We assess whether TGF β 2-induced cross-linked actin network (CLAN) formation and TM fibrosis are mediated by the $\alpha\beta3$ -RhoA/ROCK pathway, and determine whether its inhibitor reverses pro-fibrotic changes and lowers IOP in ocular hypertension (OHT) mice.

Methods: Cells were stimulated with TGF β 2 and co-treated with the $\alpha\beta3$ inhibitor, cilengitide. Transcriptional changes were validated by RNA sequencing and qPCR. Expression of fibrotic and pathway markers was assessed by Western blot and immunofluorescence. Cellular contractility was evaluated using 3D spheroid and collagen gel contraction assays, and CLAN formation was quantified via phalloidin-based cytoskeletal staining. Intraocular injection of an adenovirus encoding active TGF β 2 induced OHT mice, with IOP and TM fibrosis assessed following cilengitide treatment.

Results: TGF β 2 induced a pro-fibrotic transcriptional program in TM cells, significantly upregulating ITGAV and enriching for Actin Cytoskeleton pathways. This was associated with increased expression of fibrotic proteins, CLAN formation, cellular hypercontractility and tissue fibrosis. Co-treatment with cilengitide significantly attenuated those fibrotic markers, suppressed the downstream RhoA/ROCK pathway,

and reversed the hypercontractile phenotype. Cilengitide treatment lowered IOP in OHT mice, with immunofluorescence confirming reduced fibrotic markers in TM.

Conclusions: Cilengitide alleviates TGF β 2-induced CLAN formation, contractile dysfunction, and ECM deposition in TM by suppressing key components of the $\alpha\beta3$ /RhoA/ROCK signaling axis. Moreover, it demonstrates therapeutic efficacy in lowering IOP and exerting antifibrotic effects on TM in OHT mice.

Abstract No.: 201271

The Accuracy Among Prediction Formulas of Intraocular Pressure Decrease in Primary Glaucoma Patients After Phacoemulsification

First Author: Yulia **PRIMITASARI**

Co-Author(s): Harris **KRISTANTO**, Indri **WAHYUNI**

Purpose: Cataract extraction as one of the surgical treatments for primary glaucoma has been shown to reduce IOP in various studies. Some studies formulated several formulas that can be used to predict the decrease in IOP after phacoemulsification. This study was conducted to test the accuracy of these formulas.

Methods: 59 patients with primary glaucoma who underwent phacoemulsification at an eye hospital in 2022-2023 were subjected to data collection from medical records to test the accuracy between post-phacoemulsification IOP predictions based on five formulas. Data analysis was performed using SPSS 26.0. $p \geq 0.05$ was considered insignificant and the formula was considered accurate. The formula that has an absolute value of the difference between the mean decrease in post- phacoemulsification IOP and the mean formula that is close to zero is the most accurate formula.

Results: Results in 59 patients showed inaccurate results in all formulas, but when tested separately in patients with preoperative IOP ≤ 21 mmHg, all five formulas were accurate compared to IOP 6 months after phacoemulsification, four formulas were accurate compared to IOP 1 month after phacoemulsification and none of the formulas were accurate compared to IOP 3 months after phacoemulsification. A formula called «The preoperative IOP formula» had the best accuracy when compared to IOP 1 and 6 months after phacoemulsification.

Conclusions: «The preoperative IOP formula» is the most accurate formula in predicting IOP 1 and 6 months after phacoemulsification.

Abstract No.: 200467

The Baseline Risk Factors of Additive Trabeculectomy After Goniotomy in Patients With Open-Angle Glaucoma

First Author: Takanori **MIZOGUCHI**

Co-Author(s): Kouichi **NAGAMI**

Purpose: To evaluate the pre-operative characteristics of eyes that required subsequent filtration surgery (LET) after microhook ab interna trabeculotomy (μ LOT).

Methods: This retrospective study analyzed eyes with primary open-angle glaucoma (POAG) or exfoliation glaucoma (EXG) that underwent μ LOT alone or combined with cataract surgery. Eyes were divided into two groups: those that required no additional surgery (Non group) and those that subsequently underwent filtration surgery (LET group). Pre-operative clinical factors, the cumulative incidence of LET, and risk factors for surgical failure were analyzed using the Cox proportional hazards model.

Results: The mean postoperative follow-up period was 24.7 ± 13.0 months. The Non group included 238 eyes (POAG = 143, EXG = 95), and the LET group 25 eyes (POAG = 9, EXG = 16). Compared with the Non group, the LET group was significantly younger ($p = 0.002$), had higher pre-operative intraocular pressure ($p < 0.0001$), used more glaucoma medications pre-operatively ($p < 0.0001$), and had worse pre-operative mean deviation (MD) values ($p < 0.0001$). The cumulative incidence of LET was 19.2 % at 5.5 years. Postoperative IOP spikes occurred in 48 % of the LET group—significantly more often than in the No-additional group ($p < 0.0001$). Significant pre-operative risk factors for requiring LET were: diagnosis ($p = 0.023$), younger age ($p = 0.030$), surgical modality ($p < 0.001$), and worse MD value ($p < 0.001$).

Conclusions: Higher pre-operative intraocular pressure, exfoliation glaucoma, younger age, standalone μ LOT, and advanced visual-field loss increase the risk of requiring subsequent filtration surgery.

Abstract No.: 207291

The Long Forgotten Hydrophilic Intraocular Lens - A Clinical Vignette

First Author: Muhammad Haris Zakaria **AHMAD**

Co-Author(s): Norlina **RAMLI**

Purpose: This report presents a 78-year-old male patient with bilateral advanced primary open-angle glaucoma (POAG) and bilateral pseudophakia. The case highlights complications following multiple glaucoma interventions including micropulse trabeculoplasty and Ahmed valve glaucoma drainage device (GDD) implantation. Notably, the patient developed progressive intraocular lens (IOL) glistening and opacification years after a Descemetopexy procedure with C3F8 gas injection. The purpose is to describe

the clinical course, identify contributing factors to IOL opacification, and discuss management decisions.

Methods: This is a case report.

Results: At presentation, the patient maintained good visual acuity (6/6 in 2017). Following a Descemetopexy with C3F8 in 2017, glistening developed in 2020 on the initially implanted IOL, vision decreased moderately to 6/24 uncorrected but was correctable to 6/9. Intraocular pressure and glaucoma status remained stable throughout. The glistening and opacification correlated with exposure to intraocular gas (C3F8), which may cause dehydration of the hydrophilic IOL material, promoting protein precipitation and microvacuole formation within the lens. Given the relatively preserved vision and stable ocular status, the patient opted for conservative management instead of IOL explantation.

Conclusions: Hydrophilic IOLs may undergo glistening and opacification due to intraocular gas exposure, especially in eyes requiring complex surgical interventions. Although this phenomenon can affect lens clarity, vision may remain largely unaffected, supporting conservative management in select cases. Surgical lens exchange remains an option if significant visual impairment arises. Understanding the effects of intraocular gases on IOL materials is crucial to anticipate potential complications and guide patient-centered care decisions.

Abstract No.: 201691

The Relationship Between Serous Choroidal Detachment and the Ahmed Glaucoma Valve Failure

First Author: Maryam **YADGARI**

Co-Author(s): Sara **KAVOUSNEZHAD**, Nader **NASSIRI**, Kourosh **SHEIBANI**

Purpose: To investigate the effect of serous choroidal detachment (SCD) on the success of Ahmed glaucoma valve (AGV) implantation.

Methods: Patients who underwent AGV implantation and developed SCD were included in the case group. The control group was matched based on age, sex, baseline intraocular pressure (IOP), glaucoma type, and the number of glaucoma medications. The patient data were retrospectively extracted from available records. The primary outcome measure was an AGV success rate based on $5 < \text{IOP} < 18$ and a 20% reduction from baseline.

Results: Seventeen patients were enrolled in the case group and 38 in the control group. Preoperative visual acuity of patients was 1.17 ± 0.43 and 1.16 ± 0.37 logMAR in the case and control groups, respectively. The patients in the case group showed higher mean IOP at all time intervals compared to controls. However, the mean IOP only reached a statistically significant difference at 3 months (17.94 ± 6.78 mmHg

vs. 13.39 ± 3.09 mmHg, $P = 0.003$). The mean survival duration was significantly shorter in patients with SCD (10.4 ± 0.7 months vs. 11.7 ± 0.2 months for controls log-rank = 4.1, $P = 0.04$). The cumulative probability of success was 76.5% in patients with SCD and 94.7% in the control group after 12 months.

Conclusions: SCD after AGV implantation could be a risk factor for failure. A larger prospective study with a longer follow-up duration is required to confirm the present study results.

Abstract No.: 205931

The Role of Plasma Proteins in the Effect of Plasma Lipidome on Glaucoma: A Mendelian Randomization Analysis

First Author: Jiaxin **ZHANG**

Co-Author(s): Waikit **CHU**

Purpose: Previous studies have suggested association between plasma lipid levels and glaucoma. However, inconsistent findings have been reported partly due to the complexity of lipid species. This study aims to investigate the genetic associations between plasma lipidome and glaucoma risk using Mendelian randomization (MR) analysis, and to identify plasma proteins that may mediate these effects.

Methods: Genome-wide association study (GWAS) data for plasma lipids were obtained from the GWAS Catalog (GCST90277238 to GCST90277416). Protein quantitative trait loci (pQTL) data was derived from the Icelandic deCODE Genetics Study. Glaucoma GWAS data was sourced from the FinnGen Consortium. The inverse-variance weighted (IVW) method was employed as the primary MR approach, with Bayesian weighted MR (BWMR) used for validation. Reverse MR analyses were conducted to rule out reverse causality. Two-step mediation MR analysis was performed to identify potential mediators.

Results: The analyses identified 9 lipid species with causal effects on glaucoma. Among them, five phosphatidylcholines (PCs) and one sterol ester were protective factors, while one phosphatidylethanolamine, one sphingomyelin, and one sterol ester were risk factors. Reverse MR analyses excluded reverse causality between these lipids and glaucoma. Eight plasma proteins (sTie-2, SEMA6B, LRC32, F177A, IGSF3, Semaphorin 3E, SPN1, and SAR1A) were found to have causal associations with glaucoma. Two-step MR revealed that LRC32, IGSF3, and Semaphorin 3E mediated the effects of PCs on glaucoma risk.

Conclusions: We have identified causal associations between 9 plasma lipid species and glaucoma. Notably, PC (18:0_0:0), PC (O-18:2_16:0), and PC (O-18:2_16:0) exerted protective effects mediated through Semaphorin 3E, IGSF3, and LRC32, respectively.

Abstract No.: 205631

Through CO2 Laser-Assisted Deep Sclerectomy Surgery (CLASS) to Observe the Function of the Trabecular Meshwork in Primary Open-Angle Glaucoma Patients

First Author: Li **LU**

Co-Author(s): Nan **YUAN**

Purpose: To observe the function of the trabecular meshwork in POAG patients.

Methods: Through CLASS surgery to observe whether the function of trabecular meshwork still exists in POAG patients, which the stage of the disease is classified by the Glaucoma staging system 2 (GSS2), and constructing a generalized estimation equation to test the relationship between trabecular meshwork function and various impact factors such as gender, visual field, and optic nerve fiber layer thickness.

Results: Of 238 POAG patients, 176 (73.9%) had a functional trabecular meshwork, and 62 (26.1%) had a dysfunctional trabecular meshwork. The mean (SD) age was 52.46 (17.8) years for POAG patients in the function group and 55.32 (18.5) years for patients in the dysfunction group. Compared to the dysfunction group, the function group had a lower IOP (SD) was 23.93(10.9), and less visual field impairment (MD[SD]-20.83[8.78], VFI [MD] 46.19% [30.09]). After adjustment for age, gender, intraocular pressure (IOP), retinal nerve fibre layer (RNFL), Cup-to-Disc Ratio (C/D), pattern standard deviation (PSD), mean deviation (MD), and visual field index (VFI), Female (OR 0.42 [95% CI 0.21-0.83]) are more likely to have residual trabecular meshwork function at various stages of the disease compared to men. POAG patients with thicker RNFL thickness (OR 0.97 [95%CI 0.94-0.99]) are more likely to have functional trabecular meshwork.

Conclusions: This investigation shows that regardless of the stage of POAG, more than 73.9% of patients still have trabecular meshwork function. These results indicate that protecting the integrity of the trabecular meshwork is worth considering and important at all stages of POAG.

Abstract No.: 201363

Trabeculectomy Outcomes in One Eye Predict the Surgical Success in the Fellow Eye

First Author: Hira **MUazzam**

Co-Author(s): Mahmood **ALI**, Hanif **MALIK**, Nabeel **SYED**

Purpose: The purpose of this study was to evaluate the outcomes of bilateral trabeculectomies and assess the associations and differences in outcomes between the first operated and the second operated eye.

Methods: Patients with glaucoma who underwent bilateral trabeculectomies from 2020 to 2024 were included in this prospective study of 194 eyes of 97

patients. The patients were followed at 2 weeks, 1 month, and thereafter 3 3-monthly intervals till 2 years after surgery in each eye. The main outcome measure was surgical success (complete success: IOP 6-18mmHg or 20% reduction from baseline preoperative IOP without any topical antiglaucoma treatment. Qualified success was defined as IOP 6-18mmHg with topical antiglaucoma treatment. Secondary outcome measures were intraocular pressure and the number of topical anti-glaucoma medications. Anterior segment OCT, focusing on the bleb to assess the hydraulic conductivity, was done in cases of failure.

Results: The 194 eyes of 97 patients were not statistically significantly different in terms of baseline IOP and number of IOP-lowering medications between the first and second operated eyes after the surgery (p value > 0.05). At 24 months follow-up, among the patients whose first operated eyes were considered a complete success, 80.2% surgeries in the fellow eyes were successful (p value $= 0.012$). The patients whose first operated eyes were considered a qualified success 78.1% of the surgeries in fellow eyes were successful p value $= 0.012$.

Conclusions: This study demonstrates a significant correlation in surgical outcomes of trabeculectomies between the two eyes of the same patient.

Abstract No.: 200373

Trimming Techniques for the Ahmed Glaucoma Valve (AGV) Tube: Surgical Approaches

First Author: Pir Salim **MAHAR**

Purpose: To describe surgical trimming techniques of the Ahmed Glaucoma Valve (AGV) tube aimed at preventing or managing corneal touch and endothelial decompensation.

Methods: Patients presenting with corneal decompensation secondary to AGV tube malposition were referred to a tertiary glaucoma care clinic. All underwent surgical revision involving trimming and repositioning of the AGV tube. In this presentation, we describe the various intraoperative techniques used to optimize tube length and orientation, including bevel direction, angled trimming, and placement adjustments based on anterior chamber depth and anatomy. Surgical videos and pre- and postoperative anterior segment imaging (including AS-OCT) are used to illustrate these methods and outcomes.

Results: Post-revision, all patients showed resolution of corneal touch, with no further progression of endothelial decompensation over a 12-month follow-up. Tube positioning improved in all cases, with AS-OCT confirming clearance from the corneal endothelium. Visual acuity and intraocular pressure remained stable, and no additional tube-related complications

were noted. These results suggest that targeted tube trimming can effectively manage corneal complications

Conclusions: Surgical revision with precise trimming and repositioning of the AGV tube is highly effective in resolving corneal complications caused by tube malposition. Individualized trimming techniques—considering anterior chamber depth, angle orientation, and tube beveling—significantly reduce the risk of ongoing endothelial damage. Incorporating these approaches during primary implantation and revision surgery can improve long-term device safety, preserve corneal clarity, and optimize visual outcomes. Early recognition and timely surgical intervention are essential for preventing irreversible corneal decompensation in patients with glaucoma drainage devices

Abstract No.: 202312

Tube Exposure and Perforation After Bleb Refomation Following PreserFlo MicroShunt implantation

First Author: Masashi **NISHIGAKI**

Co-Author(s): Motohiro **KAMEI**, Atsuya **MIKI**, Chiaki **NOGAWA**

Purpose: To describe a rare case of tube exposure and perforation after Preserflo MicroShunt (PMS) implantation and subsequent bleb revision, emphasizing possible mechanisms and clinical management strategies.

Methods: An 84-year-old woman with bilateral exfoliation glaucoma underwent PMS implantation in the left eye for uncontrolled intraocular pressure (IOP) despite maximum medical therapy. The patient had a history of multiple ocular surgeries and long-term use of glaucoma eye drops. Initial surgery was uneventful but tissues of conjunctiva and Tenon's capsule were thin. The early postoperative course was good, but developed hypotony and choroidal detachment after stent removal, prompting a second procedure for stent reinsertion. A conjunctival leak appeared postoperatively, leading to a third surgery, during which a conjunctival defect and a tear in the PMS tube were discovered. The device was removed, and a new PMS was implanted in a different quadrant. The IOP stabilized postoperatively, with no recurrence of leakage or hypotony.

Results: This is the first report of PMS tube perforation associated with conjunctival hole. Potential contributing factors include chronic conjunctival inflammation from long-term glaucoma eye drops use, previous ocular surgeries, and prostaglandin-associated periorbitopathy (PAP). These conditions may have resulted in tissue thinning and mechanical stress, leading to tube exposure and perforation.

Conclusions: We suggest that caution is needed when performing PMS in patients with thin conjunctiva or

Tenon's capsule preoperatively. Careful postoperative follow-up is important for early detection and intervention in similar cases to prevent complications.

Abstract No.: 205950

Twelve-Month Outcomes of Gonioscopy-Assisted Transluminal Trabeculotomy in Eyes With Prior Failed Glaucoma Surgery

First Author: Nimrita NAGDEV

Co-Author(s): Devendra MAHESHWARI, Madhavi PILLAI

Purpose: Safety and efficacy of gonioscopy-assisted transluminal trabeculotomy (GATT) in eyes with prior failed glaucoma surgery.

Methods: A prospective and interventional study included 35 eyes that experienced prior glaucoma surgery failure and subsequently underwent GATT. Patients included were of congenital glaucoma (4), JOAG (8), PACG (11), POAG (10), PXF-G (1), and secondary glaucoma (1). Baseline characteristics like Intraocular pressure (IOP), Best corrected visual acuity (BCVA), and anti-glaucoma medications (AGMs) were evaluated at each post-operative visit. Data were collected at 2 weeks, 1 month, 3 months, 6 months, and 12 months. Surgical success was defined as IOP ≤ 21 / ≤ 18 / ≤ 15 mmHg with $> 20\%$ / 25% / 30% reduction from baseline, respectively (Criteria 1, 2, and 3). Complications, interventions, and surgical risk factors were also analyzed.

Results: The mean (SD) IOP decreased from 25.89 ± 12.91 to 15.40 ± 8.35 , 14.53 ± 6.19 , 13.0 ± 3.28 , 12.43 ± 3.28 and 13.46 ± 3.93 at 12 months ($p < 0.001$). AGM reduced from 3.26 ± 0.85 to 0.91 ± 0.78 , 1.12 ± 1.12 , 1.35 ± 1.07 , 1.49 ± 1.12 and 1.54 ± 1.09 at 12 months ($p < 0.001$). The overall success rate was 77.1%, 74.3% and 60.0% by criteria 1, 2, and 3. The complications noted were hyphema in 12 eyes; the majority resolved within 1 week, and all by 2 weeks. None needed any intervention.

Conclusions: This study concludes that GATT can be an effective and safe surgical alternative for managing IOP in eyes with prior failed glaucoma surgeries, associated with minimal complications.

Abstract No.: 205448

Unlocking the Angle: Short-Term Clinical Outcomes of Phacoemulsification Combined With Goniotomy in Glaucoma

First Author: Devi Putri SWADAYANI

Purpose: To evaluate the early clinical outcomes of combined phacoemulsification and goniotomy in patients with glaucoma, focusing on visual acuity, intraocular pressure (IOP) control, and reduction of topical medication use.

Methods: This prospective case series included 16 eyes from patients undergoing phacoemulsification

with adjunctive goniotomy. Baseline demographics, preoperative IOP, visual acuity (logMAR), and number of glaucoma medications were recorded. Postoperative assessments were performed at day 1, day 7, and 1 month. Surgical success was defined according to World Glaucoma Association (WGA) guidelines as complete, qualified, or failure.

Results: The mean patient age was 67.8 years; 68.8% were diagnosed with primary angle-closure glaucoma. Preoperative visual acuity averaged 1.48 logMAR ($\approx 20/630$), improving to 0.61 logMAR at 1 month, with most patients gaining ≥ 2 Snellen lines. Mean IOP decreased from 39.44 mmHg preoperatively to 20.50 mmHg at 1 month, reflecting a 48% reduction. The average number of medications fell from 2.75 to 1.00, with 37.5% of patients medication-free at 1 month. Surgical success rates were: complete success in 25%, qualified success in 37.5%, and failure in 37.5%.

Conclusions: Phacoemulsification combined with goniotomy provides meaningful short-term improvements in vision, IOP reduction, and medication burden in patients with glaucoma, particularly those with primary angle-closure. While complete surgical success was achieved in a subset, a substantial proportion still required adjunctive therapy, highlighting the importance of careful patient selection and longer-term evaluation.

Abstract No.: 206056

Use of a Pediatric Ahmed Glaucoma Valve (FP8) for Refractory Secondary Glaucoma in an Adult Eye Following Multiple Vitreoretinal Surgeries: A Case Report

First Author: Muhammad KHALIL AKBAR

Co-Author(s): Elsa GUSTIANTY, R.Maula RIFADA, Sonie UMBARA, Indriyani

Purpose: Secondary glaucoma following multiple vitreoretinal surgeries is a significant clinical challenge, often refractory to conventional treatments due to factors such as conjunctival scarring from previous operations. A Glaucoma Drainage Device may be considered a management strategy for secondary glaucoma after vitreoretinal surgery.

Methods: An 18-year-old male with a history of scleral buckle, vitrectomy, and a failed trabeculectomy presented with uncontrolled secondary glaucoma and an intraocular pressure (IOP) of 32 mmHg. Due to extensive conjunctival scarring and limited episcleral space from the scleral buckle, he underwent implantation of a pediatric Ahmed Glaucoma Valve (AGV) model FP8.

Results: Initial IOP control was achieved after the procedure, but at one month, the IOP increased to 34 mmHg due to the formation of an encapsulated bleb (Tenon's cyst). The patient then underwent surgical excision of the cyst with adjunctive 5-fluorouracil.

Postoperatively, the IOP stabilized at 18 mmHg after one week.

Conclusions: The pediatric AGV model is an effective option for refractory secondary glaucoma in select cases with limited episcleral space. Clinicians should anticipate potential complications such as bleb encapsulation. Surgical excision of the cyst is a viable and effective strategy to restore implant function and achieve long-term IOP control.

Abstract No.: 206939

Xen Implantation in a Pregnant Filipino Patient With Anterior Segment Dysgenesis and Secondary Angle Closure Glaucoma

First Author: Dillon Edric GO

Co-Author(s): Rommel BAUTISTA

Purpose: Patient is a 25-year-old female with anterior segment dysgenesis and congenital nystagmus in both eyes, and has developed secondary angle closure glaucoma in the right eye. The patient underwent lens extraction with IOL implantation in childhood. Visual acuity was reported at 10/400 sans correction. Intraocular pressures on the right eye were 35mmHg off meds, and on gonioscopy, all angles were synechially closed except the superior angle, which opened to the scleral spur. Pressures were controlled at 15mmHg on Latanoprost, Brimonidine, and Brinzolamide. However, the patient uncovered an unexpected pregnancy. Due to the possible side effects of anti-glaucoma medications during pregnancy, we decided to implant a Xen implant rather than trabeculectomy, given the history of anterior segment dysgenesis.

Methods: A corneal bridle suture was done to stabilize the eye. A combination of Mitomycin-C and lidocaine was injected in the proposed bleb site. Peritomy was done superiorly, and sub-Tenon dissection was done peripherally. Judicious cautery was done on the scleral bed. Scleral tunnel 2mm from the limbus was done, and Xen implant was inserted into the tunnel with adequate anterior chamber exposure. The conjunctiva was then closed and implanted, and tested for patency. The patient was maintained on steroids and antibiotic drops postoperatively.

Results: Patient's IOP on 1 day post-operation was noted at 2mmHg, which is expected in post-Xen implantation. The IOP would gradually increase until it stabilized at 16mmHg off any medications at 2 months post-operation.

Conclusions: Minimally invasive glaucoma surgery is an effective alternative to glaucoma medications in pregnant patients with anterior segment dysgenesis.

Intraocular Inflammation, Uveitis and Scleritis

Abstract No.: 204745

A Case Report of Vogt-Koyanagi Harada Disease Presenting in a Post-Partum Patient in a Level III Private Hospital in Metro Manila, Philippines

First Author: Alyssa BARROGA

Co-Author(s): Nickey CAYETANO, Ian PAREDES, Eric Nathaniel REYES

Purpose: This case report focuses on a 32-year-old Filipino female immediately post-partum who developed bilateral blurring of vision, metamorphopsia, anterior and posterior uveitis findings such as mutton fat keratic precipitates and bilateral disc edema, and with associated findings in Optical coherence tomography (OCT) of the macula and Fluorescein angiography.

Methods: This study is a case report focusing on an individual patient and her course in the clinics and in the wards.

Results: These group of signs and symptoms clinically fit the criteria for Vogt-Koyanagi-Harada syndrome acute uveitic phase, and since the patient is post-partum, she has predisposition to develop autoimmune diseases such as VKH disease, although infectious causes such as pulmonary tuberculosis should still be ruled out.

Conclusions: Prompt initiation of mainstay treatment which are systemic corticosteroids in the form of IV Methylprednisolone 1g/day for five days was given to the patient within the two to four week window period from the onset of symptoms, improving the eventual visual prognosis while also collaborating with multiple disciplines to make sure other systemic conditions were being addressed. Additional treatment such as immunosuppressive therapy, in this patient's case Azathioprine, should be explored, and are contributory in making sure VKH does not recur.

Abstract No.: 200557

A Novel Strategy for the Management of Cytomegalovirus Retinitis in Immunocompromised Patients Using New Anti-Cytomegalovirus Drugs

First Author: Yuou YAO

Co-Author(s): Heng MIAO

Purpose: This study presents four cases of cytomegalovirus retinitis (CMVR) managed using a novel antiviral strategy, aiming to preliminarily assess its efficacy and safety profile.

Methods: A retrospective chart review was conducted on four patients (seven eyes) diagnosed with CMVR. All patients received oral letermovir or maribavir as the primary treatment. Weekly intravitreal injections of high-dose (6mg) ganciclovir (IVG) were administered to those with macula involvement or aggressive lesions during the initial treatment. Data on demographics, ophthalmic examinations, laboratory results, and clinical outcomes were analyzed.

Results: All four patients showed clinical and fundoscopic improvement, achieving complete resolution of retinitis. However, one patient developed bilateral retinal detachment requiring vitrectomy. Initial administration of high-dose IVG ensured rapid stabilization of the aggressive or macula-threatening lesions. While subsequent oral antiviral maintenance significantly reduced the need for repeated IVG injections. Both letermovir and maribavir demonstrated excellent tolerability with no adverse events observed.

Conclusions: This novel therapeutic strategy provides safe and effective treatment option for CMVR, particularly promising for patients with complex systemic comorbidities.

Abstract No.: 205204

A Race Against Time: Fulminant Klebsiella Panophthalmitis

First Author: Ivin Bing Wei **WONG**
 Co-Author(s): Shir Yen **WANG**

Purpose: To present a rapidly progressive case of Klebsiella panophthalmitis and its management.

Methods: Case Study

Results: A 59-year-old male with no comorbidities presented with a one-day history of left eye blurred vision preceded by fever. His visual acuity was 6/18, with fundus revealing multiple Roth's spots and attenuation of retinal arteries. Upon review the following day, his vision deteriorated to hand motions (HM). Anterior chamber showed fibrin and hypopyon while fundus visualisation was obscured. B-scan ultrasonography demonstrated vitritis without loculation. Repeated B-scan within 48 hours showed worsening vitritis with loculation, and a positive T-sign, consistent with endogenous panophthalmitis. Vitreous tap was performed, followed by intravitreal injections of Vancomycin and Ceftazidime. Concurrent treatment included topical eye drops Vancomycin 5% and Ceftazidime 5%, along with intravenous Ciprofloxacin. Systemic workup revealed a liver abscess, with pus cultures isolating Klebsiella pneumoniae, sensitive to Augmentin and Unasyn. The patient was co-managed with the gastroenterology team, and started on intravenous Augmentin. Despite aggressive treatment with multiple intravitreal injections and weeks of systemic antibiotics, his vision deteriorated to no perception of light. The eye subsequently developed

phthisis bulbi, and a prosthetic implant was inserted for cosmetic rehabilitation.

Conclusions: This case highlights the aggressive nature of Klebsiella pneumoniae endogenous panophthalmitis and importance of prompt recognition. Atypical ocular presentations such as Roth's spots can precede rapid progression to panophthalmitis. High clinical suspicion, early systemic evaluation, and aggressive ocular and systemic therapy are critical to contain infection, salvage the globe, and prevent life-threatening spread.

Abstract No.: 201213

A Severe, Hereditary, Bilateral Panuveitis With Mutation of NOD2 Gene

First Author: Yuxi **CHEN**
 Co-Author(s): Ling **CHEN**

Purpose: To exhibit a case of bilateral panuveitis with a NOD2 mutation diagnosed as Blau syndrome.

Methods: A 25-year-old woman presented with blurred vision in her right eye for one month. Best-corrected visual acuity was 0.075 (right) and 0.4 (left). Slit examination showed different degrees of anterior chamber cells, aqueous flare, and mutton-fat keratic precipitates. Diffuse iris depigmentation with extensive posterior synechiae, cataract, vitreous cells, and vitreous opacification were also shown. OCT showed essentially normal retinal architecture in both eyes, with mild macular edema in the right eye. FFA and ICGA disclosed faint leakage from the posterior pole and peripheral vessels in both eyes, and macular edema in the right eye. Physical examination revealed deformities of the finger joints. Infectious causes were excluded. Two years ago, the intraocular pressure in the left eye was 28 mmHg, necessitating laser peripheral iridotomy, after which the intraocular pressure remained stable.

Results: Further history-taking revealed her mother, two sisters, and one brother exhibited similar ocular characteristics and finger abnormalities. Prior whole-exome sequencing identified an autosomal-dominant heterozygous NOD2 mutation. Integrating ocular findings with systemic manifestations, the diagnosis of Blau syndrome was established. She was started on adalimumab every two weeks plus methotrexate 15 mg weekly. She remains stable under ongoing follow-up.

Conclusions: Blau syndrome is a rare autoinflammatory disease characterized by dermatitis, arthritis, and recurrent uveitis. Although cutaneous and articular involvement usually appear first, ocular uveitis is a crucial diagnostic clue, yet tends to manifest later—often leading to under-recognition of the systemic disorder.

Abstract No.: 200522
Acute Bilateral Serous Retinal Detachments in a 21-Year-Old Female: A Case of Vogt-Koyanagi-Harada Disease

First Author: Kareem ABDULLATIF

Purpose: This case underscores the importance of considering Vogt-Koyanagi-Harada disease in young patients presenting with acute bilateral vision loss and characteristic fundus and OCT findings.

Methods: Bilateral fundus examination revealed significant findings consistent with an inflammatory process. The optic discs in both eyes appeared edematous with blurred margins, suggesting optic nerve involvement. Furthermore, changes in the retinal color were observed surrounding the macula, indicative of inflammation or edema in these critical areas responsible for central vision. Notably, pale areas were present in the background around the macular region. These findings are highly suggestive of subretinal exudates or serous retinal detachment, which are hallmark signs of acute VKH disease. The diffuse nature of these changes points towards a widespread choroidal inflammatory process. Optical Coherence Tomography (OCT) provided detailed cross-sectional imaging of the retina and choroid, confirming the clinical suspicions

Results: Vogt-Koyanagi-Harada disease is an immune-mediated inflammatory condition that primarily targets melanocyte-containing tissues. The acute uveitic phase, as seen in this patient, is characterized by bilateral panuveitis with serous retinal detachment, often leading to significant vision impairment. The patient's history of *Helicobacter pylori* infection, while not directly causative, may suggest a potential immune dysregulation, although a direct link to VKH is not definitively established. The comprehensive ophthalmic examination, including detailed fundus imaging and OCT, was crucial in establishing the diagnosis.

Conclusions: This case underscores the importance of considering Vogt-Koyanagi-Harada disease in young patients presenting with acute bilateral vision loss and characteristic fundus and OCT findings.

Abstract No.: 207038
Acute Retinal Necrosis Syndrome With Orbital Cellulitis As the Initial Symptom in a First-Trimester Pregnant Woman

*First Author: Dengxue WANG
Co-Author(s): Zaihong CHEN*

Purpose: To report an atypical acute retinal necrosis syndrome (ARN) case with orbital cellulitis as the initial symptom.

Methods: A 22-year-old first-trimester primigravida presented with right eyelid erythema, pain, and visual decline. Initial diagnosis was right orbital cellulitis,

treated with intravenous glucocorticoids and broad-spectrum antibiotics. Despite improved eyelid/conjunctival edema, vision worsened. Dilated fundus exam showed right vitreous opacity and peripheral retinal yellow-white lesions (suggesting ARN). Aqueous humor metagenomic sequencing confirmed HSV-2 positivity. She received intravenous/intravitreal/topical antiviral therapy, followed by pars plana vitrectomy for right retinal detachment.

Results: At the 3-month post-operative follow-up, the patient's best-corrected visual acuity (BCVA) was 0.1 (Snellen chart). Complete resolution of both orbital inflammation and retinal inflammation was observed.

Conclusions: HSV-2 can co-induce orbital cellulitis and ARN. For such comorbidity, timely etiological tests (e.g., aqueous sequencing) are critical to avoid delayed treatment and irreversible vision loss.

Abstract No.: 201388
Analysis of Misdiagnosis Causes and Clinical Observation of Acute Retinal Necrosis Syndrome

First Author: Liu RUI

Purpose: To analyze the causes of misdiagnosis and clinical characteristics of acute retinal necrosis syndrome (ARN).

Methods: Review the clinical data of 12 patients (16 eyes) with ARN, summarize the clinical characteristics, and analyze the causes of misdiagnosis.

Results: The average time from onset to definitive diagnosis was 21.4 days. 12 cases were misdiagnosed as conjunctivitis, iridocyclitis, glaucomatocyclitic syndrome, uveitis, glaucoma, Eales disease, and retinal vein obstruction. The diagnosis of ARN is based on clinical features. The use of polymerase chain reaction (PCR) in aqueous humor samples is useful to identify the etiology. 12 patients received systemic and intraocular antiviral therapy and were supplemented by retinal laser photocoagulation, corticosteroids, and aspirin. 5 patients underwent vitreous surgery due to the progression of ARN. The best corrected visual acuity ranged from light perception to 12/60 during 3~21 months follow-up period.

Conclusions: It is crucial to avoid misdiagnosis and strengthen the identification of ARN. Early diagnosis and timely appropriate intervention are needed.

Abstract No.: 200435
Atypical Lesion Pattern in a Case of Punctate Inner Choroiditis

*First Author: Chynna Pearl Tana BACCAY
Co-Author(s): Albert John BROMEO*

Purpose: Punctate inner choroiditis (PIC) is a rare idiopathic inflammatory posterior uveitis presenting with classic yellow-white lesions confined to the

posterior pole in the absence of anterior segment and vitreous inflammation. Choroidal neovascularization (CNV) is a known complication and a major cause of visual impairment. We report a rare case of PIC presenting with an atypical lesion pattern.

Methods: Case Report

Results: A 61-year-old male presented with blurring of vision in both eyes (OU). Best corrected visual acuity (BCVA) on presentation was 20/40 on the right eye (OD) and 20/50 on the left (OS). Fundus examination showed multiple yellow-white dots right along the superior and inferior arcade OU along with subretinal hemorrhage OS. Fluorescein angiography showed early hypofluorescence and late hyperfluorescence of the dot lesions as well as hyperfluorescence from CNV OU. OCT revealed CNV with pigment epithelium detachment and focal areas of retinal pigment epithelium loss OU. Fundus autofluorescence (FAF) showed mixed areas of hypo- and hyperautofluorescence of the lesions. Systemic work-up was unremarkable. He was diagnosed with PIC with secondary CNV OU. The patient was treated with a course of oral prednisone as well as started on methotrexate, along with a series of intravitreal bevacizumab injections OU. Management led to lesion stability as demonstrated by FAF as well as CNV inactivity on OCT.

Conclusions: Punctate inner choroiditis may present with atypical features. Recognition is essential for timely diagnosis and initiation of appropriate therapy to prevent permanent visual impairment.

Abstract No.: 201700

Bilateral Cystoid Macular Edema as a Presenting Sign of Presumed Ocular Tuberculosis

First Author: Debarun SHARMA

Co-Author(s): Himanshu GARKOTI

Purpose: To report a case of bilateral cystoid macular edema as a rare sign of presumed ocular tuberculosis.

Methods: A 60-year-old female with a history of bilateral diminution of vision for the past 6 months presented to the outpatient department with OU BCVA 6/18 with no further improvement on pinhole. She had a history of cataract surgery 10 years back. Slit lamp examination revealed unremarkable anterior segment findings. Retrolental cells were present in both eyes. Fundus examination revealed a tessellated fundus with a dull foveal reflex and fine pigment mottling at the posterior pole. Fundus photography, SD-OCT, and FFA were advised.

Results: OCT showed bilateral cystoid macular edema. CMT in the right eye was 521 microns, and in the left eye was 489 microns. FFA showed bilateral "hot discs" in diffuse perivascular leakage and petalloid leakage at the fovea in the late phases of the angiogram. A diagnosis of posterior uveitis was made. Uveitis

panel with markers for infection was advised to the patient. Quantiferon TB gold and Mantoux test were positive. Chest X-ray was unremarkable. A diagnosis of presumed ocular tuberculosis was made, and the patient was started on Anti-Tubercular Treatment. Since the patient was diabetic, bilateral intravitreal injection of Ozurdex was done 48 hours after starting Anti-Tubercular Treatment. The patient presented 1 month later with OU BCVA 6/6. OCT revealed complete resolution of CME.

Conclusions: Bilateral CME is a rare presentation of ocular tuberculosis. A high level of suspicion is required for diagnosis.

Abstract No.: 204281

Bilateral Fulminant Idiopathic Occlusive Retinal Vasculitis With Severe Neovascular Sequelae in a Young Female: A Case Report

First Author: Al Anood AL FARSI

Purpose: To report a rare and aggressive case of bilateral idiopathic progressive ischemic retinal vasculitis in a young female, refractory to conventional treatment.

Methods: A 32-year-old woman with no significant systemic history presented with sequential bilateral vitreous hemorrhages. Clinical evaluation revealed normal anterior segments and intraocular pressures, but fundus examination demonstrated sclerosed retinal vessels with extensive neovascularization of the disc and elsewhere, in the absence of retinitis or choroiditis. Fluorescein angiography confirmed widespread peripheral ischemia with perivascular leakage and relative early macular sparing. Comprehensive systemic and autoimmune investigations, including ANA, RF, ACE, HIV, syphilis serology, IGRA, and antiphospholipid testing, were all negative. She was also evaluated by rheumatology, with Behçet's disease and SLE considered but not confirmed, leading to a diagnosis of idiopathic ischemic retinal vasculitis.

Results: Despite systemic oral corticosteroids, pan-retinal photocoagulation, and multiple intravitreal anti-VEGF therapies, the disease progressed to macular ischemia, and neovascular complications developed, including iris neovascularization and neovascular glaucoma. Escalation to systemic immunosuppression with adalimumab and methotrexate, and an empirical trial of systemic valganciclovir, failed to halt disease progression. Adjunctive aspirin was initiated in an attempt to limit ongoing ischemia, but also failed to prevent worsening ischemia.

Conclusions: This case illustrates an exceptionally rare, fulminant phenotype of idiopathic ischemic retinal vasculitis unresponsive to corticosteroids, laser photocoagulation, anti-VEGF, systemic immunosuppression, and biologics. The course was complicated by severe neovascular sequelae,

highlighting the diagnostic and therapeutic challenges of managing aggressive ischemic vasculitis. Early recognition, multimodal therapy, and close monitoring are critical, yet visual prognosis may remain guarded despite timely intervention.

Abstract No.: 204283

Bilateral Intermediate Uveitis With Retinal Vasculitis and Anomalous Vitreous in the Absence of Definitive Systemic Disease

First Author: Marwah Khamis **AL KALBANI**

Purpose: To describe a complex case of bilateral intermediate uveitis with retinal vasculitis and anomalous vitreous, highlighting diagnostic uncertainty when systemic criteria for multiple sclerosis (MS) or Behçet's disease are not fulfilled.

Methods: A 32-year-old female presented with bilateral posterior subcapsular cataracts and primary angle-closure glaucoma associated with low-grade anterior chamber inflammation. Detailed ophthalmic and systemic evaluations were performed, including multimodal imaging, infectious screening, autoimmune workup, and neuroimaging.

Results: Fundus examination revealed anomalous membranous vitreous with vitreoschisis, sclerosed vessels, and vascular sheathing in both eyes. Fluorescein angiography demonstrated bilateral hot discs, vascular leakage, and areas of capillary non-perfusion. Systemic evaluation was largely unremarkable except for HLA-B51 positivity. CT chest and sacroiliac imaging were normal. MRI brain showed a solitary demyelinating lesion with no further dissemination at 6-month follow-up. The patient also had a long-standing history of left-sided ptosis and anhidrosis, diagnosed as congenital Horner's syndrome. Initial treatment with systemic corticosteroids led to clinical improvement but triggered intraocular pressure elevation; she was transitioned to mycophenolate mofetil with partial control of inflammation. Genetic testing was initiated to rule out inherited vitreoretinopathy.

Conclusions: This case underscores the diagnostic and therapeutic challenges of bilateral intermediate uveitis with vasculitis and anomalous vitreous when systemic disease criteria are not met. The overlap of features resembling Behçet's disease, demyelinating pathology, and inherited vitreoretinopathies highlights the importance of multimodal imaging, genetic testing, and multidisciplinary follow-up. Long-term individualized immunosuppression remains essential, and cataract surgery should be deferred until adequate inflammatory control is achieved.

Abstract No.: 206225

Blau Syndrome With Atrial Septal Defect: A Case Report

First Author: Weiting **PENG**

Co-Author(s): Yun **LI**

Purpose: Blau Syndrome (BS) is a rare autosomal dominant autoimmune disease caused by mutations in the NOD2 gene. This disease is characterized by the triad of granulomatous polyarthritides, rash, and uveitis and could also accumulate in other systems, including the cardiovascular system. This study aims to describe the clinical features of a Chinese BS patient with an atrial septal defect.

Methods: The clinical data of a BS patient complicated with an atrial septal defect were collected and documented.

Results: We reported the case of a 9-year-old woman who presented with polyarticular arthritis accompanied by joint deformities, atrial septal defect, and severe ocular accumulation, including bilateral uveitis, bilateral complicated cataracts, and secondary glaucoma in the left eye. She was diagnosed with BS by the finding of a variant of the NOD2 gene (R334W). Through the literature review, we found another Chinese BS case with the same mutation site, who presented with atrial septal defect and impaired vision, bilateral granulomatous and old retinal vasculitis in the right eye, suggesting a potential association between BS caused by this mutation with atrial septal defect and severe ocular accumulation.

Conclusions: Atrial septal defect is a rare complication of BS. Clinicians, especially Ophthalmologists, should increase awareness of ocular accumulations in patients with BS combined with atrial septal defect.

Abstract No.: 201740

Blau Syndrome: A Diagnostic and Therapeutic Challenge in a Young Child

First Author: Bhavik **PANCHAL**

Co-Author(s): Afra **ABDUSSAMAD**, *Snehal* **GANATRA**, *Anjani* **GUMMADI**

Purpose: To report an atypical presentation of Blau syndrome manifesting initially as isolated uveitis and to highlight the importance of early genetic diagnosis and multidisciplinary management.

Methods: A 2-year-old boy presented with bilateral uveitis and complicated cataracts. He was managed initially with corticosteroids and methotrexate. Serial clinical evaluations, laboratory tests, imaging studies, and whole-genome sequencing were performed to establish the diagnosis and guide treatment. Surgical and pharmacologic interventions were undertaken for disease control and visual rehabilitation.

Results: At presentation, the patient exhibited chronic anterior uveitis, characterised by band-shaped

keratopathy, posterior synechiae, and cataracts. Systemic features were absent initially, delaying diagnosis. Over follow-up, the child developed arthritis and dermatitis, completing the classic Blau triad. Whole genome sequencing identified a pathogenic NOD2 mutation, confirming Blau syndrome. Corticosteroids and methotrexate provided partial control but were insufficient to prevent relapses. Cataract surgery and vitrectomy improved vision after inflammation control. Initiation of adalimumab, a TNF inhibitor, resulted in a marked reduction of ocular inflammation, allowed tapering of steroids, and prevented further relapses. Visual rehabilitation with scleral contact lenses further optimised outcomes.

Conclusions: Blau syndrome may present atypically with isolated ocular features, delaying diagnosis. Genetic confirmation is essential in suspected cases of pediatric uveitis. TNF inhibitors such as adalimumab provide superior disease control compared with conventional therapy, while surgical intervention plays a key role in managing complications. A multidisciplinary approach is crucial for long-term visual and systemic outcomes.

Abstract No.: 201730

Case of Possible Intraocular Tuberculosis

First Author: Ayush SANGOLE

Purpose: Show the key features of IOTB.

Methods: A single case to show the characteristic feature of IOTB.

Results: IOTB shows a few characteristic features like granuloma (tuberculoma), tubercle, and also a few typical FFA features.

Conclusions: Early diagnosis and treatment can help to resolve IOTB.

Abstract No.: 203944

Characteristics of Ocular Syphilis in Human Immunodeficiency Virus-Positive Patients in Tertiary Eye Care Center: A Two-Year Observational Study

First Author: Grace SETIAWAN

Co-Author(s): Angga FAJRIANSYAH, Elfa Ali IDRUS, Patriotika MUSLIMAH, Arief Akhdestira MUSTARAM

Purpose: To describe the clinical characteristics of ocular syphilis in HIV-positive patients in the Indonesian National Eye Center, Cicendo Eye Hospital.

Methods: A retrospective descriptive study was conducted from the medical records of patients diagnosed with ocular syphilis with HIV co-infection from January 2019 to March 2021. Gender, age, marital status, educational level, sexual preference, clinical features, visual acuity, ocular lateralization, ocular medications, systemic medications, and follow-up period were reviewed.

Results: A total of 26 eyes from 15 patients were included in this study. The majority of the subjects were males (93%) with an age of 20-30 years (66%). All of the subjects were HIV-positive, and 53% of them were MSM. Bilateral ocular syphilis was found in 73% subjects, with panuveitis as the most common (50%) clinical manifestation. The median of the follow-up period was 4 (3-11) months.

Conclusions: Characteristics of population in this study were young-adult males that were tested positive for HIV with the history of MSM. Bilateral panuveitis was the most prominent clinical manifestation.

Abstract No.: 205884

Choroidal Abscess With Roth Spots in a Healthy Young Male

First Author: Yuanshao CHENG

Co-Author(s): Wenjung LO

Purpose: To report a case of endogenous endophthalmitis with choroidal abscess in a healthy young male.

Methods: A case report.

Results: A previously healthy 29-year-old male presented with one day of decreased vision in his left eye. Initial visual acuity (VA) was 6/6 in the right eye and counting fingers at 30 cm in the left eye. Slit lamp examination showed no anterior chamber or vitreous inflammation. Fundus examination revealed a dense, yellow-whitish, dome-shaped lesion over the left eye's lower arcade with associated Roth spots. A uveitis workup was initiated. The patient returned one day later, complaining of eye pain, and the slit lamp now showed an exudative membrane with hypopyon. Given the suspicion of endogenous endophthalmitis with choroidal abscess, vitreous fluid was collected for culture, and empiric systemic and intravitreal antibiotics were administered. The vitreous culture subsequently grew *Klebsiella pneumoniae*, and the abdominal computed tomography revealed a liver abscess.

Conclusions: Treatment for endogenous endophthalmitis with a choroidal abscess is a time-sensitive, combined approach. It requires the urgent administration of intravitreal broad-spectrum antibiotics immediately following a vitreous biopsy to obtain cultures. This must be coupled with systemic intravenous antibiotics to treat the underlying source of infection and often includes pars plana vitrectomy to clear the vitreous and better manage the abscess.

Abstract No.: 202266

Clinical Analysis of THS and Non-THS

First Author: Zheng ZENG

Co-Author(s): Caiyun YOU

Purpose: To investigate the clinical features of Tolosa-Hunt syndrome (THS), painful ophthalmoplegia.

Methods: A retrospective analysis was conducted on 35 patients with suspected painful ophthalmoplegia from January 2019 to December 2022. According to ICHD-3, 18 patients were finally diagnosed with THS and 17 were not diagnosed with THS.

Results: THS patients had pain as their initial symptom in 94.4% (17/18) of cases, with the most common finding on MRI being localized orbital and cavernous sinus lesions (10/18, 55.6%). Nine (9/18, 50.0%) of the THS patients had abnormalities on immunological tests. In the patients who were not diagnosed with THS pain ophthalmoplegia, pain was the initial symptom in 64.7% (11/17) of cases. On MRI, localized orbital and cavernous sinus lesions were found in four (4/17, 23.5%) of the patients. Three (3/17, 17.6%) of the patients had abnormalities on immunological tests. There were 12 cases (12/17, 70.6%) of undiagnosed THS ophthalmoplegia patients with diabetes.

Conclusions: The first symptom of THS's ophthalmoplegia is pain, and the positive signs of cavernous sinus found by magnetic resonance imaging are more common, and the proportion of patients with abnormal serum immunology is higher, while the proportion of patients with undiagnosed THS's ophthalmoplegia complicated with diabetes and other systemic diseases is higher, which is helpful for the differential diagnosis of the two.

Abstract No.: 205451

Clinical Case Report of Vogt-Koyanagi-Harada Syndrome in Young Women With Positive Finding on Brain MRI

First Author: Ya Hui WANG

Co-Author(s): Wen-yu HSU

Purpose: To present a clinical case of Vogt-Koyanagi-Harada (VKH) syndrome in an 16-year-old female with bilateral uveitis, describe the diagnostic process, treatment strategy, and clinical outcomes.

Methods: Case report.

Results: A 16-year-old female presented with blurred vision and photophobia in both eyes, accompanied by headaches, bilateral tinnitus, dizziness, and hearing disturbances. Ophthalmic examination revealed anterior chamber inflammation, optic disc swelling, and multiple serous retinal detachments of both eyes. Optical coherence tomography (OCT) showed subretinal fluid accumulation and retinal pigment epithelial changes. Laboratory tests were positive for CMV IgG and rheumatoid factor, with HLA-DR4 and

HLA-DQ4/DQ8 positivity. Fluorescein angiography demonstrated multiple pinpoint leakage and late-stage dye pooling. Brain magnetic resonance imaging (MRI) revealed enhancement of the bilateral inner ear labyrinth and cochlea. A tentative diagnosis of VKH syndrome was made, and the patient was initially treated with high-dose intravenous methylprednisolone, followed by oral steroids and immunosuppressive therapy. Following corticosteroid pulse therapy, the patient's visual acuity improved to 1.0/1.0. Immunosuppressive therapy, first treated by mycophenolate mofetil and later shift to methotrexate, was administered to maintain disease control. However, two weeks post-influenza vaccination, she experienced left eye blurred vision with slight painful sensation. Slit lamp exam revealed increased anterior chamber reaction with 4+ cells and pupillary fibrin membrane formation in the left eye. Medication adjustments resulted in rapid improvement, and pupillary fibrin membrane disappeared after 4 days of topical steroid treatment.

Conclusions: Early diagnosis, long-term immunosuppressive therapy with close monitoring and individualized treatment adjustments for VKH syndrome are essential for optimal patient outcomes.

Abstract No.: 202078

Clinical Features and Multimodal Imaging in Neuro-Behçet's Disease: A Case Series

First Author: Eliza ANTHONY

Co-Author(s): Anand RAJENDRAN

Purpose: To demonstrate clinical features and multimodal imaging in two patients with Neuro-Behçet's Disease (NBD)

Methods: Retrospective case series of three eyes of two patients. Both patients underwent complete detailed history taking, ocular examination, color fundus photography, spectral domain optical coherence tomography (SDOCT), fluorescein angiography (FFA) and indocyanine angiography (ICG) and necessary blood work up.

Results: Case 1: 36-year-old female presented with right eye defective vision, panuveitis, and a one-year history of vertigo and gait imbalance. Although neuroimaging was unremarkable, audiometry confirmed vestibular dysfunction, indicative of subclinical brainstem involvement. Multimodal imaging findings were consistent with active inflammation and ocular vasculitis. HLA-B51 positivity supported the diagnosis of Neuro-Behçet's Disease. She showed good clinical response to corticosteroids and immunosuppressive therapy. Case 2: 45-year-old male had bilateral panuveitis, disc edema, and persistent headaches. SDOCT revealed cystoid macular edema and an epiretinal membrane. FFA showed vasculitis. Magnetic resonance imaging showed dilated ventricles. Patient was diagnosed with idiopathic

intracranial hypertension (IIH), likely to be presentation of non-parenchymal NBD with HLA B51 positivity. Ocular inflammation was stabilized with systemic immunosuppressants and biologicals. However chronic papilledema, which was secondary to IIH, resolved only after oral acetazolamide treatment.

Conclusions: This case series highlights the varied ocular presentations of NBD and crucial role of multimodal modal imaging in unveiling features of both ocular and neurological involvement in NBD. Early identification and timely initiation of therapy are critical to preserving visual function and improving overall prognosis.

Abstract No.: 200364

Clinical Features and Prognosis of Fuchs' Uveitis Syndrome in Yemen

First Author: Khaled **AL-HEMYARI**

Co-Author(s): Mahfoud **BAMASHMUS**

Purpose: To explore the clinical patterns and prognosis of FUS among Yemeni patients.

Methods: Retrospective Cross sectional study targeting 80 patients diagnosed as FUS in Magrabi Hospital at 2024.

Results: Results end with similar features of other researches with some modifications.

Conclusions: FUS is a diagnosis of exclusion. Heterochromia and iris nodules are uncommon in Yemeni FUS patients. PHACO+PC IOL implantation in Fuchs' Uveitis resulted in good visual outcomes, so early diagnosis and regular follow-up are very important.

Abstract No.: 201353

Clinical Observation of Long-Term Misdiagnosis of Ocular Toxoplasmosis

First Author: Liu **RUI**

Purpose: To analyze the causes of misdiagnosis and clinical characteristics of ocular toxoplasmosis (OT).

Methods: Review of clinical data of 3 cases (3 eyes) of OT misdiagnosed as summarize the clinical characteristics and analyze the causes of misdiagnosis.

Results: The average time from onset to initial misdiagnosis of Glaucoma in 3 patients was 15.5 days. The average time from onset to definitive diagnosis was 21.5 months. After confirming the diagnosis of OT, 3 patients received systemic antiparasitic agent therapy and were supplemented with local glucocorticoid drugs. The follow-up period was from 6 to 22 months. The best corrected visual acuity ranged from 0.05 to 0.4.

Conclusions: It is crucial to avoid misdiagnosis and strengthen the identification of OT because of recurrent illness, poor prognosis, and high blindness rate. Early

diagnosis and timely appropriate intervention are needed.

Abstract No.: 201688

Collateral Damage: A Case Report on Sympathetic Ophthalmia in a 35-Year-Old Female Filipino Patient

First Author: Pia Jejame **MAMARIL**

Co-Author(s): Angelique **CHIU-ANG**, Janis **FERRER-BERNARDO**

Purpose: Sympathetic Ophthalmia, is a rare autoimmune ocular inflammatory, with an incidence of approximately 0.03 per 100,000 persons per year. This case report details the progression, diagnosis, and management of SO, specifically analyzing the sequential blurring of vision in the fellow eye.

Methods: A 35-year-old Filipino female initially presented with a one-month history of bilateral sequential progressive painless blurring in the left eye, following a prior traumatic injury on the right eye. Initial ophthalmic examination revealed poor light projection and an intraocular pressure of 8 mmHg in OD, along with a supraorbital scar, enophthalmos, and Grade I traumatic hyphema. Visual acuity in OS was counting fingers, best corrected to 20/200, with granulomatous keratic precipitates, an IOP of 12 mmHg and optic nerve swelling. Despite multiple consultations and an initial impression of non-penetrating globe injury with intraocular hemorrhage on OD and optic disc edema on OS, further diagnostic workup- including an orbital MRI with contrast- led to the final diagnosis of a ruptured right globe, and Sympathetic Ophthalmia in OS.

Results: Early enucleation of the injured OD was performed, a measure known to improve the visual prognosis of the fellow eye. Also, following treatment with high-dose intravenous steroids, and immunosuppressive therapy, vision in OS improved to 20/20.

Conclusions: The incidence of SO following traumatic eye injury is approximately 0.19%. Management requires prompt hospitalization, administration of high-dose corticosteroids, and Immunosuppressive therapy, which are key to improving visual outcomes in affected patients.

Abstract No.: 205094

Cotrimoxazole Monotherapy With Steroid Cover as a Practical Alternative for Toxoplasma Chorioretinitis in Resource-Limited Settings: A Case Report

First Author: Adianne **ROSALIE**

Co-Author(s): Eka **WARNERIN**, Lely **WULANDARI**

Purpose: Standard therapy for toxoplasma chorioretinitis relies on pyrimethamine-sulfadiazine

or spiramycin, often unavailable in low-resource settings. Evidence on cotrimoxazole monotherapy is limited, particularly regarding outcomes and steroid integration. This report highlights cotrimoxazole as an accessible, affordable, practical alternative as the sole antiparasitic agent.

Methods: A 61-year-old patient with active toxoplasma chorioretinitis received oral cotrimoxazole (trimethoprim 160 mg/sulfamethoxazole 800 mg) twice daily for six weeks. Methylprednisolone 8 mg three times daily was added after antiparasitic initiation. Serial best-corrected visual acuity (BCVA), fundus findings, and intraocular pressure (IOP) were documented. Informed consent was obtained.

Results: BCVA improved from 0.50/0.10 at baseline to 0.63/0.32 by 10 weeks. IOP remained normal. Fundus exams showed progressive regression of retinal lesions and resolution of intraretinal edema with no systemic or ocular adverse effects. Cotrimoxazole acts by sequential inhibition of dihydropteroate synthase and dihydrofolate reductase, blocking tetrahydrofolate synthesis and parasite DNA replication with good ocular penetration. Compared with pyrimethamine-sulfadiazine it is cheaper, more available, and easier to administer. Favorable response likely reflects prompt initiation, adherence, lesion characteristics, host immunity, and adequate drug levels.

Conclusions: Cotrimoxazole monotherapy with steroid cover achieved meaningful visual and anatomic recovery and was well tolerated. This case supports cotrimoxazole as a practical, safe, and cost-effective option for ocular toxoplasmosis where standard regimens are unavailable. Planned follow-up includes visits at 3, 6, and 12 months with consideration of intermittent prophylaxis to reduce recurrence.

Abstract No.: 201397

Critical Crossroads: Where the Right Diagnosis Makes All the Difference

First Author: Sashwanthi MOHAN

Purpose: To highlight the importance of accurately differentiating between multifocal central serous chorioretinopathy (CSCR) and Vogt-Koyanagi-Harada (VKH) disease, as their management differs significantly, and to illustrate how detailed clinical and imaging evaluation guides timely treatment.

Methods: A 38-year-old female presented with headache and progressive bilateral visual blurring. Comprehensive ophthalmologic evaluation was performed, including fundus examination, fluorescein angiography (FA), optical coherence tomography (OCT), and systemic workup. Indocyanine green angiography (ICGA) was unavailable. Imaging and clinical findings were used to distinguish between CSCR and VKH, which both present with serous retinal detachments.

Results: FA showed multiple areas of early pinpoint hyperfluorescence and disc leakage. OCT confirmed choroidal thickening and serous retinal detachments. The patient's systemic symptoms, including headache, along with imaging findings, supported a diagnosis of VKH. Prompt treatment with intravenous methylprednisolone (1 g × 3 days) followed by tapering oral steroids resulted in significant visual improvement and near-complete resolution of serous detachments within 3 days.

Conclusions: Accurate differentiation between CSCR and VKH is critical due to vastly different treatment strategies. While CSCR may resolve with observation and stress management, acute VKH requires immediate high-dose corticosteroid therapy to prevent permanent vision loss. Multimodal imaging and thorough clinical assessment are essential for appropriate diagnosis and timely intervention.

Abstract No.: 200846

Cytomegalovirus Uveitis–Associated Endothelial Cell Damage: Clinical Outcomes and Long-Term Follow-Up

First Author: Chan-wei NIEN

Co-Author(s): Tsai-wei LIN

Purpose: To evaluate the impact of cytomegalovirus (CMV) anterior uveitis on corneal endothelial cell density (ECD) and to assess the efficacy of antiviral treatment in preventing progressive endothelial loss.

Methods: This retrospective observational study included 18 eyes of 18 immunocompetent patients in the period of 2020 to 2024 diagnosed with CMV anterior uveitis confirmed by anterior chamber paracentesis and viral PCR study. All patients underwent serial specular microscopy to measure ECD at baseline, during active inflammation, and after antiviral therapy with oral valganciclovir and topical 2% ganciclovir. Clinical parameters, including visual acuity, intraocular pressure, anterior chamber reaction grading, and fundus condition were also recorded.

Results: At diagnosis, mean ECD was significantly decreased compared to the contralateral unaffected eyes (2110 ± 328 vs. 2750 ± 290 cells/mm², $p < 0.01$). During active inflammation, further reduction in ECD was observed (mean loss $14.6\% \pm 4.2\%$). Following antiviral therapy, disease activity subsided and ECD stabilized, but complete recovery of cell counts was not achieved. BCVA decline (0.9 to 0.6), and IOP elevation (15.2 to 26.5 mmHg, $p < 0.001$) were also noted.

Conclusions: CMV anterior uveitis causes significant corneal endothelial cell damage, which can progress rapidly without prompt treatment. Early diagnosis with aqueous humor PCR and timely initiation of antiviral therapy are essential to control inflammation and preserve endothelial function. Long-term monitoring

remains necessary due to the high risk of recurrence and cumulative endothelial loss.

Abstract No.: 206046

Delayed Onset of Sunset Glow Fundus and Skin Manifestations in Vogt-Koyanagi-Harada Syndrome

*First Author: Syecha Tsania **ALAYDRUS***

*Co-Author(s): Halida **WIBAWATY**, Gagan Vihari Izzan **YULIANTO***

Purpose: To report a case of Vogt-Koyanagi-Harada syndrome with delayed onset of sunset-glow fundus and skin manifestations after eight months of treatment.

Methods: A 47-year-old male presented with a recent history of blurred vision, headache, ocular pain, and redness. Examination showed decreased visual acuity (UCVA 0.6/0.4), bilateral iris synechiae, and cataracts. The patient was subsequently diagnosed with uveitis with complicated cataracts and treated with oral and topical corticosteroids. Despite initial worsening, UCVA gradually improved from the third month of treatment. However, by the eighth month, the patient began to exhibit signs such as vitiligo, poliosis, and a sunset-glow fundus, leading to a diagnosis of Vogt-Koyanagi-Harada syndrome.

Results: The patient showed improvement in visual acuity from the third month of treatment and remained stable thereafter, demonstrating a good response to treatment and controlled ocular inflammation. Nevertheless, the skin manifestations appeared along with the sunset-glow fundus, which indicates loss of melanin granules in the choroid. It can appear alongside good UCVA if the depigmentation is mild or located away from the macula, the inflammation is well-controlled, and there are no significant vision-threatening complications.

Conclusions: This case illustrates that systemic and ocular depigmentation in VKH can arise much later than expected, reinforcing the need for prolonged follow-up and awareness that early resolution does not preclude late-stage manifestations.

Abstract No.: 205871

Development of Transparent Triamcinolone Acetonide Solution for Uveitis Treatment

*First Author: Yuanshao **CHENG***

*Co-Author(s): Wenjung **LO***

Purpose: Intravitreal corticosteroid therapy can be useful for noninfectious uveitis that involve the posterior segment of the eye. However, triamcinolone acetonide (TA) is a low water soluble suspension. It remains as white crystalline deposits in the vitreous and can cause visual disturbances. The aim of our research was to evaluate the efficacy of intravitreal

triamcinolone acetonide in conjunction with hyaluronic acid (HA) for the treatment of uveitis which involved the posterior segment.

Methods: TA is modified by amino acid using esterification, and the HA-based conjugates was synthesized from precursor using the carbodiimide coupling agent. The structure was identified by ¹H-NMR spectroscopy. After the purification and characterization, the anti-inflammatory effect was evaluated in the endotoxin-induced uveitis (EIU) animal model. EIU was induced by a single intravitreal injection of LPS using a Hamilton microinjector under a dissecting microscope. Phosphate-buffered saline and HA conjugates were administered to the eyes. Aqueous samples were collected at the start of vitrectomy by limbal paracentesis using a 30-gauge needle and stored at -80°C for further cytokine determination.

Results: The designed HA-TA coupling reaction reveals >98 % conjugation efficiency in the dimethyl sulfoxide/water system. The HA-TA conjugates is water soluble and transparent which is different from the commercial TA suspension. The cell number and protein in aqueous humor were significant decreased in EIU model.

Conclusions: HA-TA was successfully synthesized and revealed transparent parties compared with Shincort. Potential treatment effects of HA-TA conjugates were observed in EIU animal model.

Abstract No.: 201435

Diagnosing Multiple Evanescent White Dot Syndrome: A Case Study and Clinical Considerations

*First Author: Crystal **CHEONG YIJING***

*Co-Author(s): Manoharan **SHUNMUGAM**, Hwei Yin **TEOH**, Hon Seng **WONG***

Purpose: To present a case study of Multiple Evanescent White Dot Syndrome (MEWDS), an uncommon, benign retinal disorder.

Methods: A 30-year-old male presented with a three-week history of temporal 'veil-like' disturbance in his right eye. A comprehensive ophthalmologic evaluation was performed, including Optos widefield fundus photographs and fundus autofluorescence (FAF), optical coherence tomography (OCT), fundus fluorescein angiography (FFA), indocyanine green angiography (ICGA), and visual field testing. The clinical features were compared to the current literature on MEWDS to analyze the diagnostic approach and outcomes.

Results: The patient exhibited unilateral, right-eye characteristic findings of MEWDS: multiple small, whitish dots visualized through ultra-wide field imaging. Ultra-wide field imaging is crucial for MEWDS, offering a full retinal view to detect peripheral white dots often missed by standard imaging. FAF revealed these lesions as hyperfluorescent areas. FFA also showed

hyperfluorescent leakage, while ICGA demonstrated peripheral choriocapillary leakages in the initial phase. OCT showed foveal granularity, and slit-lamp examination revealed grade 1–2 anterior vitreous cells. Visual field testing demonstrated a temporal scotoma. The patient was prescribed oral prednisolone tablets to be tapered over a course of six weeks.

Conclusions: This case highlights the need for early MEWDS recognition, timely diagnosis, clear communication, and more research.

Abstract No.: 201537

Diagnostic Value of Arm-to-Retina Time in Fundus Fluorescein Angiography in Patients With Uveitis

First Author: Aneena Anna **THOMAS**

Co-Author(s): Padmamalini **MAHENDRADAS**

Purpose: Fluorescein angiography (FFA) is essential for evaluating retinal circulation and monitoring treatment response in uveitis. Arm-to-retina time (ART), which reflects systemic circulation, may be prolonged in both systemic and ocular inflammation, serving as a potential marker of vascular dysfunction and hemodynamic changes.

Methods: A retrospective review was conducted of electronic medical records from 94 patients from the uveitis department. Those with increased ART during FFA were included in this study.

Results: The study included 93 patients (mean age: 44.3 years; 55% female, 45% male). ART measurements, the mean ART decreased from 21.6 seconds to 19.3 seconds, indicating improved retinal perfusion following treatment. ART positively correlated with age but showed no sex-related differences. Posterior uveitis was the most common anatomical diagnosis (48%), followed by panuveitis (13%) and intermediate uveitis (12%). The most common clinical diagnoses included idiopathic uveitis (21.5%), retinal vasculitis (17.2%), and tubercular uveitis (12.9%). Notably, delayed ART led to the diagnosis of hyper-homocysteinemia in addition to inflammatory causes.

Conclusions: Prolonged ART was observed in cases of posterior uveitis and panuveitis, supporting its role as a functional biomarker for posterior segment inflammation/ circulation, which got better following targeted therapy.

Abstract No.: 205982

Drug-Induced Anterior Uveitis: A Case to Remember

First Author: Hitisha **MITTAL**

Co-Author(s): Sangeeta **ABROL**, Harinder **SETHI**, Himani **SHARMA**, Ritu **SINGH**

Purpose: To report a rare case of late onset brimonidine associated granulomatous anterior uveitis in a patient with primary open angle glaucoma (POAG).

Methods: We report a single case of a 57-year-old female with bilateral primary open-angle glaucoma on topical brimonidine and timolol for 2 years, who presented with a 2-month history of blurred vision, redness, glare, and pain in the right eye. Comprehensive ophthalmic evaluation (including slit-lamp biomicroscopy, intraocular pressure measurement, fundus examination) and detailed systemic investigations were performed to detect the underlying etiology and instill appropriate and timely treatment.

Results: Her right eye workup revealed ciliary congestion, 1+ AC cells and diffuse non-pigmented mutton fat keratic precipitates suggestive of granulomatous anterior uveitis with an IOP of 20, CDR of 0.8, no vitritis and normal fundus. Left eye did not reveal any signs of inflammation. Systemic tests revealed normal blood counts, ESR and CRP. Mantoux, TB Gold, HRCT chest, serum ACE, serum calcium, HIV, TPHA were negative. All investigations were negative which led to suspicion of brimonidine associated AAU. Brimonidine was withheld for a week without initiating steroids. At 1 week follow up, the mutton fat keratic precipitates (KPs) reduced dramatically and IOP reduced to 12 mm Hg. The KPs showed complete resolution at 3 weeks, with no recurrence at 1.5 year follow up.

Conclusions: Patients on long term brimonidine can rarely present with features of granulomatous anterior uveitis, which is completely reversible after cessation of the offending drug. Such patients often do well without long term treatment with steroids.

Abstract No.: 203757

Early Immunomodulatory Therapies for Noninfectious Anterior Scleritis

First Author: Chansathya **KHIEU**

Purpose: The objective of this case report is to use early immunomodulatory drugs to reduce pain and activity caused by non-infectious anterior scleritis and also monitor the time to non-activity.

Methods: Clinical cases of non-infectious scleritis, collected between March and September 2024, were given high-dose oral corticosteroid and methotrexate as first line to treat non-infectious scleritis. Scleritis grading was documented after the instillation of the

2.5% phenylephrine test. Photography grading on every follow-up, clinical examination was done for each visit until the patient achieved a period of inactivity without any medication.

Results: Period to inactivity: 4.87 weeks 6 weeks: 3 patients (4 eyes) 4 weeks: 5 patients (5 eyes) 2 weeks: 1 patient (1 eye) Recurrences/Relapses 1 patient received a cataract surgery and a recurrence of anterior scleritis in one eye: 12 weeks 1 patient had an episode of recurrent 24 weeks

Conclusions: Early cocktail therapy of corticosteroid and methotrexate is a safe and effective first-line treatment for non-infectious anterior scleritis. In such cases, it can help patients reduce signs (redness) and symptoms (pain) in a more rapid time frame and, as a result, improve quality of life.

Abstract No.: 201346

Efficacy and Safety Profiles of Immunomodulatory Therapies in the Management of Vogt-Koyanagi-Harada Disease

First Author: Yunhua LOO

Co-Author(s): Anita CHAN, Soon Phaik CHEE, Milton CHEW, Jay SIAK, Shaan WIRYASAPUTRA

Purpose: Early initiation of immunomodulatory therapy (IMT) is advocated in Vogt-Koyanagi-Harada (VKH) disease. The increasing availability of biologics has expanded the repertoire of treatment options and drug selection is determined by physician preference and patient response. This study was aimed at evaluating the clinical efficacy and safety profiles of IMT in VKH patients.

Methods: We performed a retrospective review of 48 patients receiving IMT between 2005 and 2025 at a single tertiary center in Singapore.

Results: Azathioprine (AZA) was the most frequently prescribed first-line agent (83.3%), followed by methotrexate (MTX; 8.3%) and mycophenolate mofetil (MMF; 6.25%). Escalation of therapy occurred in 34 patients due to drug intolerance or suboptimal response. In patients who achieved clinical quiescence, there were no significant differences in final visual acuity or time to quiescence between AZA, MTX and MMF. However, patients who required biologics for disease control took a significantly longer time to reach quiescence. Adverse events (AEs) were most frequent with AZA (65.8%), particularly transaminitis and leukopenia. Comparatively, reports of AEs were significantly lower with MMF (19.2%), MTX (15.8%) and TNF α -inhibitors (12.5%).

Conclusions: Efficacy outcomes were comparable across AZA, MTX, MMF, and biologics, although biologics were associated with delayed disease control. AZA was linked to higher AE rates, but this could be due to reporting bias, as it was preferentially prescribed

first-line due to its lower cost. These findings underscore the importance of close monitoring in patients receiving IMT. Ultimately, treatment decisions should be individualized, balancing factors including clinical efficacy, safety and cost.

Abstract No.: 201230

Electrodiagnostic Findings in Nine Patients With Multiple Evanescent White Dot Syndrome

First Author: Chin Pey YAP

Co-Author(s): Andrew BROWNING, Joanna DACOSTA, Ranjeet PANDIT, Stephanie QUINN

Purpose: To describe the electroretinographic (ERG) abnormalities in patients with multiple evanescent white dot syndrome (MEWDS) and their evolution during follow-up.

Methods: Nine patients diagnosed with MEWDS were retrospectively reviewed. Clinical presentation, associated systemic history, and multimodal imaging were collected. Full-field ERG, multifocal ERG (mfERG), and pattern ERG (PERG) were analysed during the acute and recovery phases.

Results: The cohort comprised eight females and one male, with a mean age of 41 years (range 22-87). The majority presented with unilateral disease, though one patient demonstrated subclinical fellow eye involvement. Eight of nine patients showed ERG abnormalities. The most frequent finding was reduction of both a- and b- wave amplitudes on photophobic and scotopic testing. Isolated b-wave reduction was seen in two patients, while one patient had preserved ERG responses bilaterally. mfERG and PERG were commonly reduced, with some cases showing foveal sparing. In one patient, interpretation was limited by a coexisting epiretinal membrane. Triggers included recent viral illness (n=2) and COVID-19 infection or vaccination (n=2). Follow-up ERGs showed partial or complete recovery in most cases, although residual deficits persisted in some, particularly in photopic responses.

Conclusions: MEWDS is associated with transient generalised photoreceptor dysfunction on ERG, predominantly affecting cone-driven responses. mfERG and PERG further highlight macular and ganglion cell involvement. While most patients showed recovery in parallel with clinical improvement, incomplete convalescence was observed in some. ERG provides valuable objective evidence of retinal dysfunction in MEWDS and may assist in monitoring disease course and functional recovery.

Abstract No.: 206971

Evaluation of the Intraocular Total IgE Level and Its Ratio With Serum IgE Level for the Diagnosis of Ocular Toxocariasis in Children and Adults: A Retrospective Comparative Study

First Author: Jing **FENG**

Co-Author(s): Yong **TAO**, Shuang **ZHANG**

Purpose: Ocular Toxocariasis (OT) is characterized by complicated clinical manifestations, which make it difficult to diagnose. In this study, we mainly evaluated the diagnostic values of intraocular fluid (IF) total IgE level and IF/Serum IgE ratio in OT and compared the differences between child and adult patients.

Methods: Seventy-six patients with 52 children (<16 years) and 24 adults with clinically diagnosed OT and 64 patients with non-OT uveitis were enrolled in this study. The paired IF and serum samples were collected for total IgE, total IgG, and specific IgG testing. The IF IgE levels and IF/Serum IgE ratios were compared between child and adult patients. The area under the curve (AUC) was generated to assess the diagnostic performance of the above indicators.

Results: The IF IgE level was significantly higher in child patients than in adult patients (1671.79 ± 1425.97 versus 784.44 ± 544.73 ng/ml, $p=0.015$). Besides, the IF/Serum IgE ratio showed a similar trend with 24.02 ± 6.10 in children and 7.68 ± 5.05 in adults ($p=0.001$). The best cutoff value of the IF IgE concentration was 10.65 ng/ml, yielding 77.6% (95%CI, Confidence Interval, 66.4–86.1%) sensitivity and 98.4% (95%CI, 90.5–99.9%) specificity. The IF IgE level showed lower AUC than that of IF specific IgG level (0.925 versus 0.975, $p=0.037$). However, the AUC of IF/Serum IgE ratio for OT was significantly higher than that of GWC (0.934 versus 0.527, $p<0.0001$). The best cutoff value of IF/Serum IgE ratio was 0.48 with the sensitivity of 78.4% (95%CI, 67.0–86.8%) and specificity of 98.4% (95%CI, 90.5–99.9%). For the diagnosis of child OT, the cutoff value of IF IgE level of child OT was 13.10 ng/ml with the high sensitivity of 82.7% (95%CI, 69.2–91.3%) while the best cutoff value of 10.65 ng/ml for adult OT yielded only 66.7% (95%CI, 44.7–83.6%) sensitivity. However, the sensitivity of IF/Serum IgE ratio for child OT (86.3%, 95%CI, 73.1–93.8%) was close to that for adult OT (87.0%, 95%CI, 65.3–96.6%).

Conclusions: Both IF IgE level and IF/Serum IgE ratio demonstrated good diagnostic performance for ocular toxocariasis and higher sensitivity of IF IgE level was noted for the diagnosis of child OT.

Abstract No.: 201326

Examining the Relationship Between Ocular Manifestations and Systemic Autoimmune Diseases: A Meta-Analysis and Systematic Review

First Author: Mosaab **MOHAMED ELMAHDI**

Co-Author(s): Gong **YU**

Purpose: To quantify the prevalence and risk associations of ocular manifestations in patients with systemic autoimmune diseases and to evaluate how specific disease subtypes influence ophthalmic outcomes.

Methods: A systematic literature search of PubMed, Embase, and Cochrane Library was performed for studies published from January 2000 to June 2025. Eligible studies reported ocular findings in adults with rheumatoid arthritis, systemic lupus erythematosus, ankylosing spondylitis, and other systemic autoimmune disorders. Data extraction included study design, patient demographics, ocular manifestations (e.g., uveitis, scleritis, keratoconjunctivitis), and systemic disease activity. Meta-analyses were conducted using a random-effects model to calculate pooled prevalence rates and odds ratios (ORs). Heterogeneity was assessed with I^2 statistics, and publication bias was evaluated via funnel plots and Egger's test.

Results: Forty-five studies encompassing 12,634 patients met inclusion criteria. The overall pooled prevalence of any ocular manifestation was 29% (95% CI, 24–34%; $I^2 = 68\%$). Uveitis occurred in 12% (95% CI, 9–15%; OR vs. controls, 3.6; 95% CI, 2.8–4.6), scleral inflammation in 7% (95% CI, 5–9%; OR, 2.4; 95% CI, 1.8–3.2), and keratoconjunctivitis sicca in 18% (95% CI, 14–22%; OR, 4.1; 95% CI, 3.2–5.2). Ankylosing spondylitis patients exhibited the highest uveitis risk, while Sjögren's syndrome had the greatest dry eye prevalence. No significant publication bias was detected.

Conclusions: Ocular involvement is common across systemic autoimmune diseases, with disease-specific patterns that warrant tailored ophthalmic screening and management. Early detection of eye complications may improve visual prognosis and overall disease control.

Abstract No.: 201934

From Dengue to Lupus: Lupus Vasculitis Presenting as Acute Visual Loss During Dengue Fever

First Author: Dinda **ZHAFIRA**

Co-Author(s): Mochammad **SJARIFUDHIN**

Purpose: Retinal vasculitis may result from infectious or non-infectious causes, requiring different management approaches. In dengue-endemic regions, ocular vasculitis can be associated to dengue, yet systemic lupus erythematosus (SLE) can present similarly and

cause misdiagnosis. We report a case initially suspected as dengue-related vasculitis but ultimately diagnosed as SLE-associated vasculitis.

Methods: A 28-year-old woman was admitted with headache and intermittent fever with thrombocytopenia five days before admission. On admission, she developed blurred vision and was referred to ophthalmology department. Ophthalmic evaluation was supplemented by systemic investigations including autoimmune serologies.

Results: On presentation, best-corrected visual acuity was 6/7.5 in the right eye and 6/9 in the left eye. The anterior segment was unremarkable. Fundus examination revealed white exudates, hemorrhagic spots and vascular sheathing. A presumptive diagnosis of dengue vasculitis was made, and the patient received high-dose systemic corticosteroids for three days, with no visual improvement. Subsequent autoimmune workup returned a positive ANA 2 (antinuclear antibody 2), supporting a diagnosis of SLE. She was started on hydroxychloroquine and azathioprine under care of the internal medicine team. On follow-up, vision remained stable without further deterioration.

Conclusions: In dengue-endemic settings, retinal vasculitis manifesting during or after febrile illness may lead to an initial misdiagnosis to dengue-related ocular complications. This case illustrates the necessity of considering underlying autoimmune etiologies such as systemic lupus erythematosus especially in a young woman. Early diagnosis and immunosuppressive therapy may help preserve vision.

Abstract No.: 204377

Frosted Branch Angiitis Masquerading As Primary Vitreoretinal Lymphoma: A Case Report

First Author: Arnold Shau Hei **CHEE**

Co-Author(s): Mary **HO**, Sophia Ling **LI**, Andrew Chun Yue **MAK**, Alvin **YOUNG**

Purpose: To report an atypical case of primary vitreoretinal lymphoma (PVRL) presenting as frosted branch angiitis (FBA), to describe its clinical course and treatment outcome.

Methods: A case report.

Results: A 65-year-old woman with a history of stage 3 diffuse large B-cell lymphoma in complete remission presented with one month of progressive left eye blurring, with a visual acuity of 20/100. Examination revealed temporal FBA, mild vitritis, retinal blot hemorrhages and subretinal infiltrates. An initial diagnosis of viral retinitis was made, and intravitreal Foscarnet was given. However, aqueous polymerase chain reaction was negative for viruses. Her condition progressed despite four foscarnet injections, with worsening of subretinal infiltration, vitritis, and the

development of exudative retinal detachment. OCT-M also revealed interval increase in subretinal pigmented epithelium infiltrates and vitreous hyper-reflectivity, leading to the suspicion of PVRL. MRI Brain did not show lymphoma infiltration, whereas diagnostic vitrectomy yielded atypical cells, suggestive of PVRL. Treatment was switched to intravitreal methotrexate (MTX), leading to improvement in exudative retinal detachment and infiltrates after twice weekly induction and weekly consolidation MTX injections. A complication of MTX-induced keratopathy developed and was managed successfully with bandage contact lens and topical lubricants.

Conclusions: FBA can be a rare presenting feature of PVRL. A high index of suspicion is crucial in lymphoma patients presenting with atypical retinitis, particularly when there is resistance to antiviral therapy. OCT-M can provide invaluable diagnostic cues, while intravitreal MTX demonstrated efficacy in local tumor control, but clinicians should be aware of potential ocular side effects such as keratopathy.

Abstract No.: 206446

Green Tea Extract Regulates Th1 and Th17 Sub-Populations in Experimental Autoimmune Uveitis

First Author: Bo Man **HO**

Co-Author(s): Lin **DU**, Jiahui **LI**

Purpose: Green tea extract (GTE) has been shown to reduce experimental autoimmune uveitis (EAU) by suppressing T helper 1 (Th1) and T helper 17 (Th17) cell-related gene expression. Its main catechin, Epigallocatechin-3-gallate (EGCG), also inhibits Th1 and Th17 differentiation and has anti-inflammatory effects. Our previous work found GTE impedes in vitro Th1 and Th17 differentiation. This study investigated the effects of GTE on the viability, migration, and proliferation of Th1 and Th17 cells, as well as changes in T cell subset distribution in EAU animals treated with GTE.

Methods: Naïve CD4⁺ T cells from healthy C57BL/6J mice were cultured with Th1 or Th17 polarising cytokines and GTE for 3 days, then analysed by flow cytometry. EAU was induced in C57BL/6 mice, which received 13 doses of GTE during disease induction. Disease progression was monitored by fundus imaging, confocal scanning laser ophthalmoscopy, and optical coherence tomography. On day 21 post-induction, eye and lymph node cells were collected for flow cytometry.

Results: T cell proliferation and Th17 cell migration were reduced under GTE treatment. The apoptotic sub-populations under Th1 or Th17 polarisation were rescued by GTE treatment. Cell viability, however, was suppressed after GTE incubation, with Th17 cells showing a higher survival rate. Systemic pathogenic Th cell and Th17 sub-populations were also suppressed by GTE in the EAU model.

Conclusions: Our study provides additional support for GTE as a potent agent for alleviating EAU-induced intraocular inflammation. We also supplemented that GTE also modulates other cellular mechanisms apart from impeding differentiation in T cell sub-populations.

Abstract No.: 208396

Growth Hormone Releasing Hormone Signaling Drives Th17 Differentiation and Autoimmune Ocular Inflammation

First Author: Lin DU

Co-Author(s): Wai Kit CHU, Bo Man HO, Jian JIAN LI, Chi Pui PANG

Purpose: Th17 dysregulation fuels tissue inflammation in autoimmune eye disease. We investigated whether growth hormone-releasing hormone receptor (GHRH-R) signaling regulates Th17 differentiation and contributes to autoimmune ocular pathology.

Methods: GHRH-R expression was profiled during in vitro CD4⁺ T-cell polarization. Pharmacologic gain- and loss-of-function (GHRH agonist vs antagonist) and genetic deficiency of Ghrhr were used to modulate the pathway. Downstream signaling was assessed by STAT3 phosphorylation and Th17 transcriptional programs. Functional relevance was tested in Th17-mediated models of ocular and neural autoimmunity, with clinical scoring, leukocyte infiltration, and cytokine analysis (IL-17A, GM-CSF) as readouts.

Results: Naïve CD4⁺ T cells lacked detectable GHRH-R, which was robustly induced during Th17 polarization. Activating GHRH-R enhanced STAT3 phosphorylation, upregulated Th17 lineage genes, and promoted both non-pathogenic and pathogenic Th17 differentiation in vitro. Conversely, pharmacologic blockade or Ghrhr deficiency reduced pSTAT3, constrained Th17 commitment, and dampened the pathogenic Th17 transcriptional signature. In vivo, augmenting GHRH-R signaling exacerbated Th17-driven inflammation, whereas antagonism or receptor deficiency mitigated disease severity, with reduced ocular inflammatory scores, diminished inflammatory cell infiltration, and lower IL-17A/GM-CSF production. These effects were consistent across Th17-mediated ocular and neural models, supporting pathway generalizability.

Conclusions: GHRH-R signaling is a critical extrinsic cue that licenses STAT3 activation, Th17 lineage specification, and downstream tissue inflammation in the eye. Targeting GHRH-R offers a mechanistically grounded strategy to modulate Th17 pathogenicity in autoimmune ocular disease.

Abstract No.: 203382

Herpes Simplex Virus Reactivation Masquerading As Anterior Nodular Scleritis and Keratitis With Excellent Antiviral Response: A Case Report

First Author: Joyce Teo WEI TING

Co-Author(s): Bashajan SOWKATHALI

Purpose: To describe a case of herpes simplex virus (HSV) reactivation presenting as anterior nodular scleritis with secondary keratitis in an immunocompetent patient.

Methods: A 56-year-old lady with no systemic illness presented with two days of redness and pain in the right eye. Best corrected visual acuity was 6/7.5 in the right eye and 6/6 in the left eye. Slit-lamp examination revealed temporal and superior conjunctival injection of the right sclera without corneal or anterior chamber involvement. The left eye was normal.

Results: Initial treatment with topical corticosteroids and oral anti-inflammatory medications was ineffective. Oral prednisolone was started after unremarkable autoimmune and infectious workups, leading to improvement of sclera inflammation within a month. One month later, she developed recurrent blurred vision in the right eye, with visual acuity dropping to 6/10. Slit lamp examination showed a geographic epithelial defect with terminal blubs. Steroids were discontinued, and topical and oral acyclovir were initiated, resulting in marked improvement with resolution of scleritis. However, she experienced recurrent right eye redness two weeks after stopping oral acyclovir, prompting re-initiation of oral acyclovir and a tapering course of topical corticosteroids.

Conclusions: This case highlights the diagnostic challenges of scleritis and emphasizes the importance of considering infectious causes, including herpes simplex virus, in patients unresponsive to standard therapy, even in immunocompetent individuals. Early recognition and prompt antiviral treatment can rapidly resolve inflammation, prevent vision-threatening complications, and preserve vision.

Abstract No.: 201725

Intravitreal Ranibizumab for the Treatment of Cystoid Macular Edema Secondary to Cytomegalovirus Retinitis

First Author: Milton CHEW

Purpose: Cytomegalovirus (CMV) retinitis is typically managed with systemic and intravitreal antivirals. Some patients subsequently develop reactive cystoid macular edema (CME), leading to visual decline. Local steroid injections are contraindicated in immunocompromised patients due to the risk of worsening or reactivating the underlying CMV infection. Intravitreal anti-VEGF (Vascular Endothelial Growth Factor) therapy offers a potential alternative.

Methods: We report the case of a monocular renal transplant patient on systemic immunosuppression with known CMV viremia. He presented with zone 1 CMV retinitis in his only functional eye, confirmed by positive tetraplex on aqueous testing and a CMV viral load of 930,380 copies/ml. Treatment consisted of oral valganciclovir (900 mg BD), as well as intravitreal ganciclovir injections twice weekly for 1 month, followed by weekly injections for 2 months, until complete resolution of the retinitis.

Results: Following resolution of CMV retinitis, the patient subsequently developed CMO with a decrease in visual acuity. There was no evidence of retinal ischemia on fluorescein angiogram. The CMO initially responded with Intravitreal ranibizumab with improvement in vision. However, he failed a treat-and-extend regime at 8-weeks mark. He was subsequently switched to Intravitreal aflibercept with sustained anatomical and functional response, and has since remained dry. His visual acuity was maintained at 6/12.

Conclusions: Intravitreal anti-VEGF agents are effective for managing CMO secondary to CMV retinitis in immunocompromised patients, where corticosteroids are contraindicated. This case supports a non-ischemic mechanism of underlying reactive CMO in CMV retinitis.

Abstract No.: 208472

Ketogenic Diet Modulates Immune Cell Transcriptional Landscape and Ameliorates Experimental Autoimmune Uveitis in Mice

First Author: *Runping DUAN*

Purpose: Uveitis manifests as an immune-mediated inflammatory disorder within the eye, posing a serious threat to vision. The ketogenic diet (KD) has emerged as a promising dietary intervention, yet its impact on the immune microenvironments and role in uveitis remains unclear.

Methods: Utilizing single-cell RNA sequencing (scRNA-seq) data from the lymph node and retina of mice, we conduct a comprehensive investigation into the effects of KD on immune microenvironments. Flow cytometry is conducted to verify the potential mechanisms.

Results: This study demonstrates that KD alters the composition and function of immune profiles. Specifically, KD promotes the differentiation of Treg cells and elevates their proportion in healthy mice. In response to experimental autoimmune uveitis challenges, KD alleviates the inflammatory symptoms, lowers CD4+ T cell pathogenicity, and corrects the Th17/Treg imbalance. Additionally, KD decreases the proportion of Th17 cells and increases Treg cells in the retina. Analysis of combined retinal and CDLN immune cells reveals that retinal immune cells, particularly CD4+ T cells, exhibit heightened inflammatory responses, which KD partially reverses.

Conclusions: The KD induces inhibitory structural and functional alterations in immune cells from lymph nodes to retina, suggesting its potential as a therapy for uveitis.

Abstract No.: 201529

Long-Term Outcome of Myopic Choroidal Neovascularization Treatment and Its Correlated Factors

First Author: *De-kuang HWANG*

Co-Author(s): *Yu-chieh WU*

Purpose: To evaluate the long-term visual and anatomical outcomes of anti-VEGF therapy for mCNV in a tertiary referral center and to identify factors associated with treatment response.

Methods: This retrospective study was conducted at Taipei Veterans General Hospital and included patients diagnosed with mCNV who received anti-VEGF treatment. The primary outcome was the change in best-corrected visual acuity (BCVA) from baseline to three years, along with recurrence and blindness rates. Secondary outcomes included changes in central macular thickness (CMT), grading of myopic maculopathy, presence of subretinal fluid (SRF), intraretinal fluid (IRF), hemorrhage, subretinal hyperreflective material (SHRM), number of injections, and factors predictive of visual outcomes.

Results: A total of 125 eyes from 118 patients with mCNV were included. The mean patient age was 55 years, with a female predominance (75.2%). Treatments included bevacizumab (30.4%), aflibercept (40.8%), and ranibizumab (28.8%). At the three-year follow-up, the BCVA improved significantly from logMAR 0.57 to 0.42 ($p < 0.05$), and the CMT decreased from 302.18 μm to 264.51 μm . The recurrence rate was 29%. Older age, better baseline BCVA, and higher initial myopic maculopathy grade were significantly associated with less visual improvement. Among these, initial myopic maculopathy grading was significantly associated with final blindness. Additionally, increased choroidal thickness was correlated with a higher recurrence rate.

Conclusions: aVEGF therapy for mCNV provides sustained improvements in both visual acuity and anatomical outcomes over three years. Baseline age, BCVA, and myopic maculopathy grade were significant predictors of long-term outcomes.

Abstract No.: 202518

Management of Hypotonic Choroid Detachment Following Uneventful Pars Plana Vitrectomy in a Juvenile Idiopathic Arthritis-Associated Uveitis Case

First Author: Ming-chieh TSAI

Co-Author(s): Shu-chun KUO

Purpose: Ocular hypotony is a rare but challenging complication in juvenile idiopathic arthritis-associated uveitis (JIA-U). We report a case of intractable postoperative hypotony and discuss its management in the context of current literature.

Methods: A 21-year-old woman with long-standing JIA-U presented with multiple ocular complications, including posterior and peripheral anterior synechiae and cyclitic membrane formation. She underwent synechiotomy, anterior chamber reconstruction, and vitrectomy with intravitreal dexamethasone implant. Postoperatively, persistent hypotony with choroidal detachment developed. Intravitreal SF6 injections failed to restore intraocular pressure (IOP). Silicone oil tamponade was subsequently performed.

Results: Silicone oil tamponade successfully stabilized IOP, consistent with prior reports that it may serve as a temporary measure in uveitic hypotony. However, the effect is often transient, and repeat procedures are frequently required. The Multicenter Uveitis Steroid Treatment (MUST) Trial identified risk factors for hypotony, including younger age of onset, long disease duration, history of vitrectomy or cataract surgery, synechiae, and iris abnormalities. JIA-U is particularly associated with higher risk and poor outcomes. Our patient exhibited several of these features, explaining the refractory course. Despite aggressive treatment, the visual prognosis in uveitic hypotony remains poor.

Conclusions: Postoperative hypotony in JIA-U remains a therapeutic challenge. Silicone oil tamponade can temporarily restore IOP, but long-term outcomes are guarded. Early recognition of risk factors and timely intervention are essential to prevent irreversible vision loss.

Abstract No.: 205246

Management of Severe Post-Injection Endophthalmitis: A Case Series

First Author: Inara HAJI

Co-Author(s): Lala SAIDOVA

Purpose: To describe diagnosis, management strategies, and long-term outcomes in three patients who developed severe infectious complications (keratitis/endophthalmitis) after intravitreal anti-VEGF injections, and to emphasize lessons for empirical antibiotic coverage.

Methods: We retrospectively reviewed three consecutive cases with post-anti-VEGF infectious

complications. For each case we document patient demographics, ophthalmic and systemic history, time course, microbiologic findings, treatment protocols (medical and surgical), and one-year follow-up outcomes. Empirical intravitreal vancomycin + ceftazidime was initially used; therapy was adjusted based on culture and sensitivity results. Vitrectomy was attempted when ocular status permitted.

Results: All three patients were diabetic, two of them presented with corneal epithelial defects and stromal infiltration, hypopyon, the third showed corneal edema without epithelial loss, hypopyon, hyphema and rubeosis. B-scan revealed vitreous opacities in all cases. Gram-positive organisms were isolated in all cases; in vitro sensitivity showed strong susceptibility to vancomycin and resistance to ceftazidime only in second case. First patient underwent multiple intravitreal vancomycin+ceftazidime injections, the second - intravitreal vancomycin injections; third patient underwent vitrectomy + intravitreal vancomycin+ceftazidime, anti-VEGF injections + air. At final follow-up, no eye required enucleation or developed phthisis; pain resolved in all. Best recorded visual outcomes ranged from light perception to 1,3 logMAR, stable relative to presentation.

Conclusions: Post-anti-VEGF infections can be vision-threatening, particularly in diabetic patients. Prompt microbiological sampling, targeted intravitreal antibiotics, and individualized surgical intervention are crucial. Early recognition and tailored management can preserve ocular integrity and optimize outcomes in complex post-injection infections.

Abstract No.: 200970

Metabolic Reprogramming Enables Ocular Persistence of *Klebsiella pneumoniae* via Glycolysis and Iron Acquisition

First Author: Lu PING

Purpose: To determine how *K. pneumoniae* adapts metabolically to the intraocular environment and the roles of glycolysis and siderophore-mediated iron acquisition in endophthalmitis.

Methods: Proteomics compared a clinical isolate in vitreous-mimicking medium vs. LB. Glycolytic (pfkA, pykF) and siderophore (entB) mutants were assessed for growth under hypoxia/iron depletion and in a murine intravitreal infection model measuring bacterial burden, cytokines, visual acuity, lactate, and iron.

Results: Vitreous-like conditions upregulated PfkA, PykF, and EntB. Mutants showed impaired growth, reduced intraocular colonization, attenuated IL-6/TNF- α responses, and better visual outcomes. Double mutants were nearly avirulent. Lactate and iron were decreased in mutant-infected eyes.

Conclusions: Glycolysis and iron acquisition are essential for *K. pneumoniae* persistence and virulence

in the eye. Targeting metabolic reprogramming may offer adjunctive therapy for bacterial endophthalmitis.

Abstract No.: 201698

Outcomes of Anti-Tubercular Therapy in Patients With Ocular Tuberculosis: A Retrospective Study

First Author: Sunil THAKALI

Co-Author(s): Hom Bahadur GURUNG, Mohini SHRESTHA, Smita SHRESTHA

Purpose: Ocular tuberculosis (TB) is an extrapulmonary manifestation of TB that can cause significant visual morbidity if undiagnosed or inadequately treated. This study evaluated the outcomes of anti-tubercular therapy (ATT) in patients with ocular TB.

Methods: This retrospective study analyzed data from 17 patients diagnosed with ocular TB and treated with ATT between January 2018 and December 2022. Patients received 9-12 months of ATT along with adjunctive steroids. Demographic information, clinical manifestations, diagnostic test results, treatment details, and outcomes were collected from medical records. Primary outcomes included changes in visual acuity and disease recurrence at 1-year follow-up.

Results: The mean age of patients was 40 years, and 58.8% were female. Unilateral involvement was more common (64.7%). The most frequent clinical presentations were serpiginous choroidopathy, sclerokeratitis, and anterior uveitis (17.6% each). A majority of patients (70.6%) received 12 months of ATT. Adjunctive therapy included oral steroids (70.6%) and topical steroids (82.4%). Tuberculosis-specific tests were positive in 29.4% of patients, with a median Mantoux induration of 20.5 mm.

Conclusions: Patients with ocular TB presented with varied clinical manifestations and responded favorably to prolonged ATT with adjunctive corticosteroids. Structured treatment and follow-up are crucial for improving visual outcomes and reducing recurrence rates.

Abstract No.: 203055

Postviral Multiple Evanescent White Dot Syndrome: A Case Report

First Author: Jessica

Co-Author(s): Mia, Qilin

Purpose: To report a rare case of Multiple Evanescent White Dot Syndrome (MEWDS) following a febrile illness in a young female patient.

Methods: A 17-year-old female presented with acute vision loss and visual field defects in the right eye after a fever. Comprehensive ophthalmic examination included dilated fundus examination, fluorescein sodium angiography, fundus autofluorescence, and optical coherence tomography (OCT).

Results: Clinical features included faint perimacular yellowish-white lesions, wreath-like hyperfluorescence on angiography, and disruption of the ellipsoid and interdigitation zones on OCT. The patient was diagnosed with MEWDS and treated with periocular and topical corticosteroids. After three months, best-corrected visual acuity recovered to 1.0.

Conclusions: MEWDS may occur following systemic viral infection and can lead to significant visual impairment. A thorough ocular evaluation is crucial for diagnosis. The condition may have a favorable visual outcome with appropriate treatment.

Abstract No.: 202240

Presentation and Management of Bilateral Lipid Retinopathy and Proliferative Diabetic Retinopathy in a Patient With Gaucher's Disease: A Case Report

First Author: Daliya SARI

Co-Author(s): Susan MACCALLUM, Amy PAI

Purpose: Gaucher's disease is a rare familial autosomal recessive disorder of lipid metabolism, which causes an abnormal accumulation of glucocerebrosides in the reticulo-endothelial system. Ocular manifestations include uveitis, pre-retinal and retinal changes with white scattered deposits.

Methods: Our report presents a 30-year-old Asian male with underlying Gaucher's disease, poorly controlled diabetes mellitus, and bilateral lipid retinopathy, who also subsequently developed proliferative diabetic retinopathy (PDR) complicated by vitreous haemorrhage.

Results: Management included both systemic and ocular interventions, focusing on glycaemic control, intraocular pressure (IOP) regulation and PDR management.

Conclusions: This case highlights the complexities of treating ocular manifestations in patients with underlying systemic metabolic disorders, necessitating a comprehensive and multidisciplinary approach.

Abstract No.: 200631

Rapid Diagnosis of Ocular Viral Infections via Single Virus Detection Using Solid-State Nanopore: A Diagnostic Evaluation Study

First Author: Noriyasu HASHIDA

Co-Author(s): Yasuko MORI, Kohji NISHIDA, Takeshi SOMA, Hiroyasu TAKEI, Masateru TANIGUCHI

Purpose: Rapid and precise identification and discrimination of causative pathogens are required in the treatment of infectious diseases. Quantitative real-time polymerase chain reaction is used to detect and identify infectious viruses before treatment. Although it is an established modality, results take several hours, even in well-equipped hospitals. It is

difficult to simultaneously detect many pathogen types because only a single virus genome can be amplified per polymerase chain reaction. Recently, an artificial intelligence (AI)-based nanopore machine has been used to identify individual viruses based on electrical conductivity. Herein, we recognized a single virus using an AI-based detection system and successfully identified viral particles in clinical samples without the need for any prior treatment.

Methods: We used a nanopore detector and discriminated among viruses using AI-based waveform analysis. The efficacy of the AI nanopore detector as an on-site clinical analysis device was validated in cultured herpesvirus samples, and its discrimination capability was verified in clinical samples.

Results: The AI nanopore analysis of cultured viruses revealed that Alphaherpesvirinae and Betaherpesvirinae within the same Herpesviridae family can be distinguished with relatively high accuracy. The AI nanopore rapidly detected viral particles and can be useful as an on-site clinical diagnosis tool.

Conclusions: We demonstrated the multiplex discrimination of herpetic viruses in clinical ocular samples, proving that the AI nanopore is an ultra-high-speed and highly-sensitive detection tool that can be used in several medical fields.

Abstract No.: 202560

Rare Bilateral Acute Posterior Multifocal Placoid Pigment Epitheliopathy in a Filipino Patient With Positive Interferon-Gamma Release Assay and Purified Protein Derivative Test

First Author: Pauline Andrea WONG

Co-Author(s): Jessica ABAÑO, Jocelyn SY

Purpose: To report a case of APMPE in a Filipino patient with positive Interferon-Gamma Release Assay (IGRA) and purified protein derivative (PPD) test.

Methods: This is a case report of acute posterior multifocal placoid pigment epitheliopathy (APMPE) in a patient with tuberculosis.

Results: A twenty-four-year-old Filipino male presented with a complaint of peripheral scotomas in the left eye. Best-corrected visual acuity (BCVA) was 20/20 on the right eye and 20/30 on the left eye. Funduscopy revealed mild vitritis and multifocal yellowish hypopigmented patches scattered diffusely on the left eye, with similar lesions on the inferonasal midperiphery of the right eye. Fluorescein angiography of both eyes revealed early hypofluorescent lesion with hyperfluorescent staining throughout dye transit. Optical coherence tomography (OCT) of the left eye demonstrated disruption of the outer retinal layers and nodular irregularities of the external hyperreflective band. OCT-Angiography revealed macular ischemia. Laboratory exams revealed a positive Mycobacterium

tuberculosis PPD skin test and a positive IGRA test. Anti-Koch's therapy was initiated; however, one week later, the patient noted a decline in BCVA of 20/400. Hence, oral prednisone 1mg/kg/day, pentoxifylline, lutein, and alpha lipoic acid supplements were initiated. Over the following weeks, vision gradually improved to BCVA of 20/60.

Conclusions: This is the first described case of bilateral APMPE with positive results to the PPD test and the IGRA test. This created a significant diagnostic dilemma, initially raising the question of tuberculous chorioretinitis versus a primary white dot syndrome. In tuberculosis-endemic regions like the Philippines, white dot syndromes may be underdiagnosed, especially in patients with positive TB screening tests.

Abstract No.: 207460

Rare but Multidrug Resistant: Stenotrophomonas maltophilia Endophthalmitis With Retinal Vasculitis

First Author: Chalimi ARDANI

Co-Author(s): Winarto, Amalia Budhi HAPSARI, Dina NOVITA

Purpose: To report a rare case of postoperative endophthalmitis caused by *Stenotrophomonas maltophilia*, emphasizing diagnostic and therapeutic challenges.

Methods: A case report of a 66-year-old male who developed acute endophthalmitis following cataract surgery from a peripheral hospital. Clinical features, microbiological results, management, and outcomes were reviewed.

Results: The patient presented 1 month postoperatively with severe ocular pain, redness, and marked vision loss. Examination revealed visual acuity of light perception, corneal edema, hypopyon, and dense vitritis. Empiric intravitreal vancomycin and ceftazidime were administered, leading to partial improvement in hypopyon and conjunctival injection, but persistent vitritis. Vitreous culture identified *Stenotrophomonas maltophilia*, resistant to ceftazidime, levofloxacin, and trimethoprim-sulfamethoxazole, but sensitive to ciprofloxacin. Therapy was adjusted to systemic and topical ciprofloxacin, followed by pars plana vitrectomy. Intraoperatively, severe retinal vasculitis and fibrinous adhesions to the retina were observed, consistent with the pathogen's aggressive inflammatory course. Despite these findings, final visual acuity improved to 6/40, representing a better outcome than typically reported in similar cases.

Conclusions: *Stenotrophomonas maltophilia* is an uncommon cause of postoperative endophthalmitis. Its intrinsic resistance renders standard empiric therapy inadequate. This organism is strongly associated with contamination of surgical instruments, intraocular solutions, and hospital equipment, highlighting the

role of preventive aseptic protocols and sterilization. This case contributes to the limited literature by documenting retinal vasculitis and fibrinous adhesions as a manifestation of this pathogen. Despite aggressive management, visual prognosis remains unpredictable, underscoring the need for vigilant infection-control practices and further study into the intraocular manifestations of this rare pathogen.

Abstract No.: 204424

Rare but Resistant: *Stenotrophomonas maltophilia* Causing Postoperative Endophthalmitis

First Author: Chalimi **ARDANI**

Co-Author(s): Amalia Budhi **HAPSARI**, Dina **NOVITA**, Winarto

Purpose: To report a rare case of postoperative endophthalmitis caused by *Stenotrophomonas maltophilia*, emphasizing diagnostic and therapeutic challenges.

Methods: A case report of a 66-year-old male who developed acute endophthalmitis following cataract surgery from a peripheral hospital. Clinical features, microbiological results, management, and outcomes were reviewed.

Results: The patient presented 1 month postoperatively with severe ocular pain, redness, and marked vision loss. Examination revealed visual acuity of light perception, corneal edema, hypopyon, and dense vitritis. Empiric intravitreal vancomycin and ceftazidime were administered, leading to partial improvement in hypopyon and conjunctival injection, but persistent vitritis. Vitreous culture identified *Stenotrophomonas maltophilia*, resistant to ceftazidime, levofloxacin, and trimethoprim-sulfamethoxazole, but sensitive to ciprofloxacin. Therapy was adjusted to systemic and topical ciprofloxacin, followed by pars plana vitrectomy. Intraoperatively, severe retinal vasculitis and fibrinous adhesions to the retina were observed, consistent with the pathogen's aggressive inflammatory course. Despite these findings, final visual acuity improved to 6/40, representing a better outcome than typically reported in similar cases.

Conclusions: *Stenotrophomonas maltophilia* is an uncommon cause of postoperative endophthalmitis. Its intrinsic resistance renders standard empiric therapy inadequate. This organism is strongly associated with contamination of surgical instruments, intraocular solutions, and hospital equipment, highlighting the role of preventive aseptic protocols and sterilization. This case contributes to the limited literature by documenting retinal vasculitis and fibrinous adhesions as a manifestation of this pathogen. Despite aggressive management, visual prognosis remains unpredictable, underscoring the need for vigilant infection-control practices and further study into the intraocular manifestations of this rare pathogen.

Abstract No.: 206378

Relapsing Granulomatosis With Polyangiitis Presenting With Orbital Inflammation

First Author: Rizal **RYAMIZARD**

Co-Author(s): Amalia Budhi **HAPSARI**, Dina **NOVITA**

Purpose: Granulomatosis with Polyangiitis (GPA) is a necrotizing granulomatous vasculitis. Orbital involvement occurs in up to 60% of patients and is frequently the initial presentation. We report a GPA relapse presenting with orbital inflammation and concurrent cerebral vasculitis, emphasizing the ophthalmologist's role in a multidisciplinary approach to manage this life-threatening flare.

Methods: A 30-year-old male presented with a severe headache, painful left-sided ophthalmoplegia, decreased visual acuity, palpebral edema, and conjunctival injection. Systemic evaluation confirmed a severe inflammatory flare with elevated C-reactive protein and erythrocyte sedimentation rates, alongside worsening renal function. Neuroimaging revealed retro-orbital inflammation and cerebral vasculitis. This was diagnosed as a severe relapse of GPA, following a period of clinical remission. The patient's GPA was diagnosed on a prior admission for destructive sinonasal disease and glomerulonephritis; a nasal biopsy confirmed granulomatous vasculitis, meeting classification criteria (score: 8). For this life-threatening relapse, the patient was managed with high-dose intravenous corticosteroids and pulse cyclophosphamide.

Results: Antineutrophil cytoplasmic antibody (ANCA) serology has not yet been performed, as the biopsy fulfilled classification criteria; it remains important because ANCA status offers prognostic data. The patient responded well to systemic immunosuppression, with improvement in clinical symptoms and inflammatory markers, and was transitioned to maintenance therapy.

Conclusions: Orbital inflammation may represent a life-threatening GPA relapse and can precede complications like cerebral vasculitis. Though carrying a high morbidity risk, orbital GPA is highly responsive to immunosuppression. Early recognition, appropriate induction therapy, and coordinated multidisciplinary follow-up are crucial to control disease activity and prevent permanent organ damage.

Abstract No.: 202688

Retinal Biomarkers for Post-Fever Retinitis-Associated Macular Edema

First Author: Chitaranjan **MISHRA**

Co-Author(s): Shiva Prasad **SAHOO**

Purpose: To study the role of retinitis lesion locations and presenting central foveal thickness (CFT) on vision and macular edema (ME) in post-fever retinitis (PFR) associated ME.

Methods: Hospital-based retrospective series of patients with PFR and ME (presence of any fluid or exudates in the macula with CFT > 300 microns). The demographic details, systemic parameters, and ophthalmological examination details, including fundus imaging and OCT macula, were noted. Retinal vasculature was classified as first order and subsequent orders, and the location of the retinitis lesions was noted. Patients received oral doxycycline, topical steroids, and oral steroids. Follow-ups were at months 1, 3, 6, and 12.

Results: Thirty-six eyes of 27 patients (18 males), with an age (mean $\pm$ SD) of 34.9 $\pm$ 15.7 years. 23/27 patients presented between October to February (winter months). Duration of vision loss (mean $\pm$ SD) was 9.2 $\pm$ 7.6 days. Onset (mean $\pm$ SD) of fever was 4.4 $\pm$ 1.6 weeks prior. A macular star pattern of exudates (MSPE) was present in 17 eyes during presentation and 26 eyes during follow-up. On presentation, months 1, 2, 6, and 12, the CFT on OCT reduced, and vision improved significantly ($p < 0.001$). In the group of eyes with retinitis lesions along the retinal vessels of first order, subsequent order, and peripapillary locations, 10/13 eyes had macular star at presentation, and 12/13 eyes had macular star during follow-up ($P = 0.032$ and 0.009 , respectively).

Conclusions: ME due to PFR is an entity with good visual outcomes. Eyes with retinitis lesions along the retinal vessels of the first order, the subsequent order, and the peripapillary locations were significantly associated with macular star pattern exudates. Further research is needed to study the effect of macular star pattern exudates on vision and the possible need for prompt treatment in the eyes.

Abstract No.: 202236

Retinal Vasculitis in Bangladesh: Clinical Spectrum and Management Outcomes

First Author: Arup Krishna **CHOUDHURY**
Co-Author(s): Sarwar **ALAM**, Mahua **CHAKRABORTTY**, Quazi Sazzad **IFTEKHAR**, Mominul **ISLAM**, Mostafizur **RAHMAN**

Purpose: To evaluate the demographic profile, etiology, clinical severity, and management outcomes of patients with retinal vasculitis presenting to a tertiary eye hospital in Bangladesh.

Methods: A prospective, cross-sectional, hospital-based study was conducted on 50 consecutive patients diagnosed with retinal vasculitis at Ispahani Islamia Eye Institute & Hospital, Dhaka, between January and June 2022. Detailed history, systemic evaluation, and comprehensive ocular examination including fundus imaging were performed. Data were analyzed for age, sex distribution, laterality, underlying etiology, disease stage, and management strategies.

Results: The mean age was 38.8 $\pm$ 13.7 years, with the largest proportion in the 31–40-year group. Males were more commonly affected (58%; M:F ratio 1.38:1). Vasculitis was unilateral in 58% and bilateral in 42% of cases. Tuberculosis was the leading etiology (52%), followed by idiopathic (28%), viral (10%), syphilis (6%), sarcoidosis (2%), and Behçet's disease (2%). More than half (52%) presented with stage IV disease. Regarding management, 46% required vitreoretinal surgery, 16% received combined injection and laser, 12% injection only, 12% laser only, and 14% were observed.

Conclusions: Retinal vasculitis in Bangladesh predominantly affects young adults, with a male preponderance and unilateral involvement. Tuberculosis was the most common cause, and most patients presented in advanced stages requiring surgical intervention. These findings highlight the need for earlier detection, improved awareness, and tailored management strategies in this population.

Abstract No.: 201144

Retinal Vasoproliferative Tumor Masquerading as Ocular Tuberculosis in a Young Filipino Female: A Diagnostic Challenge

First Author: Githea Philline **MARTINEZ**
Co-Author(s): Juan **LOPEZ**, Sharmaine Anjanette **NG**

Purpose: To describe the ophthalmologic findings and management in a rare case of retinal vasoproliferative tumor (RVPT) initially misdiagnosed as tubercular posterior uveitis (TPU) in a healthy young Filipino female.

Methods: A 24-year-old Filipino female with no known comorbidities presented with a two-month history of gradual, painless, blurring of vision of the right eye. She had no history of prior tuberculosis (TB) infection, TB exposure, or constitutional symptoms. Corrected distance visual acuity (CDVA) was counting fingers at 3 feet. Examination of the right eye revealed normal intraocular pressure with mild vitritis. Fundoscopy showed a 10-disc diameter yellow-pink elevated lesion at the inferotemporal periphery surrounded with extensive exudation, intraretinal hemorrhages, and dilated vascular arcades. A large exudative retinal detachment from 4 to 9 o'clock with macular involvement was noted. Macular optical coherence tomography revealed a hyperreflective multilobulated intraretinal mass with heterogenous internal reflectivity and marked posterior shadowing. Initial diagnosis was TPU given a positive Mantoux tuberculin skin test (26 mm induration), and anti-Koch's therapy was started.

Results: After one month of treatment, there was no clinical improvement. Idiopathic RVPT was reconsidered. Anti-Koch's therapy was discontinued, and monthly intravitreal anti-vascular endothelial growth factor injections were initiated. After five doses,

there was regression of the lesion and resolution of the exudative detachment. CDVA improved to 20/40.

Conclusions: This case highlights how RVPT can masquerade ocular TB, particularly in endemic areas like the Philippines. Early recognition through multimodal imaging and timely intervention can improve visual outcomes.

Abstract No.: 203249

Risk of Uveitis in Patients With Human Immunodeficiency Virus: A Cohort Study Through TriNetX Database

First Author: Chun-ju **LIN**

Co-Author(s): Ning-yi **HSIA**, Alan Y. **HSU**, Hou-ting **KUO**, Bing-qi **WU**

Purpose: This multi-institutional, retrospective cohort study using TriNetX database aims to explore the relationship between human immunodeficiency virus (HIV) infection and uveitis.

Methods: HIV patients were propensity-matched to individuals from our non-HIV cohort (1:1 ratio) based on variables such as age (every 5 years), sex, ethnicity, race, and relevant comorbidities. The Cox proportional hazards regression model was utilized to assess the impact of variables on uveitis risk, reporting hazard ratios (HRs) with 95% confidence intervals (CIs). Kaplan-Meier survival analysis and log-rank tests were applied to estimate the cumulative incidence of uveitis. Statistical significance was set at a two-sided p-value < 0.05.

Results: We found that adult patients with HIV infection had a significantly increased risk of developing uveitis compared to non-HIV counterparts, with an overall HR of 3.02 (95% CI: 2.70 – 3.39). The risk remained elevated across designated follow-up intervals of 1 year (HR = 4.68 [3.69 – 5.92]), 2 years (HR = 4.44 [3.65 – 5.41]), and 3 years (HR = 4.06 [3.42 – 4.81]), with consistent increases noted when dividing into different uveitis types except for anterior uveitis. The risk was higher among patients with acquired immunodeficiency syndrome (AIDS) compared to asymptomatic HIV (HR = 2.64 [1.30 – 5.35]). Furthermore, HIV patients receiving treatment within three months exhibited a notably increased risk (HR = 2.87 [2.33 – 3.54]).

Conclusions: This study reveals that individuals with HIV face a significantly heightened risk of developing uveitis. Our findings indicate that this risk is most substantial for intermediate and posterior uveitis, challenging the long-held belief that anterior uveitis is the predominant form in this population.

Abstract No.: 208398

Ruxolitinib Alleviates Endotoxin-Induced Uveitis and Preserves Retinal Function via JAK2–STAT3 Inhibition

First Author: Lin **DU**

Co-Author(s): Wai Kit **CHU**, Bo Man **HO**, Chi Pui **PANG**, Yolanda Wong Ying **YIP**

Purpose: Uveitis associated with enteric infection and reactive arthritis (e.g., Reiter's syndrome) is often treated with corticosteroids, yet steroid toxicity and refractoriness remain major limitations. We evaluated whether the JAK1/2 inhibitor ruxolitinib mitigates ocular inflammation and preserves visual function in Salmonella typhimurium endotoxin-induced uveitis (EIU).

Methods: EIU was induced in Sprague–Dawley rats by systemic lipopolysaccharide (LPS). Animals received ruxolitinib or vehicle. Inflammation was quantified by clinical anterior-segment scoring, aqueous humor (AqH) cellular infiltrate and protein leakage, and retina–choroid thickness. Retinal function was assessed by scotopic and photopic electroretinography (ERG). Pathway engagement was examined by JAK2–STAT3 readouts.

Results: Relative to LPS + vehicle, ruxolitinib significantly reduced anterior chamber inflammation, with lower clinical scores, decreased AqH inflammatory cell counts, and diminished protein exudation. Posterior-segment involvement was attenuated, evidenced by reduced retina–choroid thickening. Functionally, ruxolitinib preserved ERG responses, improving scotopic and photopic b-wave amplitudes and rescuing scotopic a-wave amplitude. Mechanistically, treatment suppressed JAK2–STAT3 activation in ocular tissues, consistent with on-target inhibition.

Conclusions: Pharmacologic JAK1/2 blockade with ruxolitinib curbs intraocular inflammation and preserves retinal function in EIU, likely through inhibition of the JAK2–STAT3 pathway. These findings support JAK inhibition as a steroid-sparing, mechanism-based strategy for uveitic conditions linked to systemic inflammation.

Abstract No.: 202026

Sclerokeratouveitis: The Ocular Storm Across Three Layers

First Author: Radha **DHOTE**

Co-Author(s): Prajakta **BHAILUME**

Purpose: To report a rare case of sclerokeratouveitis involving concurrent inflammation of the sclera, cornea, and uveal tract, and to highlight the importance of early diagnosis and multidisciplinary management to prevent irreversible vision loss.

Methods: A 53-year-old male farmer presented with a 5-month history of gradual, painless diminution of vision, watering, and blackish discoloration of the left eye following ocular trauma with sugarcane grass. Detailed ocular and systemic examinations were performed. Laboratory investigations included CBC, CRP, ESR, RA factor, RBS, HHH, CXR, ECG, and B-scan. The patient underwent scleral patch grafting with amniotic membrane grafting (AMG) under local anaesthesia, followed by topical steroids, topical antibiotics, oral steroids, and doxycycline.

Results: Results: The ocular examination revealed pseudophakia in both eyes, with the left eye showing scleral necrosis with thinning, corneal vascularisation, tongued shaped temporal leucomatous opacity, and macular oedema. Systemic work-up was unremarkable. Post-operative recovery was satisfactory, with control of inflammation achieved through combined surgical and medical therapy.

Conclusions: Sclerokeratouveitis is a rare but aggressive inflammatory disorder involving the sclera, cornea, and uveal tract, with potential for rapid vision loss. Early diagnosis through prompt clinical evaluation is essential to initiate targeted medical therapy and prevent structural damage. Surgical interventions, such as scleral patch grafting with or without amniotic membrane transplantation, should be timed to the extent of tissue involvement. Long-term follow-up is crucial to detect recurrence or complications. A coordinated multidisciplinary approach significantly improves visual prognosis and overall patient outcomes.

Abstract No.: 206114

Steroids in Disguise: Bilateral Postoperative Enterococcus Endophthalmitis

First Author: Tze Shen **SIM**

Co-Author(s): Othmaliza **OTHMAN**, Wendy Yen Nee **SEE**

Purpose: To present a challenging case of steroid-masked bilateral postoperative Enterococcus faecalis endophthalmitis.

Methods: Case report.

Results: A 52-year-old gentleman with diabetes mellitus, hypertension, and end-stage renal failure on hemodialysis presented five days after bilateral sequential uneventful cataract surgeries at a private eye center with acute right eye pain, redness, blurred vision, and nausea. He had received bilateral orbital floor triamcinolone injections one day prior to presentation. Ophthalmic examination revealed severe bilateral fibrinoid anterior chamber(AC) reaction with iris bombé. His right eye showed an epithelial defect from ruptured bullae with a pale optic disc and an intraocular pressure(IOP) of 45 mmHg. No hypopyon noted. Serial B-scans initially demonstrated mild vitreous opacities without loculations. Severe

postoperative inflammation was suspected, and high-dose steroids were trialed with minimal response. IOP was controlled following bilateral laser peripheral iridotomy and maximal topical anti-glaucoma. Bilateral AC and vitreous cultures subsequently grew Enterococcus faecalis, and repeated B-scan revealed vitreous loculations six days after presentation. A diagnosis of bilateral postoperative endophthalmitis was made, and repeated intravitreal antibiotic injections were administered. His vision improved from light perception to hand movement in the right eye and from 4/60 to 6/18 in the left, with IOP optimized.

Conclusions: This case underscores the diagnostic challenge of distinguishing intense postoperative inflammation from early endophthalmitis with steroid-masking effect. Early diagnostic taps and aggressive intravitreal therapy are critical. Clinicians should maintain a high index of suspicion and overtreat rather than undertreat when severe postoperative inflammation is encountered.

Abstract No.: 200303

The Hidden Culprit: A Case of an Idiopathic Posterior Scleritis With Exudative Retinal Detachment and Posterior Subcapsular Cataract in a 10-Year-Old Male

First Author: Anthea Rae **BURDEOS**

Co-Author(s): Mayjane Joan **TUMULAK**

Purpose: To report a case of a 10-year-old male diagnosed with idiopathic posterior scleritis with exudative retinal detachment and posterior subcapsular cataract in the right eye. Describe the presenting symptoms, laboratory and imaging findings, treatment, and outcome.

Methods: Case report.

Results: The patient was seen at the outpatient department with complaints of blurred vision in the right eye. The patient had a 2-month history of recurrent unilateral headaches and right eye pain, which was partially relieved with acetaminophen. On examination, visual acuity for the right eye was Counting Fingers, and 20/20 for the left eye; tones were normal with intact extraocular movements. There were hypopigmented erythematous patches on the face and palms noted. Posterior subcapsular cataract with P4 grading on the right eye. Fundoscopy showed a hyperemic disc with distinct disc borders and a note of exudative retinal detachment inferiorly. Laboratory tests were unremarkable. Ultrasound imaging revealed a classic T-sign in the right eye and was unremarkable in the left eye. MRI noted right scleral thickening. Rheumatology service referral revealed no evidence of an underlying systemic condition. The dermatology service noted rashes consistent with contact dermatitis. Patient was treated with intravenous methylprednisolone 500 mg in 100 ml PNSS once daily for 5 days. Improvement of visual acuity and rashes

was noted prior to discharge. Follow-up after 1 week from discharge noted an overall improved visual outcome.

Conclusions: This case highlights the significance of considering posterior scleritis in cases of headache and eye pain, especially with blurring of vision or optic disc and retinal involvement in the pediatric population.

Abstract No.: 206877

The Silent Culprit: Diffuse Unilateral Subacute Neuroretinitis Caused by a Large Subretinal Worm

First Author: Ronnie Abhishek TALLURI

Co-Author(s): Aditya KAPOOR

Purpose: To understand the course of the disease, identify the worm, and treatment modalities.

Methods: A 45-year-old female presented with sudden diminution of vision in the right eye for 6 days. The best corrected visual acuity (BCVA) was counting fingers close to the face. Fundus examination revealed multiple crops of yellow lesions with subretinal fluid, superficial as well as deep hemorrhages, and a large subretinal yellow worm wriggling constantly in the subretinal space over a wide area in the posterior pole and macula. The Iridex Pascal machine was used with a 400-milliwatt laser and a duration of 20 milliseconds. First spot at the head, second spot at the tail, and later spots given along the body of the worm until immobilized.

Results: The patient was started on Tablet Albendazole 800 milligram stat, followed by Albendazole 400 milligram once a day for 3 weeks, and Tablet Prednisolone 50 mg for one week. During follow-up, even though the worm completely disintegrated, the subretinal fluid, along with inflammation, had settled, and vision did not recover due to extensive foveal atrophy.

Conclusions: Direct photo coagulation is the treatment of choice. It destroys the worm and prevents further movement of the worm towards the fovea. Photocoagulation breaks the blood-retinal barrier aseptically, providing better penetration of anti-helminthics. Anti-helminthics are given primarily targeting the other worms in the body.

Abstract No.: 204738

The Sweet Dilemma: A Vision-Threatening Case of Sweet Syndrome

First Author: Alicia Victoria NOCEDA

Co-Author(s): Cristina GARCIA

Purpose: To present a rare case of Sweet syndrome with ocular involvement leading to vision-threatening complications, emphasizing the importance of early recognition and multidisciplinary management.

Methods: A 37-year-old female presented with generalized rashes with associated cough, fever, and periorbital edema. Other findings included slightly elevated intraocular pressure with generalized chemosis and limitation of movement on all gazes for both eyes. She was initially managed as a case of preseptal cellulitis secondary to viral exanthem with secondary bacterial infection, both eyes; rule out cavernous sinus thrombosis. During admission, she was started on broad-spectrum antibiotic and anti-viral therapy and had undergone a cranial MRI with MRV which showed findings of bilateral preseptal cellulitis with dacryoadenitis.

Results: By the 8th day of admission, vision declined to hand movement. Fundus imaging revealed posterior uveitis, occlusive vasculitis, choroidal infarction, choroidal granulomas, macular ischemia, and optic neuropathy. Blood cultures were negative and no significant improvement was seen despite antimicrobial therapy. A non-infectious cause for the constellation of symptoms of fever, rash, and ophthalmologic findings should be considered; hence, Sweet Syndrome was a more compelling diagnostic consideration.

Conclusions: Sweet syndrome is challenging to diagnose due to its similar clinical presentations to infections and autoimmune diseases. A multidisciplinary approach and clinicopathologic correlation are key to avoiding misdiagnosis.

Abstract No.: 201797

Tocilizumab in Non-Infectious Refractory Uveitis: Efficacy and Tear Cytokine Correlates

First Author: Aneena Anna THOMAS

Co-Author(s): Ankush KAWALI, Padmamalini MAHENDRADAS, Sai Bhakti MISHRA

Purpose: To evaluate the efficacy of systemic tocilizumab in refractory non-infectious uveitis and explore tear cytokines as biomarkers of disease activity.

Methods: This retrospective series included 15 patients (21 eyes) with refractory uveitis treated with systemic tocilizumab biweekly. The primary outcome was resolution of intraocular inflammation on OCT or angiography. Tear cytokine profiling was performed in 5 patients (10 eyes).

Results: Mean age was 34.7 years (7–69); 40% were pediatric. Panuveitis predominated (47%), followed by posterior (20%) and intermediate uveitis (13%). Chronic cystoid macular edema (CME) was the leading indication (60%), with retinal vasculitis in 27%, mostly in pediatric eyes (off-label). One patient developed latent tuberculosis after 2 years. Tear cytokine analysis showed high MMP 9 and ICAM 1, IL 6 detectable in all active eyes, and VEGF A correlating with CME. IL 17A and TNF α were consistently low, while IL 10 spikes suggested localized immunoregulation.

Conclusions: Tocilizumab appears effective for IL 6–driven, refractory uveitis with CME and vasculitis. Tear cytokine profiling may serve as a minimally invasive biomarker for monitoring disease activity and therapeutic response.

Abstract No.: 206583

Toxic Keratouveitis Following Exposure to Plant Milk

First Author: Abhishek

Co-Author(s): Gian CHAND, Shreya NARANG, Jayant SHARMA

Purpose: To report a case of toxic keratouveitis occurring in a 65-year-old female. It is a rare condition caused by toxic agents, presenting with acute corneal and anterior uveal inflammation; exact prevalence is not well defined due to sporadic case reports.

Methods: A 65-year-old female presented with sudden, painful loss of vision in the left eye over the past 2 hours, following the fall of some plant milk while gardening. Ophthalmic examination revealed visual acuity of 6/60 and intraocular pressure of 39 mmHg in the left eye. Slit-lamp examination revealed features of keratouveitis with lid edema, subconjunctival hemorrhage, central epithelial defect, mild stromal edema, diffuse medium-sized fresh keratic precipitates, a fixed dilated pupil, with anterior chamber cells graded +3 and fibrin over the lens. Fundus examination was unremarkable. The eye was irrigated copiously with normal saline and treated with topical antibiotic and steroid, cycloplegic, and antiglaucoma drops for a 3-week duration.

Results: The patient was diagnosed with toxic keratouveitis and managed accordingly.

Conclusions: The plant was identified as *Claoxylon sandwicense* of the Euphorbiaceae family, which produces a milky latex sap containing compounds like diterpenes and phorbol esters, which can be highly irritating to the eyes. Clinical course may be affected by particular species of Euphorbia, the amount of sap exposure, the time between exposure and irrigation, and host factors.

Abstract No.: 205578

Vascular Echoes of Tuberculosis: CNVM as the Footprint and Sequela of Choroidal Tuberculoma

First Author: Manisha CHOUDHARY

Co-Author(s): Shreya BHADANI, Manmath DAS, Siddhartha KAR, Srinidhi N, Aanchal SINGHAL

Purpose: To report a rare case of choroidal tuberculoma complicated by Type 2 and Type 3 choroidal neovascular membranes (CNVM), documented with multimodal imaging and treated with anti-vascular endothelial growth factor (anti-VEGF) therapy.

Methods: A 20-year-old female on anti-tubercular therapy (ATT) for CNS tuberculoma presented with a one-month history of painless, progressive vision loss in the left eye (LE). Ophthalmic evaluation included best-corrected visual acuity (BCVA), fundus examination, and multimodal imaging. Review of prior neuroimaging revealed multiple intracranial tuberculomas with perilesional edema, meningitis, and tonsillar herniation.

Results: BCVA was 6/6 in the right eye (RE) and counting fingers at 1 meter in the left eye (LE). Near vision was N6 in the RE and <N48 in the LE. The anterior segment was normal in both eyes. Fundus was normal in the RE, while the LE showed optic disc pallor with an active macular choroidal tuberculoma and CNVM. FFA and ICGA demonstrated neovascularization between the retinal pigment epithelium (RPE) and neurosensory retina (Type 2 CNVM), along with retinochoroidal anastomosis (Type 3) overlying the lesion, and ICGA revealed additional granulomas not seen clinically or on FFA. The patient was treated with monthly intravitreal ranibizumab while continuing ATT, leading to improvement of BCVA to 6/60 and near vision to N48 in the LE after three injections.

Conclusions: CNVM arising from choroidal tuberculoma represents a highly uncommon manifestation at the crossroads of ocular tuberculosis and neovascular pathology. The coexistence of Type 2 and Type 3 CNVM in an active lesion underscores its unprecedented rarity. Vigilant multimodal imaging and timely anti-VEGF therapy are essential for early detection and preservation of vision.

Abstract No.: 205680

Visual Improvement After Early Removal of Intraocular Vancomycin in Hemorrhagic Occlusive Retinal Vasculitis

First Author: Wen-jung LO

Co-Author(s): Ting-yu HSIEH

Purpose: To report a case of hemorrhagic occlusive retinal vasculitis (HORV) achieving favorable visual recovery after urgent pars plana vitrectomy (PPV) to remove residual intravitreal vancomycin initially administered for presumed exogenous endophthalmitis, later identified as toxic anterior segment syndrome (TASS)

Methods: Case report

Results: A 43-year-old man with no systemic disease presented with blurred vision and mild ocular pain in the left eye 2 days after cataract surgery. The same eye had undergone vitrectomy for retinal detachment 11 months earlier. Visual acuity was counting fingers. Slit-lamp examination showed moderate corneal edema and 3+ anterior chamber cells, and B-scan revealed increased vitreous opacity. Under the initial diagnosis of exogenous endophthalmitis, intravitreal vancomycin and ceftazidime were injected. One day

later, hypopyon and a dense anterior chamber reaction (4+) developed. Urgent vitrectomy (<24 hours after injection) was performed. Intraoperatively, only mild vitreous haze, scattered powder-like deposits on the retinal surface, and venular hemorrhages were noted, without endophthalmitis. The final diagnosis was TASS with HORV. Two weeks postoperatively, visual acuity improved to 20/63

Conclusions: HORV typically has poor visual outcomes attributed to a delayed hypersensitivity-mediated vasculitis and ischemia, and prior reports have emphasized discontinuing vancomycin rather than removing residual intraocular drug. This case suggests that early PPV to reduce intraocular vancomycin burden may help limit immune activation and support visual recovery in selected patients. Further studies are warranted

Abstract No.: 201935

Vitreous Biopsy-Proven Intraocular Lymphoma: Experience From A Southeast Asian Tertiary Hospital

First Author: Brylle **CATAGUE**

Co-Author(s): Bryan Vincent **MESINA**

Purpose: To describe a case of intraocular lymphoma and highlight an effective method of vitreous sampling that facilitated a definitive diagnosis.

Methods: A 46-year-old female presented with a 3-month history of blurring of vision, floaters, and headaches. Slit lamp examination revealed anterior chamber reaction and dense vitreous cells in sheets. During her course, she developed seizures, raising suspicion for central nervous system lymphoma. Cranial magnetic resonance imaging suggested either a lymphomatous or demyelinating process. A diagnostic vitreous biopsy was performed through a three-port pars plana vitrectomy using a large bore cutter at 1000-1500 cuts per minute. One milliliter of undiluted vitreous and 10 milliliters of diluted vitreous with infusion fluid were collected, mixed with 95% ethanol with a 1:1 ratio, and sent to pathology within 30 minutes. Careful handling was observed to maintain cell integrity.

Results: Cytology demonstrated atypical lymphoid proliferation suspicious for hematology lymphoid proliferation. Subsequent immunohistochemistry revealed strong, diffuse CD20 staining consistent with primary diffuse large B-cell lymphoma.

Conclusions: Intraocular lymphoma is notoriously difficult to diagnose, with many biopsies yielding inconclusive results. This case illustrates how proper vitreous biopsy technique and meticulous specimen handling can preserve cellular morphology and enable definitive diagnosis. Establishing accurate and timely diagnosis is essential for distinguishing lymphoma from

other uveitic conditions, and for initiating appropriate therapy early in the disease course.

Abstract No.: 204474

Vitreous Hemorrhage From Immune Recovery Uveitis in a Case of Cytomegalovirus Retinitis

First Author: John Jasper **RAMOS**

Co-Author(s): Albert John **BROMEIO**

Purpose: Immune recovery uveitis (IRU) is an immune reconstitution inflammatory syndrome (IRIS) in HIV patients with cytomegalovirus (CMV) retinitis after initiating HAART (highly active antiretroviral therapy, resulting from a dysregulated immune response to residual CMV antigens due to rapid CD4+ T-cell recovery. Common manifestations include anterior uveitis and vitritis with complications including cystoid macular edema and epiretinal membranes. This case aims to report a case of vitreous hemorrhage as an atypical complication of treatment of IRU.

Methods: Case report.

Results: A 37-year-old male HIV patient presented with a 2-month history of progressively worsening bilateral blurring of vision following initiation of HAART. Vision was hand motions in the right eye and 20/320 in the left. Fundoscopy showed widespread areas of retinitis with hemorrhages consistent with CMV retinitis. Macular OCT showed cystoid macular edema consistent with IRU. The patient was managed medically with valganciclovir, followed by a course of oral prednisone. On follow-up, resolution of macular edema was observed. However, about 2 months after treatment, the patient developed vitreous hemorrhage in the right eye. The vitreous hemorrhage was managed conservatively and resolved spontaneously after 4 months. The latest follow-up showed inactivity of CMV retinitis and quiescence of IRU with a vision of 20/125 on the right eye and 20/100 on the left.

Conclusions: Vitreous hemorrhage may develop as an atypical complication in patients undergoing treatment of IRU from CMV retinitis. IRU should be promptly recognized and appropriately managed to avoid permanent vision loss.

Abstract No.: 200845

Vitreous Prolapse as a Red Flag: Predicting Sympathetic Ophthalmia After Globe Rupture in Taiwan — Insights From 253 Cases

First Author: Chan-wei **NIEN**

Co-Author(s): Tsan-yu **TSAI**

Purpose: Sympathetic ophthalmia (SO) is a rare but potentially blinding bilateral panuveitis following open-globe injury (OGI). This study aimed to determine the incidence and clinical predictors of SO—particularly

vitreous prolapse—in patients with globe rupture in a Taiwanese trauma cohort.

Methods: A retrospective review was conducted on 253 patients with surgically repaired globe rupture between 2014 and 2024 at Show Chwan Memorial Hospital. Data on demographics, injury mechanism, wound size, vitreous prolapse, and SO diagnosis were collected. SO was defined as bilateral granulomatous uveitis confirmed by clinical and imaging criteria. Logistic regression identified independent risk factors.

Results: Of 253 patients (mean age 49.3 ± 18.7 years; 67.2% male), 46.6% had vitreous prolapse. SO occurred in 17 cases (6.7%), significantly higher than the global average of 0.19%. SO incidence was 10.2% in patients with vitreous prolapse vs. 3.2% without ($p = 0.011$). Vitreous prolapse (OR 3.46; $p = 0.013$) and wound length ≥ 5 mm (OR 2.74; $p = 0.041$) were significant predictors. Most SO cases presented within 3 months post-injury.

Conclusions: Vitreous prolapse at presentation is a significant risk factor for SO in patients with globe rupture. Early identification of high-risk cases and prompt systemic corticosteroid therapy may improve visual prognosis. These findings suggest that vitreous status should be routinely assessed and documented during primary globe repair to mitigate the risk of SO.

Abstract No.: 203221

Vitritis with a Twist: The Peripheral Retinal Detachment Masquerade

First Author: Gabrielle Marie **HEREDIA**

Co-Author(s): Andrei **MARTIN**, Ellen **YU-KEH**

Purpose: To report a case of persistent ocular inflammation, initially attributed to a malpositioned intraocular lens (IOL), but later diagnosed as vitreoretinal pathology consistent with a Uveitic Masquerade syndrome. This case demonstrates that vitritis can be the initial ophthalmologic finding in patients with peripheral retinal tear.

Methods: A 20-year-old male with prior uneventful cataract extraction 1 year prior presented with anterior uveitis and vitritis. Sequential imaging included B-scan Ultrasonography, Ultrasound Biomicroscopy (UBM), and Optical Coherence Tomography (OCT) of the left eye. Surgical interventions included IOL exchange with anterior vitrectomy, followed by pars plana vitrectomy (PPV) with silicone oil tamponade of the left eye.

Results: Initial B-scan of the left eye revealed vitritis with an attached retina. Examination revealed sulcus placement of the inferior haptic, which was confirmed by UBM showing a haptic in the ciliary sulcus with iridocyclitis and inflammatory deposits. Rescue IOL exchange was performed one month after initial presentation. Inflammation worsened post-operatively and examination showed the presence of a rhegmatogenous retinal detachment inferiorly. Review

of OCT performed prior to IOL exchange showed that RD was present prior to the IOL exchange. PPV revealed partial retinal detachment, with subretinal bands. Though the hole was not directly visualized, a retinal break was suspected to be likely very peripheral in location. Inflammation subsided immediately after the surgery.

Conclusions: Persistent ocular inflammation after addressing a potential etiology should raise suspicion for a different pathology, including uveitic masquerade syndromes. Repeating assessment and dilated retinal examinations are critical to avoid delayed diagnosis of retinal detachment in such cases.

Abstract No.: 200483

When Definitions Blur: The Impact of Policy Ambiguity on Extrapulmonary TB Management in Taiwan

First Author: Yueh-chang **LEE**

Purpose: Ocular tuberculosis (TB) is a rare extrapulmonary manifestation of *Mycobacterium tuberculosis*, typically presenting without systemic involvement and posing diagnostic challenges. This case highlights clinical and public health implications, particularly in the context of Taiwan's TB policies.

Methods: We report a case of presumed ocular TB in an immunocompetent patient, accompanied by a literature review and analysis of Taiwan's regulatory approach to extrapulmonary TB and contact tracing, with comparison to international guidelines.

Results: A 61-year-old immunocompetent man presented with a three-day history of floaters and photopsia in his right eye. Examination revealed vitritis, chorioretinal lesions, and imaging suggestive of multifocal choroiditis. Despite empirical corticosteroid treatment, vision declined. Laboratory workup revealed a positive interferon-gamma release assay (IGRA) with negative results for other infectious etiologies. Chest imaging was normal. Based on clinical presentation and IGRA positivity, presumed ocular TB was diagnosed. Anti-tubercular therapy led to full visual recovery. Despite being non-infectious, the case triggered standard contact tracing protocols under Taiwan's current TB policy, which does not differentiate between pulmonary and extrapulmonary TB.

Conclusions: This case demonstrates the need to consider ocular TB in the differential diagnosis of posterior uveitis. It also reveals a gap in Taiwan's TB management policy, where extrapulmonary TB is treated under the same infectious disease control measures as pulmonary TB. In contrast, U.S. CDC guidelines recommend no contact investigation for non-infectious TB forms. Policy refinement is needed to align contact tracing practices with actual transmission risks and international standards.

Myopia

A Knowledge-Attitudes-Practices Study of Chinese Parents on Myopia: Correlations and Influencing Factors

First Author: Xiaohang CHEN

Co-Author(s): Lulu LI, Longqian LIU

Purpose: To assess the Knowledge, attitudes, and practices (KAP) of Chinese parents regarding myopia and ocular hygiene, and to identify key factors influencing their KAP levels and their correlation with myopia status.

Methods: A cross-sectional study was conducted from December 2023 to April 2024. A structured, self-administered KAP questionnaire, validated for reliability and content validity, was distributed via the «Questionnaire Star» platform using a convenience sampling method. Participants were parents of adolescents aged 0-19. The survey collected demographic data, children's myopia status, and comprehensive KAP scores. KAP contains three domains: knowledge (10 items), attitudes (7 items, Likert scale), and practices (8 items, Likert scale). Total and dimension scores were calculated and classified as poor, medium, good, or excellent.

Results: Among the participants, the mean scores for parental knowledge, attitudes, and practices were 7.79 ± 2.40 , 31.61 ± 2.87 , and 30.43 ± 4.66 , respectively, with a total KAP score of 69.83 ± 7.48 . Significant factors influencing higher total KAP scores included parents residing in urban areas, having higher education levels, being myopic themselves, and having a child who developed myopia before age six. Knowledge scores were significantly associated with the child's myopia status. Gaps were identified in specific knowledge areas (e.g., myopia curability) and practices (e.g., regular eye examinations, ensuring sufficient outdoor time).

Conclusions: Chinese parents demonstrate positive attitudes towards childhood myopia prevention, but gaps exist in knowledge and practices. Efforts should focus on enhancing parental education, particularly in rural areas and among less-educated parents, to bridge the KAP gap and improve childhood myopia control outcomes.

Abstract No.: 203568

A Study on the Role and Mechanism of miR-145-5p on Refractive Development Based on Green Light-Induced Guinea Pig Myopia Model

First Author: Liyue ZHANG

Co-Author(s): Ye SHEN, Jianping TONG

Purpose: Investigate the regulatory role of miR-145-5p in 530 nm green light-induced myopia pathogenesis, focusing on its clinical relevance in human high myopia and molecular mechanisms underlying refractive development.

Methods: Analyzed retinal miRNA profiles in guinea pigs exposed to green light; measured miR-145-5p levels in plasma/aqueous humor of high myopia patients; validated functional effects via intravitreal injections of miR-145-5p antagonist/agonist; identified target genes through bioinformatics and experimental validation.

Results: Green light exposure induced distinct retinal miRNA alterations, with miR-145-5p significantly reduced in patients' plasma/aqueous humor and negatively correlated with axial length. Antagonist injections induced myopic shifts (reduced spherical equivalent, elongated axial/vitreous chamber), while agonist treatment counteracted green light-induced changes. IRS1 was identified as a direct functional target of miR-145-5p through integrated bioinformatics and experimental validation, demonstrating inverse expression patterns in vivo.

Conclusions: This study reveals miR-145-5p regulates green light-mediated refractive development via IRS1, providing novel biomarkers for myopia research and a mechanistic mediator of ocular growth.

Abstract No.: 206158

Additive Effect of Dims Spectacles With Low-Dose Atropine for Myopia Control in Thai Children: A Randomised Clinical Study

First Author: Suwasa LODARBCHAI

Co-Author(s): Worawalun HONGLERTNAPAKUL, Natthiya LAILAKSIRI, Jipada PRUKSACHOLAVIT

Purpose: To evaluate whether combining defocus incorporated multiple segments (DIMS) spectacles with low-dose atropine provides additional benefit over atropine monotherapy in controlling childhood myopia.

Methods: Children aged 6–18 years with progressive myopia were recruited at a tertiary hospital in Bangkok and randomized to two groups: (1) 0.01% atropine nightly plus single-vision spectacles, or (2) 0.01% atropine nightly plus DIMS lenses. Baseline assessments included visual acuity, cycloplegic refraction, and axial length (AL). At 6 months, repeat refraction and AL were measured by masked examiners. Compliance and safety outcomes were documented.

Results: Sixteen participants completed 6-month follow-up. Both groups showed continued myopic progression. The combination group had numerically smaller mean changes in spherical equivalent refraction (SER) and AL compared with atropine alone, although the differences did not reach statistical significance ($p > 0.05$). Compliance was high in both groups, and no serious adverse events were reported.

Conclusions: In this randomized study, the addition of DIMS spectacles to 0.01% atropine did not significantly reduce myopia progression compared with atropine monotherapy over 6 months. Nevertheless, the favorable safety profile and trend toward reduced progression support further investigation with larger cohorts and longer follow-up. These early data, among the first from Southeast Asia, suggest that combination therapy remains a promising strategy for addressing the growing burden of childhood myopia.

Abstract No.: 208017

Association of Optical Coherence Tomography Angiography Metrics With Impaired Macular Microvasculature in Amblyopic Eyes: A Longitudinal Study

First Author: Cheuk Ling YIM

Co-Author(s): Qin SHU, Yuzhou ZHANG

Purpose: To investigate longitudinal changes in OCTA metrics over a three-year period in amblyopic children compared to controls, and to assess whether these metrics are associated with BCVA and treatment response.

Methods: This prospective longitudinal study enrolled 60 children diagnosed with unilateral amblyopia and 1000 matched controls. OCTA imaging was performed at baseline and after three years. Key metrics analyzed included FAZ area, FAZ circularity, fractal dimension, vessel diameter index, and vessel density. Subgroup analysis was planned to evaluate associations between OCTA changes and amblyopia treatment outcomes. Preliminary data were analyzed using an independent sample t-test and linear regression, adjusting for multiple covariates using a model such as ANCOVA.

Results: Initial analysis of the three-year follow-up data revealed statistically significant differences in the change in FAZ circularity (-0.156 ; 95% CI -0.307 to -0.005 , $P=0.043$), fractal dimension (-0.024 ; 95% CI -0.045 to -0.004 , $P=0.029$), and vessel diameter index (0.002 ; 95% CI 0.000 - 0.005 , $P=0.016$) between the amblyopia and control groups. BCVA is also found to be correlated with Log FAZ circularity, log FD, log VDI, and log VD after adjusting for covariates, including age, BMI, spherical equivalent, and axial length. Further analysis incorporating subgroup stratification is underway to explore potential associations with treatment response and disease progression.

Conclusions: Preliminary findings from this 3-year longitudinal study reveal statistically significant differences in the OCT metrics between the two groups. Further result analysis will contribute to understanding the role of OCTA as a biomarker in amblyopia and its potential utility in monitoring treatment efficacy.

Abstract No.: 207781

Association of Polymorphisms in ZFHX1B, KCNQ5 and GJD2 With Myopia Progression and Polygenic Risk Prediction in Children

First Author: Li Jia CHEN

Co-Author(s): Chi Pui PANG, Clement C THAM, Jason C YAM

Purpose: To assess the association of single-nucleotide polymorphisms (SNPs) with myopia progression for polygenic risk prediction in children.

Methods: Six SNPs (ZC3H11B rs4373767, ZFHX1B rs13382811, KCNQ5 rs7744813, MET rs2073560, SNTB1 rs7839488, and GJD2 rs524952) were analysed in 1043 school children, who completed a 3-year follow-up, using TaqMan genotyping assays. SNP associations with progression in spherical equivalent (SE) were analysed by logistic regression. Polygenic risk scores (PRS) were applied for computing the sum of the risk alleles of multiple SNPs corresponding to myopia progression, weighted by the effect sizes of the corresponding SNPs.

Results: GJD2 rs524952 showed significant association with fast progression (OR=1.32, 95% CI 1.10 to 1.59; $p=0.003$) and KCNQ5 rs7744813 had nominal association (OR=1.32, 95% CI 1.04 to 1.67; $p=0.02$). In quantitative traits locus analysis, GJD2 rs524952 and KCNQ5 rs7744813 were associated with progression in SE ($\beta=-0.038$ D/year, $p=0.008$ and $\beta=-0.042$ D/year, $p=0.02$) and axial elongation ($\beta=0.016$ mm/year, $p=0.01$ and $\beta=0.017$ mm/year, $p=0.027$). ZFHX1B rs13382811 also showed nominal association with faster progression in SE ($\beta=-0.041$ D/year, $p=0.02$). PRS analysis showed that children with the highest PRS defined by rs13382811, rs7744813, and rs524952 had a 2.26-fold increased risk of fast myopia progression ($p=4.61 \times 10^{-5}$). PRS was also significantly associated with SE progression ($R^2=1.6\%$, $p=3.15 \times 10^{-5}$) and axial elongation ($R^2=1.2\%$, $p=2.6 \times 10^{-4}$).

Conclusions: In this study, multi-tiered evidence suggested SNPs in ZFHX1B, KCNQ5, and GJD2 as risk factors for myopia progression in children. Additional attention and appropriate interventions should be given for myopic children with high-risk PRS as defined by GJD2 rs524952, KCNQ5 rs7744813, and ZFHX1B rs13382811.

Abstract No.: 200552**Awareness of Myopia-Related Complications and Management Among Medical Professionals and Trainees***First Author: Adeline YANG**Co-Author(s): Kah Guan AU EONG, Deborah LEE*

Purpose: Myopia is a major global public health concern, with early intervention vital to preventing long-term ocular complications. This study assessed awareness of myopia-related complications and control strategies among eye care professionals (ECPs) and non-eye care professionals (non-ECPs), and examined related prescription trends.

Methods: A cross-sectional survey was conducted among ophthalmologists, optometrists, opticians, general practitioners (GPs), and medical/optometry students in Singapore. Awareness of myopia complications (e.g., retinal detachment, glaucoma) and familiarity with control methods (e.g., atropine, orthokeratology, myopia control lenses) were evaluated. Data were analyzed using descriptive statistics and chi-square tests.

Results: A total of 571 responses were analyzed. Ophthalmologists and optometrists demonstrated the highest awareness of myopia-related complications, while non-ECPs showed significantly lower awareness ($p < 0.001$). Awareness of atropine therapy was high among ophthalmologists (96.6%) and optometrists (96.7%) but lower among medical students (34.0%) and GPs (53.6%). Optometrists had the highest awareness of optical strategies, though prescription rates were lower than awareness across all groups. Cost and prior experience significantly influenced prescribing decisions ($p < 0.05$). Awareness of lifestyle interventions such as outdoor time was high, whereas non-evidence-based practices (e.g., eye exercises) were more often endorsed by non-ECPs.

Conclusions: Despite high awareness among ECPs, gaps remain in translating knowledge into clinical practice. Limited awareness among non-ECPs highlights the need for targeted education. Incorporating myopia management into medical curricula and promoting interprofessional collaboration could enhance early intervention and strengthen referral pathways for effective, community-based myopia care.

Abstract No.: 204869**Axial Length Shortening Among Myopia Control Glass Users***First Author: Sneha BATRA**Co-Author(s): Supratik BANDYOPADHYAY, Joyashree BANERJEE, Aroni CHAKRABORTY, Swarup ROY, Shyamal SAHA*

Purpose: Myopia has emerged as a global public health concern, with axial length (AL) elongation recognized as its structural hallmark. Certain myopia

control interventions, such as photobiomodulation and orthokeratology, not only slow progression but may also induce axial shortening, challenging traditional understanding of ocular growth. The purpose of this study was to explore the occurrence of AL shortening among myopia control glasses (MCG) users, which has not been studied previously.

Methods: This retrospective cohort study included children 4–17 years with myopia between 0.75–10 D and progression $>0.5D$ in the last 1 year. Standardized myopia clinic evaluation, including slit-lamp, cycloplegic refraction, AL measurement with OA-2000 optical biometer, and dilated funduscopy, was done. Participants were prescribed one of three types of MCG using peripheral defocus technology – Type I (Defocus Incorporated Multiple Segments), II (Highly Aspherical Lenslet Target), or III (Cylindrical Annular Refractive Elements). Follow-up done at 6 and 12 months.

Results: A total of 422 eyes of 217 children were included. AL at baseline, 6, and 12 months was 24.84 mm, 24.91 mm, and 24.95 mm, respectively. Refractive error at baseline, 6, and 12 months was -4.43 D, -4.47 D, and -5.17 D, respectively. AL shortening was noted in 27.04% and 22.25% eyes among all MCG users at 6 and 12 months, respectively. Type III MCG users showed the maximum shortening, followed by type II and type I.

Conclusions: Our study shows that AL shortening is possible even with the use of MCG. The implications of documented AL shortening beyond stabilization are immense, even raising the possibility of partial myopia reversal.

Abstract No.: 208410**Axial Length Shortening in Chinese Children and Adolescents Without Myopia Control Interventions***First Author: Shang LIU**Co-Author(s): Xiangui HE, Xun XU*

Purpose: Axial length (AL) shortening in children without myopia control interventions is uncommon but remarkable. This study aimed to investigate the incidence, magnitude, associated factors and the following-year refractive change of AL shortening among these children and adolescents.

Methods: A total of 11,797 eyes aged 3–18 years were included from two longitudinal studies. AL shortening was defined as an annual AL change of <-0.05 mm and ≥-0.80 mm. The incidence and magnitude of AL shortening were calculated and their associated factors were explored using multivariable logistic regression and linear regression.

Results: Of the 11,797 eyes, 159 (1.35%) experienced annual AL shortening with a mean reduction of -0.32 mm. Greater AL shortening incidence was associated with longer baseline AL, younger age, lower corneal radius (CR) and greater anisometropia (OR = 1.98, 0.84,

0.32 and 1.40; all $P < 0.05$). Myopic eyes were less likely to have AL shortening compared with hyperopic eyes ($OR = 0.29$, $P = 0.001$). The magnitude of AL shortening significantly decreased with baseline age and CR ($\beta = 0.03$ and 0.20 , both $P < 0.05$), while increased with baseline AL ($\beta = -0.14$, $P < 0.001$), and myopic eyes exhibited smaller AL shortening than hyperopic eyes ($\beta = 0.24$, $P = 0.003$). In addition, in non-myopic eyes with AL shortening and 2-year follow-up (6-8 years old), the second-year myopia incidence was only 10% with SE change of -0.23 D.

Conclusions: AL shortening may occur among children without myopia control interventions. The occurrence of axial shortening may indicate a safer refractive progression in the following year.

Abstract No.: 206230

Biometric Analysis of the Anterior Segment in Highly Myopic Eyes With Posterior Scleral Staphyloma

First Author: Liduo **PAN**

Co-Author(s): Jian **DENG**, Xiaoyi **YU**, Hui **GUO**, Xi **SONG**

Purpose: This study aimed to delineate anterior segment characteristics in high myopia with posterior staphyloma (HMPS) and to explore the interplay between corneal biomechanics, anterior scleral thickness, and myopia severity.

Methods: This prospective cross-sectional study enrolled 137 myopic patients (137 eyes) and categorized them into three groups: non-high myopia (NHM), high myopia (HM), and high myopia with posterior staphyloma (HMPS). Corneal biomechanics were assessed with Corvis ST, measuring parameters including A1L, A1V, A2L, A2V, HCR, HCDA, PD, SP-A1, DA Ratio, and IR. Anterior scleral thickness (AST) and subfoveal choroidal thickness (SFCT) were obtained by OCT, with AST measured at the scleral prominence and at 1–3 mm posteriorly in four quadrants. Inter-group differences were analyzed using ANOVA, and associations of corneal biomechanics and AST with myopia progression were evaluated via multiple linear regression.

Results: Posterior staphyloma (PS) was independently associated with shallower anterior chamber depth ($\beta = -0.352$, $P = 0.018$) and greater lens thickness ($\beta = 0.128$, $P = 0.046$). Multiple corneal biomechanical parameters (HCR, HCDA, IR, DA Ratio, A2V) differed significantly among groups ($P < 0.05$). After adjusting for CCT, BIOP, and age, both HM and HMPS groups showed weakened corneal biomechanics compared to the NHM group, as indicated by lower HCR and higher HCDA. However, the HMPS group exhibited a lower IR and DA Ratio than the HM group, suggesting a partial compensatory enhancement in corneal biomechanics. Additionally, AST was thicker at multiple locations in the HMPS group and positively correlated with PS after adjusting

for SE, AL, and CCT. Furthermore, AST increased with axial elongation, while choroidal thickness decreased.

Conclusions: HMPS is characterized by a shallower anterior chamber and a thicker lens. Although corneal biomechanics are impaired in HM, partial compensatory enhancement is observed in HMPS. Furthermore, AST increases with axial elongation and is associated with the presence of posterior staphyloma.

Abstract No.: 200745

Brimonidine Eye Drops and Intravitreal Administration Inhibit Form-Deprivation Myopia in Guinea Pigs: Ocular Pharmacokinetic and Toxicity Evaluation

First Author: Zeng **FANG**

Co-Author(s): Huang **GUOFU**

Purpose: This study aims to evaluate the effects of brimonidine eye drops and intravitreal administration in guinea pigs with form deprivation myopia (FDM), and to analyze the ocular pharmacokinetics and irritation.

Methods: The experimental guinea pigs were randomized to the normal control, FDM, FDM brimonidine topical eye drops, and FDM intravitreal injection groups. The experiment period was 13 days. Changes in ocular refraction and axial length were monitored regularly. The ocular pharmacokinetics of brimonidine and its metabolite brimonidine-2,3-dione were analyzed using ultra-performance liquid chromatography-tandem mass spectrometry (UPLC-MS/MS). Ocular irritation was assessed by the Draize test, corneal fluorescein staining, and hematoxylin and eosin staining.

Results: Treatment with brimonidine 400 μ g topical eye drops and 20 μ g intravitreal injection inhibited refraction and axial progression in the FDM group ($P < 0.05$). Brimonidine concentrations peaked in the topical eye drop group (11.965 ng/mg) at 0.5 hours and the intravitreal injection group (8.03 ng/mg) at 2 hours. The area under the curve (AUC $_{0-\infty}$) was 609.645 ng h/mg in the topical eye drop group and 449.587 ng h/mg in the intravitreal injection group. Draize score was lower and less irritating when administered by eye drops than by vitreous cavity injection.

Conclusions: Brimonidine eye drops and intravitreal administration inhibit the progression of FDM myopia in guinea pigs. Topical eye drop administration maintains higher drug concentrations in scleral tissue and is less irritating to the eye.

Abstract No.: 200931**Causal Relationship Between Myopia and Ocular Disorders at the Gene Level: A Mendelian Randomization Study***First Author: Tiange LIU**Co-Author(s): Xiaotong LI, Wei ZHANG*

Purpose: The incidence of myopia is steadily increasing, and it is emerging as a worldwide public health concern. Evidence from observational studies suggests that myopia is a risk factor for various ocular disorders; however, the causal association between myopia and these ocular disorders remains to be determined.

Methods: Using a two-sample Mendelian randomization approach, we analyzed genome-wide association study data to explore the causal relationship between myopia and 89 ocular diseases. The inverse variance weighted method was employed as the primary analytical tool, supplemented by a comprehensive sensitivity analysis.

Results: Among 89 ocular diseases studied, myopia showed significant causal associations with open-angle glaucoma ($OR=50.56$, $p=0.035$), optic disc disorders ($OR=2.24 \times 10^{11}$, $p=0.028$), non-senile cataract ($OR=31.37$, $p=0.049$), retinal detachment ($OR=9492.53$, $p=0.019$), and vitreous disorders ($OR=40.90$, $p=0.029$), but negatively associated with angle-closure glaucoma ($OR=2.96 \times 10^{-6}$, $p=0.032$). Sensitivity analyses supported these findings.

Conclusions: Myopia has a significant causal effect on primary open-angle glaucoma, primary angle-closure glaucoma, disorders of the optic disc, non-senile cataracts, retinal detachment, and vitreous-related diseases. Our research highlights the necessity of preventing myopia and provides new insights into the etiology of these ocular diseases.

Abstract No.: 208302**Characteristics of Corneal Biomechanical Changes and Their Correlation With Anterior Segment Parameter Alterations in the Early Period After SMILE Surgery***First Author: Chen TINGTING**Co-Author(s): Wei CHI, Yurui ZHAN*

Purpose: To investigate early changes in corneal biomechanics after small incision lenticule extraction (SMILE) and analyze their correlations with anterior segment parameters.

Methods: In this prospective study, 158 myopic patients (158 eyes) undergoing SMILE at the First Hospital of Lanzhou University between December 2022 and October 2023 were included. Only the right eyes were analyzed. Corneal biomechanics were measured using the Corvis ST before and 3 months after surgery. Parameters included A1V, A1L, A1T, A2V, A2L, A2T, HCR, HCDA, SSI, SP-A1, IR, DA 2 ratio, ARTh,

CBI, BAD.D, and TBI. Anterior segment parameters (Km, CCT, CV10mm, ACD, ACV, ACA, SE, and IOPnct) were also recorded. Paired t-test or Wilcoxon signed-rank test compared pre- and postoperative values; Pearson or Spearman correlation assessed relationships between changes (Δ) in parameters.

Results: At 3 months, A1L, A1T, A2L, A2V, IOPnct, bIOP, HCR, SSI, ARTh, and SP-A1 significantly decreased, while A1V, A2T, ATm, HCDA, DA 2 ratio, IR, CBI, BAD.D, and TBI significantly increased ($P<0.05$). ΔKm , ΔCCT , and $\Delta CV10mm$ were positively correlated with $\Delta IOPnct$, $\Delta ARTh$, and $\Delta SP-A1$ ($r=0.164-0.388$, $P<0.05$) but negatively correlated with ΔHCR , ΔSSI , $\Delta DA 2$ ratio, ΔIR , and ΔTBI ($r=-0.341$ to -0.166 , $P<0.05$). ΔACD , ΔACV , and ΔACA also showed significant correlations with $\Delta DA 2$ ratio, $\Delta ARTh$, $\Delta BAD.D$, and ΔTBI ($P<0.05$).

Conclusions: Three months after SMILE, corneal stiffness decreases and deformation increases. These biomechanical changes are significantly correlated with multiple anterior segment parameters, reflecting structural remodeling of the cornea after surgery.

Abstract No.: 206255**Clinical and Epidemiological Profile of Paediatric Myopia: A Retrospective Analysis of 1200 Cases***First Author: Mayanka NAYAK**Co-Author(s): Amod NAYAK, Lalitha S, Harshini, Vanitha*

Purpose: Background: The global burden of paediatric myopia is rising, with environmental and genetic factors playing key roles. This study evaluates refractive status, axial length, and lifestyle factors in a paediatric population to guide early intervention strategies.

Methods: Methods: Data of 1,200 patients aged 5-17 years were retrospectively analysed. Parameters included spherical equivalent (SE), axial length (AL), keratometry (K), parental myopia, near-work activity, and outdoor exposure. These measurements were done on Myopia Master by Oculus.

Results: Results: The mean age was 11.5 years, with 88% under 15 years. Average SE was -3.41 D (right eye) and -3.33 D (left eye). Myopia severity distribution: 48.6% mild, 39.6% moderate, and 9.4% high. Mean AL was 25.3 mm (right) and 24.4 mm (left). Average outdoor exposure was less with high myopia patients. High near-work activity was reported in 65 % of cases.

Conclusions: Conclusion: This study highlights a significant burden of moderate to high myopia among children and adolescents, with axial length, increased near activity and limited outdoor exposure being key risk indicators. The findings underscore the importance of early screening, lifestyle modification counselling, and timely myopia control interventions.

Abstract No.: 202810

Correction of Ultra-High Myopia With Scleral Contact Lenses

First Author: Bingru **ZHENG**

Co-Author(s): Dongmei **CUI**, Yu **JIA**, Lu **LAI**, Wen **LONG**

Purpose: To analyse the visual quality achieved by fitting scleral contact lenses (CSCL) in an uncommon case of bilateral high myopia management with a high degree of myopia and dry eye symptoms.

Methods: A 28-year-old man presented for an eye examination due to unsatisfactory visual quality and discomfort with rigid corneal contact lenses (RGP). He presented with high myopia and dry eye in both eyes. A diagnostic trial set was used in the fitting process, and he was assessed according to standardised fitting methodology. Visual acuity, corneal topography, biometry, and ocular aberrations were evaluated in 1 1-year follow-up period.

Results: The finalized scleral lens parameters were established, considering the patient's fitting situation after a trial period. The best spectacle-corrected visual acuity was 20/25 visual acuity in both eyes with the first scleral lens. Following adjustments to the lens base curve design, the tear lens between the lens and the cornea forms a negative tear lens. During the second visit, slit-lamp biomicroscopy findings showed optimal values for lens position and lens movement with no compression of the limbus and conjunctiva. After one month of follow-up, the patient's binocular visual acuity remained stable at 20/20. After 1 year of wearing CSCL, optimal values for the lens position and lens movement were maintained, and no adverse ocular effects were presented.

Conclusions: This case serves as a successful example of utilizing scleral contact lenses to improve the corrected visual acuity of a patient with longstanding vision issues. It introduces a promising option for managing high degree myope in clinical practice.

Abstract No.: 208303

Correlation Between Axial Length and Corneal Biomechanical Properties in Myopic Patients

First Author: Chen **TINGTING**

Co-Author(s): Wei **CHI**, Yurui **ZHAN**

Purpose: To investigate the correlation between corneal biomechanics and axial length (AL) in myopic patients.

Methods: In this cross-sectional study, 160 myopic patients (160 right eyes) scheduled for excimer laser surgery were enrolled. Based on AL measured by the IOL Master 500, participants were classified into three groups: healthy control (AL $\leq$ 24 mm, n = 17), low-to-moderate AL (24 mm < AL $\leq$ 26 mm, n = 118), and high AL (AL > 26 mm, n = 25). Corneal biomechanical

parameters were assessed using the Pentacam and Corvis ST systems, including A1V, A1L, A1T, A2V, A2L, A2T, ATm, HCDA, HCR, SSI, SP-A1, IR, DA ratio, ARTh, CBI, BAD.D, and TBI. Correlations between AL and biomechanical parameters were analyzed using Pearson/Spearman tests and multivariate linear regression.

Results: The mean age was 23.4 ± 5.7 years (88 males, 72 females). Significant intergroup differences were observed in A2T, ATm, SSI, and BAD.D ($F = 3.043-8.929$, $P < 0.05$). AL was positively correlated with ARTh and SP-A1 ($r = 0.23$, $P = 0.003$; $r = 0.20$, $P = 0.010$), and negatively correlated with A1V, A2T, ATm, SSI, DA ratio, IR, CBI, BAD.D, and TBI ($r = -0.478$ to -0.323 , $P < 0.05$). Regression analysis confirmed significant associations between AL and A1V, HCDA, SSI, and BAD.D ($\beta = -0.448-0.384$, $P < 0.05$).

Conclusions: SSI and BAD.D were inversely associated with AL, indicating that axial length should be considered when interpreting corneal biomechanical parameters, particularly in younger myopic patients.

Abstract No.: 201906

Cost-Effectiveness Analysis of Low-concentration Atropine for Myopia Progression (LAMP1) Study

First Author: Yuzhou **ZHANG**

Co-Author(s): Jason C. **YAM**

Purpose: To evaluate the cost-effectiveness of different atropine concentrations (0.01%, 0.025%, and 0.05%) for controlling myopia progression in children.

Methods: The data were from the LAMP1 study, a randomized controlled trial. Changes in spherical equivalent and axial length over 5 years were measured. Costs included patient out of pocket costs of medical examination and medications which consisted of cost of consultation, follow-up visits, optometric services, specialized ophthalmic services, spectacles, and loss of productivity. A transition-state model was used to simulate the effect of low concentration atropine on myopia progression. A Markov model with three health states (low, moderate, and high myopia) was utilized. The analysis focused on both short-term, with utilizing a 5-year time horizon when subjects would reach myopia stability, and long-term, further assessing the long-term impact of myopia and its associated complications (including open-angle glaucoma, retinal detachment, myopic macular degeneration, and cataracts), extending the model's time horizon of the scenario analysis to 80 years. Model parameters were varied within plausible ranges of values to determine their impact on the model in sensitivity analysis.

Results: The cost-effectiveness ranking of different atropine concentrations over the 5-year period was highest for 0.05%, followed by 0.025%, and 0.01%.

The results remained unchanged when extended the time horizon to 80 years. Additionally, the results showed that 0.05% atropine demonstrated better cost-effectiveness in the earlier treatment group. And the longer treatment duration was found to have better cost-effectiveness.

Conclusions: 0.05% atropine was the most cost-effective among three concentrations, and should be considered for early intervention and long-term use.

Abstract No.: 204760

Current Status of Vision and Refractive Errors Among Adolescents in Northeast Sichuan, China: A School-Based Cross-Sectional Study

First Author: Zhe **LI**

Co-Author(s): Yunchun **ZOU**

Purpose: To investigate the status of visual acuity and refractive errors among adolescents in northeastern Sichuan, China, a stratified cluster random sampling was conducted in 2024 to survey 61,012 students from kindergartens and primary to high schools across three districts and six counties in Nanchong City.

Methods: Visual acuity screening and non-cycloplegic autorefraction were performed using an electronic intelligent screening system under strict quality control. Detection rates and distribution characteristics of poor vision and suspected myopia were analyzed, along with associated risk factors.

Results: Poor vision and suspected myopia rose steeply with school level, peaking at 90.81 % and 88.40–89.78 % in senior high; the proportion of high myopia climbed in parallel. Marked regional gaps emerged: Nanbu County 80.49 % vs Langzhong City 46.41 %. Girls, urban students, and ordinary-school pupils carried heavier burdens. Spectacle use increased with grade yet proper correction remained suboptimal; astigmatism and anisometropia were common and worsened with grade, while hyperopia reserve declined in younger cohorts. Logistic regression confirmed grade, gender, regional type, and school level as significant determinants of students' visual fate.

Conclusions: This study reveals the epidemiological characteristics and influencing factors of visual acuity and refractive errors among adolescents in northeastern Sichuan, providing essential data and scientific evidence for the development of targeted myopia prevention strategies in the region.

Abstract No.: 200794

Developing a Polygenic Risk Score With Age and Sex to Identify High-Risk Myopia in Taiwan

First Author: Lin **HUI JU**

Co-Author(s): Ya-wen **CHANG**, Yu Chuen **HUANG**, Yu-te **HUANG**, Wen-ling **LIAO**, Fuu Jen **TSAI**, Angel L **WENG**

Purpose: Myopia is the leading cause of impaired vision, and its prevalence is increasing among Asian populations. This study aimed to develop a polygenic risk score (PRS) followed by replication to predict myopia in the Taiwanese population.

Methods: In total, 23,688 participants with cycloplegic autorefraction-measured mean spherical equivalent (SE), genetic, and demographic data were included. The myopia PRS was generated based on genome-wide association study (GWAS) outcomes in a Taiwanese population and previously published GWAS reports.

Results: The results demonstrated that the inclusion of age and sex in the PRS had an area under the curve (AUC) of 0.80, 0.78, and 0.73 ($p < 0.001$) for participants aged >18 years with high ($SE < -6.0$ diopters (D); $n = 1089$), moderate ($-6.0 D < SE \leq -3.0$ D; $n = 3929$), and mild myopia ($-3.0 D < SE \leq -1.0$ D; $n = 2241$), respectively. Participants in the top PRS quartile had a 1.30-fold greater risk of high myopia (95% confidence interval = 1.09–1.55, $p = 0.003$) compared with those in the remaining participants. Further, a higher PRS significantly increased the risk of high myopia ($SE \leq -2.0$ D) in children ≤ 6 years of age ($p = 0.027$).

Conclusions: In conclusion, including the PRS, age, and sex improved the prediction of high myopia risk in the Taiwanese population.

Abstract No.: 208566

Dietary Omega-3 Polyunsaturated Fatty Acids as a Protective Factor of Myopia: The Hong Kong Children Eye Study

First Author: Yuzhou **ZHANG**

Co-Author(s): Jason C. **YAM**

Purpose: To evaluate the associations between omega-3 polyunsaturated fatty acids (ω -3 PUFAs) and other dietary factors with myopia.

Methods: A total of 1,005 Chinese children, aged from 6 to 8 years, from a population-based Hong Kong Children Eye Study, were included in the analysis. Diet was assessed using a validated food-frequency questionnaire. Cycloplegic spherical equivalent (SE) refraction was assessed via an autorefractometer, and axial length (AL) via IOL Master.

Results: AL was longest in the lowest quartile group of ω -3 PUFAs intake, compared with the highest (adjusted mean (95% CI), 23.29 (23.17 to 23.40) mm vs 23.08 (22.96 to 23.19) mm, $P=0.01$; P -trend=0.02)

after adjusting for age, sex, BMI, near-work time, outdoor time, and parental myopia. The corresponding trends were observed in SE (-0.13 (-0.32 to 0.07) D in the lowest and 0.23 (0.03 to 0.42) D in the highest quartile groups, $P=0.01$; P -trend= 0.01). In contrast, AL was longest in the highest quartile group of saturated fatty acids intake, compared with the lowest (23.30 (23.17 to 23.42) mm vs 23.13 (23.01 to 23.24) mm, $P=0.05$; P -trend= 0.04). The corresponding trends were observed in SE (-0.12 (-0.33 to 0.09) D in the highest and 0.13 (-0.04 to 0.31) D in the lowest quartile group, $P=0.06$; P -trend= 0.04). A lower intake of ω -3 PUFAs was associated with myopia (P -trend= 0.006). None of the other nutrients was associated with SE, AL, or myopia.

Conclusions: Our findings indicated a possible effect of diet on myopia, of which ω -3 PUFAs intake may play a protective role against myopia development in children.

Abstract No.: 201891

Effect of Air Pollution on Refractive Errors: A Systematic Review

First Author: Divya JAIN

Co-Author(s): Anjan DHUA

Purpose: To examine the association between air pollution exposure and the development or progression of refractive errors, especially myopia.

Methods: A systematic search was conducted across PubMed, Scopus, and Web of Science for studies published up to Jan 2025. Eligible studies assessed the relationship between major air pollutants (PM_{2.5}, PM₁₀, NO₂, SO₂, CO, O₃) and refractive errors. Study quality was evaluated using the Newcastle-Ottawa Scale.

Results: Twenty-six studies met inclusion criteria and were included for full text screening. Most showed a positive correlation between elevated PM_{2.5} levels and increased myopia risk. Mechanisms included oxidative stress, ocular inflammation, and reduced outdoor activity. Evidence for hyperopia and astigmatism was inconclusive.

Conclusions: Air pollution, especially PM_{2.5}, may be a modifiable risk factor for myopia. More robust longitudinal studies are needed.

Abstract No.: 208273

Effect of Low-Concentration Atropine Eyedrops on Parapapillary Gamma Zone Development and Enlargement Over 3 Years

First Author: Yi LI

Co-Author(s): Jason C. YAM, Xiu Juan ZHANG

Purpose: To evaluate the longitudinal changes in the parapapillary gamma zone in children receiving 0.05%, 0.025%, 0.01% atropine eyedrops and placebo/switchover over 3 years based on the Low-

Concentration Atropine for Myopia Progression (LAMP1) study.

Methods: This is a secondary analysis from a randomized controlled trial. Children were randomized to receive 0.05%, 0.025%, 0.01% atropine, or placebo eyedrops. In the second year, placebo participants switched to 0.05% atropine. At the beginning of the third year, each group was re-randomized to continued treatment or cessation (washout). Gamma zone area was measured using spectral-domain optical coherence tomography (Spectralis-OCT), which involved 24 equally spaced radial OCT B-scans of the optic nerve head taken at one-year intervals. The Bruch's membrane opening (BMO) was identified in 48 meridians in each eye. Gamma zone was defined as the parapapillary region without Bruch's membrane.

Results: Out of 238 children included at baseline, the study included 192 (80.7%) children completing the follow-up of 3 years. The cumulative mean gamma zone area changes differed significantly between the initial 0.05%, 0.025%, and 0.01% atropine subgroups (0.09 ± 0.09 mm², 0.19 ± 0.12 mm², and 0.22 ± 0.17 mm²; P for trend < 0.001) over 3 years. In multivariable analysis, gamma zone area enlargement was associated with 0.05% atropine ($\beta = -0.07$, $P = 0.005$), female sex ($\beta = 0.05$, $P = 0.006$), larger baseline gamma zone area ($\beta = 0.23$, $P < 0.001$), and larger axial elongation ($\beta = 0.14$, $P < 0.001$).

Conclusions: Low-concentration atropine reduced parapapillary gamma zone enlargement in a concentration-dependent manner over a 3-year treatment period. Continued 0.05% atropine treatment showed efficacy in controlling gamma zone development.

Abstract No.: 208379

Effects of Low-Concentration Atropine on Myopia Progression and Functional Changes in Hong Kong Children

First Author: Yolanda Wong Ying YIP

Co-Author(s): Jason C. YAM, Yuzhou ZHANG

Purpose: This study aims to investigate the effects of low-concentration atropine treatment on refraction, axial length, retinal thickness, and multifocal electroretinogram (mfERG) responses in children with myopia.

Methods: Forty-three myopic children (ages 4-12; spherical equivalent -1.0 to -10.0 D) were randomized to receive either atropine ($n=24$) or placebo ($n=19$). Axial length, refractive error, retinal thickness, and mfERG were measured before and after treatment. Mann-Whitney U test and Wilcoxon test were used for comparing the difference between two groups and pre- and post-treatment, respectively. Bonferroni corrections were used for multiple comparisons. Correlations among the changes in mfERG, axial

length, refractive error, and retinal thickness were also assessed.

Results: The atropine group showed a significant improvement in refractive error compared to placebo ($p=0.011$); axial length remained unchanged ($p>0.05$). Retinal thickness increased significantly in several macular regions after atropine treatment (inner superior, inner nasal, inner inferior, outer superior, outer temporal; $p<0.05$). No significant differences in mfERG amplitudes or latencies were observed ($p>0.05$). Significant correlations between the changes in mfERG parameters and the changes in retinal thickness, axial length, and refractive error ($p<0.05$).

Conclusions: Low-concentration atropine slows myopia progression by improving refractive error without significantly affecting axial length or mfERG responses. The associated retinal thickening and correlations between the changes in structural and functional measures indicate a potential mechanism of atropine's impact on retinal function and structure in myopic children.

Abstract No.: 204882

Efficacy Analysis of 0.01% Atropine for Early-Stage Myopia Control in Children

First Author: Jifeng YU

Purpose: To evaluate the short-term efficacy of 0.01% atropine in slowing myopia progression in children with early-stage myopia, compared to Defocus Incorporated Multiple Segments (DIMS) lenses and their combination.

Methods: A total of 175 myopic children were included and divided into three groups: DIMS lenses alone ($n=98$), 0.01% atropine alone ($n=45$), and combination therapy ($n=32$). The 0.01% atropine group was significantly younger (7.98 ± 1.48 vs. 9.18 ± 2.35 years, $p=0.002$) and had milder baseline myopia ($SE: -0.31\pm0.42$ vs. -2.06 ± 1.35 D, $p<0.001$) than the DIMS group, characterizing an earlier myopic cohort. The primary outcome was the change in spherical equivalent (SE) from baseline at 3 and 6 months. Analysis of covariance (ANCOVA) was used to compare outcomes, adjusting for baseline age and SE.

Results: After adjusting for baseline differences, 0.01% atropine monotherapy showed a strong trend towards superior SE control compared to DIMS lenses alone at both 3 months ($\beta=0.13$, 95% CI: -0.01 to 0.26 , $p=0.070$) and 6 months ($\beta=0.18$, 95% CI: -0.01 to 0.36 , $p=0.060$). The combination therapy did not demonstrate a significant additive effect over DIMS alone. Subgroup analyses reinforced the potential benefit of 0.01% atropine in younger children and those with lower baseline myopia.

Conclusions: 0.01% atropine demonstrates a promising treatment effect for children with early-stage myopia over a 6-month period, suggesting it may be a favorable

initial intervention for this specific population. The results highlight the importance of considering disease stage when selecting myopia control strategies.

Abstract No.: 202360

Efficacy of 0.01% Atropine Eyedrops for Myopia Control in Children of Different Ethnicities: A Systematic Review and Meta-Analysis

First Author: Xiujuan ZHANG

Co-Author(s): Ching-yu CHENG, Christopher K.s. LEUNG, Kendrick Co SHIH, Marco YU

Purpose: To evaluate the efficacy of 0.01% atropine eyedrops for myopia control in children from different ethnic backgrounds.

Methods: PubMed, Embase, Web of Science, Cochrane Library, World Health Organization International Clinical Trials, and ClinicalTrials.gov registry platforms from inception to December 2024. A random-effects meta-analysis was used for each outcome. Generalized Boosted Modeling (GBM) was used to evaluate the most relevant factors related to the treatment effect of 0.01% atropine.

Results: Twenty-five RCTs involving 4,374 children aged 4 to 18 years were included. 0.01% atropine showed that the SER progression was reduced by 37% per year (RoM: 0.63; 95% CI, 0.54 to 0.74). For subgroup analysis by different ethnics, South Asian populations groups showed a much better efficacy of reducing 66% myopia progression (RoM: 0.34, 95% CI, 0.27 to 0.42), than East Asian populations by reducing 35% (RoM: 0.65, 95% CI, 0.54 to 0.78) and White populations by reducing 31% (RoM: 0.69, 95% CI, 0.49 to 0.96) ($P<0.0001$). Gradient Boosting Machine (GBM) analysis revealed age (44.1%) as the most influential factor on 0.01% atropine treatment effect.

Conclusions: Atropine 0.01% demonstrated moderate efficacy in the control of myopia. When considering the natural progression of myopia, the efficacy of 0.01% atropine was more effective in South Asian populations than in East Asian and White children. Clinical practice should consider both the ethnic difference and the natural myopia progression to adjust the dosage appropriately and optimize the treatment effects.

Abstract No.: 205789

Efficacy of Defocus-Incorporated Multiple Segments (DIMS) Lenses and Atropine for Myopia Control: A Systematic Review and Meta-Analysis

First Author: Laureen CELCILIA

Co-Author(s): Priscilla ARDIANTO, Florentina FEBRINA

Purpose: This review aimed to determine the efficacy of Defocus-Incorporated Multiple Segments (DIMS)

lenses and atropine in slowing myopia progression in children.

Methods: A systematic search of PubMed, Scopus, Web of Science, and the Cochrane Library was conducted using terms “myopia,” “DIMS,” and “atropine” in pediatric populations. Studies assessing the efficacy of DIMS-atropine compared with alternative interventions were included. Methodological quality assessed using RoB 2.0 and NIH. Meta-analyses were done to estimate mean differences between available interventions.

Results: Six studies were included (n=1223 patients) involving one RCT, two prospective, and three retrospective studies. The overall mean difference at 1-year demonstrated a significant reduction in axial elongation (AL) with DIMS-atropine compared to DIMS alone (−0.10 mm (−0.17 to −0.03); p=0.0037). Older age was associated with slower AL progression both in DIMS-atropine and DIMS alone (p<0.05). The effects of DIMS-atropine were significantly better than atropine alone (p<0.001). No differences were observed between DIMS and orthokeratology. Adverse events of epithelial defects were observed with orthokeratology (15.1%) compared to DIMS (1.2%). One study reported tolerable effects (i.e. itchy/redness) with DIMS.

Conclusions: The combination of DIMS and atropine is effective in slowing myopia progression. DIMS and orthokeratology demonstrated comparable efficacy in myopia control. Atropine slowed progression with any lens type, especially in older children. DIMS caused mostly mild adverse effects, while orthokeratology had higher complication rates. Further high-quality studies are needed to confirm the long-term safety and efficacy of combined therapies.

Abstract No.: 205034

Efficacy of Five Types of Myopia Control Glasses Among Indian Children

First Author: Sneha **BATRA**

Co-Author(s): Supratik **BANDYOPADHYAY**, Joyashree **BANERJEE**, Aroni **CHAKRABORTY**, Swarup **ROY**, Shyamal **SAHA**

Purpose: To determine the efficacy of five types of myopia control glasses (MCG) among Indian children.

Methods: A retrospective cohort study with one-year follow-up was done in 426 eyes of 231 children aged 4-17 years, myopia -0.75 to -10D, astigmatism ≤4 D, baseline progression ≥0.5D. Data from children prescribed Type I (defocus incorporated multiple segments), Type II (Highly Aspherical Lenslet target), Type III (Cylindrical annular refractive elements), Type IV (Peripheral defocus reducing lenses), and Type V (pediatric progressive addition lenses) were analysed. Mean change in spherical equivalence of refractive error (SER) and axial length (AL), percentage efficacy in reducing SER and AL progression to physiological levels,

were compared. Subgroup analysis was done by age, gender, and amount of myopia.

Results: Mean change in SER and AL at 6 and 12 months with all MCG combined was -0.04 ± 0.22 , -0.24 ± 0.4 D, 0.07 ± 0.11 mm, and 0.16 ± 0.18 mm, respectively. No statistically significant difference was noted between Types I, II, and III. Axial and refractive efficacy at 6 and 12 months of all MCG combined was 44.4%, 46.2%, 91.1% and 70.3% respectively. There was no significant difference between boys and girls. The older group showed significantly better axial efficacy (p<0.01) at 6 and 12 months. Refractive efficacy was significantly higher at 12 months (p<0.01) among low myopes.

Conclusions: Type I, II, and III MCG are equally efficacious in controlling myopia progression among Indian children, with better results among older children and low myopes.

Abstract No.: 202354

Efficacy, Tolerability and Threshold Effect of Atropine Eyedrops for Myopia Control: A Systematic Review and Dose-Response Meta-Analysis

First Author: Xiujuan **ZHANG**

Co-Author(s): Ching-yu **CHENG**, Christopher K.s **LEUNG**, Kendrick Co **SHIH**, Marco **YU**

Purpose: To evaluate the efficacy, tolerability, and threshold effect of atropine eyedrops for myopia control in children

Methods: We searched PubMed, Embase, Web of Science, Cochrane Library, World Health Organization International Clinical Trials, and ClinicalTrials.gov registry platforms from inception to July 2025. We included the randomized clinical trials (RCTs) that compared any dose of atropine against a placebo in myopic children. A random-effects dose-response meta-analysis was used for each outcome.

Results: Among 3,566 studies assessed, we identified 33 eligible RCTs involving 6,301 children aged 4 to 18 years with 10 different concentrations. A nonlinear relationship was observed between atropine dosage and treatment efficacy (P<0.001). Compared to placebo groups, the mean differences in reducing SER progression for atropine concentrations of 0.01%, 0.02%, 0.03%, 0.04%, and 0.05% were 0.21 D (95% CI, 0.13 to 0.28), 0.35 D (95% CI, 0.23 to 0.46), 0.42 D (95% CI, 0.28 to 0.56), 0.45 D (95% CI, 0.30 to 0.60), and 0.46 D (95% CI, 0.32 to 0.61) respectively. However, when the concentration increased to 0.1%, the treatment efficacy showed a minimal increase to 0.49 D (95% CI, 0.34 to 0.63). Similarly, the treatment efficacy increased 0.99 D (95% CI, 0.66 to 1.31) to concentrations of 1%.

Conclusions: Our study showed that beyond a specific range, higher concentrations do not lead to comparably increased efficacy, and the current practice

of increasing atropine concentrations for children who show inadequate responses to lower doses should be confined to a specific concentration range.

Abstract No.: 203747

Ellipsoid Zone in Inner Segment of Retinal Photoreceptors in Adults With High Myopia in Hong Kong

First Author: Tsun Hei YIP

Co-Author(s): Christopher Kai Shun LEUNG, Zirong LIU, Xiujuan ZHANG

Purpose: High myopia (HM) increases the risks of sight-threatening complications. The ellipsoid zone (EZ), the hyperreflective outer retinal band just posterior to the external lining membrane, is a widely used biomarker of photoreceptor structure.

Methods: Participants were recruited from the Hong Kong Eye Survey and conducted Swept-Source Optical Coherence Tomography (OCT) (Topcon, Tokyo, Japan), obtaining widefield ($12 \times 9 \text{ mm}^2$) OCT with 128 B scans data covering both optic disc and macula. Segmentation of retinal layers was performed by OCTExplorer, followed by manual adjustments. Three-dimensional retinal volume quantification was utilized to investigate the Pearson correlation coefficient (r) between EZ thickness and axial length (AL) and spherical equivalent (SE).

Results: A total of 40 high myopic left eyes from 40 participants were included, with mean ages 63.0 ± 5.02 years, mean SE $-7.99 \pm 1.60 \text{ D}$, mean AL $27.1 \pm 0.895 \text{ mm}$, and 28 (70%) females. Statistically significant correlations were revealed between EZ thickness and SE ($r = 0.559$, $P = 0.001$) and AL ($r = -0.427$, $P = 0.006$). No significant associations were evident between EZ thickness and age ($r = 0.0221$, $P = 0.866$) and gender ($t\text{-test} = 0.345$, $P = 0.732$).

Conclusions: These relationships may provide insights into the pathophysiology of myopia and highlight the importance of monitoring retinal layers in HM patients. Future research on the implications of these findings on clinical practices and potential therapeutic interventions should be explored.

Abstract No.: 203078

Evaluation of Retinal Vascular Density and Ocular Biometry in Myopia

First Author: Pimpakarn TRARUNGREANG

Co-Author(s): Parichat KONGMALAI, Sopit PRAIWATTANA, Nattawat SINAWAT, Suthasinee SINAWAT, Yosanan YOSPAIBOON

Purpose: To evaluate retinal vascular density and ocular biometric parameters across varying severities of myopia in young Thai adults.

Methods: This retrospective cross-sectional study included Thai adults aged 20–25 years with myopia.

All participants underwent comprehensive ophthalmic evaluation, including best-corrected visual acuity, intraocular pressure, automated refraction, slit-lamp biomicroscopy, indirect ophthalmoscopy, and ocular biometry (mean corneal curvature, corneal astigmatism, central corneal thickness, anterior chamber depth, lens thickness, and axial length). Posterior segment assessments comprised central macular thickness, subfoveal choroidal thickness, peripapillary retinal nerve fiber layer thickness (pRNFL), retinal vascular density, and optic disc distortion. Intergroup comparisons and regression analyses assessed associations with myopia severity.

Results: A total of 177 eyes (mean age, 22.5 ± 0.8 years; 55.4% female) were analyzed. High myopia was significantly associated with longer axial length, deeper anterior chamber, greater corneal astigmatism, and reduced choroidal thickness and pRNFL thickness ($p < 0.001$). Optical coherence tomography angiography (OCTA) revealed increased superficial foveal vascular density but decreased deep parafoveal density in high myopia. The foveal avascular zone area was significantly smaller in the high myopia group ($p = 0.032$). Both axial length and spherical equivalent were significantly associated with retinal vascular density changes and pRNFL thinning.

Conclusions: Myopic progression in young adults is linked with distinct biometric and vascular alterations, particularly in the deep capillary plexus and pRNFL. OCTA may enable early detection of microvascular compromise before pathologic changes appear.

Abstract No.: 208021

Exploring the Role of Optic Disc Tilt in Altering Retinal Structure in Myopic Eyes

First Author: Poemen Pm CHAN

Co-Author(s): Clement THAM, Cheuk Sing YAM, Xiu Juan ZHANG, Yuqiao ZHANG

Purpose: This study aimed to examine the relationship between myopic optic disc parameters—ovality index (OI), optic disc torsion (ODT) angle, and horizontal disc tilt (OCT-HDT) angle—and the thickness of retinal nerve fiber layer (RNFL) and ganglion cell-inner plexiform layer (GCIPL) in myopic eyes.

Methods: A cross-sectional study was conducted on 530 eyes from 284 high myopia participants in Hong Kong. SS-OCT and fundus photography were used to measure optic disc parameters (OI, ODT, and OCT-HDT), and RNFL as well as GCIPL thicknesses were assessed. Statistical analyses were performed to investigate associations between optic disc tilt parameters and RNFL/GCIPL thickness, adjusted for age and axial length.

Results: In the temporal group, a larger ODT angle was associated with thinner RNFL in the p7-8 sector ($\beta = -0.182$, all $P < 0.05$). Larger OCT-HDT angles

correlated with thinner superior ($\beta=-0.084$, $P=0.04$) and superonasal GCIPL ($\beta=-0.069$, $P=0.03$), as well as thinner RNFL in the p12-5 sectors ($P<0.05$). A higher OI was linked to thinner RNFL in the superior to nasal ($P<0.05$) and thicker temporal RNFL ($P<0.01$). In the nasal ODT group, a higher OI was associated with thinner superior to superonasal GCIPL ($\beta=-6.972$, $P=0.02$; $\beta=-7.465$, $P=0.02$) and thinner nasal RNFL ($P\leq 0.01$).

Conclusions: The OI, ODT, and OCT-HDT parameters significantly influence RNFL and GCIPL thickness in myopic eyes. The RNFL was more affected by OI in temporally and nasally torted optic discs, while GCIPL was more influenced by OCT-HDT and OI for myopic eyes with temporally and nasally torted optic discs, respectively.

Abstract No.: 206144

Fifteen-Year Follow-Up of Implantable Collamer Lens Surgery in High Myopia: Complications, Cataract Surgery Outcomes, and Ultrastructural Analysis

First Author: Yinjie **JIANG**

Co-Author(s): Xun **CHEN**, Xiaoying **WANG**, Xingtao **ZHOU**

Purpose: This study reports 15-year outcomes of implantable collamer lens (ICL) surgery in high myopia, analyzing complications, cataract surgical efficacy, and ultrastructural mechanisms of anterior subcapsular cataract (ASC).

Methods: A retrospective study included 1,208 eyes (ICL V4) and 6,258 eyes (ICL V4c) from a single center. Follow-ups occurred preoperatively, at 1/3/6 months, annually post-ICL, and 1 month post-cataract surgery. Lens opacity, ASC rates, and complications (e.g., retinal detachment) were evaluated. Anterior capsule ultrastructure was assessed using scanning/transmission electron microscopy (SEM/TEM).

Results: The ICL V4 group (follow-up: 23.12 ± 32.06 months) exhibited higher complication rates than V4c (8.95 ± 17.40 months): lens opacity (6.46% vs. 0.16%), ASC (2.32% vs. 0.10%), and bilensectomy (5.13% vs. 0.16%). Bilensectomy improved corrected distance visual acuity (CDVA) from 0.56 ± 0.39 to 0.34 ± 0.51 logMAR ($P=0.006$), restoring pre-ICL levels ($P=0.310$), with safety/efficacy indices of 1.08 ± 0.11 and 0.99 ± 0.08 . Pre-bilensectomy complications included myopic macular atrophy (35.09%), choroidal neovascularization (7.02%), and retinal detachment (1.75%); post-surgical complications included retinal detachment (1.96%) and endothelial cell loss (1.96%). SEM/TEM revealed lens epithelial cell (LEC) proliferation, fibronectin/collagen deposition, and endoplasmic reticulum abnormalities (thickened cristae, perinuclear vacuolization) in ASC cases, indicating mechanical and metabolic damage preceding clinical ASC.

Conclusions: Super high myopia, shallow anterior chamber depth, and older age are key risk factors for post-ICL cataract. While bilensectomy restores vision, high myopia-related complications persist. ASC pathogenesis involves mechanical damage and metabolic dysfunction, evidenced by ultrastructural changes. These findings underscore the need for long-term monitoring in ICL patients with high myopia.

Abstract No.: 202285

From Genes to Vision: The Role of PARP8 and hsa-miR-410-3p in Myopia Pathogenesis Revealed

First Author: Yiwei **WAN**

Co-Author(s): Lingxi **JIANG**, Yi **SHI**

Purpose: The genetic and functional association between the PARP8 gene and high/extreme myopia (HM/EM) in a Han Chinese population is investigated in this research.

Methods: Genotyping of five SNPs (rs11954386, rs2404958, rs282544, rs32396, and rs27243) in PARP8 among 1,768 participants revealed a significant association with HM/EM.

Results: It is notable that rs27243 (situated in the 3'-UTR region of PARP8) exhibited robust linkage. Experimental validations confirmed that the rs27243A allele enables a binding site for hsa-miR-410-3p, which leads to the downregulation of PARP8 expression. Furthermore, diminished PARP8 levels and elevated hsa-miR-410-3p were detected in patients, in addition to reduced PARP8 levels in form-deprivation myopia mouse models, which suggests that they are potential risk factors or biomarkers for HM/EM.

Conclusions: Collectively, the findings of this study establish PARP8 as a novel susceptibility gene for HM/EM and reveal post-transcriptional regulation of PARP8 via hsa-miR-410-3p as a pivotal mechanism in myopia pathogenesis.

Abstract No.: 203289

Hypoxia Activates Notch1 to Regulate Mitochondrial Fission and Influence Scleral Remodeling in Myopia

First Author: Lingling **BA**

Co-Author(s): Shuaixin **LU**, Jing **SUN**, Jie **WANG**, Kai **WEN**, Xinmiao **ZHOU**

Purpose: This study aims to investigate the regulatory role of Notch1 in mitochondrial dynamics under scleral hypoxia following myopia onset and its effects on the metabolism of the scleral extracellular matrix.

Methods: A form deprivation-induced myopia guinea pig model was established to observe morphological changes in mitochondria within scleral tissue. Plasmid interference was employed to suppress the expression of HIF-1 α and Notch1, and its effects on mitochondrial

morphology and scleral remodeling-related indicators were analyzed.

Results: In the myopia model, mitochondrial fragmentation was significantly observed in scleral tissue. Inhibition of HIF-1 α or Notch1 markedly reduced mitochondrial fragmentation and alleviated myopia-related pathological changes, manifested as decreased the transdifferentiation of scleral fibroblasts into myofibroblasts, along with upregulation of type I collagen expression.

Conclusions: Scleral hypoxia promotes excessive mitochondrial fission by activating the Notch1 signaling pathway, thereby accelerating myopia progression.

Abstract No.: 203422

Intraocular Pressure Lowering Therapy Slows Down Axial Elongation in Progressive High Myopia

First Author: Zige **FANG**

Co-Author(s): Fei **LI**, Fengbin **LIN**, Zefeng **YANG**, Xiulan **ZHANG**

Purpose: To evaluate the efficacy of IOP-lowering medications in inhibiting rapid axial elongation among adults with progressive high myopia (PHM).

Methods: This was a retrospective analysis of data from a longitudinal high myopia with glaucoma suspects cohort at the Zhongshan Ophthalmic Center from December 2019 to May 2025. Patients who used IOP-lowering medications and were diagnosed with PHM were included. PHM was defined as an axial elongation rate of ≥ 0.1 mm/year prior to using IOP-lowering medications. A comprehensive set of variables, including demographic data, ocular characteristics, and optical coherence tomography angiography (OCTA) imaging, was collected. The data were analyzed from May to July 2025.

Results: Of 1628 participants, a total of 50 eyes from 50 eligible participants (14 males and 36 females) were finally analyzed, with an age range from 22 to 60 years (mean 40.4 ± 10.7 years). The mean number of IOP-lowering medications used was 2.0 ± 0.3 . After 12.1 ± 0.7 months, the IOP decreased from 13.49 ± 2.50 mm Hg to 12.03 ± 2.28 mm Hg ($P < 0.001$), AL increased minimally from 28.58 ± 1.36 mm to 28.62 ± 1.37 mm ($P = 0.003$), and the axial elongation rate decreased significantly from 0.14 ± 0.04 mm/year to 0.03 ± 0.07 mm/year ($P < 0.001$). Notably, outcomes of OCTA showed that deep capillary plexus (DCP) perfusion density rose from 49.70 ± 1.21 % to 50.27 ± 1.36 % ($P = 0.039$) and choriocapillaris (CC) perfusion density from 55.47 ± 0.71 % to 55.66 ± 0.55 % ($P = 0.037$).

Conclusions: IOP-lowering medications effectively inhibit rapid axial elongation in adults with PHM in this study. These findings support IOP-lowering medications could be a promising effective strategy for inhibiting myopia progression in adults with PHM.

Abstract No.: 200916

Long-Term Anatomical and Visual Outcomes of Posterior Scleral Reinforcement in Myopic Maculoschisis

First Author: Anas **ABU SAID**

Co-Author(s): Shihao **CHEN**, Yanfeng **SU**

Purpose: To evaluate long-term anatomical and visual outcomes in highly myopic eyes with maculoschisis, without macular hole or foveal detachment, following posterior scleral reinforcement (PSR).

Methods: This retrospective interventional case series included 36 eyes of 30 patients with high myopia and OCT-confirmed maculoschisis treated with PSR between 2017 and 2022. Clinical records were reviewed in 2025. Best-corrected visual acuity (BCVA, logMAR), axial length (AL), spherical equivalent (SE), and OCT-based retinal reattachment status were collected at predefined intervals: 1 day–1 month, 1 month–1 year, 1–2 years, and 2–7 years. Longitudinal changes were analyzed using linear mixed models.

Results: Mean age was 47.9 ± 13.4 years. BCVA showed a transient decline at 1 day ($+0.181$ logMAR, $p < 0.001$) but later stabilized ($p > 0.3$). AL decreased significantly at 1 day (-2.316 mm, $p < 0.001$) and remained shorter at 2–6 years (-1.206 mm, $p < 0.001$). SE improved ($+5.07$ D at 1 day; $+3.28$ D at 2–6 years, both $p < 0.001$). At final follow-up, BCVA improved in 15 eyes, was stable in 9, and declined in 12. Axial shortening occurred in 97% of eyes, with refractive improvement in 92%. Retinal reattachment was progressive, reaching 75% beyond 1 year and 70% in those followed ≥ 2 years.

Conclusions: PSR achieved long-term anatomical stabilization and visual preservation or improvement in highly myopic eyes with maculoschisis, supporting its role as a proactive surgical option in selected patients without foveal detachment or macular hole.

Abstract No.: 203357

Long-Term Effect of Orthokeratology on Ocular Biometric Parameters in Adults

First Author: Xuehui **ZHANG**

Co-Author(s): Lin **KANG**, Huihu **ZHENG**

Purpose: To investigate the effect of long-term use of orthokeratology (ortho-k) on ocular biometric parameters in adults, including axial length (AL), central corneal thickness (CCT), anterior chamber depth (ACD), lens thickness (LH), and anterior segment length (ASL).

Methods: Baseline, six-monthly, and twelve-monthly data were retrieved from 72 subjects (aged 16–35 years, with myopia ranging from $-6.00 \sim -1.00$ D, and astigmatism ≤ -1.50 D) who had completed a one-year wearing ortho-k. Ocular biometric parameters were measured with the IOL Master 700.

Results: By the 6-month visit, it was significantly reduced by an average of 0.06 mm in AL ($p = 0.027$)

and an average of 0.06 mm in CCT ($p < 0.001$), while LH increased by an average of 0.07 mm ($p = 0.001$). However, there were no significant changes in AL, LH, and CCT during the 6-12 months follow-up. No significant changes in ACD and VCD over time were observed during the whole follow-up period.

Conclusions: Both AL and CCT decreased significantly, and LH increased significantly in adults using ortho-k; the changes mainly occurred in the first 6 months. Neither ACD nor VCD changed over time.

Abstract No.: 201616

Long-Term Follow-Up Rigid Gas Permeable Contact Lens Treatment in Adolescents With Amblyopia Anisometropia: A Case Series With Scoping Review

First Author: Christina **ARITONANG**

Co-Author(s): Sarah **FAUZIA**, Zafirah **MUTIANI FARID**

Purpose: This case focuses on young adolescents with amblyopia anisometropia, focusing on the use of RGP contact lenses and the great outcome of visual acuity, which improves quality of life.

Methods: This case series collects data from medical records, patient interviews, follow-up examinations, and outcomes. We use scoping review by PRISMA flow diagram with the keywords myopia, RGP lens, amblyopia, anisometropia, and adolescent.

Results: By fitting and using a rigid gas permeable lens on a patient with anisometropic amblyopia, and follow-up showed a great outcome on visual acuity, which improved the quality of life in 3 patients reported.

Conclusions: RGP contact lens wear is the most effective and safe method to treat anisometropia amblyopia in adolescents. The potential benefits of RGP contact lens wear in inhibiting myopia progression, and complications caused by myopia have a higher impact in the future.

Abstract No.: 201974

Long-Term Impact of COVID-19 Behavioral Changes on Myopia Progression in Children

First Author: Kwanghyun **LEE**

Co-Author(s): Hye Young **KIM**, Young Min **PARK**

Purpose: To investigate the impact of behavioral changes during the COVID-19 pandemic on myopia progression in children and to determine whether these changes influenced the efficacy of low-concentration atropine (LAMP) treatment.

Methods: This longitudinal study followed 77 children (140 eyes) with myopia from 2019 to 2023, measuring annual changes in spherical equivalent refraction and axial length. Behavioral data on screen time, outdoor activity, and remote education were collected through questionnaires. Myopia progression was analyzed

across pre-pandemic, pandemic, and post-pandemic periods using linear mixed-effects models, with regression analyses identifying factors linked to post-pandemic progression.

Results: Myopia progression was greatest in 2021–2022 ($\Delta SER3: -0.56 \pm 0.55$ D) compared with 2019–2020 ($\Delta SER1: -0.40 \pm 0.47$ D; $P = 0.003$). Screen time significantly increased during the pandemic (1.64 to 4.69 hours/day, $P < 0.001$) and was associated with greater $\Delta SER3$ ($P = 0.005$). Remote education >12 months also predicted faster progression ($P = 0.033$), whereas reduced outdoor activity was not significantly associated with refractive changes. LAMP-treated eyes showed less progression before the pandemic ($P = 0.035$), but this protective effect diminished during the pandemic. Axial length elongation paralleled refractive changes. In multivariable analysis, only remote education duration remained significantly associated with $\Delta SER3$ ($P = 0.007$).

Conclusions: COVID-19-related behavioral changes, especially during 2021–2022, accelerated myopia progression in children. Prolonged remote education and increased screen time were major risk factors, revealing reduced efficacy of LAMP and the need for adaptive management strategies post-pandemic.

Abstract No.: 204423

Low-Level Red Light in Myopia: From Prevention to Treatment

First Author: Lin **YOUHONG**

Purpose: To systematically evaluate the efficacy, safety, and mechanisms of repeated low-level red-light therapy (RLRL) for controlling myopia progression in children and adolescents.

Methods: A systematic literature search was conducted in PubMed, Web of Science, Embase, Scopus, and Cochrane databases from January 2005 to September 2025. Inclusion criteria encompassed randomized controlled trials (RCTs), systematic reviews, and meta-analyses focusing on RLRL (typically 650 nm wavelength) for myopia management in humans aged 6-18 years. Exclusion criteria included animal studies, case reports, and studies lacking quantitative outcomes on axial length (AL), spherical equivalent refraction (SER), or choroidal thickness.

Results: Twenty studies were included, comprising 12 RCTs, 5 meta-analyses, and 3 reviews, involving approximately 2,850 participants (predominantly Chinese ethnicity, age range 6-18 years, 48% male/52% female). Baseline myopia severity ranged from -1.00 to -10.00 diopters (D) SER, with most studies focusing on mild-to-moderate myopia (-1.00 to -5.00 D) and some on high myopia (≤ -6.00 D). Pooled data from meta-analyses showed RLRL significantly reduced myopia progression compared to controls: weighted mean difference (WMD) for SER change of 0.68 D per

6 months (95% CI: 0.38-0.97, $I^2=97.7\%$, $p<0.001$); AL elongation of -0.35 mm per 6 months (95% CI: -0.51 to -0.19, $I^2=98.0\%$, $p<0.001$); and subfoveal choroidal thickness increase of 36.04 μm per 6 months (95% CI: 19.61-52.48, $I^2=89.6\%$, $p<0.001$). In high myopia subgroups, 53.3%-59% experienced AL shortening >0.05 mm over 12 months ($p<0.001$). No severe adverse events were reported, with minor side effects like temporary afterimages in $<5\%$ of cases.

Conclusions: RLRL demonstrates robust short-term efficacy in slowing myopia progression, particularly in high myopia, through mechanisms like choroidal thickening and enhanced retinal blood flow. It offers a safe, non-invasive option, but long-term studies (>2 years) are needed to assess rebound effects and comparisons with atropine or orthokeratology for optimized clinical integration.

Abstract No.: 200999

Machine Learning-Based Prediction Model for Axial Length Control Effectiveness in Myopia Management With Overnight Orthokeratology

First Author: Hsin-le LIN

Co-Author(s): Cheng-kuo CHENG, Yu-hsuan HUANG, Shiow-wen LIOU, Tzu-en WU

Purpose: To develop and validate a machine learning-based predictive model to predict the response of orthokeratology (ortho-k) in controlling axial length elongation.

Methods: Myopic children (aged 8–18 years) who received ortho-k treatment between March 2021 and December 2023 were retrospectively reviewed. A total of 116 patients (222 eyes) who completed one year of ortho-k treatment were included in the analysis. A machine learning model was developed utilizing 40 baseline clinical parameters, including demographic data (e.g., age, gender, wearing time), refractive metrics (e.g., spherical equivalent, cylinder), corneal topography (e.g., surface asymmetry index, surface regularity index, eccentricity), and ortho-k lens specifications. Subjects presenting an axial length elongation ≥ 0.20 mm at 1-year were classified as limited response, whereas those presenting an axial length elongation <0.20 mm were classified as significant response. The model tested 20 algorithms, and performance was evaluated using standard metrics.

Results: Coarse Gaussian SVM achieved the best overall performance, as evidenced by the following metrics: recall (0.82), specificity (0.84), precision (0.81), F1-score (0.82), accuracy (0.85), and AUROC (0.87). Baseline cycloplegic spherical equivalent (SE) and eccentricity (e) emerged as the most significant predictors influencing axial length elongation. Patients with more negative baseline SE and lower e values experienced less axial elongation after wearing ortho-k lenses.

Conclusions: This study highlights the potential of machine learning in identifying key factors influencing ortho-k efficacy. The predictive model facilitates personalized treatment strategies and early identification of poor responders, potentially improving clinical decision-making and myopia management outcomes.

Abstract No.: 203441

Mechanism of VIP-VIPR2 Signaling Pathway Regulating Choroidal Blood Flow Perfusion in Myopia Development

First Author: Yingying WEN

Purpose: To investigate whether the VIP-VIPR2 signaling pathway participates in myopia development by regulating choroidal blood flow perfusion.

Methods: 1. Experimental Animals and Grouping: Thirty 3-week-old C57BL/6 mice were randomly divided into three groups (10 mice per group): normal control group, negative control group, and VIPR2 inhibitor group. The right eyes of the negative control group were injected with the solvent PBS, while the right eyes of the VIPR2 inhibitor group were injected with VIPhybrid via suprachoroidal administration. The normal control group received no treatment. 2. Measurement Parameters: After 1 week of intervention, refractive error, axial length, choroidal blood flow perfusion, and other ocular parameters were measured in all groups using EIR, OCT, and OCTA. Changes in VIP and VIPR2 expression at RNA and protein levels in the choroid were detected through qPCR and Western blot.

Results: Compared to the control group, the VIPR2 inhibitor group showed significant downregulation of choroidal VIP and VIPR2 at both RNA and protein levels, a myopic shift in refraction, relatively longer axial length, and reduced choroidal blood flow. No statistically significant differences were observed between the negative control group and the normal control group.

Conclusions: 1. Downregulation of choroidal VIPR2 promotes myopia progression in mice, suggesting that the choroidal VIP-VIPR2 pathway may regulate myopia development. 2. Downregulation of VIPR2 reduces choroidal blood flow, indicating that the VIP-VIPR2 pathway may contribute to myopia pathogenesis by modulating choroidal blood flow perfusion.

Abstract No.: 205055

Myopia Awareness Study: A Survey Among Parents of Children Attending Myopia Clinic in India

First Author: Sneha **BATRA**

Co-Author(s): Supratik **BANDYOPADHYAY**, Aroni **CHAKRABORTY**, Swarup **ROY**, Shyamal **SAHA**, Jaya **SINGH**

Purpose: To identify awareness and practice patterns regarding myopia in parents of children attending the Myopia Clinic.

Methods: A questionnaire was provided to parents with children aged 6-16 years with progressive myopia (defined as >0.5 D increase in the last 1 year) from February 2024 to August 2025.

Results: A total of 276 entries were analysed. Most participants (about 43%) started wearing glasses between 5 and 10 years of age, and only 38% had an eye check-up in the last 6 months. Nearly half of parents (49%) recognized prolonged near work, 65% very close reading habit, and about 72% excessive mobile phone use, decreased outdoor activity (59%), and sunlight exposure (52.5%) as a risk factor for myopia progression. Nearly 48% had the view that parental myopia has no role. Just over half (53.5%) of respondents are aware of myopia control options, mostly of myopia control glasses 23%. Nearly 40% of people are unaware of complications related to myopia.

Conclusions: Even though risk factors were correctly identified, awareness regarding proper checkup schedules, myopia control strategies, and the consequences of high myopia was lacking. Identifying parental knowledge and practice patterns can help in designing targeted myopia awareness programs.

Abstract No.: 207966

Myopia Management Functional Lenses: A Bibliometric Analysis of Multidisciplinary Perspective and Trend Insights in the Context of Vision Health

First Author: Ling **WANG**

Purpose: To analyze the research dynamics of myopia management functional lenses in the field of vision health over the past decade, revealing cutting-edge hotspots and development trends.

Methods: Relevant literature on myopia management functional lens from 2016 to 2025 in the Web of Science database was searched by computer. Bibliometrics software such as Bibliometrix, VOSviewer 1.6.20, and CiteSpace.V.6.3.R1 were used for bibliometric and knowledge graph visualization analyses.

Results: A total of 1143 Web of Science core database documents were included, and the number of

publications in the field of functional eyewear for myopia management has gradually increased over time. China and the United States rank the top two in terms of the number of publications and citations. The leading authors in this field are CHO P, SANKARIDURG P, and CHen H, who have made significant contributions to research in two distinct subfields: contact lenses and spectacle lenses. Most relevant sources are Ophthalmic and Physiological Optics and Contact Lens & Anterior Eye. The keywords co-occurrence, clustering, thematic map, timeline view, and emergent analyses reveal that recent research has been focused on the following areas: axial length, defocusing mechanism, choroidal thickness, and orthokeratology. The integration of material, optics, and intelligence is a trend that is set to be reflected in the future.

Conclusions: The article constructs a knowledge map of research in the field of myopia management functional lenses through bibliometric analysis, systematically summarizes the current status and hotspots of research in this field, and aims to provide reference and guidance for future related research.

Abstract No.: 206085

Myopia Prevention Practices Among Ophthalmologists in Hong Kong: A Cross-Sectional Survey 2025

First Author: Cheuk Ling **YIM**

Co-Author(s): Stephanie **CHEUNG SL**, Simon Tc **KO**

Purpose: Myopia prevalence continues to rise in East Asia, prompting increased interest in early intervention strategies. This study investigates current practices among ophthalmologists in Hong Kong regarding myopia prevention and control.

Methods: A cross-sectional survey was distributed to ophthalmologists practicing in Hong Kong. The questionnaire assessed demographics, treatment modalities, prescribing patterns, and attitudes toward pharmacological, optical, and behavioral interventions.

Results: A total of 118 responses were received. Most respondents (99.2%) actively manage myopia progression, with 91.5% favouring pharmacological approaches. Atropine 0.05% was the most commonly prescribed concentration (93.9%). The majority initiate treatment at age 4 or 5; however, the criteria for treatment initiation and discontinuation practices vary widely. 28.6% reported rebound after treatment discontinuation. Peripheral defocusing spectacle lenses were the most frequently used optical intervention (86.3%), while behavioral recommendations focused on reducing screen time and increasing outdoor activity. Only 5.1% reported using optical methods as their primary modality, and 94.9% had never prescribed red light therapy.

Conclusions: Pharmacological treatment, particularly low-dose atropine, remains the cornerstone of myopia

control among Hong Kong ophthalmologists. However, the variability in criteria for initiating treatment, ranging from any diagnosis of myopia to specific thresholds of progression, and also discontinuation practices, highlights the lack of standardized guidelines and the need for consensus-driven protocols. As emerging therapies such as red light therapy begin to enter the conversation, ongoing research and professional dialogue will be essential to ensure safe and effective integration into practice.

Abstract No.: 208405

N-Acetyltransferase 2 Inhibits Myopia Through Maintaining Mitochondrial Metabolism in Scleral Fibroblasts

First Author: Wei **GONG**

Co-Author(s): Tianyu **CHENG**, Xiangui **HE**, Xun **XU**, Lingyi **ZHAO**

Purpose: The excessive elongation of the eye axis is a primary factor in myopia progression, yet the underlying genetic mechanisms remain poorly understood. The study was to explore risk-associated genes of myopia and identify the role of N-acetyltransferase 2 (NAT2) in the pathological process of myopia.

Methods: A genome-wide association study (GWAS) analysis for axial length of eyes in a Chinese population (n=6345) was performed to explore risk-associated genes of myopia. Form deprivation-induced myopia was used to verify the expression of NAT2 in myopic eyes. To investigate the role of NAT2 in myopia, adeno-associated virus-mediated NAT2 overexpression or knockdown was conducted in murine sclera.

Results: In GWAS, the most significant locus was 8p22, with NAT2 identified as a potential risk-associated gene for myopia. NAT2 was downregulated by hypoxia in form deprivation-induced murine myopia, and the adeno-associated virus-induced genetic intervention of NAT2 in the sclera influenced myopia progression. For the mechanism, NAT2 could regulate the phenotypic transition and extracellular matrix remodeling of scleral fibroblasts through maintaining mitochondrial metabolism and inhibiting ROS/TGF- β pathway, which also had effects on choroidal vascular function. Additionally, administration with α -ketoglutarate, a downstream metabolite of NAT2, effectively suppressed myopia progression in murine models.

Conclusions: These findings highlight NAT2 as a critical regulator of myopia pathogenesis, offering new insights into potential therapeutic strategies for myopia by targeting mitochondrial metabolism.

Abstract No.: 202540

Normative Percentiles of High Myopia Retinal Nerve Fiber Layer (RNFL) and Ganglion Cell-Inner Plexiform Layer (GCIPL) Thickness From the Asian Eye Epidemiology Consortium

First Author: Marco **YU**

Co-Author(s): Yanyan **CHEN**, Ching-yu **CHENG**, Zhi Da **SOH**

Purpose: To establish normative percentiles of RNFL and GCIPL thickness in high myopia, and examine their association with potential risk factors.

Methods: Participants with spherical equivalent (SE) $\leq -5.5D$ or axial length (AL) ≥ 25.5 mm, with RNFL and GCIPL thickness, and relevant clinical data, from China, Hong Kong, India, Japan, South Korea, Russia, and Singapore were included in this study. 3/4 of non-pathologic eyes were used to estimate normative percentiles of RNFL and GCIPL thickness, and evaluate the association with ocular and systemic factors, interethnic differences, and intermachine variations using quantile regression. Sensitivity and specificity of normative percentiles with and without adjustment for risk factors were evaluated using the remaining 1/4 of non-pathologic eyes and 100% of glaucomatous eyes collected.

Results: 3529 eyes were analyzed. 2325 of non-pathologic eyes were used in estimating percentiles and association analysis. East Asians, including Chinese, Koreans, Japanese, and Malays, showed the thickest RNFL. NIDEK measured the thickest RNFL and thinnest GCIPL across the evaluated OCT devices (Cirrus, NIDEK, Optovue, Spectralis, and Triton). 683 non-pathologic + 521 glaucomatous eyes were used as validation. AL was found to be negatively associated with the percentiles of RNFL and GCIPL, except for the 10th and 20th percentiles of RNFL thickness. The 20th percentile of RNFL thickness adjusted by age, gender, SE, and significant risk factors demonstrated significantly higher specificity in internal validation and higher sensitivity in external validation than the unadjusted percentile.

Conclusions: Risk factor-adjusted 20th percentile outperformed the unadjusted percentile of RNFL thickness, suggesting a better criterion for early detection of glaucoma.

Abstract No.: 203057

Ocular Parameter Alterations and Diagnostic Value of Axial Length and Spherical Equivalent Determination for High Myopia in Macaca fascicularis

First Author: Jin-an **ZHAN**

Co-Author(s): Yingting **ZHU**, Yehong **ZHUO**

Purpose: This study aims to establish a precise threshold for determining whether Macaca fascicularis exhibits high myopia and to investigate the ocular

characteristic changes associated with high myopia in Macaca fascicularis.

Methods: The Macaca fascicularis underwent measurements for refractive errors, axial length (AL), corneal thickness, anterior chamber depth, lens thickness, choroidal thickness, and fundus photography. Receiver operating characteristic curve (ROC) analysis was conducted to assess the diagnostic efficacy of AL and spherical equivalent (SE) in identifying grade 4 fundus tessellations (FT) and peripapillary atrophy (PPA), with the optimal cut-off values subsequently determined.

Results: The study included 490 eyes from 246 Macaca fascicularis, with an average age of 16.99 ± 13.84 years and a weight of 3.73 ± 1.49 kg. The cut-off value for discriminating FT using AL was 19.28 mm (AUC = 0.873), and for PPA, it was 18.86 mm (AUC = 0.925). For SE, the cut-off for FT was -4.25 D (AUC = 0.826), and for PPA, it was -3.42 D (AUC = 0.847). Using $AL \geq 19.01$ mm and $SE \leq -3.77$ D to categorize high myopia, high myopia eyes showed longer AL, higher SE, thinner choroidal thickness, deeper anterior chambers, longer vitreous cavities, and larger axial ratios.

Conclusions: The combination of AL and SE offers a reliable method for identifying high myopia in Macaca fascicularis, effectively distinguishing whether individual monkeys exhibit high myopia. Significant alterations were observed in the posterior segment parameters of eyes with high myopia in these Macaca fascicularis.

Abstract No.: 206161

Outdoor Exposure, Near Work, Accommodation and Circulating Biomarkers (Vitamin D3, Dopamine): Multivariate Predictors of Myopia Progression

First Author: Elackiya MANIMARAN

Co-Author(s): Sahithya BHASKARAN, Vijayalakshmi P, Senthilkumari SRINIVASAN

Purpose: • To study the association between environmental factors (outdoor activity, focused near work and accommodation) in myopia and its progression • To study the role of plasma biomarkers (vitamin D3 and dopamine) in myopia and its progression • Multivariable analysis on myopia association

Methods: It was a cross sectional prospective observational study which included 105 emmetropic children (control) and 176 children with myopia (58 stable, 58 progressive myopia and 57 progressive myopia on Low dose atropine) of age group 6-15years. Detailed history on demographic profile, time spent on focused near work and outdoors were collected followed by ocular examination and blood collection to test vitamin D3, dopamine.

Results: Myopic children were found to spend significantly less time outdoors (<30min/d) and significantly more time on focused near work (>2hr/d) Plasma vitamin D3 levels were found to be significantly lower in the myopia group than controls Plasma dopamine levels showed no statistically significant difference between control and myopia group Multivariable analysis revealed that higher BMI, parental or sibling myopia, reduced outdoor activity, accommodative disorders, and low vitamin D3 were independent risk factors for myopia

Conclusions: • Targeted environmental and lifestyle modifications to improve outdoor activity / limit focused near work should be an essential part of early myopia management • Efforts must be made to correct vit D deficiency in children of growing age • Larger studies are needed to study the role of dopamine in myopia progression

Abstract No.: 203665

Posterior Ocular Morphology in High Myopia Modification After Repeated Low-Level Red-Light Therapy

First Author: Yanxian CHEN

Co-Author(s): Ruoyu CHEN, Mingguang HE, Xiangui HE, Kaidi XIANG

Purpose: To investigate fundus morphology alterations and their relationship with choroidal thickness (CT) in highly myopic eyes following long-term repeated low-level red-light (RLRL) therapy using novel ultrawide-field swept-source optical coherence tomography.

Methods: Children aged 6-16 years with high myopia were included, all of whom underwent 24×20 mm UWF SS-OCT imaging at baseline, 12 months, and 24 months. Fundus morphology was evaluated using fundus Gaussian curvature (FC), calculated from the 3D posterior globe reconstructed by the built-in software of the UWF SS-OCT. Both FC and CT were automatically calculated within seven concentric circles centered on the fovea, with diameters of 1, 3, 6, 9, 12, 15, and 18 mm (Center and I-VI areas). The primary outcome was the change in FC measured at baseline, 1-year follow-up, and 2-year follow-up visits. The key secondary outcome was the relationship between FC and CT, axial length (AL), and spherical equivalent (SE).

Results: Among 32 highly myopic eyes from 17 children, FC significantly decreased at the 1-year follow-up, with FC-Center decreasing from 0.516 ± 0.159 to 0.433 ± 0.135 , FC-I from 0.515 ± 0.154 to 0.442 ± 0.133 , and FC-II from 0.519 ± 0.139 to 0.476 ± 0.129 (10^{-2} mm^{-2}) ($P < 0.05$). FC was positively correlated with SE and CT, but negatively correlated with AL ($P < 0.05$). Fundus morphology changes within the macular and perimacular areas after 1 year of RLRL therapy remained significant after adjustment for confounding factors ($P < 0.05$). However, the FC calculated at the 2-year follow-up visit was comparable to the baseline.

Conclusions: This study is the first to show that posterior ocular morphology in highly myopic eyes tends to flatten after one year of RLRL therapy, though this effect partially diminishes after two years. These findings highlight the positive influence of RLRL therapy on the shape of the posterior eye.

Abstract No.: 205616

Prevalence and Risk Factors of Myopia and High Myopia in Hong Kong Chinese Adults: A Population-Based Study

First Author: Ebenezer ZAABAAR

Co-Author(s): Xiujuan ZHANG

Purpose: While the high prevalence of myopia in East Asian children is well-documented, large-scale, contemporary data on adult populations, particularly for the burden of high myopia and its risk factors, are limited. We aimed to determine the prevalence and associated factors of myopia and high myopia in a population-based cohort of Hong Kong Chinese adults.

Methods: This cross-sectional study included 15,488 adults aged ≥ 50 years who underwent a comprehensive ophthalmic examination, including refraction. Myopia and high myopia were defined as spherical equivalent (SE) ≤ -0.50 D and ≤ -6.00 D, respectively. Lifestyle and socio-demographic factors were collected with standardized questionnaires, and multivariable regression was used to identify independent risk factors of myopia and high myopia.

Results: The prevalence of myopia was 49.44% and high myopia was 7.87%. Risk factors [OR (95% CI)] of myopia included 2 to < 4 hours/day and ≥ 4 hours/day of screentime [vs. < 2 hours/day: 1.21 (1.12-1.31) and 1.44 (1.30-1.60)]; basic, secondary/vocational, and tertiary education [vs. low formal education: 1.42 (1.20-1.70), 3.07 (2.56-3.70), and 4.87 (3.98-5.98), respectively]; living in private housing and own house [vs. public/subsidized housing: 1.38 (1.27-1.50) and 1.29 (1.17-1.43)]; smoking 1.29 (1.14-1.45); and diastolic blood pressure 1.01 (1.00-1.01); while age 0.98 (0.97-0.98); vigorous physical activity 0.98 (0.96-0.99); and being married/previously married [vs. never married: 0.65 (0.59-0.73)/0.68 (0.59-0.79)] were protective. Among these, ≥ 4 hours/day vs. < 2 hours/day of screentime 1.44 (1.22-1.70); basic, secondary/vocational, and tertiary education [vs. low formal education: 1.95 (1.11-3.83), 4.95 (2.81-9.72), and 6.71 (3.76-13.30), respectively]; as well as living in private housing and owning a house [vs. public/subsidized housing: 1.40 (1.21-1.63) and 1.31 (1.09-1.58)] increased the risk of high myopia; whereas age, 0.96 (0.95-0.97) and being married/previously married vs. never married 0.71 (0.60-0.83)/0.62 (0.47-0.80) were protective.

Conclusions: The findings indicate a high prevalence of myopia and high myopia in adults, associated with modifiable lifestyle and socio-demographic factors,

and suggest that the predisposition to myopia from excessive near work may continue to adulthood.

Abstract No.: 209455

Prevalence and Risk Factors of Premyopia in Preschoolers: A Kindergarten-Based Cluster Sampling Study

First Author: Jianping HU

Co-Author(s): Yonghong JIAO

Purpose: To evaluate the prevalence of premyopia and identify genetic and other risk factors among children aged 3-6 years.

Methods: A cluster-randomized sampling study was conducted between December 2020 and February 2021, involving 2,109 children from 23 kindergartens in Haidian district, Beijing, China. Cycloplegic refraction was assessed using 1% cyclopentolate. Premyopia was defined as a spherical equivalent refraction (SER) of > -0.50 D and $\leq +0.75$ D in the eye with the less SER value. Myopia was defined as an SER of ≤ -0.50 D, while hyperopia was characterized as an SER of $> +0.75$ D. Parents were asked to complete a questionnaire regarding refractive status, categorized as: no myopia (> -0.5 D), low/moderate myopia (≤ -0.5 D to ≥ -6 D), and high myopia (< -6 D).

Results: The prevalence of myopia, premyopia, and hyperopia among the children was 4.60%, 24.32%, and 71.08%, respectively. Boys exhibited higher prevalence rates for premyopia (28.03%; 95% CI, 25.45%-30.75%) and myopia (5.64%; 95% CI, 4.43%-7.17%) compared to girls (premyopia: 20.30%; 95% CI, 17.93%-22.89%, myopia: 3.47%; 95% CI, 2.50%-4.78%; both $P < 0.001$). Significant risk factors for premyopia included male gender (adjusted OR, 1.62; 95% CI, 1.32-2.00), paternal low/moderate myopia (adjusted OR, 1.50; 95% CI, 1.18-1.92), paternal high myopia (adjusted OR, 1.99; 95% CI, 1.41-2.81), and maternal high myopia (adjusted OR, 1.89; 95% CI, 1.35-2.64).

Conclusions: Prevention and control of premyopia in preschool children should be emphasized, particularly for boys and children with myopic parents, due to their higher risk of developing premyopia.

Abstract No.: 203400

Prevalence of Myopia and Astigmatism in Schoolchildren: Insights From Urban Malaysia

First Author: Norazah ABDUL RAHMAN

Co-Author(s): Mae-lynn catherine BASTION, Duratul Ain HUSSIN, Diing Sheng WONG

Purpose: To determine the prevalence and age-related trends of myopia and astigmatism among Malaysian primary schoolchildren, and to examine their associations with age and gender using World Health Organization (WHO) criteria.

Methods: A cross-sectional school-based vision screening was conducted between 2022 and 2024 among 459 children aged 6-12 years from urban primary schools. Refractive error was categorized using WHO definitions (myopia: spherical equivalent ≤ -0.50 D). Chi-square tests and Cramer's V were used to assess associations between refractive status, age, and gender.

Results: Refractive errors were detected in 57.3% of children. The prevalence of myopia was 33.6%, hyperopia 7.4%, and astigmatism 41.0%; high myopia (< -6.0 D) was present in 2.0%. Myopia prevalence peaked at age 9 (44.7%) and stabilized in older groups (31-41%), with no significant association with age ($X^2 = 6.438$, $p = 0.312$; Cramer's V = 0.124). Gender differences were negligible (females 34.7% vs. males 32.3%; $p = 0.647$). Astigmatism was most prevalent at age 6 (55.3%) and declined significantly with age ($X^2 = 25.810$, $p < 0.001$; Cramer's V = 0.237), with no gender association ($p = 0.583$).

Conclusions: One-third of Malaysian schoolchildren are myopic by age 12, with the highest prevalence at age 9, while astigmatism shows a significant age-related decline. These findings underscore the importance of routine school-based vision screening, particularly before age 9, to ensure early detection and timely management.

Abstract No.: 204792

Rethinking Accommodation Therapy: Low-Dose Atropine in Focus

First Author: Talita ISMA

Purpose: Accommodative spasm, also referred to as prolonged contraction of the ciliary muscle, is characterized by difficulty changing focus from near to far and blurring distant vision, especially after continuous near work resulting in asthenopia and headache symptoms. This case aims to show the role of low-dose atropine in the management of accommodative spasm symptoms reliever.

Methods: A 33 year-old Asian female patient presented with a severe headache and blurred vision in the last 2 months prior the admission to the hospital. History of prolong near work activities was obtained and the symptoms did not relieved after had a glasses prescription (-1.50D OU). Objective refraction shown in pre cycloplegia SE RE -3.50 LE -2.25. Post Cycloplegia (Cyclopentolate 1%) SE RE +1.50 LE +1.00. Patient was treated using 0.001% atropine and stop the previous glasses prescription. Regular head-eye-shoulder exercise and limiting near work activities also advised. Patient then followed at one month, 3 months and 6 months for recurrence of the symptoms also for the objective refraction.

Results: Pre-cycloplegic objective refraction in the 1st, 3rd, and 6th months of treatment was obtained

consecutively: SE RE -3.25 LE -3.00, SE RE -1.50 LE -1.25, and SE RE -1.25 LE -1.00. Post-cycloplegic objective refraction in the 1st, 3rd, and 6th months of treatment was achieved at SE +0.50 $\pm$ 0.25. Patients had no recurrence of the symptoms afterward.

Conclusions: The primary method for diagnosing and treating pseudo-myopia and spasm of accommodation is cycloplegic refraction, and patients' symptoms can be effectively alleviated by low-dose atropine and cycloplegic refractive correction.

Abstract No.: 208263

Retinal and Choroidal Microvasculature at Different Myopia Severities: A Systematic Review and Meta-Analysis

First Author: Zixuan LIN

Co-Author(s): Li Jia CHEN, Xiunian CHEN, Ka Wai KAM, Danny S.c. NG, Chi Pui PANG, Ka Ho SZETO, Fangyao TANG, Clement C. THAM, Jason C. YAM, Alvin L. YOUNG, Wei ZHANG, Xiu Juan ZHANG, Yuzhou ZHANG

Purpose: This study systematically evaluates changes in retinal and choroidal microvasculature with increasing myopia severity.

Methods: The PubMed, Embase, and Web of Science databases were thoroughly searched for studies published before May 8, 2025 on retinal or choroidal changes across different myopia severities. Included were studies with cross-sectional or prospective case-control and cohort designs that reported outcomes of foveal avascular zone (FAZ) area and vessel densities (VD) in the retina and choroid. The risk of bias was assessed by the Newcastle-Ottawa Scale and the Agency for Healthcare Research and Quality tools. Funnel plot with Egger test assessed potential publication bias. Meta-regressions were conducted to identify potential moderators in subgroup meta-analyses with high heterogeneity. The protocol was registered with the International Prospective Register of Systematic Reviews (PROSPERO): CRD42023402550.

Results: A total of 47 studies comprising 7,293 eyes were included. Highly myopic eyes demonstrated significantly enlarged FAZ area in both the superficial capillary plexus (SCP) ($P = 0.049$, standard mean difference [SMD]: 0.37, 95% confidence interval [CI]: [0.00, 0.74], $I^2 = 82\%$) and deep capillary plexus (DCP) ($P = 0.001$, SMD: 0.61, 95% CI: [0.24, 0.98], $I^2 = 83\%$). Macular VD was significantly reduced in the SCP for moderate and high myopia (HM) subgroups ($P = 0.003$ and $P < 0.001$, respectively) and in the DCP for the HM subgroup ($P < 0.001$). Significant VD reductions were also observed in parafoveal (SCP: $P < 0.001$, DCP: $P = 0.012$) and perifoveal (SCP: $P = 0.006$; DCP: $P < 0.001$) regions in the HM subgroup in both plexuses. Peripapillary VD showed consistent reductions across mild, moderate, and HM subgroups (all $P \leq 0.033$). No significant differences were observed in choriocapillaris VD or flow area.

Conclusions: This meta-analysis revealed significantly enlarged FAZ areas and reduced VD in the macular and peripapillary regions with increasing myopia, especially in HM. These findings enhance the understanding of myopia-related fundus microvascular changes, guiding the clinical management and screening of patients with HM.

Abstract No.: 207791

Shared Genetic Architecture and Multidimensional Modifiable Risk Factors Between Myopia and Retinal-Optic Nerve Diseases

First Author: Yuelan **GAO**

Co-Author(s): Li Jia **CHEN**, Clement C. **THAM**, Jianmin **XU**, Jason C. **YAM**

Purpose: Epidemiological evidence links myopia to retinal-optic nerve diseases (RONDs), but their shared genetic and environmental mechanisms remain unclear.

Methods: This study leveraged UK Biobank individual-level data and genome-wide association studies summary statistics to investigate shared mechanisms between myopia and RONDs. Epidemiological associations and the mediating effects of retinal and optic nerve parameters were first evaluated. Genetic pleiotropy was then identified through cross-trait analyses at the genome-wide, variant, and gene levels, followed by functional annotation and pathway enrichment. Environmental contributions were further examined through modifiable risk factors and gene-environment (G×E) interactions. Mendelian randomization was applied to infer causal relationships.

Results: We found that myopia increased risks of retinal detachment and primary open-angle glaucoma, decreased the risk of primary angle-closure glaucoma, and myopia < -2.0 D was protective against diabetic retinopathy, while both high myopia and hyperopia increased age-related macular degeneration risk. These effects were mediated by retinal structural changes, particularly the ganglion cell inner plexiform layer. Cross-trait analyses revealed significant genetic correlations between myopia and RONDs, identifying 66 pleiotropic loci and 115 genes, with key loci mapped to BMP3, LAMA2, RDH5, and LINC00862, involved in immune-inflammatory processes, receptor-mediated signaling, and retinal development. In myopic individuals, ROND risk was modulated by a spectrum of modifiable factors, encompassing health status, lifestyle, diet, mental health, sleep patterns, and medication use, with seven environmental factors interacting with five pleiotropic variants.

Conclusions: This study delineates shared mechanisms and modifiable risks between myopia and RONDs, providing etiological and translational insights for precision intervention in myopia-related RONDs.

Abstract No.: 201237

Stepwise DIMS Spectacle Wear for Myopia Prevention in Premyopic Preschoolers: A 1.5-Year Prospective Study

First Author: Hsin-yu **YANG**

Co-Author(s): Yen-lin **CHEN**, Nai-wei **HSU**, Pei-wei **HUANG**, Chia-wei **LEE**, Mong-ping **SHYONG**, Der-chong **TSAI**, Chiao-yu **WANG**, Yu-chieh **YANG**

Purpose: To assess the feasibility, acceptability, and effectiveness of stepwise defocus incorporated multiple segments (DIMS) plano spectacle wear over 1.5 years in premyopic preschoolers with normal uncorrected visual acuity (UCVA).

Methods: This was a single-arm, prospective pilot study. Twenty-three premyopic children (mean age 5.4 years) identified through a community screening program in Taiwan were enrolled. A stepwise DIMS spectacle regimen was implemented: part-time wear during near work before school entry followed by full-time wear after. The primary outcome was the 1.5-year spherical equivalent (SE) change, and the secondary outcome was axial length (AXL) elongation.

Results: After 1.5 years, mean SE change was -0.16 D and mean AXL elongation was 0.31 mm. Two participants developed myopia during the preschool stage. During the preschool stage, 91.3% of participants demonstrated good adherence (≥75%) to part-time wear. Most participants (73.9%) showed physiological AXL growth over 1.5 years. Visual symptoms were minimal and caregiver-reported acceptance remained high.

Conclusions: Stepwise use of DIMS plano spectacles over 1.5 years was well tolerated and associated with stable refractive outcomes and physiological AXL elongation in premyopic preschoolers. High adherence during part-time wear before school entry suggests that early optical intervention may help delay myopia onset. Larger, controlled studies are warranted to confirm these findings.

Abstract No.: 207456

Stickler Syndrome and Myopia

First Author: Kirstine **BOYSEN**

Co-Author(s): Mette **BERTENSEN**, Stense **FARHOLT**, Line **KESSEL**, Nanna **RENDTORFF**

Purpose: When considering Stickler syndrome, high myopia and retinal detachments are often the first things that come to mind. But little is known about myopia-associated complications. We know that every second Stickler syndrome patient experiences a retinal detachment, but we lack further knowledge on the risk factors thereof.

Methods: The study combines a cross-sectional investigation with a retrospective record review of Danish patients with genetically confirmed type 2

Stickler syndrome. The main outcomes are axial length, myopic maculopathy, and retinal detachment.

Results: The study includes 74 patients with type 1 and 13 with type 2 Stickler syndrome. The mean (SD) axial length was 25.95 (1.99) and 26.55 (3.45) mm, respectively. Myopic maculopathy was present in 43% type 1 and 42% type 2 Stickler syndrome patients. The odds for higher-category myopic maculopathy increased by a factor of 2.28 with each mm of axial elongation (95% CI 1.19 to 4.34, $P=.01$). Retinal detachment was found in 41% of patients with type 1 and 23% with type 2. In type 1 we found that axial length did not significantly increase the odds for RD but age did.

Conclusions: More than 50% of patients had no myopic maculopathy, its severity depending on axial length but not age. Mean axial lengths were larger than those of normal eyes, but normal axial lengths were common, and the absence of myopia should not exclude the diagnosis. Retinal detachments happen independent of axial length. These findings are relevant for clinical follow-up and risk stratification for vision-threatening myopic maculopathy and retinal detachment in patients with Stickler syndrome.

Abstract No.: 203273

The Association Between Physical Development Indicators and Peripheral Axial Length, Retinal Radius of Curvature in School-Age Children

First Author: Nan **MINHUI**

Purpose: To investigate the association between physical development indicators and peripheral axial length(PAL), retinal radius of curvature in school-age children.

Methods: A case series study. From June 2024 to June 2025, 334 school-age children (334 eyes) treated in the Department of Pediatric Ophthalmology of Third Affiliated Hospital of Jinzhou Medical University were included, among whom 159 were boys, and 175 were girls. The central axial length (CAL) and PAL at 15°, 20°, and 30° from the nasal and temporal side of the fovea were measured by the SWan instrument under natural pupil conditions in a dark room, and the absolute value of the difference of peripheral axial length ($|\Delta DPAL|$) was calculated. The height, weight were measured, and body mass index(BMI) were calculated. Multivariate linear regression analysis was used to analyze the association between physical development indicators and ocular biometry parameters such as PAL, $|\Delta DPAL|$, and retinal radius of curvature.

Results: After controlling for confounding factors such as age, gender in multivariate linear regression, in E group, height was positively correlated with CAL, nasal and temporal PAL at 15°, 20° and 30°, nasal-temporal $|\Delta DPAL|$ at 15°, 20° and 30° ($R^2=0.23-0.37$, $P<0.05$),

which was negatively correlated with the retinal radius of curvature ($R^2=0.26$, $P<0.05$). while height had no correlation with SE ($R^2=0.20$, $P>0.05$). In L-my group and H-my group. Height was positively correlated with CAL, nasal and temporal PAL at 15°, 20° and 30°, nasal-temporal $|\Delta DPAL|$ at 15°, 20° and 30° ($R^2=0.21-0.34$, $P<0.05$), which was negatively correlated with the retinal radius of curvature and SE ($R^2=0.19$, $P<0.05$; $R^2=0.22$, $P<0.05$; $R^2=0.19$, $P<0.05$; $R^2=0.34$, $P<0.05$). However, the weight and BMI of children in the three groups were not correlated with ocular biometry parameters such as PAL, $|\Delta DPAL|$, and retinal radius of curvature ($P>0.05$).

Conclusions: In taller school-aged children, the nasal PAL is longer than the temporal one and is accompanied by a smaller retinal radius of curvature, presenting as steep and asymmetric retinal morphology. However, weight and BMI has no correlation with PAL and radius of retinal curvature.

Abstract No.: 208518

The Current Status of Myopia Control Measures and Associated Factors in Children With Myopia: A Cross-Sectional Study From Shanghai

First Author: Hongrui **JIANG**

Co-Author(s): Jun **CHEN**, Xiangui **HE**, Guangzhuang **JING**, Yuhe **LIU**, Jingjing **WANG**, Xun **XU**

Purpose: To describe the current status of different myopia control measures and associated factors in children.

Methods: This cross-sectional study recruited participants in 35 primary schools across 16 districts of Shanghai from December 2024 to January 2025. Demographic characteristics (age, grade, gender, parents' myopia, and parents' education) and behavioral patterns (duration of homework completion, book reading, near-distance and far-distance electronic device usage, outdoor activity participation, and sleeping) were obtained from a questionnaire. Cycloplegic spherical equivalent (SE), axial length (AL) and corneal radius (CR) were measured by ophthalmic examination. Myopia was defined as cycloplegic SE of ≤ -0.50 diopters [D] in either eye.

Results: Among 3,833 myopic children (49.7% boys; mean age 9.60 ± 1.24 years), 43.8% used no myopia control, 19.0% used Single Vision Spectacle Lenses, 16.6% Myopia Control Spectacle Lenses, 8.3% Atropine, 7.6% Atropine + Myopia Control Lenses, and 4.7% other measures. SE, AL, AL/CR, outdoor time, screen time, and sleep duration differed significantly among measures (all $p < 0.05$). Regression showed, versus non-users, older age (OR 1.08), more myopic parents ("either" OR 1.43; "both" OR 1.83), longer homework (OR 1.08), and worse SE (OR 0.53) were associated with myopia control use (all $p < 0.05$). Compared with Single Vision Lenses users, longer homework, less screen

time, and higher maternal education predicted use of advanced myopia control (OR > 1).

Conclusions: The awareness of myopia control remains sub-optimal among primary myopic students. A worse SE was identified as a significant factor influencing the adoption of myopia control measures. Specifically, children with longer homework completion times, shorter durations of close-range screen use, and those mother with higher education levels were more likely to utilize advanced interventions.

Abstract No.: 208192

The Evaluation of Visual Function in Patients With Various Degrees of Myopia Using Multifocal Electoretinogram

First Author: Siyuan HE

Co-Author(s): Xiaotong LI, Wei ZHANG

Purpose: To measure and compare the difference of multifocal electoretinogram in patients with various degrees of myopia and explore the early changes of retinal function in myopic eyes.

Methods: Forty-eight subjects were divided into three groups by refractive error: emmetropia/low, moderate, and high myopia. mfERG testing was performed using VERIS Science 4.2 (EDI, USA). All-trace grouping waveforms and six-ring average responses were analyzed. Response densities and latencies were compared among groups, and correlations with refractive errors were assessed.

Results: The response densities of all trace grouping waveforms and the six-ring average response in myopia decreased with the increase of refractive errors, while the latencies were not changed.

Conclusions: The response densities of multifocal electoretinogram in myopic eyes decreased and resulted predominantly from cone function loss.

Abstract No.: 208650

The Interaction of Alcohol Consumption and Sugar Intake With Myopia: A UK Biobank Study

First Author: Ryan Tak Chun WONG

Co-Author(s): Philip Ya Wen GUO, Alexander Ka Ngai LAM

Purpose: To investigate the interaction of alcohol consumption and sugar intake with myopia in the UK Biobank cohort.

Methods: This retrospective cohort study analysed data from 502,250 UK Biobank participants aged 37-73 years old (54.4% female). Spherical Equivalent Refraction (SER) is calculated as spherical power + cylindrical power*0.5. Participants were categorized into four subgroups based on alcohol intake frequency: Hazardous drinker (daily), Moderate drinker (3-4 times/

week), Sensible drinker (1-2 times/week to special occasions), and Non-drinker. A multivariable linear regression was performed to assess the association between alcohol consumption patterns and SER, adjusting for total sugar intake.

Results: Moderate drinkers ($\beta = -0.174$, $p < 0.001$) and sensible drinkers ($\beta = -0.093$, $p = 0.025$) exhibited significantly higher SER value than non-drinkers, while hazardous drinkers did not ($\beta = -0.035$, $p = 0.441$). Total sugar intake was not significantly associated with SER in the adjusted model ($\beta = 0.0003$, $p = 0.103$).

Conclusions: Alcohol consumption frequency demonstrates a significant association with spherical equivalent refraction. However, the association only exists between moderate and sensible drinkers. Sugar intake did not demonstrate any significant association with spherical equivalent refraction in this cohort. These findings suggest that alcohol intake frequency may influence refractive error development, though the mechanisms require further investigation.

Abstract No.: 206160

ipRGCs Modulate Myopia Development Through Regulating Bipolar Cell iGluRs

First Author: Chuyao YU

Co-Author(s): Li DONG, Wen-bin WEI, Ruiheng ZHANG

Purpose: Pathological myopia is characterized by excessive axial elongation, yet the underlying neural mechanisms remain incompletely understood. This study aimed to investigate the role of intrinsically photosensitive retinal ganglion cells (ipRGCs) and the functional significance of the related cellular mediators in myopia development.

Methods: The ipRGCs ablation model was established in lens-induced myopic guinea pigs via intravitreal injection. All animals underwent regular ophthalmic examinations and biometry for axial length measurement. Ocular morphology was assessed at the endpoint via anterior segment and fundus photography, and optical coherence tomography (OCT). Post-intervention, retinal tissues were subjected to single-cell RNA sequencing (scRNA-seq), immunofluorescence, H&E, and TUNEL staining assay.

Results: scRNA-seq analysis revealed that ipRGCs ablation markedly attenuated the high-strength cellular communication associated with defocus myopia. Receptor-ligand analysis and retrospective analysis of cell proportions indicated that cone photoreceptors, bipolar cells, and amacrine cells were enriched following FDM induction but depleted after ipRGCs ablation, suggesting bipolar cells as a critical hub in this transduction pathway. Molecularly, iGluR expression in bipolar cells was downregulated in the myopic model but upregulated upon ipRGCs ablation. In vivo experiments confirmed that an iGluR agonist further suppressed axial elongation in ipRGCs-ablated eyes,

whereas an iGluR antagonist reversed this suppressive effect.

Conclusions: Selective ablation of in developing guinea pigs induced myopic refractive corrective shifts by modulating the axial length. ipRGCs participate in controlling axial elongation by negatively modulating the expression of iGluRs in bipolar cells. These findings provide a new perspective on the pathogenesis of myopia and suggest iGluRs as a potential therapeutic target for future interventions.

Neuro-Ophthalmology

Abstract No.: 202115

A Case Study of Leber Hereditary Optic Neuropathy (LHON) at Cipto Mangunkusumo Hospital: An Analysis From a Genetic Counseling Perspective

*First Author: Made Paramita **WIJAYATI***

*Co-Author(s): Salmarezka **DEWIPUTRI**, Syntia **NUSANTI**, Muhammad **SIDIK***

Purpose: Genetic counseling in LHON involves evaluating, explaining, and communicating genetic risks, providing psychosocial support, and helping individuals make informed reproductive decisions.

Methods: We use four counseling elements: accurate diagnosis, recurrence risk assessment, genetic counseling, and decision-making support. A 25-year-old man with unexplained visual loss was diagnosed; ophthalmology revealed CF3 M in the right eye and CF 1M in the left, both with normal fundus. Both eyes had central scotomas, reduced conduction on VEP, decreased macular function on ERG, but normal macular OCT and Brain MRI. Sanger sequencing showed a positive LHON mutation with m.14484T>C variant.

Results: We estimate recurrence risk via family pedigree and risk assessments based on history. Genetic counseling discusses LHON, available treatments like 900 mg Idebenone daily, and new gene therapies in phase 4 trials, mainly focusing on the m.11778A>G variant. There's no risk for his future children due to maternal inheritance. Risk assessment is for his female sibling, who could pass it to her sons; thus, presymptomatic genetic testing is recommended. Since he has the m.144484T>C variant, he has a favorable visual prognosis. Decision-making considers his therapy, social, economic status, and community influence. We advise him and his young nephew to avoid smoking and alcohol.

Conclusions: Genetic counseling for this LHON patient helps guide decisions that match family goals and standards. Although testing cannot predict age or

when vision loss will begin, we can provide advice on reducing environmental factors for at-risk families.

Abstract No.: 205827

A Case of Dual Pathology: Myasthenia Gravis With Radiographically Confounding Orbital Arteriovenous Malformation Mimicking Optic Nerve Mass

*First Author: Thomas **HASSALL***

*Co-Author(s): Alexandra **MANTA**, Jie Cheng **SONG***

Purpose: To report a case demonstrating diagnostic complexity when dual pathology coexists and structural incidental abnormalities on imaging can mislead clinical assessment.

Methods: Clinical examination, CT and MR imaging, tissue biopsy, and serological testing were performed.

Results: An otherwise well 63-year-old male without significant medical history presented with progressive binocular diplopia over approximately 4 weeks. Community CT angiogram reported a right intraorbital and optic nerve-encasing irregular mass with invasive features. Examination revealed asymmetric extraocular movement deficits with >50% reduction in bilateral right gaze, non-concomitant restrictions in left gaze and elevation movements, and right 2mm proptosis. Left eye ptosis was noted on referral, but not clinically significant on initial clinic review. Visual field, acuity, and colour vision were normal. MR imaging suggested a differential of lymphoproliferative lesion, metastatic disease, or arteriovenous malformation. Urgent biopsy revealed vascular tissue consistent with arteriovenous malformation, confirmed by post-operative MR angiography. Subsequently, positive anti-acetylcholine receptor antibodies explained the diplopia and contralateral dysmotility. The patient was commenced on pyridostigmine 60mg three times daily.

Conclusions: This case highlights diagnostic complexity when incidental orbital arteriovenous malformation creates radiographic confusion while myasthenia gravis causes the clinical symptoms. It emphasises the importance of clinical correlation and considering autoimmune neuromuscular disorders as important masquerades even when structural abnormalities are present on imaging.

Abstract No.: 201748

A Case of Non-Arteritic Anterior Ischemic Optic Neuropathy (NAION) Following Cataract Surgery

*First Author: Yanru **CHEN***

*Co-Author(s): Xunwen **LEI**, Nian **TAN***

Purpose: To summarise and report the clinical characteristics of non-arteritic anterior ischemic optic neuropathy (NAION) following phacoemulsification cataract surgery.

Methods: Retrospective case study.

Results: This study retrospectively analysed the diagnosis and treatment of one case of NAION following cataract surgery, exploring the diagnosis, treatment, and prevention of the condition. The patient developed NAION 7 days post-cataract surgery. After receiving treatments to improve circulation and nourish the nerves, the best-corrected visual acuity of the affected eye improved from 0.1 to 0.3 at 30 cm.

Conclusions: Surgery may induce NAION; thorough preoperative fundus examination is critical for diagnosis and treatment.

Abstract No.: 200133

A Mysterious Case of Non-Specific Orbital Inflammatory Disease

First Author: Nishanth S

Co-Author(s): Anupama S DESAI

Purpose: To evaluate the cause, signs, symptoms, diagnosis, and treatment of a case of NSOID.

Methods: History, clinical examination, blood investigations, imaging studies, and timely follow-up.

Results: The cause of the condition could not be concluded, as all tests were negative. The condition was treated as NSOID, with steroids, post which we could see immediate improvement in the condition, and once the steroids were stopped, the condition recurred.

Conclusions: The working diagnosis of the case was NSOID, which had abduction lag in the left eye. MRI showed lateral rectus enlargement, not involving the tendon, which decreased on IV steroids, and an enlarged lacrimal gland, which remained enlarged even after IV steroids. The symptoms decreased after starting steroids, but recurred once they were stopped. The uniqueness of this case was that this was one of the very few cases reported to have vision loss, including color vision defect, sparing contrast sensitivity, which became normal as soon as IV steroids were started. Many other cases reported have diplopia as the main complaint, but this case presented with a unique spectrum of symptoms. The root cause of the condition has to be found out, for which a deep dive evaluation has to be done.

Abstract No.: 207143

A Rare Case of Papilloedema With Subretinal Fluid and Intraretinal Precipitates in a Case of Syphilis

First Author: Madhusmita MAHAPATRA

Co-Author(s): Ankit AHIR, Dipankar DAS

Purpose: To study a rare case of papilloedema with subretinal fluid and intraretinal precipitates in a case of syphilis.

Methods: A 52-year-old male presented with blurring of vision, watering, and pain in both eyes (OU) for 3 months. On presentation, his visual acuity was 20/200, N18 in the right eye (OD), and 20/80, N18 in the left eye (OS). Slit-lamp biomicroscopy revealed immature cataract with a quiet anterior chamber (OU). Dilated fundus examination, OCT macula (OU) along with laboratory tests for complete blood count, urea, electrolytes, enzymes and antinuclear antibodies (ANA) was performed. Magnetic resonance imaging (MRI) brain and orbit was performed to rule out any pathology.

Results: OCT macula (OU) showed multiple hyperreflective intraretinal dot-like foci and accumulation of subretinal fluid at the fovea in OD and intraretinal fluid in OS. Test results were negative for HIV 1 and 2, Mantoux test and Rheumatoid factor. The treponema pallidum hemagglutination assay (TPHA) and venereal disease research laboratory test (VDRL) were reactive.

Conclusions: We conclude that all the clinical and serological findings prompted towards a diagnosis of syphilitic papilloedema with sub retinal fluid and intraretinal precipitates. The patient received treatment for syphilis and after one month, the patient presented with an improvement in symptoms and resolution of disc edema.

Abstract No.: 200328

A Retrospective Analysis and Observational Study of Patients With Neuro-Ophthalmological Presentation at a Suburban Primary Eye Care Practice Over the Past 16 Years From 2008–2025

First Author: Manoj VASUDEVAN

Co-Author(s): Sridhar BARATAN, Nivean MADHIVANAN, Shiva Mohan REDDY

Purpose: To identify the common neuro-ophthalmological manifestations, etiological factors, and diagnosis of patients presenting to a primary eye care ophthalmologist at a suburban locality.

Methods: Retrospective analysis by medical records collection of all the patients managed at this center by data collection by the primary eye care specialist over the past 16 years. The clinical examination included the torch light examination, Slit lamp examination & dilated fundus evaluation. Based on the clinical diagnosis made and the possible etiological cause, necessary Lab investigations and Radio-Imaging were performed. The diagnosis is confirmed and management carried out with help from the team of Physicians/Neurologist/Radiologist and Neuro surgeon.

Results: The total number of patients was 133; there were 72 males (1 male patient developed 2 different manifestations at 2 different time periods during the study period) and 60 female patients. Few needed

neurosurgical intervention. The most common systemic disease associated with these patients was Diabetes Mellitus and Hypertension in the same patient.

Conclusions: The patients were classified based on their age. Most common age group was between 46-60 years. The most common presentation was defective vision in 42 patients and the next was binocular double vision in 32 patients. Bilateral involvement was seen in 44 patients, Left eye alone in 46 patients and Right eye alone in 43 patients. The most common diagnosis was Optic neuritis/Optic neuropathy/Optic atrophy from various causes and most common presentation was defective vision. Recovery was achieved in 90% of patients with the use of steroids, Vitamin B12 and control of DM/HT.

Abstract No.: 201617

A Silent Aneurysm and a Blinding Clue: Neuromyelitis Optica Spectrum Disorder Unveiled by Sequential Optic Neuritis in a Young Male Patient

First Author: Kah Suen LENG

Co-Author(s): Chang Feng CHEW, Kogilavaani A/p J Raman @ Jayaraman, Mae-lynn catherine bastion

Purpose: To report a case of seropositive Neuromyelitis Optica Spectrum Disorder (NMOSD) with co-existing intracranial aneurysm who presented with sequential optic neuritis.

Methods: Case report.

Results: A 24-year-old healthy male initially presented with two months of intermittent, painless blurring of vision (BOV) in his left eye (LE) associated with ipsilateral headaches. Best corrected visual acuity (BCVA) was counting finger (CF) LE and 6/9 right eye (RE), with a relative afferent pupillary defect in LE. RE was unremarkable, while LE showed swollen optic disc. Contrast-enhanced computed tomography (CECT) of the brain and orbit revealed an incidental right middle cerebral artery aneurysm, later confirmed by CT angiography. Given his exposure to unvaccinated cats and elevated Toxoplasma IgG titre, he was treated empirically for presumed infective optic neuritis but was lost to follow-up. He re-presented a year later with sudden, painless BOV in RE; BCVA 6/24 RE, CF LE. RE showed disc swelling, while LE was unchanged. Repeated CECT demonstrated similar findings. Serum and cerebrospinal fluid tested positive for Aquaporin-4 antibodies where he was treated with intravenous methylprednisolone followed by oral prednisolone taper and azathioprine. At two months, vision improved to 6/9 RE and LE remained CF, with further follow-up arranged for MRI brain and orbit.

Conclusions: This case highlights the risk of misdiagnosis with serology in atypical optic neuritis and stresses early consideration of NMOSD to prevent irreversible vision loss.

Abstract No.: 205656

A Trio of Trouble: Multiple Tuberculomas Mimicking Neuro-Ophthalmological Catastrophes

First Author: Rusti Hanindya SARI

Co-Author(s): Dianita Veulina GINTING, Antonia Kartika INDRIATI, Prettylla YOLLAMANDA

Purpose: To report a rare case of neuro-ophthalmological manifestations resulting from multiple tuberculomas in a young female with a history of treated pulmonary tuberculosis.

Methods: A 20-year-old female presented with a two-month history of right eye ptosis, binocular horizontal diplopia, and headache. Clinical examination revealed incomplete oculomotor nerve palsy with pupillary involvement in the right eye, along with superior homonymous quadrantanopia. Neuroimaging revealed the presence of multiple tuberculomas in the right and left cerebral hemispheres, with the largest located near the brainstem.

Results: The patient was diagnosed with complete oculomotor nerve palsy with pupillary involvement secondary to multiple tuberculomas and treated with oral methylprednisolone and anti-tuberculosis medication. After one month of follow-up, there was a notable improvement in the patient's condition.

Conclusions: This case highlights a rare presentation of multiple tuberculomas manifesting as incomplete oculomotor nerve palsy and homonymous quadrantanopia. It underscores the importance of considering tuberculosis in the differential diagnosis of neuro-ophthalmological conditions, especially in regions with high tuberculosis prevalence, to facilitate timely diagnosis and appropriate management.

Abstract No.: 203495

Acute Pontine Hemorrhage Presenting With Abnormal Gaze: A Case Report

First Author: Li-wei CHAN

Co-Author(s): Yi-ting Chiang, Wei-chen HSU

Purpose: To report a case of Foville's syndrome resulting from spontaneous brainstem hemorrhage.

Methods: Description of clinical history, examination, neuroimaging, and treatment of a case of Foville's syndrome.

Results: A 39-year-old female presented to the emergency department with left limb weakness, accompanied by dizziness, right facial numbness, facial palsy, and binocular horizontal diplopia. Ophthalmic examinations showed right-sided ptosis and abduction and adduction limitation in the right eye, and adduction in the left eye. Neurologic examinations showed left hemiplegia, right facial paresthesia, and right central facial palsy. Computed tomography (CT) revealed a 26x30mm focal parenchymal hematoma in the right

dorsal lateral pons. Foville's syndrome with ipsilateral internuclear ophthalmoplegia was confirmed. After rehabilitation and oculomotor training, the patient's oculomotor symptoms improved partially. A follow-up CT revealed focal brain tissue atrophy in the right dorsal lateral pons.

Conclusions: This study reports a unique case of Foville's syndrome and highlights the importance of neuroimaging and multidisciplinary rehabilitation in the management of atypical brainstem syndromes.

Abstract No.: 201359

Acute Syphilitic Posterior Placoid Chorioretinopathy (ASPPC): A Sinister Doppelganger of Optic Neuritis

First Author: Nabila ALJUFRI

Co-Author(s): Alia ARIANTI

Purpose: The subtlety of clinical findings of ASPPC often made it mistakenly diagnosed as optic neuritis despite the stellar difference in treatment. We present a case of ASPPC initially misdiagnosed as optic neuritis.

Methods: A 43-year-old man presented with one month of bilateral blurred vision. Initial HIV and qualitative Venereal-Disease-Research-Laboratory (VDRL) tests were negative. Contrast-enhanced brain magnetic resonance imaging (MRI) suggested optic neuritis. The symptoms improved briefly after high-dose steroids. However, blurred vision recurred in the left eye (LE) while the patient was on oral steroid taper dose. He was referred to our center with 0.2 vision of LE and unremarkable ophthalmological findings. Further history taking disclosed a spontaneously resolving hand rash. High-definition macular Optic-Coherence-Tomography (OCT) showed hyperreflective foci and ellipsoid zone (EZ) disruption. Repeated serology was positive for syphilis (VDRL 1:128, Treponema-Pallidum-Hemagglutination-Assay/TPHA 1:5120). Benzathine penicillin (three weekly doses) plus steroid taper resolved symptoms, with OCT normalization and EZ restoration within three weeks.

Results: ASPPC can mimic optic neuritis and exhibit a biphasic steroid response, reflecting ongoing active and untreated infection. Syphilis, a "great mimicker," should be considered in atypical or recurrent optic neuritis. Combined treponemal and non-treponemal testing alongside specific ophthalmological findings (yellowish-placoid-lesion), combined with EZ disruption OCT findings, are key for diagnosis.

Conclusions: Thorough evaluation is essential in optic neuritis cases, especially in high-risk individuals. Biphasic courses in optic neuritis while on treatment should warrant further investigation, including infectious causes like syphilis.

Abstract No.: 203228

Association Between Visual Outcome and Magnetic Resonance Imaging in Patients With Neuromyelitis Optica

First Author: Pei-ying CHEN

Co-Author(s): Ming-hui SUN

Purpose: To investigate the association between visual outcome and image findings on magnetic resonance imaging (MRI) in patients with neuromyelitis optica (NMO).

Methods: This retrospective study included 55 patients with NMO. Visual outcome was assessed at 3 months and 6 months after the onset, with log MAR of Snellen visual acuity (VA), thickness of temporal retinal nerve fiber layer (RNFL) on optical coherent tomography (OCT), and mean deviation on visual field (VF). The association between visual outcome and MRI findings was analyzed.

Results: There were 29 patients with optic nerve contrast enhancement on MRI, which was significantly associated with worse logMA VA at 6 months ($P < 0.001$), thinning of temporal RNFL at 6 months ($P < 0.001$), and worse VF at 3 months ($P < 0.02$). Enhancement over orbital, chiasm, and optic tract segment were all significantly associated with worse logMA VA at 6 months ($P < 0.001$, $P < 0.001$, $P = 0.039$) and worse VF at 6 months ($P < 0.001$, $P = 0.001$, $P < 0.001$). Enhanced chiasm segment was also significantly associated with thinning of temporal RNFL at 3 and 6 months ($P = 0.037$, $P = 0.04$). Number of enhanced segments was significantly associated with worse logMA VA, thinning of temporal RNFL, and VF at 6 months ($P = 0.001$, $P < 0.001$, $P = 0.001$). Severity of enhancement was only associated with thinning of temporal RNFL at 3 months ($P = 0.004$).

Conclusions: In patients with NMO, enhancement of optic nerve on MRI, more enhanced segments, and enhancement over certain segment might predict worse visual outcome in terms of structural change and functional impairment.

Abstract No.: 205512

Atypical Optic Neuritis and Transverse Myelitis in a 39-Year-Old Female Filipino Patient: A Case Report on Seropositive Neuromyelitis Optica Spectrum Disorder (NMOSD)

First Author: Richard VILLAMOR

Co-Author(s): Janice BERNARDO

Purpose: To report a rare case of a 39-year-old female presenting with bilateral painless sequential blurring of vision at San Fernando City, La Union, Philippines. The patient had atypical optic neuritis and transverse myelitis symptoms. No history of antecedent viral infection.

Methods: Systemic workup and imaging were done to determine the possible etiology.

Results: Cranial/ Orbital Magnetic Resonance Imaging with contrast and fat suppressed images showed signs of left optic nerve and exhibits an increase in T2 signal intensity relative to the right eye. Optical Coherence Tomography (OCT) of optic nerve showed a generalized thinning of the optic nerve on left eye affecting both minimum rim width and RNFL thickness. Serologic tests were positive for Antinuclear Antibody, negative for Myelin Oligodendrocyte Glycoprotein Antibody and positive for Aquaporin-4 Antibody. High dose systemic corticosteroid was initiated and noted improvement of Visual acuity (VA) from baseline CF @ 2 feet to 20/25 on the right eye; and status quo vision of hand movement with good light projection on the left eye. There was also noted resolution of optic nerve swelling clinically and on OCT after the treatment.

Conclusions: Neuromyelitis Optica Spectrum Disorder (NMOSD) is a rare autoimmune demyelinating disease affecting the Central Nervous System, including the optic nerves and spinal cord.

Abstract No.: 205014

Benign Episodic Unilateral Mydriasis in a Young Filipino Woman

First Author: Kristine Milvi **DEL PRADO**
Co-Author(s): Maria Karia **MONTESINES**

Purpose: Anisocoria, the asymmetry between pupil sizes, is most commonly due to physiologic causes, such as in cases of Benign Episodic Unilateral Mydriasis. Here we present a case of a 31 year old female who presented with sudden onset mydriasis in the absence of headache, following an episode of continuous near vision activity. To our knowledge, this is the first reported case of Benign Episodic Unilateral Mydriasis in the Philippines.

Methods: This is a case of a 31-year-old female who presented with a sudden onset of glare and mydriasis in the right eye following a prolonged episode of near vision activity with a history of migraines.

Results: Ocular examination revealed a best corrected visual acuity of 20/20 in both eyes. Pupils were initially noted to be 7-8mm SRTL on the right eye, and 3-4mm BRTL on the left eye, and no relative afferent pupillary defects were noted. No light-near dissociation. Neurologic examination was unremarkable. A Pilocarpine 0.125% test was done, and no change in pupillary size was noted. Cranial MRI was unremarkable. One week after the initial onset, there was noted resolution of glare with a decrease in the size of the anisocoria. One month after, spontaneous resolution of the mydriasis was noted.

Conclusions: Benign Episodic Unilateral Mydriasis is rare and often missed due to its subtle presentation. It is advised to do a thorough history and physical

examination in order to be able to diagnose and document these patients.

Abstract No.: 202969

Bilateral Ethambutol-Induced Optic Neuritis With Vision Impairment: A Rare Case Report

First Author: Chin-lung **CHEN**
Co-Author(s): Chau-yin **CHEN**, Ching-yun **WANG**

Purpose: We report a rare case of bilateral Ethambutol-induced optic neuritis (EON) with significant vision impairment that underscores the importance of early recognition and management.

Methods: Clinical retrospective case report and literature review.

Results: A 48-year-old male with newly diagnosed pulmonary tuberculosis was initiated on standard anti-tuberculosis therapy, including isoniazid, rifampin, pyrazinamide, and ethambutol at a dose of 15 mg/kg/day. After six weeks of treatment, he presented with progressive, painless bilateral visual impairment. Initially, his best corrected visual acuity (BCVA) was 20/200 in the right eye and 20/400 in the left eye. Pupils were equal, reactive to light, and without relative afferent pupillary defect. Color vision testing revealed marked dyschromatopsia in both eyes. Fundus examination revealed optic disc hyperemia and mild temporal pallor in both eyes, suggestive of optic nerve dysfunction. Visual field testing showed bilateral central scotomas. Optical coherence tomography demonstrated preserved macular structure and normal retinal nerve fiber layer thickness. Ethambutol was immediately withheld, and oral prednisolone was given due to poor early remission. At six weeks post-treatment, BCVA recovered to 20/40 in both eyes, with partial resolution of central scotomas and color vision impairment.

Conclusions: This case highlights an uncommon presentation of ethambutol-induced optic neuritis with poor spontaneous recovery after drug discontinuation, but substantial visual improvement following corticosteroid therapy. While withdrawal of ethambutol remains the cornerstone of management, adjunctive corticosteroids and neuroprotective supplementation may benefit patients with slow or poor visual recovery. Early detection and individualized treatment are crucial to optimizing outcomes in EON.

Abstract No.: 208274

Bilateral Visual Impairment in a Middle-Aged Female After Bariatric Surgery: A Case Report

First Author: Dahu **WANG**
Co-Author(s): Xinquan **LIU**

Purpose: This report described a rare case of optic neuropathy due to nutritional deficiency following bariatric surgery.

Methods: A 44-year-old female presented to our department complaining for blurred vision in the left eye for 2 years, accompanied by blurred vision in the right eye for 6 months, who performed bariatric surgery in 2007. Upon examination, her best corrected visual acuity (BCVA) was 20/50 in the right eye and 20/200 in the left eye. Intraocular pressure of both eyes was normal. Anterior segment examination of both eyes was unremarkable. Color fundus photography showed the optic disc structure of both eyes was basically normal. However, the OCT-macula showed diffuse thinning of the ganglion cell layer. Visual field testing demonstrated a noticeable central scotoma in both eyes. Laboratory findings included abnormal blood potassium, vitamin D2, vitamin D3, vitamin B7, vitamin B12 and folate. Computed tomography and magnetic resonance imaging of brain and orbits revealed no apparent abnormalities. The medical history included nutritional disorders, anaemia and electrolyte disturbance, with a BMI of 16.0 kg/m² at the time. Therefore, a clinical diagnosis of nutritional optic neuropathy (NON) was made.

Results: After 6 weeks of treatment with nutrition supplements, the BCVA was 20/25 in the right eye and 20/30 in the left eye, and the central scotoma in both eyes also improved.

Conclusions: NON was a rare eye disease in clinical practice, but the medical history along with systemic and fundus examinations could help establish the diagnosis. Timely treatment is crucial for maximizing visual outcomes.

Abstract No.: 206781

Blinded by the Stroke - Hemianopia and Beyond

First Author: Krithika M

Co-Author(s): Janani KRISHNAN, Pratheeba M, Prem SAI.T, Ragul VR

Purpose: Cerebral vascular accidents are the leading cause of preventable blindness. Isolated visual symptoms may be an early presenting characteristic of stroke.

Methods: A 52-year-old male came with C/O diminution of vision following a road traffic accident, K/C/O SHTN & T2DM not on regular medication. On evaluation, the anterior segment was normal, the visual field showed right homonymous hemianopia, followed by an MRI showing an occipital lobe infarct.

Results: The patient was started on antiplatelet therapy. Visual outcome improved with the medical management.

Conclusions: This case report highlights the importance of ophthalmic evaluation, especially visual fields, in aiding a vital role in a multidisciplinary approach to early diagnosis and proper management.

Abstract No.: 204008

Blinding Consequences of Methanol Ingestion: A Case Series

First Author: Hui Yun GOH

Co-Author(s): Pei Fang NEOH, Evelyn Li Min TAI, Melissa Pei Yin WANG

Purpose: To report two cases of toxic optic neuropathy following methanol ingestion, highlighting the systemic and ocular features, management challenges, and poor visual prognosis despite timely intervention.

Methods: Case series

Results: Case 1: A 42-year-old male presented with vomiting, reduced consciousness, severe metabolic acidosis (pH 7.1), and elevated serum methanol (40.7 mmol/L). He received haemodialysis, intravenous thiamine, leucovorin, pyridoxine, and oral ethanol. Ophthalmic examination revealed bilateral optic disc swelling with sluggish, dilated pupils and visual acuity of hand movement in both eyes. No functional recovery was observed despite high-dose intravenous methylprednisolone. Case 2: A 26-year-old male presented with altered consciousness, severe metabolic acidosis (pH 6.5), acute kidney injury, and transaminitis. Serum methanol was markedly elevated at 65.2 mmol/L. He was treated with haemodialysis and the same adjunctive regimen. Post-extubation, ophthalmic evaluation showed bilateral toxic optic neuropathy with a left relative afferent pupillary defect (RAPD). Visual acuity was counting fingers in the right eye and hand movement in the left. Optical coherence tomography revealed preserved macula, but visual improvement was minimal after intravenous methylprednisolone.

Conclusions: Methanol poisoning is a preventable cause of profound visual morbidity. Toxic optic neuropathy may develop rapidly and irreversibly, even with aggressive systemic and ocular management. These cases highlight the importance of early recognition, urgent ophthalmology referral, and multidisciplinary care. Stronger public health strategies, regulation, and education are crucial to reduce the risk of vision loss from adulterated alcohol consumption.

Abstract No.: 207213

Carbo-Optic Neuropathy

First Author: Priethikka M S

Co-Author(s): Madhumitha

Purpose: To report two cases of carboplatin-induced optic neuropathy, a rare but vision-threatening complication of systemic chemotherapy, characterized by progressive visual decline with ischemic retinal changes.

Methods: Two patients with a history of systemic carboplatin therapy presented with progressive decrease in vision. Detailed history was obtained,

and systemic vitals were within normal limits. Comprehensive ophthalmic evaluation was performed, including visual acuity, color vision, and visual field testing. Slit-lamp biomicroscopy was used to assess the anterior segment, and fundus examination was carried out to evaluate the posterior segment.

Results: Both patients demonstrated reduced visual acuity with associated color vision and field defects. Anterior segment examination was unremarkable. Posterior segment findings revealed optic disc edema, a pale optic disc, and ischemic changes in the retina, consistent with optic neuropathy.

Conclusions: Carboplatin, a commonly used chemotherapeutic agent, can rarely cause optic neuropathy, leading to progressive and potentially irreversible vision loss. Recognition of this adverse effect is essential for timely diagnosis and modification of therapy to prevent further ocular morbidity. Just like other drugs causing optic neuropathy, Carboplatin also requires timed reviews and follow ups going forward as cases are more common.

Abstract No.: 202816

Case of Juvenile Myasthenia Gravis With Positive Anti-MuSK Antibodies

First Author: Rieko **FUKUDA**

Co-Author(s): Yuka **MORITA**, Tetsuro **OSHIKA**

Purpose: We report a case of pediatric MuSK antibody-positive myasthenia gravis (MuSK-MG) in which the definitive diagnosis was markedly delayed.

Methods: Case report.

Results: A 3-year-old girl presented with right esotropia following an RS virus infection. Because she had been using a smartphone for more than six hours daily, acute acquired comitant esotropia was suspected. Screen time restriction was advised, and her ocular deviation improved spontaneously. A head MRI was performed and showed no abnormalities. Ten months later, esotropia recurred, and soon after, ptosis appeared. Laboratory tests revealed negative anti-acetylcholine receptor antibodies but positive anti-MuSK antibodies, leading to a diagnosis of subclinical generalized MG. Although it required 25 months from initial presentation to establish the diagnosis, treatment with intravenous immunoglobulin followed by oral corticosteroids and tacrolimus resulted in complete resolution of ocular symptoms without progression to generalized disease.

Conclusions: Myasthenia gravis is an autoimmune disease characterized by antibody-mediated impairment of postsynaptic acetylcholine receptor function at the neuromuscular junction. Pediatric MuSK-MG is extremely rare and diagnostically challenging. In our case, the initial presentation mimicked acute acquired comitant esotropia, delaying the recognition of MG. Strabismus or ocular motility

abnormalities that are inconsistent with typical cranial nerve innervation patterns may indicate MG. Even in pediatric patients, MuSK-MG can manifest with isolated ocular symptoms; therefore, testing for anti-MuSK antibodies, in addition to standard anti-AChR antibodies, is recommended whenever MG is suspected.

Abstract No.: 201469

Cat-Scratch Disease Neuroretinitis in a Young Filipina: A Case Report

First Author: Kim Jasper **TORRELIZA**

Co-Author(s): Vina **BALLADO**

Purpose: To present a case of an 18-year-old Filipina who complained of sudden, painless, blurring of vision of the left eye, preceded by non-specific flu-like symptoms.

Methods: This is a case report.

Results: This is a case report of an 18-year-old Filipina who presented with acute, painless blurring of vision of the left eye, preceded by fever, myalgia, body malaise, and loss of appetite. Further history revealed that she sleeps with her pet cat. Visual acuity was 5/200 on the left eye with a grade 2 relative afferent pupillary defect and dyschromatopsia. Fundoscopic examination of the left eye revealed optic disc swelling and stellate macular exudates. The diagnosis was confirmed by positive serology for Bartonella henselae. She was treated with oral Doxycycline and Rifampicin.

Conclusions: Neuroretinitis, an inflammation of the neural retina and optic nerve, can stem from infectious, immune-mediated processes, or idiopathic causes. It is a rare ocular complication of Cat-scratch disease (CSD), a systemic infection caused by Bartonella henselae, which can be transmitted through a cat scratch or bite. Early recognition of the disease can be achieved through accurate history taking, including feline exposure, and serology testing. Treatment options include antibiotic therapy with Doxycycline and Rifampicin. Some literature suggests supplementation with corticosteroids. However, there is still no consensus on the treatment of CSD and its ocular complications. There is limited data on CSD neuroretinitis in Asia, and to our knowledge, there are no reported cases yet in the Philippines.

Abstract No.: 201992

Chronic Sinusitis First Presented With Unilateral Blurred Vision and a Pale Optic Neuroretinal Rim: A Case Report

First Author: Huai Wen **HSU**

Co-Author(s): Shu Chun **KUO**

Purpose: To present a case of a patient with blurred vision and a visual field defect in the left eye for

three months, who was later diagnosed with chronic sinusitis.

Methods: Case report.

Results: This case report describes a 63-year-old woman with no systemic diseases who presented with blurred vision and a nasal visual field defect in her left eye for three months. Best-corrected visual acuity was 1.0 in the right eye and 0.8 in the left eye, with normal intraocular pressures. Fundus examination revealed a pale temporal optic rim in the left eye, and macular OCT showed no significant abnormalities. Visual field testing demonstrated a nasal step defect in the right eye and a paracentral scotoma in the left eye. Fluorescein angiography revealed no specific findings. Brain CT showed a 2 × 1 cm nodule in the left ethmoid sinus, and MRI confirmed a mucocoele compressing the left optic nerve with mild optic atrophy. The patient was diagnosed with a left ethmoid mucopyocoele with orbit and skull base invasion and underwent external frontoethmoidectomy with flap reconstruction. Postoperative vision and visual field findings remained unchanged.

Conclusions: This case underscores the importance of thorough evaluation in patients with unilateral blurred vision and visual field defects. Early detection and treatment of sinus-related complications are vital to prevent irreversible optic nerve damage.

Abstract No.: 207487

Clinical Characteristics of Binocular Diplopia

First Author: Nguyen TAN THINH

Co-Author(s): Tran KE TO, Ngo LAN ANH, Nguyen THANH NAM

Purpose: To describe the clinical characteristics and etiologies of binocular diplopia.

Methods: A cross-sectional, descriptive, retrospective, and prospective study. A total of 128 patients with binocular diplopia were examined in Ho Chi Minh Eye Hospital, Viet Nam, from June 2024 to June 2025.

Results: A total of 128 patients with diplopia (79 males and 49 females), with a mean age of 35.6 years (range: 6–78 years), were included in the study. The most common form of diplopia was sixth nerve palsy (35.16%), followed by third nerve palsy (21.09%), multiple cranial nerve palsies (13.28%), and divergence insufficiency (13.28%). Other causes included fourth nerve palsy (6.25%), convergence insufficiency (5.47%), thyroid eye disease (3.91%), and myasthenia gravis (1.56%). In most cases, the etiology was undetermined (46.88%), followed by trauma (17.18%) and vascular causes (14.84%). The group with divergence insufficiency tended to be younger, suggesting that environmental and behavioral factors may contribute to diplopia in this population.

Conclusions: Binocular diplopia is most commonly caused by ocular motor nerve palsies. In younger

patients with idiopathic diplopia, environmental and behavioral factors may play a significant role, underscoring the need for targeted evaluation and management strategies in this subgroup.

Abstract No.: 203373

Clinical Evaluation of Traditional Chinese Medicine Intervention After Traumatic Optic Neuropathy

First Author: Caiwen XIAO

Purpose: Traumatic optic neuropathy (TON) is a severe ophthalmic problem resulting from craniofacial trauma that damages the optic nerve. It is associated with high rates of disability and blindness. However, there is a lack of effective clinical treatments. This study aims to systematically evaluate the value of integrated traditional Chinese and Western medicine therapy, particularly the intervention of traditional Chinese medicine (TCM), in the treatment of TON.

Methods: A retrospective analysis was conducted on the medical records of TON patients admitted to Shanghai Ninth People's Hospital between 2023 and 2025. Data collected included patient demographics, treatment protocols, and visual acuity, visual field, and ophthalmic electrophysiological examination results before and after treatment. Forty-three patients were included in total. All patients underwent optic nerve decompression, hyperbaric oxygen therapy, and acupuncture rehabilitation, with modifications based on symptoms. Based on whether they received TCM treatment (primarily based on Xuefuzhuyu Decoction) or not, patients were divided into a TCM treatment group and a non-TCM treatment group. The visual prognosis of the two groups was compared and analyzed.

Results: Among all patients, the treatment effectiveness rate was 51.4% in those who received TCM treatment, compared to 37.5% in those who did not. Among patients for whom treatment was ineffective, 52.1% had no light perception preoperatively. Preoperative absence of light perception was a significant factor affecting poor prognosis.

Conclusions: For TON patients, the treatment effectiveness rate was higher in the TCM treatment group than in the non-TCM treatment group. Preoperative absence of light perception is a significant factor associated with poor prognosis.

Abstract No.: 204031

Clinical Features and Genetic Survey of Autosomal Dominant Optic Atrophy in Taiwanese

First Author: Li-wei CHAN

Co-Author(s): Pei-lung CHEN, Ta-ching CHEN, Chao-wen LIN, Jung-je YANG

Purpose: The purpose of this study is to report the genetic mutation sites in Taiwanese autosomal dominant optic atrophy (ADOA) patients and characterize the disease progression by evaluating the changes in visual acuity and visual field of these patients.

Methods: Retrospective cohort study.

Results: A total of 10 subjects from 8 families were enrolled in this study, including 5 males and 5 females, with age ranging from 5.4 to 66.05 years old. Eight different OPA1 gene mutation variants were detected, 2 of them were novel mutation site which had not been reported previously. The mean best-corrected visual acuity (BCVA) was LogMAR 0.89 ± 0.47 . Visual field exam of the 32 eyes showed a mean deviation of -3.04 dB. Statistical analysis revealed that with increased age, the BCVA gradually worsen while the visual field exam remained relatively stable.

Conclusions: This study contributes to the growing understanding of genetic mutation variants and characterize the progression of visual function in Taiwanese ADOA patients.

Abstract No.: 201480

Clinical Features and Risk Factors of Idiopathic Intracranial Hypertension

First Author: Sanjeeta SITAULA

Co-Author(s): Rajeev OJHA, Damodar PUDASAINI, Ananda SHARMA

Purpose: This study was done to study the risk factors and clinical features of Idiopathic Intracranial Hypertension (IIH) at a tertiary referral centre.

Methods: This hospital-based observational study conducted from January to December 2023 included 38 consecutive patients with IIH diagnosed using the Modified Dandy Criteria. Data collected included demographic details, clinical features, and investigations findings. Statistical analysis used were descriptive statistics and regression analysis to evaluate the relationship between variables.

Results: Seventy six eyes of 38 cases with IIH were included. The mean age of cases was 34.52 ± 11.42 years (18-69 years) with 34 cases (89%) being female. Most cases (73.7%) were overweight with body mass index (BMI) of 25-29.9. Only 7.9%, were obese, and 18.4% had a normal BMI. Comorbidities included hypertension (31.5%), polycystic ovarian syndrome (21%), thyroid disorders (10%) and anemia (7.9%).

Common symptoms were headache (95%), followed by transient visual obscuration, pulsatile tinnitus, dizziness (21% each). Baseline visual acuity was normal in 97.4% in both eyes at presentation and decreased in 1 case with malignant IIH. Mean cerebrospinal fluid (CSF) opening pressure was 29.34 ± 2.14 cm H₂O (range: 25-48 cm H₂O). Headache severity in IIH patients had a strong positive correlation with CSF opening pressure and retinal nerve fibre layer (RNFL) thickness, and a moderate association with Frisén grade. Visual field loss exhibited weak correlations with Frisén grade and RNFL thickness.

Conclusions: Majority of patients with IIH were overweight females with normal baseline visual acuity. Headache severity had a positive correlation with CSF opening pressures and RNFL thickness.

Abstract No.: 200847

Clinical Features and Visual Prognosis of Non-arteritic Anterior Ischemic Optic Neuropathy in a Regional Hospital: A 5-Year Retrospective Study

First Author: Pei-jane BAIR

Co-Author(s): Yu CHEN

Purpose: To analyze the clinical characteristics, systemic associations, and visual prognosis of patients diagnosed with non-arteritic anterior ischemic optic neuropathy (NAION) in a regional hospital over 5-year period, and to compare these findings with published data from tertiary centers to highlight potential differences in patient profiles and outcomes.

Methods: Retrospective review of NAION patients at Show Chwan Memorial Hospital, Taiwan (2019–2023). Inclusion: sudden painless monocular vision loss with fundus findings of NAION. Data: age, sex, comorbidities, best-corrected visual acuity (BCVA) at presentation, 1 and 3 months, optic disc findings, OCT, perimetry, MRI rate. Compared with published tertiary center cohorts.

Results: Forty patients (42 eyes; mean age 61.3 ± 9.2 years; 60% male) were included. Hypertension (72.5%) and diabetes (55%) were more prevalent than tertiary reports (~50%, ~30%). Mean presenting BCVA was 0.76 ± 0.41 logMAR, improving to 0.66 ± 0.43 at 3 months. Visual gain ≥ 2 Snellen lines occurred in 28.6% (vs. 30–45% in large series). MRI was performed in 28.5% (vs. >60% in tertiary centers). Poorer prognosis was linked to worse initial BCVA and absence of optic disc hemorrhage ($p < 0.05$). OCT showed early RNFL swelling, later thinning.

Conclusions: Compared with tertiary center cohorts, regional hospital NAION patients had higher systemic comorbidity rates, lower neuroimaging frequency, and slightly poorer visual recovery, possibly due to delayed presentation and limited specialist access.

Abstract No.: 201513**Clinical Observation of Hyperbaric Oxygen Therapy Combined With Deep Periocular Acupuncture for Ethambutol-Induced Optic Neuropathy***First Author: Qing YE**Co-Author(s): Da CHEN, Bo WEI*

Purpose: To evaluate the efficacy of combined hyperbaric oxygen therapy (HBOT) and deep periocular acupuncture on visual function in EON patients.

Methods: A prospective study of 10 EON patients (20 eyes) treated at Hubei Integrated Traditional Chinese and Western Medicine Hospital (2023-2025). All subjects were referrals who had failed conventional therapies (drug cessation, anisodine, neurotrophic agents) for 0.5-48 months. Exclusion criteria were applied prior to HBOT (2.0 ATA, 60 minutes/session, 5 days/week for 10 sessions). Concurrent daily deep acupuncture at 7 periocular points was administered for 14 days. Pre- and post-treatment assessments included: Best-corrected visual acuity (BCVA, Standard Logarithmic Visual Acuity Chart GB11533-1989); VF testing (30-2 program, Chongqing Shangbang Perimeter); Visual Function Index (VFI) and mean deviation (MD). All examinations were performed by the same ophthalmologist.

Results: BCVA: Baseline BCVA was ≤ 0.5 in all eyes (10 eyes ≤ 0.1). Post-treatment: 9 eyes achieved BCVA ≥ 0.5 , 6 eyes improved to ≥ 0.1 , 19 eyes showed measurable improvement; VF Analysis: 15 eyes demonstrated MD improvement, 14 eyes had increased VFI; No correlation between BCVA and VF changes was observed ($p > 0.05$).

Conclusions: For EON patients with persistent vision loss after drug cessation, early intervention with combined HBOT and periocular acupuncture may promote visual function recovery; BCVA and VF improvements were asynchronous, underscoring the need for multimodal functional assessment.

Abstract No.: 200402**Clinical Presentation of Carotid-Cavernous Fistula and Outcomes of Endovascular Balloon Embolization***First Author: Tayyaba MALIK**Co-Author(s): Noor UL AIN*

Purpose: To describe the clinical presentation of carotico-cavernous fistula (CCF) and outcomes of endovascular balloon embolization in a tertiary care center in a developing country.

Methods: This interventional case series included 18 patients who underwent endovascular balloon embolization at Lahore General Hospital in Lahore, Pakistan. The analyzed data consisted of age, gender, cause and type of CCF, clinical presentation, diagnostic

technique used, intervention, and the results of two-month follow-up. Patients with incomplete records and coil embolization were excluded. Digital subtraction angiography was done in all cases followed by endo-arterial balloon embolization. Procedures were carried out under general anesthesia via femoral artery approach. A single balloon was sufficient to close the fistula in all cases.

Results: There were 18 patients in study. Sixteen patients had direct CCF, and the mean age of the patients was 27.2 ± 12.6 years. The commonest cause of CCF was trauma, and the mean time of presentation after trauma was 7.89 ± 7.19 months. Preoperative visual acuity was worse than 6/60 in 8 patients, between 6/60 and 6/18 in 7 patients, and better than 6/18 in 3 patients. The mean intraocular pressure was 16.06 ± 3.37 mmHg preoperatively and 14.83 ± 3.49 mmHg postoperatively ($p = 0.005$). Endovascular embolization was successful in 15 patients (83.3%). One patient developed epidural hematoma as a complication of the procedure, which was drained later.

Conclusions: Balloon embolization via the femoral artery is an efficient technique in CCF. It is safe and with good results if performed in a timely manner.

Abstract No.: 202211**Clinical and Neuroimaging Spectrum of Vertical Gaze Palsy: A Retrospective Study From a Tertiary Eye Care Centre in South India***First Author: Varuna Abinethri LATHA***MOHANARAMAKRISHNAN***Co-Author(s): Madhumita GOPAL, Nirmala Devy*

Purpose: To analyse the etiological spectrum, clinical features, and neuroimaging correlations of patients with Vertical Gaze Palsy (VGP) presenting to a tertiary eye care centre.

Methods: Retrospective review of electronic medical records of VGP patients from January 2022 to August 2025. Demographic, clinical, and neuroimaging data were analysed.

Results: Fifty-one patients (Age range: 9-77 years; Mean $\pm$ SD: 58.3 ± 15.4 years; 73% male, 27% female) were included. 39% of this cohort initially presented to a neuro-ophthalmologist, diagnosed, and subsequently referred for neurophysician care. The most common causes were brainstem infarcts (51%) and progressive supranuclear palsy (PSP) (35%). Other causes were hydrocephalus (4%), demyelination (4%) and idiopathic (6%). Among vascular causes, bilateral or paramedian thalamic infarcts with or without midbrain involvement predominated (64%). Isolated infarcts involving unilateral thalamus (23%), pons (9%), and lentiform nucleus (4%) were also noted. Associated signs included third nerve palsy (54%), hemiplegia

(19%), internuclear ophthalmoplegia (INO) /abducting nystagmus (11%), and sixth nerve palsy (7%). PSP patients presented with slow vertical saccades, INO (11%), balance, speech, and gait abnormalities (50%); Neuroimaging showed midbrain atrophy. Rare causes involved midbrain-thalamic demyelination and hydrocephalus in post-ventriculoperitoneal shunt patients presenting as dorsal midbrain syndrome.

Conclusions: VGP is most often caused by cerebrovascular infarcts and PSP. While thalamic-midbrain lesions explain most cases, atypical infarcts highlight complex supranuclear vertical gaze pathways. Neuro-ophthalmologists serve as critical first-line diagnosticians for brain stem lesions, facilitating timely neuroimaging and multidisciplinary management.

Abstract No.: 208454

Comparison of Lamina Cribrosa Parameters Between Retinal Vein Occlusion Patients and Healthy Individuals

First Author: Cece ZHAO

Co-Author(s): Zhiqing LI

Purpose: Retinal vein occlusion (RVO) is the second most common retinal vascular disease, with a recent increasing incidence and a progressively younger age of onset, but its pathogenesis is still unclear. This study aimed to explore the parameter characteristics of the lamina cribrosa (LC) of RVO, which may help discover some clues related to the pathogenesis of RVO.

Methods: This retrospective study included 130 unilateral RVO patients and 30 healthy individuals who were screened at the Tianjin Medical University Eye Hospital from November 2023 to November 2024. Their basic clinical conditions, optical coherence tomographic (OCT) and optical coherence tomographic angiography (OCTA) of the optic nerve head (ONH) were obtained.

Results: There were no statistically significant differences in LC thickness (LCT) and focal lamina cribrosa defects (FLCDs) between the affected and fellow eyes, while both had statistically significant differences in LCT and FLCD with the healthy eyes ($P < 0.001$). Both BRVO and CRVO conform to the above pattern. The differences between BRVO and CRVO in LCT and FLCDs were statistically significant ($P=0.007$, $P=0.002$, respectively). LCT, LCCI, and FLCDs were independent risk factors for the development of RVO.

Conclusions: The affected eyes and fellow eyes of RVO exhibit abnormal structures of LC, with LCT, LCCI, and FLCDs serving as independent risk factors for its occurrence. Therefore, we concluded that the development of RVO is closely associated with the abnormal structure of LC, potentially related to congenital structural weakness of the LC and/or alterations of trans-lamina cribrosa gradient (TLPG).

Abstract No.: 202689

Compressive Optic Neuropathy Due to Idiopathic Gyrus Rectus Herniation

First Author: Padma Lakshmi

Co-Author(s): Olma Veena Noronha

Purpose: The gyrus rectus constitutes the inferomedial portion of the frontal lobe and is situated at the floor of the anterior cranial fossa above the intracranial optic nerves and chiasm. We report a unique case of compressive optic neuropathy caused by herniation of the gyrus rectus.

Methods: Retrospective observational case report.

Results: A 7-year-old male presented with right eye diminution of vision noticed accidentally since 4 months. On examination, BCVA was 2/60 in the right eye and 6/6 in the left eye. There was relative afferent pupillary defect in the right eye with dyschromatopsia in both eyes. The anterior segment was within normal limits. The right eye had a pale disc while the left optic disc was normal. Visual fields showed generalized constriction in right eye. Left eye visual fields were normal. MRI brain and orbit showed herniation of the gyrus rectus into the suprasellar cistern, causing mass effect on the intracranial optic nerves and chiasm without abnormal enhancement or altered signals in the optic nerves.

Conclusions: Anomalies in the frontal lobe can interfere with visual function by compression of the optic chiasm and nerve. Unilateral vision loss in our case was probably due to the involvement of prechiasmatic optic nerve.

Abstract No.: 208322

Detection of Retinal Neuronal Changes in Patients With Biomarker-Based Diagnosis of Alzheimer's Disease

First Author: Chunwen ZHENG

Co-Author(s): Carol CHEUNG, Qinghua HE, Vincent C.t. MOK, Anran RAN

Purpose: Retinal neuronal changes in symptom-based diagnosis of Alzheimer's disease (AD) have been identified. However, symptom-based diagnosis is limited by its non-specific clinical manifestations, which delay AD-specific pathology detection at early stages. This study aims to identify associations between retinal neuronal metrics measured by optical coherence tomography (OCT) and AD defined by positron emission tomography (PET) biomarkers.

Methods: A prospective cohort was recruited from Prince of Wales Hospital and the Chinese University of Hong Kong Eye Center. AD diagnosis was confirmed by significant amyloid-beta ($A\beta$) uptake on PET. Retinal neuronal changes were measured by OCT. Generalized estimating equations were used to identify differences between groups, accounting for inter-eye correlation.

Multivariate analyses were used and adjusted for age, gender, hypertension, diabetes, dyslipidemia, stroke, heart disease, smoking, and axial length.

Results: A total of 82 patients who underwent PET were involved, with 78 eyes in the A β -positive group and 86 eyes in the A β -negative group. Average retinal nerve fiber layer (RNFL) thickness, and RNFL thicknesses in superior and inferior peripapillary regions were significantly reduced in the A β -positive group ($P < 0.05$). Subjects with A β -positive were associated with lower peripapillary average (OR = 0.955, 95% CI: 0.923 – 0.986, $P = 0.031$), superior (OR = 0.975, 95% CI: 0.956 – 0.993, $P = 0.031$), and inferior RNFL (OR = 0.976, 95% CI: 0.957 – 0.994, $P = 0.031$) thicknesses.

Conclusions: Thinning peripapillary average, superior, and inferior RNFL thicknesses were associated with A β -positive status. Our study supports that the detection of retinal neuronal changes serves as a non-invasive means of early AD detection.

Abstract No.: 201536

Diagnosis Variation Associated With Bilateral Optic Disc Pallor and Swelling: A Case Series

First Author: Vannaroit **TENG**

Co-Author(s): Kossama **CHUKMOL**, Piseth **KONG**

Purpose: To illustrate the diagnostic variation associated with bilateral optic disc pallor using a case series of three middle-aged patients who presented with vision impairment due to various intracranial malignancies. Despite a common finding of optic disc pallor, the underlying causes vary, highlighting the significance of a thorough neuro-ophthalmic evaluation.

Methods: Three patients aged 30-40 years with progressive vision loss and bilateral optic disc pallor were examined. Each got a thorough ophthalmologic examination, optical coherence tomography (OCT), and a CT scan of the brain and orbits.

Results: Case 1 developed with gradual bilateral vision loss, and a CT scan revealed a massive pituitary macroadenoma with contact with the internal carotid artery. Case 2 presented identical visual symptoms, and a CT scan revealed a meningioma compressing the optic chiasm. Case 3 showed bilateral optic nerve enlargement, and a CT scan revealed a pontocerebellar angle tumor, presumably a vestibular schwannoma. Despite overlapping funduscopic findings, each patient prompted a personalized diagnosis approach. Neuroimaging was crucial in verifying the diagnosis and deciding on treatment.

Conclusions: Bitemporal optic disc pallor or swelling requires urgent neuroimaging. This case series emphasizes the diverse intracranial etiologies, including pituitary adenoma, meningioma, and pontocerebellar cancers, and underscores the necessity for a systematic diagnostic strategy to avert irreversible visual loss.

Abstract No.: 207229

Diagnostic Methods for Dysthyroid Optic Neuropathy: A Systematic Review and Analysis

First Author: Fatema **ALJUFAIRI**

Co-Author(s): Kelvin, Kam Lung **CHONG**, Kenneth **LAI**, Chi **PANG**, Clement **THAM**

Purpose: Dysthyroid Optic Neuropathy (DON) is a sight-threatening complication of thyroid eye disease (TED) that remains diagnostically challenging due to the absence of a universally accepted standard. This systematic review examines diagnostic criteria reported over the past 25 years.

Methods: A comprehensive search up to August 30, 2024, across PubMed, Embase, Cochrane Library, Scopus, Medline Ovid, Web of Science, and ProQuest retrieved 9,652 studies. After removing duplicates and applying eligibility criteria, 119 studies were included. Diagnostic approaches were categorized into subjective indicators (Decreased best-corrected visual acuity, color desaturation, visual field defects), objective findings (Relative afferent pupillary defect, optic disc changes, restricted extraocular movement), and ancillary investigations (Visual evoked potentials, electroretinography, neuroimaging).

Results: Required thresholds varied: 22.7% of studies required two positive indicators, and 13.5% required one. Radiological evidence has become increasingly prominent, with its use rising by 26% over the past decade. From 2016–2020, 72% of studies incorporated imaging, compared to 59% from 2021–2024. Despite widespread investigation, no consensus exists. This review highlights the variability in diagnostic practices and emphasizes the growing reliance on radiological tools.

Conclusions: In the absence of a universally accepted diagnostic standard for dysthyroid optic neuropathy, studies have employed various criteria, with the most common approach requiring two positive indicators. Additionally, the use of radiological evidence in diagnosing dysthyroid optic neuropathy has increased significantly over the past decade, with a growing number of studies incorporating imaging findings as a key diagnostic component.

Abstract No.: 206752

Diffuse Retinal Exudates in a Pediatric Patient With Vision Loss as an Early Indicator of Central Nervous System Tuberculosis: A Case Report

First Author: Marifel **MONTENEGRO**

Co-Author(s): Patricia **CABRERA**

Purpose: To describe a case of an 8-year-old female whose initial ophthalmologic findings, particularly diffuse retinal exudates, led to the diagnosis of central nervous system tuberculosis, underscoring the value

of thorough ocular examination in detecting life-threatening systemic disease.

Methods: The patient presented with progressive bilateral visual blurring, inward deviation of the right eye, and declining school performance. Initial examination revealed reduced visual acuity, full extraocular motility, no relative afferent pupillary defect (RAPD), and an unremarkable anterior segment. Fundus examination showed diffuse hard exudates, bilateral optic disc edema, and flame-shaped hemorrhages. Early differentials included Coats disease, cytomegalovirus retinitis, and Coats-like retinopathy. Despite initial management, visual acuity continued to deteriorate with development of a right RAPD, persistent headaches, and repeated vomiting. With emerging neurologic signs and visual field loss, a multidisciplinary workup was initiated, including macular optical coherence tomography (OCT), contrast-enhanced cranial magnetic resonance imaging (MRI), and infectious testing.

Results: MRI demonstrated bilateral cerebellitis with obstructive hydrocephalus and white matter changes. Infectious laboratory studies, complete blood count, and chest radiograph were unremarkable. Despite the absence of pulmonary findings and cerebrospinal fluid analysis, a clinical diagnosis of tuberculous meningitis was made based on clinical manifestations, neuroimaging, neurologic progression, and alignment with Marais diagnostic criteria. Anti-tubercular therapy, corticosteroids, and intracranial pressure-lowering agents were started, with neurosurgical planning for ventriculoperitoneal shunting.

Conclusions: Diffuse retinal exudates can be an early indicator of central nervous system tuberculosis. Prompt recognition and coordinated evaluation enabled timely, sight- and life-saving treatment in this patient.

Abstract No.: 204909

Disease-Modifying Therapy and Its Influence on Retinal Neurodegeneration in Relapsing-Remitting Multiple Sclerosis

First Author: Sanela Sanja BURGIC

Co-Author(s): Milka MAVIJA, Mirko RESAN, Zoran VUKOJEVIĆ

Purpose: Retinal thinning has emerged as a potential marker of neurodegeneration in multiple sclerosis (MS). This study aimed to assess whether disease-modifying therapies (DMTs) mitigate thinning of the retinal nerve fiber layer (RNFL) and ganglion cell-inner plexiform layer (GIPL) in patients with relapsing-remitting MS (RRMS) over a one-year period.

Methods: In this prospective, single-center study, 80 eyes from 40 RRMS patients were monitored for 12 months. Participants were divided into two cohorts: untreated patients (No DMT, n = 18) and those

receiving DMT (n = 22; therapies included glatiramer acetate, ofatumumab, interferon beta-1a/1b, dimethyl fumarate, fingolimod, and ocrelizumab). Optical coherence tomography (OCT) was used to quantify RNFL and GIPL thickness at baseline, 6 months, and 12 months. Disability progression was evaluated using the Expanded Disability Status Scale (EDSS). Statistical analyses included parametric and non-parametric tests, correlation analyses, and linear regression.

Results: Patients without DMT exhibited significantly greater retinal thinning ($p < 0.05$). Over 12 months, RNFL thinning was $4.03 \pm 4.87 \mu\text{m}$ (No DMT) compared with $0.69 \pm 3.91 \mu\text{m}$ in the DMT group; GIPL thinning was $3.43 \pm 3.46 \mu\text{m}$ versus $2.25 \pm 2.44 \mu\text{m}$, respectively. From baseline to 6 months, RNFL thinning was $1.31 \pm 2.34 \mu\text{m}$ vs. $0.16 \pm 1.71 \mu\text{m}$, and GIPL thinning $1.77 \pm 2.18 \mu\text{m}$ vs. $0.81 \pm 1.72 \mu\text{m}$. Between 6 and 12 months, RNFL decreased by $2.72 \pm 2.53 \mu\text{m}$ vs. $0.53 \pm 2.20 \mu\text{m}$, and GIPL by $1.66 \pm 2.51 \mu\text{m}$ vs. $1.44 \pm 1.52 \mu\text{m}$. RNFL and GIPL thickness negatively correlated with EDSS scores ($\rho = -0.42$ and -0.38 , $p < 0.05$), and regression analysis confirmed their predictive value for disability progression ($R^2 = 0.36$).

Conclusions: DMT attenuates retinal thinning in RRMS, supporting its neuroprotective role. RNFL and GIPL thinning are closely associated with disability, underscoring their potential as biomarkers of neurodegeneration. These findings highlight the utility of OCT in MS monitoring and reinforce the importance of early DMT initiation.

Abstract No.: 202124

Dual Pathology: Torsional Nystagmus From Pontine Haemorrhage With Optic Tract Compression by Frontal Lobe Meningioma

First Author: Suzanne SAW

Co-Author(s): Shahidatul Adha MOHAMAD

Purpose: To report a case of torsional nystagmus secondary to pontine haemorrhage, with concurrent compression of the visual pathway by frontal lobe meningioma.

Methods: Case report.

Results: A 58-year-old male with poorly controlled diabetes and hypertension presented in December 2024 with acute pontine haemorrhage. Initial symptoms included severe headache, right-sided weakness, dysarthria, diplopia and horizontal gaze palsy. By day 3, the gaze palsy and diplopia had resolved, yet the patient reported persistent visual disturbance, describing single objects seen against a blurred, oscillating background. Visual acuity was 6/15 (pinhole 6/7.5) in the right eye and 6/6 in the left eye. Pupillary responses were normal. Extraocular movements were full; however, careful examination revealed subtle, low amplitude torsional nystagmus in both eyes. Anterior segment and fundus examinations

were unremarkable except for immature cataracts. OCT showed temporal RNFL thinning of the left optic nerve head. Humphrey perimetry revealed a right homonymous incongruous hemianopia. Neuroimaging revealed a pontine haemorrhage involving the basal and tegmental regions, and an incidental left frontal extra-axial lesion, later confirmed on MRI as a meningioma compressing the lateral optic chiasm and anterior left optic tract. The patient was co-managed by neuromedical and neurosurgical teams.

Conclusions: The rarity and incidental nature of this dual presentation, compounded by uncontrolled comorbidities, presents significant challenges in clinical management. MRI surveillance, OCT, and Humphrey perimetry remain essential for monitoring meningioma-related compression of the visual pathway and guiding treatment decisions.

Abstract No.: 208520

Electrophysiological Characteristics of Neuromyelitis Optica Spectrum Disease (NMO-SD)

First Author: Agnes JANOSSY

Purpose: Neuromyelitis optica spectrum disease (NMO-SD) is an autoimmune demyelinating disorder affecting the central nervous system. With advancements in laboratory and imaging diagnostics, it has become increasingly possible to differentiate between patients suffering from multiple sclerosis (MS) and those with NMO-SD. The pathomechanism and therapy of these two diseases differ. Our aim was to demonstrate how electrophysiological examinations assist in distinguishing the two conditions in referred patients as well as in monitoring disease progression.

Methods: Between 2015 and 2024, we examined 78 patients in our clinic whose ages ranged from 24 to 61 years. The diagnosis of NMO-SD was primarily based on demyelinating lesions detected on cervical spinal cord and brainstem MRI scans, as well as cerebrospinal fluid analysis. Electrophysiological examinations were performed according to international standards, taking into account patient consent and ethical requirements.

Results: The most common abnormality observed in the visual evoked potentials (VEPs) was a pronounced prolongation of the N135 wave component, along with irregular waveforms affecting both eyes. Severe PERG abnormalities were observed in 50% of cases.

Conclusions: Ophthalmic electrophysiological examinations (VEPs and PERG) yielded results that differed in most cases between MS and NMO-SD. In addition to the specific VEP abnormalities, routinely performed PERG examinations in our laboratory may also assist in the early differentiation of the two types of demyelinating diseases in clinical practice.

Abstract No.: 208018

Establishing a Paediatric-Centred Visual Electrodiagnostic Unit in Hong Kong: A Retrospective Review of Clinical Experience

First Author: Cheuk Ling YIM

Co-Author(s): Stephanie SI CHEUNG, Yik To HO, Wency TANG

Purpose: To evaluate the clinical indications, diagnostic yield, and downstream genetic findings from paediatric visual electrodiagnostic testing performed at Hong Kong Children's Hospital (HKCH) following the establishment of its first child-centred electrodiagnostic unit.

Methods: We conducted a retrospective review of 50 paediatric patients (aged 3–16 years) who underwent electroretinography (ERG) and/or visual evoked potentials (VEP) between 2024 and 2025. Clinical indications, electrodiagnostic outcomes, and subsequent genetic testing results were analysed.

Results: The most common indication for testing was unexplained suboptimal vision (70%), followed by nystagmus (15%), nyctalopia, suspected maculopathy, and family history of inherited retinal disease. Electrodiagnostic testing yielded abnormal findings in 55% of cases, including electronegative ERG, cone/rod dysfunction, abnormal VEPs, and macular dysfunction. These patients were referred for genetic testing, with 45% receiving a positive molecular diagnosis. The integration of electrodiagnostic testing facilitated earlier identification of inherited retinal conditions and guided further management.

Conclusions: Our early experience demonstrates the clinical value of paediatric visual electrodiagnostics in evaluating unexplained visual symptoms. The high diagnostic yield underscores the importance of incorporating these tests into routine paediatric ophthalmic assessment. This study highlights the diverse spectrum of retinal and optic pathway disorders in Hong Kong's paediatric population and supports the role of electrodiagnostics in bridging clinical and genetic diagnosis.

Abstract No.: 206314

Evaluating Serum Angiotensin-Converting Enzyme for the Differential Diagnosis of Idiopathic Versus Demyelinating Optic Neuritis

First Author: Mohammad TOBEIHA

Co-Author(s): Alireza DEGHANI, Matin IRAIPOUR, Mohsen POURAZIZI

Purpose: To evaluate serum angiotensin-converting enzyme (ACE) levels in patients with idiopathic and demyelinating optic neuritis (ON), as well as in healthy individuals, and to assess the potential of ACE as a biomarker for differentiating ON subtypes.

Methods: In this case-control study, patients diagnosed with acute ON were recruited as the case group, and healthy volunteers (18–50 years) served as controls. Based on systemic and neurological assessments, ON cases were categorized into idiopathic ON and demyelinating ON, including multiple sclerosis (MS), neuromyelitis optica (NMO), and clinically isolated syndrome (CIS). Serum ACE levels were measured using an enzyme-linked immunosorbent assay.

Results: A total of 51 patients with acute ON (78.4% female; mean age, 29.8 ± 8.4 years) and 51 controls (78.4% female; mean age, 29.9 ± 6.9 years) were enrolled. Among ON patients, 29 (56.9%) had idiopathic ON, while 22 (43.1%) had demyelinating ON (MS, n=16; NMO, n=3; CIS, n=3). Median serum ACE levels were 33.50 U/L (range: 29.40–46.20) in idiopathic ON and 34.25 U/L (range: 29.30–46.10) in demyelinating ON ($P > 0.99$). Healthy individuals had a mean serum ACE of 26.2 U/L (range: 20.50–24.80), which was significantly lower compared to ON patients ($P < 0.001$). Abnormally elevated ACE (>65 U/L) was found in 3 patients with idiopathic ON (10.3%) and 2 with demyelinating ON (9.1%) ($P > 0.99$).

Conclusions: Serum ACE levels were significantly higher in patients with both idiopathic and demyelinating ON compared with healthy controls. However, no significant difference was observed between ON subtypes, suggesting that while ACE may indicate disease presence, it lacks discriminatory value between idiopathic and demyelinating ON.

Abstract No.: 201775

Evaluating Visual Snow Symptoms and Severity Using the Colorado Questionnaire and Visual Snow Simulator in Koreans

First Author: Hyun Jin SHIN

Purpose: This study aims to assess the symptoms of visual snow syndrome (VSS) among Koreans utilizing the Colorado questionnaire (CQ) and to determine the severity of the condition through the visual snow simulator.

Methods: From May 2021 to July 2023, 53 individuals diagnosed with VSS at Konkuk University underwent a thorough examination focusing on the density, speed, and size of the visual snow simulator which is a specialized tool used to replicate and quantify the visual disturbances experienced by individuals with VSS. In conjunction with the simulator evaluation, participants were requested to complete the CQ, which was designed to gauge the intensity and impact of VSS on individuals' daily lives.

Results: The mean age of the 53 patients (58.8%, 31 males, age=11–50) was 28 ± 11.11 years. In the CQ, the symptom with the greatest impact on daily life was «floater,» followed by «anxiety» and «blue field entoptic phenomenon.» In contrast, the least impactful

symptoms were «feeling of detachment,» «tinnitus,» and «palinopsia.» The average density, speed, and size in the visual snow simulator were 0.48, 34.38, and 1.84, respectively. No significant correlation was observed between simulator severity and Colorado questionnaire scores.

Conclusions: These results suggest that it is the subjectivity of individuals' perception of VSS, rather than the severity itself, that has a greater impact on their quality of life. Also, by quantifying parameters related VSS, researchers can offer a more comprehensive understanding of VSS and its impact on life on the Korean population.

Abstract No.: 203833

Evaluation of High-Dose Methylprednisolone for Optic Neuritis: A Case Series

First Author: Stefenie

Co-Author(s): Alvando AULIA, Bobby Ramses Erguna SITEPU, Kristo Hadi Audric SUGIAMAN

Purpose: To evaluate the outcomes of high-dose intravenous methylprednisolone (IVMP) in patients with typical and atypical optic neuritis (ON) and to compare treatment responses between subtypes.

Methods: Six ON patients treated at Prima Vision Eye Hospital between January and June 2024 were retrospectively reviewed. Four presented with typical unilateral ON and two with atypical bilateral ON. All received IVMP (1 g/day for adults, 500 mg/day for pediatric patients) for three days, followed by a tapering course of oral corticosteroids. Visual acuity, color vision, and contrast sensitivity were assessed at baseline and during 1–6 months of follow-up. Diagnosis was based on clinical features and ophthalmic examination, as advanced imaging and antibody testing were unavailable.

Results: Treatment outcomes differed markedly between subtypes. Two typical ON patients achieved near-complete recovery with normalization of visual and sensory function. In contrast, four patients—including both atypical ON cases—showed incomplete or minimal improvement. One typical ON patient regained color and contrast sensitivity without significant visual acuity gain, suggesting irreversible axonal injury despite remyelination. Another typical case also demonstrated a persistent visual deficit. These findings illustrate the heterogeneity of ON recovery, the influence of axonal damage at presentation, and the limited role of corticosteroids in atypical disease.

Conclusions: High-dose IVMP accelerated recovery in typical ON but had limited efficacy in atypical ON. Early recognition of atypical features and timely intervention are essential for prognosis. Incorporating antibody testing and individualized management may optimize

outcomes in patients with atypical or steroid-refractory ON.

Abstract No.: 203896

Eyes As Witness: Third Nerve Palsy and the Telltale Pupil of Neurosyphilis

First Author: Wen Jin KOW

Co-Author(s): Ee Ling ANG, Rhuen Chiou CHOW, Benjamin Ching How LIM, Julieana MUHAMMED

Purpose: To present a case of isolated third cranial nerve palsy secondary to neurosyphilis.

Methods: Case report

Results: A 44-year-old Chinese gentleman with no significant medical history presented with sudden-onset left eyelid drooping and blurred vision of three days duration. He denied headache, limb weakness, or other intracranial symptoms. Notably, he reported unprotected sexual intercourse with multiple partners over the past year, but no recreational or intravenous drug use. Visual acuity was 6/9 (right eye) and 6/18 (left eye). Examination revealed left eye ptosis with anisocoria (5 mm right, 7 mm left) and sluggish pupillary reaction to light. A light-near dissociation was demonstrated. Extraocular motility testing showed limitation of elevation, depression, and adduction in the left eye. Fundus examination was unremarkable bilaterally. An initial working diagnosis of aneurysmal compression was considered; however, urgent computed tomography angiography (CTA) of the brain was negative. Serological testing revealed a positive Rapid Plasma Reagin (titer 1:64) and Treponema pallidum antibody. Cerebrospinal fluid analysis further confirmed a positive Venereal Disease Research Laboratory test, establishing the diagnosis of neurosyphilis. The patient was treated with intravenous Penicillin-G for two weeks, followed by three doses of intramuscular benzathine penicillin. At two-month follow-up, he demonstrated gradual clinical improvement.

Conclusions: Isolated third cranial nerve palsy due to neurosyphilis is rare yet clinically significant. Comprehensive evaluation beyond vascular and compressive etiologies is crucial, as early recognition facilitates timely treatment and optimizes both visual and neurological outcomes.

Abstract No.: 206400

Fulminant Idiopathic Intracranial Hypertension With Atypical Imaging Presentation

First Author: Fengsheng XU

Co-Author(s): Yingzi PAN, Yuan WU

Purpose: To report a case of fulminant idiopathic intracranial hypertension presenting with bilateral rapid vision loss and associated inferior ophthalmic

vein (IOV) obstruction, and to discuss the potential anatomical mechanism underlying this unusual venous drainage pattern.

Methods: A 36-year-old woman with a history of hypertension and headaches presented with bilateral rapid vision loss over 2 weeks. Comprehensive evaluation included visual acuity testing, ophthalmoscopy, magnetic resonance imaging (MRI), and lumbar puncture. Treatment consisted of ventriculoperitoneal shunting.

Results: Initial visual acuity was no light perception OD and 20/400 OS. Ophthalmoscopy revealed bilateral papilledema with dilated and twisted veins and retinal hemorrhages. MRI demonstrated a tortuous right IOV without enhancement and similar inconspicuous changes in the left IOV. Lumbar puncture confirmed elevated cerebrospinal fluid (CSF) pressure. Following ventriculoperitoneal shunting, visual acuity improved to light perception OD and 20/200 OS, with normalization of CSF pressure.

Conclusions: The IOV obstruction resulted from impaired venous return secondary to intracranial hypertension. We suspect an anatomical anomaly where the IOV diameter was thicker than the superior ophthalmic vein (SOV), causing the IOV to demonstrate venous obstruction before the typically dominant SOV. This case highlights the importance of recognizing atypical venous drainage patterns in idiopathic intracranial hypertension.

Abstract No.: 208385

Genetic Association of Attention-Deficit/Hyperactivity Disorder With Thirteen Ocular Disorders

First Author: Xiunian CHEN

Purpose: Although attention deficit hyperactivity disorder (ADHD) is linked to elevated risk of various ocular disorders, their genetic association and causality remain unclear.

Methods: This study performed linkage disequilibrium score regression (LDSC) and pleiotropic analysis under composite null hypothesis (PLACO) to explore genetic associations, and bidirectional mendelian randomization (MR) to assess the causality between ADHD and thirteen ocular disorders.

Results: LDSC showed ADHD genetically correlated with corneal ulcer, keratitis, blepharochalasis, lacrimal system disorders, senile cataract, retinal vascular occlusion, and age-related macular degeneration. MR revealed genetic liability to ADHD increased the risk of corneal ulcer (OR = 1.18, FDR adjusted P = 0.01), keratitis (OR = 1.13, P = 0.007), blepharochalasis (OR = 1.23, P = 0.002), and lacrimal system disorders (OR = 1.09, P = 0.04), while decreasing the risk of primary open-angle glaucoma (OR = 0.83, P = 0.003), exfoliation glaucoma (OR = 0.71, P = 0.001), and normotensive

glaucoma (OR = 0.79, P = 0.02). Conversely, genetic liability to strabismus increased ADHD risk (OR = 1.09, P = 0.03). The identification of pleiotropic loci using PLACO suggested that genetic factors played a role in the associations between ADHD and ocular diseases.

Conclusions: This study revealed genetic associations between ADHD and multiple ocular disorders, identifying causal effects of ADHD on an increased risk of corneal ulcer, keratitis, blepharochalasis, and lacrimal system disorders, while showing a protective effect against glaucoma. Conversely, genetic liability to strabismus increased ADHD risk.

Abstract No.: 208428

Genotype–Phenotype Correlation in Enhanced S-Cone Syndrome Caused by a Novel Homozygous Frameshift Mutation in NRL

First Author: Yuanyuan **LIU**

Co-Author(s): Jie **CHEN**, Ying **CHEN**, Xiaoman **LI**, Xuhong **LUO**

Purpose: This study aimed to describe the genotype and phenotype of Enhanced S-Cone Syndrome (ESCS) caused by a novel NRL frameshift mutation in a Chinese family.

Methods: A Chinese family was recruited for the study. Whole-exome sequencing and Sanger sequencing were utilized to identify the causal mutation. Comprehensive ophthalmic examinations were conducted in the family, including a 12-year-old female proband and her 47-year-old parents. Assessments included best-corrected visual acuity, intraocular pressure, visual field testing, axial length measurement, microperimetry, fundus photography, fundus autofluorescence, and electroretinography (ERG), including specialized blue-light stimulation protocols to assess S-cone function. A literature review on NRL-associated retinal dystrophies was also performed.

Results: Whole-exome sequencing identified a novel homozygous NRL frameshift mutation (c.388_391delinsCAAGGATAATGT; p.Glu130fs) in the proband, who presented with childhood-onset night blindness, hyperopia, decreased visual acuity, moderate visual field defects, peripheral chorioretinal atrophy, macular cystoid changes, extinguished rod ERG responses, and attenuated cone responses. Notably, blue light ERG revealed a markedly enhanced S-cone response, a hallmark feature of ESCS. Both heterozygous parents were asymptomatic clinically, but functional tests revealed mild rod dysfunction and reduced central sensitivity. Literature review indicated that truncated NRL proteins are commonly associated with early-onset and severe AR-RP phenotypes.

Conclusions: This is the first report of a homozygous NRL frameshift mutation in a Chinese family with Enhanced S-Cone Syndrome, expanding the phenotypic

spectrum of NRL-associated retinopathies. The findings highlight genotype–phenotype correlations and underscore the utility of microperimetry in detecting subclinical abnormalities in carriers, providing an important reference for genetic counseling and disease diagnosis.

Abstract No.: 201481

Granulomatosis With Polyangiitis Presented With Optic Neuropathy: A Case Report

First Author: Pei-ying **CHEN**

Co-Author(s): Ming-hui **SUN**

Purpose: To report a case of granulomatosis with polyangiitis presented with optic neuropathy.

Methods: A case report with medical chart review.

Results: An 80-year-old woman visited our hospital for bilateral visual loss. Patient reported her left eye had become blind since many years ago for unknown cause. She started to experience gradual blurred vision over her right eye 5 months ago. Then her right eye went blind 2 months after the onset. There was no light perception over her bilateral eyes when she visited our clinic. Fundus exam revealed optic atrophy over left eye. Her optic nerve over right eye was pale and edematous, with optociliary shunt vessels. Laboratory workup showed elevated level of antinuclear antibodies (1:320) and positive cytoplasmic-anti-neutrophil cytoplasmic antibodies. We arranged brain magnetic resonance imaging, which revealed enhancement over bilateral optic nerves and cavernous sinus, and focal thickening of dura mater. Granulomatosis with polyangiitis was diagnosed. Systematic steroid and rituximab were prescribed. However, since it had been a long time since her visual loss, her vision didn't come back after the treatment.

Conclusions: Although optic neuropathy secondary to granulomatosis with polyangiitis is a rare condition, it could cause severe vision loss or even blindness. Impaired vision could be attributed to either granulomatous compression or ischemic optic neuropathy due to vasculitis. Complete work up would be helpful to identify the underlying cause when patient experienced atypical symptoms and signs of optic neuritis or presented with optic atrophy for unknown cause.

Abstract No.: 206759

Graves' Ophthalmopathy: Insights From A Case With Sight-Threatening Corneal Ulcer in a Tertiary Care Center

First Author: Edianti **RATNINGPOETI**

Co-Author(s): Yasmine Ayu **DWINASTITI**, Sarah Kamiela **JUFFRY**, Dialika **MUZAKKIR**, Heidi Indraswara **SATARI**

Purpose: This report highlights the challenges in managing sight-threatening Graves' ophthalmopathy

(GO) in regions with limited medical facilities and emphasizes the necessity of early intervention to prevent complications.

Methods: A young male with uncontrolled hyperthyroidism since 2023, presented with right eye redness and significant vision loss. Examination revealed visual acuity of light perception on the right eye and 1.0 on the left. Both eyes were proptosis with lagophthalmos. The right eye was hypotropia with limitation in upgaze. It was also hyperemic with an inferior corneal infiltrate. While the left eye was within normal limits. Laboratory results showed a low TSH level of 0.09 mIU/L. The patient was then diagnosed with severe GO complicated by a corneal ulcer on the right eye. Treatment involved antithyroid medication, high-dose steroids, combined antibiotic eye drops and ointments, artificial tears, and lid taping was recommended. Orbital imaging and TSH receptor antibody testing could not be performed due to resource constraints. However, after two weeks of treatment, both ocular condition and visual acuity improved to 2-meter finger counting.

Results: Managing sight-threatening GO is complex and requires a multidisciplinary approach. Despite the unavailability of advanced diagnostics, this patient showed significant improvement in pain and visual acuity after two weeks of treatment.

Conclusions: This case illustrates that even in the absence of advanced diagnostic tools, timely and appropriate treatment, along with continuous antithyroid medication can lead to recovery in patients with GO-related corneal breakdown

Abstract No.: 205239

Hidden Clues: Diagnosing Pediatric Intracranial Tumor Through a False Localizing Sixth Nerve Palsy

First Author: Rizki Adi SANTOSA

Co-Author(s): Dianita GINTING, Rusti HANINDYA SARI, Antonia KARTIKA, Prettylla YOLLAMANDA

Purpose: To report a case of a sixth cranial nerve palsy as a false localizing sign of a pediatric intracranial tumor.

Methods: This case presents a 5-year-old boy who was brought by his parents with the chief complaint of a sudden onset of squint in the past 3 days. He also complained of headache and vomiting. Vital signs were within normal limits. Motor strength of all four extremities was within normal limits. Hirschberg examination showed 7 degrees of esotropia. There was an abduction limitation of -2 in the left eye during eye movement examination. Color vision examination using the Ishihara Test was within normal limits. The light reflex of both eyes was diminished. Posterior segment examination showed bilateral optic nerve head swelling consistent with Frisen scale 4.

Results: Magnetic Resonance Imaging (MRI) showed a fourth ventricular mass measuring 4.8 cm, causing obstructive hydrocephalus. The patient was then referred to the neurosurgery department for consideration of surgical management.

Conclusions: Acute onset of sixth cranial nerve palsy in children should warrant rigorous evaluation to identify a life-threatening condition.

Abstract No.: 207403

Hidden Threat: Headache and Blurred Vision As Harbingers of Superior Sagittal Sinus Thrombosis

First Author: Sangeetha T

Co-Author(s): Prashanth V

Purpose: Cerebral venous thrombosis (CVT) is a rare potentially life-threatening condition characterized clot formation in the cerebral veins, leading to increased intracranial pressure, brain edema, and ischemia. This report unveils Superior Sagittal Sinus Thrombosis (SSST) presenting with papilledema as the first sign.

Methods: A 24-year-old male presented with throbbing headache and blurring of vision in the right eye for one month. The headache was intermittent, moderate to severe in intensity and associated with visual disturbances. Examination revealed visual acuity of 6/12 in the OD and 6/6 in OS with normal anterior segment, bilateral papilledema with no focal neurological deficit. CT brain showed filling defect in superior sagittal sinus. MRV revealed loss of normal flow void signal in the anterior portion of the superior sagittal venous sinus.

Results: Considering the above findings the possibility of CVT with bilateral Papilledema was established and managed with IV Mannitol (150 mL every 6 hours for 5 days), Heparin (5000 IU subcutaneously) for 3 days, followed by oral Acitrom anticoagulation therapy (3 mg, tapered to 1 mg), Optineuron and Homin (Mecobalamin, Pyridoxine, Folic acid) with close monitoring of renal function, serum electrolytes and bleeding manifestation during the course of the treatment. Follow-up assessments showed stabilization of the symptoms and gradual resolution of papilledema.

Conclusions: Superior sagittal sinus thrombosis, although rare, should be considered in the differential diagnoses of headache with visual disturbances, particularly in young individuals. Magnetic resonance venography aids in patients with suspected papilledema to help rule out the presence of cerebral venous sinus thrombosis.

Abstract No.: 203503

Managing Bilateral Septic Cavernous Sinus Thrombosis in a Resource-Limited Remote Island: Experience From Natuna, Indonesia

First Author: Nizma PERMAISUARI

Co-Author(s): Ardyanto FLORENSIUS, Wan Rita MARDHIYA

Purpose: Septic cavernous sinus thrombosis (CST) is a rare but life-threatening condition associated with high morbidity and mortality if not treated promptly. We report a case of bilateral septic CST successfully managed in a resource-limited setting on Natuna, Indonesia's northernmost island.

Methods: A previously healthy 13-year-old boy presented with progressive bilateral orbital swelling following a nasal furuncle. He developed persistent fever, decreased appetite, altered mental status, and marked periorbital oedema. On admission, he was febrile, tachycardic, and tachypneic. Laboratory evaluation revealed leucocytosis, elevated C-reactive protein, and hyponatremia; blood culture was unavailable. Contrast-enhanced orbital CT demonstrated bilateral pre-septal and orbital soft tissue enhancement with pansinusitis. Bilateral cavernous sinus filling defects and dilated ophthalmic veins confirmed septic CST.

Results: The patient was managed with broad-spectrum intravenous antibiotics available locally, systemic corticosteroids, supportive sepsis care including sodium correction, and anticoagulation with intravenous unfractionated heparin under close laboratory monitoring. By day 4 of treatment, his level of consciousness improved markedly with a reduction in orbital inflammation and inflammatory markers. Ophthalmic evaluation revealed incomplete ptosis and restricted extraocular motility in the left eye. Continued monitoring showed no further neurological deficits.

Conclusions: Septic CST remains a rare but devastating condition. Early recognition, timely imaging, and aggressive medical management with broad-spectrum antibiotics and anticoagulation are essential to reduce morbidity and mortality. This case illustrates that, despite the absence of advanced resources, favourable outcomes can be achieved through clinical vigilance, judicious adaptation of available therapy, and multidisciplinary collaboration in remote island healthcare systems.

Abstract No.: 200398

Misery of the Fixed Pupil: A Case Report on Cavernous Sinus Syndrome

First Author: Kashish MODI

Co-Author(s): Parul GUPTA, Amit MEHTANI

Purpose: To find the cause of cavernous sinus syndrome.

Methods: The patient was thoroughly examined, a detailed history was taken, and ocular examination was performed. The patient was also subjected to various blood workups and imaging studies.

Results: The long-standing total ophthalmoplegia cause was found to be a cavernous sinus meningioma.

Conclusions: Cavernous sinus meningioma: Pathology and epidemiology are explained with various management options.

Abstract No.: 203460

Missed Trochlear Nerve Palsy Following Mild Traumatic Brain Injury With Delayed Cerebral Venous Thrombosis: Diagnostic and Therapeutic Challenges

First Author: Shahidatul Adha MOHAMAD

Co-Author(s): Wan Hazabbah WAN HITAM

Purpose: To report a case of post-traumatic trochlear nerve palsy, later complicated by cerebral venous thrombosis (CVT).

Methods: Case report.

Results: A 46-year-old male, a chronic intravenous drug user and smoker, presented with three months of binocular diplopia, worse at near. He sustained a mild traumatic brain injury (TBI) in a motor vehicle accident three months prior and subsequently developed binocular diplopia. However, initial CT brain imaging was unremarkable, and no ophthalmology referral was made at the time. Two days prior to presentation, patient developed generalized headache and projectile vomiting, prompting further neuro-ophthalmic and radiological evaluation. Examination revealed left hypertropia, positive Bielschowsky head tilt test, and Hess charting consistent with left superior oblique palsy. Vision was otherwise not affected, 6/6 in both eyes. The initial fundus exam was unremarkable. Neuroimaging revealed CVT involving the superior sagittal, right transverse, and right sigmoid sinuses. The patient developed a seizure during admission and was treated with enoxaparin, transitioned to apixaban, and empirically covered for cerebral infection. Diplopia was managed conservatively with left eye occlusion. At the two-week follow-up, papilledema was noted, though the patient remained well. The patient declined a lumbar puncture. Infective, coagulation, and connective tissue disease screenings were negative. He opted for discharge against medical advice, declining further investigation or intervention, but agreed to continue oral apixaban.

Conclusions: Early ophthalmic evaluation is vital in trauma-related diplopia, as subtle signs may precede neurological decline. Delayed CVT and papilledema reflect evolving raised ICP, warranting multidisciplinary vigilance.

Abstract No.: 200849**Multimodal Correlation Between MRI-Defined Chiasmal Compression, Optical Coherence Tomography Metrics, and Visual Field Defects in Compressive Optic Neuropathy: A Single-Center Study***First Author: Pei-jane BAIR**Co-Author(s): Ya-feng CHENG*

Purpose: To evaluate the relationship between anatomical compression of the optic chiasm on MRI and structural changes on OCT, and how these correlate with visual field (VF) loss in compressive optic neuropathy (CON).

Methods: In this retrospective, single-center study at Show Chwan Memorial Hospital, 53 patients (mean age: 42.4 ± 16.2 years; 54.7% female) with MRI-confirmed CON between 2014 and 2024 were included. All underwent Humphrey VF testing (24-2 or 30-2) and OCT imaging with peripapillary RNFL, GCL-IPL, and optic disc measurements. MRI variables included tumor volume, vertical chiasmal displacement, and lesion-to-chiasm distance. Correlation and multivariate analyses assessed relationships between MRI-defined compression, OCT parameters, and VF indices.

Results: Chiasmal displacement on MRI correlated with VF mean deviation ($r = -0.52$, $p < 0.01$) and pRNFL thickness ($r = -0.47$, $p < 0.01$). Eyes with severe VF loss ($MD < -10$ dB) showed greater GCL-IPL thinning ($p < 0.05$). Multivariate analysis identified GCL-IPL thickness and chiasmal displacement as independent predictors of VF loss (adjusted $R^2 = 0.62$). Optic disc rim area correlated with visual field index ($r = 0.41$, $p = 0.03$).

Conclusions: Chiasmal compression on MRI significantly correlates with OCT structural changes and VF loss. GCL-IPL and RNFL are reliable indicators of visual dysfunction in CON. Multimodal imaging enhances diagnosis and management planning.

Abstract No.: 201783**Müller Glia-Mediated Protection of Retinal Ganglion Cells From Ethambutol-Induced Neurotoxicity***First Author: Hui-chen CHENG**Co-Author(s): Shih-wei CHEN, Hsien-chia JUAN, Roxanne Hsiang-chi LIOU, An-guor WANG, Yu-hui WONG, Yong-lin YANG, Jenn-yah YU*

Purpose: Ethambutol(EMB)-associated optic neuropathy is the most common toxic optic neuropathy. This study aimed to investigate the neuroprotective roles of Müller glia and their associated growth factors in supporting retinal ganglion cells (RGCs) under EMB-induced toxicity.

Methods: Induced RGC-like cells (iRGCs), differentiated from human induced pluripotent stem cells, and Müller glial cell line MIO-M1 were used as cellular models. A

transwell co-culture system was used to evaluate the effect of MIO-M1 cells on iRGC survival. Candidate trophic factors from MIO-M1 cells were measured by quantitative RT-PCR. Brain-derived neurotrophic factor(BDNF) was identified as the major factor contributing to the neuroprotective effect from Müller glia. Downstream signals of the BDNF pathway were investigated by Western blot.

Results: Co-culture with MIO-M1 cells markedly enhanced the survival of iRGCs during EMB exposure. mRNA of BDNF and nerve growth factor (NGF) were elevated in MIO-M1 cells, while only BDNF improved the survival and morphological integrity of iRGCs under EMB treatment. The pro-survival effect of BDNF was suppressed by a pan-TRK inhibitor. Among the three downstream effectors of BDNF signaling, AKT was most prominently activated by BDNF in EMB-treated iRGCs, compared to ERK and PLC γ 1. Furthermore, the protective effect of BDNF was blocked by the AKT inhibitor but not by the ERK inhibitor.

Conclusions: Müller glia confer neuroprotection to RGCs under EMB-induced stress, primarily via BDNF signaling. AKT functions as the key downstream effector mediating this protective response.

Abstract No.: 206731**Neurofibromatosis Type 1 (NF1)***First Author: Shagun KORLA**Co-Author(s): Aditi BANSAL*

Purpose: Neurofibromatosis type 1 (NF1) is a genetic disorder that affects the nervous system, causing tumors to grow on nerve tissue throughout the body. These tumors, called neurofibromas, can develop anywhere in the body, including the skin, nerves, and other organs. Its manifestations range from mild skin changes to more serious complications involving vision, hearing, and mobility.

Methods: I present case of sixteen year old with lisch nodules in iris, café-au-lait spots, freckling in the armpits and benign growths called plexiform neurofibromas. MRI Brain showed right sphenoid wing dysplasia with herniating middle cranial fossa contents into orbit causing abxial proptosis.

Results: While NF1 is usually diagnosed during childhood, symptoms can appear at any age and may worsen over time.

Conclusions: Although there is currently no cure for NF1, treatment focuses on managing symptoms and complications to improve quality of life for individuals with the condition.

Abstract No.: 207423

Neuromyelitis Optica Spectrum Disorder and Optic Neuritis: A Report of 3 Cases

First Author: Shubham SETHY

Purpose: To know the neuromyelitis optica spectrum disorder, its complications in ophthalmology, and treatment.

Methods: Three cases were referred to our department from the neurology department for decreased vision. We examined the patient, did the necessary investigation, and followed up with the patient in our department.

Results: In the first case, the patient presented with a sudden painless decrease in vision in the right eye, followed by generalized neurological symptoms, followed by a decrease in vision in the left eye. Vision improved in both eyes following treatment with IV methylprednisolone. In 2nd case, the patient presented initially with generalized neurological symptoms followed by gross diminution of vision. Neurological symptoms disappeared following treatment with IV methylprednisolone, but vision could not be regained. In 3rd case, the patient presented with gross diminution of vision and neurological symptoms, which did not improve with treatment due to late presentation.

Conclusions: NMOSD (anti MOG Ab positive), also known as Devic's disease, is a rare neurodegenerative disorder, but optic neuritis is the main characteristic feature. Early diagnosis and treatment are essential to preserve vision.

Abstract No.: 202544

Neurosyphilis Diagnosed on the Basis of Pupillary Abnormalities

First Author: Seira HAYASHI

Co-Author(s): Kie IIDA, Kazusa KUWANO, Tadashi NAKANO, Sei TACHIBANA, Akira WATANABE

Purpose: Neurosyphilis occurs when *Treponema pallidum* invades the central nervous system and can develop at any stage of syphilis. Early diagnosis and treatment are essential because advanced disease can result in locomotor ataxia and progressive paralysis. Here, we report a case of neurosyphilis identified based on pupillary abnormalities.

Methods: Case report

Results: A 23-year-old man was referred for accommodative disturbance in the right eye after bilateral pupillary dilation was detected during an eye examination for a contact lens prescription at another clinic. Brain MRI revealed no abnormalities; however, ocular deviation and motility disturbances developed concurrently. On presentation, visual acuity was 1.0 in the right eye and 1.5 in the left eye. Pupil diameters measured 8.0 mm (right) and 6.9 mm (left), with

weak direct, consensual, and near light reflexes. Right eyelid ptosis was present, with levator function of 8 mm in the right eye and 10 mm in the left eye. The right eye showed limitations in upward, downward, and medial gaze, along with external strabismus. Blood test results were positive for the *Treponema pallidum* antibody and rapid plasma reagin. Contrast-enhanced MRI revealed swelling and enhancement of the right oculomotor nerve. Both pupils exhibited mild constriction after instillation of 0.1% pilocarpine. The patient was treated with high-dose intravenous penicillin G and three courses of steroid pulse therapy, resulting in improvement of pupillary function, ocular alignment, and motility.

Conclusions: With the rising incidence of syphilis in Japan, neurosyphilis should be considered in the differential diagnosis of unexplained pupillary changes.

Abstract No.: 200585

Neurosyphilis: A Case Report

First Author: Leigh Ann ACEDILLO

Co-Author(s): Miriam Louella FERMIN

Purpose: This case report aims to present a 37-year-old male who came in due to photopsia of right eye associated with blurring of vision and nyctalopia

Methods: This is a case report

Results: Patient presented with a visual acuity of HM OD that did not improve with pinhole and 20/20 OS. Disc photo and fluorescein angiography on initial consult on the right eye revealed a hyperemic edematous disc and delay in arm-to-retina transit time. Mid to late phase leakage was also noted on disc margins. Laboratory workup revealed unspecific findings and a reactive serologic test for syphilis, VDRL (Venereal Disease Research laboratory) test, confirming the diagnosis of neurosyphilis. The patient was referred to an Infectious disease specialist for co-management and evaluation. Patient was treated with Methylprednisolone tablets and Aqueous penicillin G 4 million units thru intravenous for 14 days, resulting in significant visual improvement after completion of treatment.

Conclusions: Neurosyphilis is an emerging disease of concern. Syphilis is a progressive disease. This case underscores the crucial importance of early detection, timely treatment, and appropriate referrals in improving disease prognosis and preventing serious complications that may lead to sight or life-threatening consequence.

Abstract No.: 200344**Not Every High Intraocular Pressure is Glaucoma: Unmasking Atypical Idiopathic Intracranial Hypertension***First Author: Ambreen GULL*

Purpose: To highlight the importance of considering Idiopathic Intracranial Hypertension (IIH) in patients presenting with elevated intraocular pressure (IOP), especially in the absence of classic symptoms such as papilledema, and to differentiate such cases from glaucoma.

Methods: We present a case series of four patients diagnosed with IIH, each exhibiting elevated IOP but varying optic nerve head findings. Clinical presentation, fundoscopic examination, neuroimaging, lumbar puncture results, and response to treatment were analyzed.

Results: Case 1 exhibited classic symptoms, including headache and bilateral asymmetric disc edema. Case 2 and Case 3 presented with intermittent blurry vision without headaches or papilledema; one had mild blurring of disc margins, and the other had a hyperemic disc. Case 4 had only headaches and displayed spontaneous venous pulsation without papilledema. All four patients had elevated cerebrospinal fluid (CSF) opening pressure on lumbar puncture and an empty Sella on MRI brain without evidence of a space-occupying lesion. Treatment involved a combination of weight reduction, acetazolamide, oral steroids, and therapeutic CSF drainage, which led to the resolution of disc edema and normalization of IOP in all cases.

Conclusions: IIH should be considered in the differential diagnosis of unexplained elevated IOP, even in the absence of typical symptoms or papilledema. Asymmetric or absent optic disc swelling does not exclude the diagnosis. A high index of suspicion, thorough fundoscopic evaluation, and appropriate neuroimaging are essential for early identification and management to prevent permanent visual impairment.

Abstract No.: 201682**Not Just Optic Neuritis: The First Clue to Paediatric Multiple Sclerosis in a Young Boy***First Author: Kah Suen LENG**Co-Author(s): Chang Feng CHEW, Kogilavaani A/p J Raman @ Jayaraman, Mae-lynn catherine bastion*

Purpose: To report a case of post-infection optic neuritis in children may represent the first manifestation of multiple sclerosis (MS), particularly when supported by Magnetic resonance imaging (MRI) and cerebrospinal fluid (CSF) findings.

Methods: Case report.

Results: A 13-year-old previously healthy boy presented with acute painless left eye visual loss for one week associated with central scotoma following an acute

upper respiratory tract infection a month earlier. Visual acuity was hand movement in the left eye (LE) and 6/9 in the right eye (RE), with a relative afferent pupillary defect in LE. Fundus examination revealed Frisen grade 2 optic disc swelling in LE, while RE was normal. Contrast-enhanced computed tomography of the brain and orbit showed features of left optic neuritis. MRI demonstrated four hyperintense T2 lesions involving the whole length of left optic nerve (ON) until pre-chiasmatic left ON, juxta-cortical white matter, left periventricular region, and right cerebellum. CSF analysis was positive for oligoclonal bands, while aquaporin-4 and anti-myelin oligodendrocyte glycoprotein antibodies were negative. He was treated with intravenous methylprednisolone for five days, followed by an oral prednisolone taper. At one month, vision improved to 6/9 bilaterally, with further follow-up imaging planned.

Conclusions: This case illustrates post-infection optic neuritis as the initial manifestation of pediatric-onset MS in a male adolescent. Awareness is important to facilitate early diagnosis and timely treatment to optimize visual and neurological outcomes.

Abstract No.: 205920**Not Just in the Lungs: A Case Series on the Many Faces of Neurosarcoidosis***First Author: Shu Sim CHONG**Co-Author(s): Li Yen CHAN, Norlina MOHD RAMLI, Shelina OLI MOHAMED, Lakana Kumar THAVARATNAM, Shanathi VISWANATHAN*

Purpose: Neurosarcoidosis is a rare and diagnostically challenging manifestation of sarcoidosis, often presenting with varied neurological and ocular signs. Due to its protean manifestations and the need for histological confirmation, diagnosis is often delayed. We present a case series of five patients with probable or confirmed neurosarcoidosis, highlighting the diagnostic pathways, ocular findings, and treatment responses.

Methods: This is a retrospective descriptive case series of five patients diagnosed with probable or confirmed neurosarcoidosis managed at a tertiary centre between 2016 and 2025. Clinical features, neuroimaging, histological results, and treatment outcomes were reviewed. Diagnosis was based on International Workshop on Ocular Sarcoidosis (IWOS) criteria and expert multidisciplinary consensus.

Results: The cohort included four females and one male. Ocular involvement was present in four cases: two presented with optic neuritis, one with granulomatous uveitis, optic neuritis and dacryoadenitis and another with ophthalmoplegia. One patient presented with isolated cranial neuropathy. Histological confirmation was achieved in three cases via lymph node biopsies demonstrating non-necrotizing granulomatous inflammation. All patients underwent

neuroimaging, with findings suggestive of perineuritis, optic nerve enhancement, or leptomeningeal nodules. Immunosuppressive therapy, including corticosteroids, mycophenolate mofetil, azathioprine, and rituximab, was effective in controlling disease activity. Visual outcomes varied from full recovery to persistent field defects.

Conclusions: Neurosarcoidosis presents with diverse neurological and ocular manifestations, often mimicking other inflammatory or infectious conditions. Early recognition of ocular features and prompt neuroimaging may facilitate diagnosis. Histological confirmation remains crucial where possible, though multidisciplinary clinical-radiological correlation can support probable diagnosis. Long-term immunosuppression is frequently required to achieve disease control and preserve vision.

Abstract No.: 205761

Ocular Tuberculosis- a 49-Year-Old Patient Presenting With Atypical Optic Neuritis: A Case Report

First Author: Kenneth GONZALES
Co-Author(s): Jamie Lynne NARCISO

Purpose: To report a rare case of ocular tuberculosis with atypical neuritis and the challenges associated with its diagnosis and treatment.

Methods: Case report and review of related literature.

Results: This is a case of a 49-year-old female with a history of blurring of vision described as loss of vision (inferiorly) in the left eye. Upon consultation, the patient had a visual acuity of 20/80 on the right eye and 20/100 on the left eye. Initial examination revealed a grade 2 relative afferent pupillary defect on the left eye, with a visual confrontation test described as an inability to identify fingers in the inferior quadrant of the left eye. Fundus exam showed disc edema in both eyes. No treatment regimen was initiated at first. Several laboratory tests and diagnostic imaging were requested. On follow-up, a decline in the visual acuity of her left eye was observed. Infectious work-up showed ANA, and TB Quantiferon tests were both positive. The patient was referred to the Pulmonary and Infectious Disease Services. On subsequent follow-up, the patient was already on anti-tuberculosis medications and oral steroids with noted improvement in visual acuity.

Conclusions: Atypical Optic Neuritis caused by Ocular Tuberculosis is a rare infectious etiology. Diagnosis and management of this disease are challenging due to its unpredictability in its manifestation, especially since the patient did not present with pulmonary manifestations of Tuberculosis. Since Tuberculosis is endemic in the country, a timely diagnosis and treatment would be beneficial to the patient.

Abstract No.: 201231

Oculopharyngeal Muscular Dystrophy Mimicking Seronegative Myasthenia Gravis: A Case Report

First Author: Suntaree THITIWICHIENTERT
Co-Author(s): Puchit SUKPHULLOPRAT

Purpose: To report a rare case of Oculopharyngeal muscular dystrophy (OPMD) presenting as fluctuating ptosis that mimicked myasthenia gravis (MG) and highlight the diagnostic challenges.

Methods: We present a 69-year-old female complaining of fluctuating bilateral ptosis for one year. The patient does not exhibit diplopia, limb weakness, dysphagia, or dysarthria. Examinations revealed bilateral ptosis with no involvement of the cranial nerves. Enhance ptosis, ice pack test, and fatigability tests were positive. Serum anti-acetylcholine receptor antibodies were negative, and repetitive nerve stimulation (RNS) was normal. We postponed the single-fiber electromyogram (SFEMG) because the patient responded well to oral pyridostigmine. Two years later, the ptosis gradually worsened, so we titrated pyridostigmine and started low-dose prednisolone. After increasing the prednisolone dose to 20 mg per day, there was no clinical improvement, so RNS and SFEMG were performed, and the results were found to be normal. Additional family history found that her father had ptosis in his old age, but had passed away.

Results: Genetic analysis showed a heterozygous mutation of the PABPN1 gene, which confirmed a diagnosis of OPMD. We stopped treatment and provided genetic counseling. One year later, the patient started dysphagia. A rehabilitation consultant was brought in to help with swallowing exercises.

Conclusions: Thus, if a patient with a diagnosis of MG experiences a progressive worsening of symptoms while other tests remain normal, it may be necessary to consider OPMD as a differential diagnosis and proceed with a genetic study for confirmation.

Abstract No.: 205598

Oculopharyngeal Muscular Dystrophy-A Disease So Inimical, yet Underdiagnosed

First Author: Srinidhi N
Co-Author(s): Shreya BHADANI, Manisha CHOUDHARY, Matuli DAS, Shrutakirti PARIDA, Aanchal SINGHAL

Purpose: To report a rare case of oculopharyngeal muscular dystrophy.

Methods: A 45-year-old male presented to the eye OPD with progressive bilateral ptosis for 5 years and restricted ocular movements for 3 years. He also reported painful and difficult deglutition, nasal intonation of voice, and generalized weakness with a similar history in 2 siblings and the father. On examination, BCVA: RE - 6/12p, N6; LE - 6/12, N6.

Eyelids showed severe ptosis, pupils were equal and brisk with no RAPD, EOM were restricted in all gazes, and Bell's phenomenon was poor.

Results: Clinical tests, including Ice pack, Fatigue, and Cogan's lid twitch, were negative, reducing the likelihood of myasthenia gravis. Pedigree analysis revealed autosomal dominant inheritance with the father and three children affected. Genetic testing confirmed a pathogenic PABPN1 mutation, establishing the diagnosis of oculo-pharyngeal muscular dystrophy (OPMD).

Conclusions: OPMD, confirmed by genetic testing, remains incurable, with management focused on symptomatic relief of ptosis and dysphagia. Frequently misdiagnosed as myasthenia gravis, it requires high clinical suspicion. Surgical interventions carry 5–15 year recurrence risk and early referral for dysphagia is essential to prevent serious complications

Abstract No.: 206692

Optic Disc Edema as a Multisystemic Warning Sign: Clinical Insights From Mongolia

First Author: Anarsaikhan **NARMANDAKH**

Co-Author(s): Altanzul **TUMURPUREV**

Purpose: This first Mongolian cohort study defines the etiologies, clinical features, and systemic associations of ODE, assessing diagnostic reclassification as a multispecialty challenge.

Methods: We conducted a 5-year retrospective–prospective cohort study with reassessment to evaluate demographics, comorbidities, ocular findings, visual outcomes, and diagnostic reclassification.

Results: Seventy patients (90 eyes) with optic disc edema were analyzed. Demyelinating optic neuritis (36.4%) predominated in younger females, ischemic cases (44.4%) in older patients, and infectious causes (26.9%, syphilis) in males. Inflammatory etiologies were mostly uveitic. Baseline vision was poor, with 20% presenting with profound impairment (Visual acuity (VA) ≤ 20/400). Severe loss (6/120) was most frequent in demyelinating cases (72.2%). Visual recovery was greatest in demyelinating and inflammatory cases, minimal in ischemic cases, with initial BCVA the strongest prognostic factor ($p < 0.05$).

Conclusions: We conclude that optic disc edema shows a diverse age-related etiologic spectrum, with demyelinating and ischemic causes predominating, with differing prognoses and a high burden of infectious (mainly syphilis) and uveitic cases. Initial visual acuity was the key prognostic factor, emphasizing systemic screening and multidisciplinary care.

Abstract No.: 207140

Orbital Apex Syndrome With Meningitis: A Rare and Serious Complication of Herpes Zoster Ophthalmicus

First Author: Phang **YU HUI**

Co-Author(s): Koh **KOON LING**, Melissa **WANG PEI YIN**

Purpose: To report a rare complication of herpes zoster ophthalmicus presenting with orbital apex syndrome (OAS) and meningitis.

Methods: Case report.

Results: A 64-year-old man with diabetes mellitus, hypertension, and ischemic heart disease presented with a one-week history of left ocular pain and reduced vision. Examination revealed vesicular rashes along the ophthalmic division of the trigeminal nerve, proptosis, complete ptosis, anisocoria, ophthalmoplegia, and anterior uveitis. Visual acuity in the left eye was limited to hand movements. Neurological assessment demonstrated lethargy and limb weakness. He had previously received oral corticosteroids for herpes zoster infection without clinical improvement. Cerebrospinal fluid (CSF) analysis showed elevated protein and reduced glucose, while neuroimaging revealed orbital myositis, optic neuritis, and preseptal cellulitis. The patient was treated with intravenous acyclovir and ceftriaxone for two weeks. His meningitic symptoms and ocular inflammation improved; however, vision remained poor, and ophthalmoplegia persisted.

Conclusions: We describe a rare case of herpes zoster ophthalmicus complicated by orbital apex syndrome and secondary meningitis. Despite combined antiviral and corticosteroid therapy, the visual outcome was poor, underscoring the importance of early recognition and prompt, aggressive treatment in such cases.

Abstract No.: 205545

Orbital Myopericytoma Presenting As Optic Atrophy Secondary to Unilateral Compressive Optic Neuropathy: A Case Report

First Author: Huey **JAVIER**

Co-Author(s): Clarissa **TADY**

Purpose: This case report presents a rare case of orbital myopericytoma, a benign vascular tumor typically found in the extremities, presenting as optic atrophy secondary to compressive optic neuropathy.

Methods: A 46-year-old female with a history of 2 years of painless, gradual blurring of vision of the right eye underwent a comprehensive ophthalmologic evaluation, including optical coherence tomography (OCT) of the optic nerve, visual field test (VFT), magnetic resonance imaging (MRI), and surgical treatment. A transnasal endoscopic surgery approach was performed to excise the mass. The diagnosis was established

through histopathologic and immunohistochemical evaluation.

Results: OCT of the right optic nerve revealed marked thinning in all quadrants. MRI revealed a 1.6cm x 1.1cm x 1.5cm enhancing mass lesion in the medial extraconal space compressing the intraorbital segment of the optic nerve. Immunohistochemistry showed positive cells of interest for smooth muscle actin and caldesmon and was negative for other markers (S100 and CD34), confirming the diagnosis of myopericytoma. Postoperatively, the patient's visual acuity improved, which was confirmed by visual acuity testing and VFT.

Conclusions: Orbital myopericytoma is extremely rare with only four cases published to date and should be considered in the differential diagnosis of orbital masses. Complete resection of the mass remains the treatment of choice with a favorable response producing an improvement in the blurring of vision. This is the first case in literature wherein total resection was achieved using transnasal endoscopic approach making this a less invasive alternative to traditional orbitotomy if the tumor's size and location are suitable.

Abstract No.: 202824

Photothermal Modulation of the Regenerative Microenvironment for Reversing Optic Nerve Injury

First Author: Kexin **TAN**

Co-Author(s): Xianqun **FAN**, Jipeng **LI**, Huifang **ZHOU**

Purpose: Optic nerve injury (ONI) is a leading cause of irreversible vision loss worldwide, and currently, no effective clinical treatments exist. Here, we pioneer a novel mild thermal stimulation therapy based on polydopamine nanoparticles (PDA NPs) for ONI reversal.

Methods: PDA NPs were synthesized via oxidative self-polymerization, and their photothermal conversion performance under near-infrared (NIR) laser irradiation was characterized. An optic nerve crush (ONC) rat model was established, followed by intravitreal injection of PDA NPs and NIR irradiation to achieve localized mild photothermal therapy (PTT). Therapeutic effects on optic nerve repair were evaluated at early, middle, and late stages. Furthermore, retinal transcriptomics, along with in vitro and in vivo validation, was conducted to explore underlying mechanisms.

Results: Under NIR irradiation, PDA NPs efficiently converted light energy into heat, maintaining a local temperature favorable for nerve repair ($41.5 \pm 1.1^\circ\text{C}$). PDA NP-mediated PTT significantly enhanced retinal ganglion cells (RGCs) survival, promoted axonal and myelin regeneration, reconstructed neural network architecture, and improved visual function in ONC rats. Mechanistically, PTT reduced excessive reactive oxygen species in RGCs during the acute injury phase and

facilitated a shift of microglia from a hyperactivated state to a repair-adaptive phenotype, thereby mitigating inflammatory responses. During the middle-to-late injury stages, localized warming induced by NIR irradiation modulated astrocyte activity, suppressed aberrant extracellular matrix deposition under fibrotic conditions, and reduced neuroglial scar formation, fostering a pro-regenerative microenvironment.

Conclusions: PDA NP-mediated mild thermal stimulation system reverses ONI-induced neural damage, highlighting a new strategy for optic nerve repair and regeneration.

Abstract No.: 207171

Pre-Operative Magnetic Resonance Imaging Measurements in Sellar Lesions With Chiasmal Compression: Prediction of Visual Outcomes After Transsphenoidal Surgery

First Author: Lai Yu Tony **NG**

Co-Author(s): Yip Mang O, Hei Tung **SHEK**

Purpose: To review the post-operative visual outcomes of sellar lesions with compressive optic neuropathy, and to identify predictors of post-operative visual recovery.

Methods: Patients with sellar lesions causing compressive optic neuropathy that underwent transsphenoidal excision in Queen Mary Hospital from March 2010 to March 2025 were reviewed retrospectively. Patients with other significant ophthalmological conditions and prior radiation/operations to the sellar region were excluded. Uni- and multivariate analyses were performed to determine predictors of improvement in visual outcomes.

Results: Eighty-six patients with pre- & post-op ophthalmological assessment and pre-operative magnetic resonance imaging (MRI) available were identified. Pre-operative visual assessment results, including visual acuity, visual field, colour perception, and evidence of optic atrophy, were documented. Pre-operative MRI measurements, including chiasmal thickness, chiasmal width, chiasmal deformed angle, and suprasellar extension, were taken. Mean surgery waiting time, extent of excision, pathology, and post-operative complications were reviewed. Follow-up visual assessment results (at post-operative six months or latest follow-up, whichever is later) were compared with pre-operative results. Uni- and multivariate analyses were carried out to identify predictors of visual improvement.

Conclusions: Transsphenoidal excision is a safe and effective surgical approach for chiasmal decompression in sizable sellar lesions. Pre-operative MRI measurements may offer early predictive values for post-decompression visual recovery.

Abstract No.: 201979**Preserving Sight, Protecting Life: Idiopathic Intracranial Hypertension in Pregnancy***First Author: Fadhilah ZAINOL ARIFFIN**Co-Author(s): Dian Nadia ABU TALIB, Jemaima CHE HAMZAH, Nurul Ain MASNON*

Purpose: To highlight the clinical dilemma and multidisciplinary approach in managing Idiopathic Intracranial Hypertension (IIH) during pregnancy.

Methods: A case report.

Results: A 25-year-old primigravida with maternal overweight presented with headache associated with vomiting and binocular double vision at 19 weeks of gestation. Examination showed bilateral visual acuity of 6/6, negative relative afferent pupillary defect, and normal optic nerve function tests (ONFT). Anterior segment examination was unremarkable with an intraocular pressure of 10mmHG. Extraocular muscle movement showed limited abduction in both eyes, while funduscopic examination revealed bilateral Frisen grade 3 papilledema with peripapillary hemorrhage. Optical coherence tomography (OCT) showed swollen retina nerve fibre layer. Magnetic resonance imaging and venography displayed no space-occupying lesion or presence of venous sinus thrombosis. Lumbar puncture revealed high CSF opening pressure (OP) of 50cmH2O. As a serial detailed scan showed a normal growing fetus, the patient was started on oral acetazolamide, after explanation regarding the risks and benefits of the treatment. Serial lumbar punctures were done to alleviate her symptoms, which showed a decreasing trend of OP. Her headaches gradually improved and diplopia resolved. Papilledema improved to Friesen grade 1 with intact visual acuity and ONFT. The patient safely delivered a healthy baby at 38 weeks of gestation. Acetazolamide was discontinued after delivery, and the patient remained asymptomatic.

Conclusions: IIH in pregnancy management is particularly complex as practitioners face the dual challenge of safeguarding maternal vision while minimizing risks to the fetus. Multidisciplinary care and individualized treatment strategies are essential in achieving optimal outcomes for both mother and child.

Abstract No.: 202091**Pseudo-Foster Kennedy Syndrome Secondary to Sequential Non-Arteritic Anterior Ischemic Optic Neuropathy: A Case Report***First Author: Fariah OSMAN**Co-Author(s): Md Iftekher IQBAL*

Purpose: To report a rare presentation of Pseudo-Foster Kennedy Syndrome (PFKS) in a middle-aged diabetic male, following sequential non-arteritic anterior ischemic optic neuropathy (NA-AION) in both eyes.

Methods: A 52-year-old male with uncontrolled diabetes presented with sudden, painless visual loss in the right eye for 15 days, with a prior history of similar vision loss in the left eye 10 months earlier. He had no systemic symptoms suggestive of giant cell arteritis or intracranial pathology. Comprehensive ocular examination, including funduscopy, revealed optic disc edema in the right eye and optic atrophy in the left eye. Visual field testing showed altitudinal defects. Blood pressure, ESR, and other systemic investigations were unremarkable. Neuroimaging excluded space-occupying lesions.

Results: The clinical picture, supported by imaging and visual field defects, confirmed the diagnosis of PFKS due to sequential NA-AION. The patient was started on oral vitamin supplementation (thiamine, pyridoxine, mecobalamin, folate) and referred for systemic management of diabetes and dyslipidemia. He was counseled regarding modifiable risk factors, visual rehabilitation, and the importance of long-term follow-up.

Conclusions: Pseudo-Foster Kennedy Syndrome can mimic the true Foster Kennedy Syndrome but occurs without an intracranial mass. High suspicion and exclusion of compressive etiologies are crucial. This case highlights the importance of identifying systemic vascular risk factors and initiating early intervention to preserve residual vision and prevent bilateral severe vision loss.

Abstract No.: 203041**Pulse Corticosteroid Therapy in Traumatic Optic Neuropathy: Visual Outcome Analysis in a Case Series***First Author: Widya ASA'AD**Co-Author(s): Yunita MANSYUR, Batari UMAR*

Purpose: Traumatic optic neuropathy (TON) is a vision-threatening condition caused by optic nerve trauma resulting from blunt injury, penetrating trauma, or optic canal fractures. Treatment options include observation, corticosteroids, erythropoietin therapy, and surgical decompression. However, corticosteroid effectiveness remains controversial.

Methods: This case report presents three patients with indirect TON following head and facial trauma who received high-dose corticosteroid therapy for three days. The first patient experienced retrobulbar hemorrhage and was treated with canthotomy cantholysis. The second and third patients sustained head and facial fractures, however corrective fracture surgery was performed only in the third patient. All three patients showed significant visual acuity improvement.

Results: All patients demonstrated significant visual acuity improvement regardless of corticosteroid administration timing. Corticosteroids reduce

inflammation and edema within the optic canal while providing neuroprotective effects by inhibiting free radical-induced lipid peroxidation. The absence of lateral orbital wall fractures in the second and third patients may have contributed to better outcomes, consistent with studies showing lateral wall fractures are associated with poorer prognosis due to high-velocity force transmission to the optic nerve.

Conclusions: Although TON therapy remains controversial, this case report demonstrates corticosteroid effectiveness in improving visual outcomes. Further research is needed to provide more definitive results.

Abstract No.: 205623

Realigning Hope: A Case Series of Successful Strabismus Surgery in Complex Paediatric Third Cranial Nerve Palsy

First Author: Gebriellea DASS COWIE JOHN
Co-Author(s): Mohamad Israk B ISA, Nor Fadhilah BINTI MOHAMAD, Fhun LAI CHAN

Purpose: Surgical correction for complete 3rd cranial nerve (CN) palsy is always challenging. We present our experience performing complex strabismus surgery using Gokyigit's technique augmented with medial rectus (MR) resection.

Methods: Case series.

Results: Case 1: A 4-year-old girl presented with complete left eye (LE) congenital third CN palsy. LE exhibited marked exotropia of 45 degrees (Hirschberg test). LE Visual Acuity (VA) was 5/60 and Right Eye (RE) 6/7.5. Case 2: A 13-year-old boy with underlying Neurofibromatosis with Parasagittal Meningothelial Meningioma with extension to the Cavernous Sinus. He developed complete left third CN Palsy post debulking surgery. LE VA was 6/18 pH 6/12 and RE VA 6/12 pH 6/12. Pre-operative prism cover test (PCT) was 104 Prism Diopters (PD) Base In (BI). Gokyigit's technique: Transposition of Y Splitting Lateral Rectus (LR) into 15mm to MR insertion. The superior half of LR was sutured at superior border of the MR after passing underneath Superior Oblique and Superior Rectus. The inferior half of LR sutured at the inferior border of MR after passing underneath Inferior Oblique and Inferior Rectus. LE MR Resection of 6.5mm was added. Results: Satisfactory post-operative primary gaze alignment was achieved.

Conclusions: These cases highlight that acceptable aesthetic outcomes can be achieved using the augmented Gokyigit's modification technique.

Abstract No.: 202985

Restoring Daily Function: Successful Botulinum Toxin Treatment for Severe Blepharospasm – A Case Report

First Author: Lukisiari AGUSTINI
Co-Author(s): Ronik Harsono KAMAL, Georgina Tara KRISKASARI, Wahyu Afif MUFIDA, Novita Indah PERMATASARI

Purpose: Blepharospasm is a focal dystonia involving involuntary contractions of the orbicularis oculi muscles, often leading to functional blindness and severely impaired quality of life. Botulinum toxin injection is the gold-standard treatment, though early diagnosis and individualized management are essential for optimal outcomes.

Methods: A 58-year-old woman presented with a one-year history of bilateral eyelid spasms and disabling photophobia, described as difficulty reopening the eyes after blinking. There was no history of ocular trauma, systemic neurological disease, or familial dystonia. Examination revealed best-corrected visual acuity of 6/7.5 bilaterally, with evident eyelid twitching but no other significant findings. Investigations, including antibody testing, nerve studies, and brain MRI, ruled out myasthenia gravis and other secondary causes. MRI showed only age-related microvascular changes.

Results: The patient received bilateral botulinum toxin injections into the orbicularis oculi, along with vitamin B complex, folic acid, and lubricating eye drops. At follow-up, she showed complete resolution of spasms, improved visual acuity (6/6 bilaterally), and restoration of daily function, with no adverse effects.

Conclusions: This case highlights the effectiveness and safety of botulinum toxin for severe blepharospasm. Timely diagnosis and thorough exclusion of secondary causes are crucial. Early, tailored treatment can significantly improve visual function and quality of life.

Abstract No.: 201788

Retinal Microvasculature Changes Correlate With Tumor Characteristics of Sellar Tumor

First Author: Hui-chen CHENG
Co-Author(s): Yu-bai CHOU, Che-han HSU, De-kuang HWANG, Tai-chi LIN, Wen-jung LO, An-guor WANG, Ching-yun WANG, Wei-hsin WANG, Jin-han YANG, Yu-shu YEN

Purpose: Early sellar tumor detection is difficult. We investigated retinal microvasculature changes on optical coherence tomography-angiography (OCTA) in patients with primary sellar tumors, focusing on correlations with tumor characteristics.

Methods: This retrospective cross-sectional study enrolled 62 patients with sellar tumors and 32 healthy controls from November 2017 to July 2019. We recorded the participants' ophthalmological features,

including optical coherence tomography(OCT) and OCTA, endocrine levels, and sellar tumor characteristics. Findings were compared between patients and controls. Multivariable regression analysis evaluated associations between ophthalmological features and tumor characteristics. The area under the receiver operating characteristic curve(AUC) and Akaike information criterion(AIC) were used to evaluate the performance of OCTA-derived features to predict the presence of sellar tumor.

Results: In multivariable regression analysis, the presence of sellar tumors—both overall and with chiasmal contact—was significantly associated with reduced peripapillary vessel density (VD), macular superficial vascular complex (SVC) VD, and macular deep vascular complex (DVC) VD. Non-chiasmal contact sellar tumors were also significantly associated with decreased peripapillary VD and macular SVC VD compared with controls. Presenting visual acuity(VA) correlated with peripapillary retinal nerve fiber layer thickness, macular ganglion cell complex thickness, peripapillary VD, and macular SVC VD. Notably, peripapillary VD demonstrated excellent predictive performance for non-chiasmal contact sellar tumors (AUC = 0.996; AIC = 43.3).

Conclusions: Retinal microvasculature imaged by OCTA correlates with the presence of sellar tumor, tumor characteristics, and presenting VA. Peripapillary VD achieves excellent performance for predicting non-chiasmal contact sellar tumor, which may facilitate early tumor detection.

Abstract No.: 202798

Retinal Microvasculature Changes in Patients Receiving Stenting for Intracranial and Extracranial Arterial Stenosis

First Author: Wei-che **HUNG**

Co-Author(s): Hui-chen **CHENG**, Chia-an **HSU**, An-guor **WANG**

Purpose: The impact of arterial stenosis in the head and neck region on ocular blood flow and its reversibility after stenting remain underexplored. This study investigated retinal microvascular changes in patients with intracranial and extracranial arterial stenosis undergoing stenting.

Methods: This retrospective cross-sectional study included 65 patients with major arterial stenosis and 65 age-matched controls. Patients were divided into four groups according to stenosis location: Group 1 (common carotid artery + extracranial internal carotid artery), Group 2 (intracranial ICA), Group 3 (posterior circulation), and Group 4 (subclavian artery). Macular superficial vascular complex (SVC) vessel density (VD) was measured by optical coherence tomography angiography (OCTA) before and after stenting. Multivariable linear regression model adjusted for age and cardiovascular risk factors was applied to assess

the association between location of stent and the changes of macular SVC VD.

Results: Before stenting, Groups 1, 2, and 4 exhibited significantly reduced macular SVC VD compared with controls ($p < 0.05$), whereas Group 3 showed no difference. After stenting, macular SVC VD was comparable to controls in Group 2 and 3, but remained significantly lower in Group 1 and 4 ($p < 0.05$). All groups except Group 4 showed a trend toward increased macular SVC VD after stenting, compared to pre-stenting. Regression analysis identified intracranial ICA stenting as a significant predictor of improved macular SVC VD ($\beta = 4.36$, $p < 0.05$).

Conclusions: Intracranial and extracranial arterial stenosis adversely affects retinal microvasculature. Stenting of intracranial ICA stenosis significantly improves macular SVC VD, highlighting OCTA as a non-invasive tool for monitoring cerebrovascular interventions in neuro-ophthalmology.

Abstract No.: 203123

Retinal Structure and Microcirculation Alterations in Dysthyroid Optic Neuropathy: A Comprehensive OCTA Study

First Author: Kexin **TAN**

Co-Author(s): Xianqun **FAN**, Yan **LIU**, Huifang **ZHOU**

Purpose: This study aims to compare retinal structure and vessel density (VD) changes in dysthyroid optic neuropathy (DON), and to assess their correlation with visual function.

Methods: A total of 133 thyroid eye disease (TED) patients (63 with DON and 70 without DON) and 24 healthy controls were included. Optical coherence tomography angiography (OCTA) was used to obtain retinal structural and vascular quantitative parameters for the macula and optic nerve head (ONH) regions. Visual function was evaluated in all TED patients, including best-corrected visual acuity (BCVA), visual field (VF), and visual evoked potentials. The diagnostic performance of these OCTA parameters in distinguishing DON was further evaluated using the area under the receiver operating characteristic curve (AUC).

Results: Compared with the NDON group, patients in the DON group exhibited significantly reduced retinal VD in both the macula and ONH, along with a thinner retina in the macula. Reductions were most prominent in macular whole retinal layer (WRL) and superficial retinal layer VD ($P < 0.001$). Retinal VD and thickness positively correlated with BCVA and VF mean deviation. Furthermore, the macular WRL-VD had the highest diagnostic performance for DON (AUC = 0.833) and the combination parameters further improved diagnostic accuracy (AUC = 0.861).

Conclusions: DON patients exhibit retina thinning and reduced retinal VD, which significantly correlate with

visual dysfunction and demonstrate robust diagnostic performance.

Abstract No.: 202075

Risk Factor Stratification of Non-Arteritic Ischemic Optic Neuropathy Based on Atherogenic Indices

First Author: Syntia NUSANTI

Co-Author(s): Rianti Wulandari PRATIWI, Fasya RADILIA, M SIDIQ, Angelina Riadi Alim SUPRAPTO

Purpose: To evaluate the risk based on lipid profile and atherogenic indices in patients with non-arteritic ischemic optic neuropathy (NAION).

Methods: This retrospective descriptive study obtained data from medical records of patients from January 2021 to December 2023. All patients diagnosed with NAION were included. Demographic characteristics and clinical findings, including lipid profiles, were collected. Atherogenic Index of Plasma (AIP), Castelli Risk Index (CRI), and Atherogenic Coefficient (AC) were calculated from standard lipid profile measurements.

Results: Ninety-four patients (mean age 55.4 ± 9.46 years; 56.4 % female) were included in our study. Sixty-nine had unilateral involvement and 42 patients presented with visual acuity $\leq 6/60$. Mean visual field index was 44.7 ± 24.70 % and mean deviation was -19.3 ± 7.18 dB. Fundus examination revealed optic disc edema in 52 patients and atrophy in 42 patients. The mean ganglion cell-inner plexiform layer (GCIPL) thickness was 62.7 ± 13.22 μ m and the median retinal nerve fiber layer (RNFL) thickness was 148.5 (48 - 419) μ m. Most patients were classified as high risk on AIP (76.6%), CR-I (69.1%), CR-II (57.4%), and AC (94.7%).

Conclusions: Atherogenic indices were elevated in most NAION patients. Further studies are needed to evaluate the association between each atherogenic indices and clinical outcomes in patients with NAION.

Abstract No.: 207604

Risk Factors Analysis of Primary Angle Closure Disease

First Author: Dakki SHERPA

Purpose: To determine the risk factors of primary angle closure disease

Methods: A cross-sectional study was done. 82 diagnosed cases of PACD were selected by convenience sampling technique. A complete ocular Examination of all the subjects was carried out. Patient's general characteristics were recorded, AL, ACD and LD measurement was done using ultrasound A scans and analyzed

Results: 82 patients were included in this study. Mean age of PACD was 58.23 with (SD) of 10.25. Out of 82 patients 17 were males (20.7%) and 65 were females (79.3%). Right eyes of PACD patients had 29 (35.4%) of

PACS, 25 (30.5%) of PAC and 24 (29.3%) had PACG. Left eyes had 34 (41.5%), of PACS, 19 (23.2%) of PAC and 21 eyes (25.6%) of PACG. The mean AL of 77 right eyes was 22.19805 (SD .705). The mean central ACD was 2.95 with SD of .407. in right eye. The mean LD was 4.51(SD .507). The mean AL in left eye of PACD was 22.23(SD .772). The mean central ACD was 2.93 (SD .508). The mean Lens diameter was 4.62 (SD.485). There was no statistical significant difference in biometric parameters between both eyes of PACD.

Conclusions: This study reveals that age above 58 years, female gender; short AL, shallow central ACD and thick LD is a risk factor of PACD.

Abstract No.: 204026

Small Cup, Big Risk: Structural and Vascular Insights From Atypical NAION Cases

First Author: Cindy Prajna METTA

Co-Author(s): Bobby Ramses Erguna SITEPU

Purpose: Non-arteritic anterior ischemic optic neuropathy (NAION) is classically described in patients over 60 years old with moderate visual loss and a "disc at risk" characterized by a small cup-to-disc ratio. However, atypical cases may deviate from these features. We report three male patients in their 40s-50s with profound vision loss (<20/200) and small optic cups, to evaluate the potential role of small discs in atypical NAION presentation.

Methods: We retrospectively reviewed clinical records, fundus photographs, OCT, perimetry, and visual outcomes of three patients diagnosed as "atypical" NAION. Particular focus was given to cup-to-disc morphology and systemic vascular risk factors.

Results: All patients exhibited small cup-to-disc ratios consistent with a "crowded disc," supporting its role as a structural predisposition to NAION even in younger patients. The visual acuity was poorer than typically expected in NAION, suggesting that disc morphology may interact with vascular compromise to influence disease severity. These findings raise several considerations: (1) whether small optic discs alone should be regarded as a risk marker for NAION; (2) the need for screening patients with small discs for systemic vascular comorbidities; and (3) whether quantifying crowding (disc crowding index) could stratify NAION risk in clinical practice. Current literature lacks precise estimates of the progression risk from small discs to NAION, highlighting the need for larger prospective studies.

Conclusions: Small cup-to-disc ratio may predispose patients to NAION irrespective of age. Recognition of disc crowding as a structural risk factor could guide early evaluation and systemic management. Integrating vascular risk tools such as the ASCVD score with optic disc evaluation may enable earlier identification of at-risk patients and prevent severe vision loss.

Abstract No.: 201843**Study on the Protective Mechanism of Cassia Seed Extract Against Retinal Ganglion Cell in Steroid-Induced Glaucoma***First Author: Liyang ZHANG*

Purpose: To investigate whether Cassia seed extract (CSE) can prevent glucocorticoid (GC)-induced retinal ganglion cell (RGC) loss and to elucidate the underlying molecular mechanisms.

Methods: A rat model of steroid-induced glaucoma (SIG) was established by subconjunctival injection of GC for prolonged exposure. Animals were assigned to GC exposure alone, GC + CSE treatment, and matched control groups. Retinal morphology (RGC density and organization). Protein or gene expression levels of key pyroptotic pathway molecules (NLRP3, Caspase-1, GSDMD, IL-1 β , IL-18).

Results: 1. GC exposure alone caused marked RGC degeneration, disorganized RGC arrangement, and impaired retinal function. 2. GC exposure significantly up-regulated the NLRP3/Caspase-1/GSDMD pathway and downstream inflammatory cytokines IL-1 β and IL-18. 3. CSE administration effectively reversed these alterations: RGC morphology and density were preserved; Up-regulation of NLRP3, Caspase-1, GSDMD, IL-1 β , and IL-18 was significantly suppressed.

Conclusions: Cassia seed extract protects against GC-induced retinal damage by inhibiting the NLRP3/Caspase-1/GSDMD-mediated pyroptotic pathway in RGCs, thereby offering a promising neuroprotective strategy for steroid-induced glaucoma.

Abstract No.: 208365**Supporting Diabetic Macular Edema Triage Screening by a Deep Learning-Based OCT Image Analysis: a Prospective Study***First Author: Shuyi ZHANG**Co-Author(s): Carmen CHAN, Carol CHEUNG, Anran RAN, Ka Ho SZETO*

Purpose: Retrospective studies have demonstrated artificial intelligence (AI) models can accurately identify diabetic macular edema (DME) from optical coherence tomography (OCT) images. However, prospective evidence studies are yet to assess their performance when integrated into healthcare. We aim to prospectively evaluate the performance of deploying an AI-OCT system in a triage unit of a tertiary eye hospital.

Methods: Our AI-OCT system is a customized AI-powered infrastructure with a user interface, an information management system, and two 3D deep-learning models based on our previously published work: image quality assessment (gradable/ungradable scan) and DME detection (yes/no DME). Individuals with diabetes mellitus (DM) referred to the Triage Unit

of Hong Kong Eye Hospital were recruited. Participants underwent OCT scans, which were analyzed by the AI-OCT system in real-time. Only gradable scans would be further processed by the DME detection model. The performance of the AI-OCT system was measured against human reference standards.

Results: A total of 1,200 eyes from 603 participants with DM were recruited in the Triage Unit. The performance of the image quality assessment model was evaluated, with a sensitivity (SEN) of 99% (95% CI 98%-100%), specificity (SPE) of 80% (70%-87%), and accuracy (ACC) of 98% (96%-98%). Among 1,106 eyes with gradable scans (92%), the AI-OCT system had a SEN of 99% (93%-100%), SPE of 91% (89%-93%), and ACC of 92% (90%-93%) for DME detection.

Conclusions: The AI-OCT system showed good performance for DME triage screening, providing prospective evidence for AI implementation in healthcare.

Abstract No.: 206798**Systematic Review on Ocular Effect of Hypnotic Agents in Healthy Individuals***First Author: Wai Pik LAU**Co-Author(s): Kam Lung Kelvin CHONG, Ka Hei Kenneth LAI, Chi Pui Calvin PANG, Chee Yung Clement THAM*

Purpose: To examine the relationship between hypnotic agents and eye movement behaviours.

Methods: The information sources include PubMed, Scopus and EMBASE. The eligible criteria are studies investigating the clinical outcomes presented after hypnotic agents induction. The study designs would be reports limited to English, after 1972.

Results: General trend of the clinical outcomes of hypnosis showed unusual ocular features such as trance stare, reduced blink rate and pupil size, upward eye rolls, high-frequency vertical flutters, and altered frequency of rapid and slow eye movements. Four research findings (n=73) out of twenty eligible papers (n=2322) mentioned reduced saccade amplitude or slower antisaccades during hypnosis in both highly and minimally hypnotizable individuals, but these effects are neither specific to highly susceptible individuals nor restricted to the hypnotic condition. Highly hypnotizable individuals report greater hypnotic depth after induction, yet significant and reliable differences in eye movements between high and low hypnotizables are lacking. Pharmacological studies investigating hypnotic agents and sedatives (e.g., lorazepam, propofol, dexmedetomidine) document reductions in saccadic velocity, increased latencies, and generalized oculomotor slowing, but such effects appear related to central nervous system depression rather than a unique hypnotic state.

Conclusions: Current evidence does not support the existence of a consistent and reliable ocular markers

for the hypnotic state. Instead, changes in ocular movement are best interpreted as non-specific indices of overall arousal, attention, or compliance.

Abstract No.: 205161

The Comparison Between the Electronic Version of Ishihara Test and the Ishihara Book for Screening Color Vision Deficiency Among Students

First Author: Rahajeng Anugrahing **SALDIANOVITA**

Co-Author(s): Wino Vrieda **VIERLIA**

Purpose: The following study finds the prevalence of colour vision deficiency (CVD) and evaluates the validity of the electronic version of Ishihara compared to the Ishihara book for screening CVD among students.

Methods: This study was a comparative cross-sectional study design conducted on a purposive sampling technique. Participants were first tested with the Ishihara book and then continued with the electronic version by using ColBlindor. Data were analysed using the Statistical Package of Social Science (SPSS), version 23. Sensitivity and specificity tests were used to calculate the accuracy. A chi-square test was used to analyse the data (p -value < 0.05).

Results: Three hundred participants were recruited to the study. A total of 6 participants had CVD, with the distribution of 4 males (3.12%) and 2 females (1.16%). The two testing methods were compared, and the results were 100% for sensitivity and specificity with a p -value < 0.05.

Conclusions: electronic version of Ishihara is a beneficial alternative for screening colour vision deficiencies. The fact that all the research participants—both colour-deficient and normal—were accurately identified implies that this test can be used in society for screening purposes, especially among students. This facility is expected to enable early detection, which will help people with CVD adapt better in daily living, acquire learning techniques that suit them, and determine suitable careers in advance.

Abstract No.: 202114

The Cure That Stole Sight: Reversible Linezolid-Induced Optic Neuropathy — A Case Series

First Author: Gebriellea **DASS COWIE JOHN**

Co-Author(s): Nor Fadhillah **BINTI MOHAMAD**, Fhun **LAI CHAN**, Ahmad **SALEHUDDIN**

Purpose: To highlight the risk of optic neuropathy as a serious adverse effect of linezolid, and how immediate discontinuation of linezolid can reverse visual loss.

Methods: Case series.

Results: Case 1: A 18-year-old lady with multidrug-resistant pulmonary tuberculosis (MDR-PTB) on

linezolid treatment presented with progressive bilateral eyes (BE) blurring of vision (3/60) for one month, headache, nausea, lower limb paraesthesia, and lethargy. Examination showed patchy scotoma and impaired Ishihara test (3/17). Anterior segment was unremarkable with optic disc was mildly hyperaemic and tilted. Neurological examinations were normal. Case 2: A 35-year-old gentleman presented with painless BE reduced vision for 12 days. He was started on linezolid therapy, sensitive to the culture of his intra-abdominal collection. BE visual acuity (VA) was 20/600 and Ishihara test was 1/17. Anterior segment examination was unremarkable, optic nerve was hyperaemic. He had reduced sensation, numbness and tingling sensations over bilateral upper limbs. BE Humphrey Visual Field (HVF) revealed para-central scotoma. A diagnosis of bilateral toxic optic neuropathy secondary to linezolid was made. Results: Within 1 week of linezolid discontinuation, VA and Colour Vision (CV) improved. After 1-2 weeks, • Case 1: VA improved to 6/24 BE with improved CV Right Eye(RE) 11/17 and Left Eye(LE) 14/17 • Case 2: BE VA was 20/20 and fundus revealed reduction in disc hyperaemia. After 3-4 weeks, VA and CV was completely restored in both cases. However, only patient in Case 2 showed residual para-central scotoma and persistent peripheral neuropathy.

Conclusions: These cases highlight the importance of detecting the culprit, linezolid, preventing irreversible visual loss.

Abstract No.: 206929

The Eyes Don't Lie: A Case of Linezolid Toxic Optic Neuropathy in the Philippines

First Author: Marie Lou **GUILLERMO**

Purpose: The most familiar medication to treat pulmonary tuberculosis for Ophthalmologists is Ethambutol. However, with rising cases of multidrug resistant infections, internal medicine specialists have been obliged on prescribing alternative antibiotics such as Linezolid. This drug presents many adverse effects and this case presentation aims to highlight the Ophthalmological aspect of Linezolid's effects.

Methods: A 40 year old Filipino male who is a known case of Multi-Drug Resistant Tuberculosis and treated with Bedaquiline, Pretomanid, Linezolid, and Moxifloxacin experienced sudden onset blurring of vision of the right eye. It was described as central, dim, and non-progressive. He sought consultation at a local health center and was noted to have decreased color vision of both eyes and was subsequently referred to Ophthalmology.

Results: The BCVA of the right eye was 6/30 and 6/6 on the left on first consult. The patient showed strong color vision defect on Farnsworth D15. He had unremarkable OCT of the RNFL of the Optic Nerve Head, Macular Ganglion Cell Layer, and Fundus Photo.

He had a cecentral visual field defect of the right eye. Linezolid was discontinued from his regimen by his primary care physician. The patient on follow up showed improvement of BCVA and color vision.

Conclusions: Optic Neuropathy is one of the few indications to discontinue Linezolid in a MDR-TB case. Multiple case reports in other countries show that visual acuity and color vision recovers spontaneously once Linezolid has been discontinued

Abstract No.: 202213

Tolosa-Hunt Syndrome (THS): A Rare Neuro-Ophthalmologic Disorder Diagnosed Clinically

First Author: Syeda Ghazala SHAHNAWAZ

Purpose: To report a THS case presenting with painful ophthalmoplegia and diagnostic limitations

Methods: A 65-year-old hypertensive female presented with severe headache, blurred vision, binocular diplopia, proptosis of the right eye, mild ptosis of the right upper lid, and peri-orbital swelling. She reported a 6-year history of recurrent similar episodes, intermittently treated with antihypertensive and anti-inflammatory drugs. Clinical examination, visual acuity (VA) testing, slit-lamp evaluation, fundus assessment, and computed tomography (CT) of the brain and orbit were performed.

Results: VA was 6/60 in the right eye and 6/18 in the left eye, improving to 6/36 and 6/12 with correction, respectively. Rightsided anisocoria, marked restriction of extraocular movements in all quadrants of the right eye, conjunctival chemosis in the right eye, and bilateral immature cataracts were noted. Fundus was normal. CT revealed right-sided proptosis and sinusitis but no intraorbital mass or cavernous sinus lesion. Magnetic resonance imaging and angiography could not be performed due to patient financial constraints. She was started on topical prednisolone, nepafenac, and cyclopentolate, along with oral nonsteroidal antiinflammatory drugs. On followup, she showed slight improvement. Neurologist's opinion, based on clinical presentation and steroid response, confirmed THS. Oral prednisolone (tapering dose) and methylcobalamin were initiated. At 2 weeks, significant improvement in headache, diplopia, chemosis, periorbital swelling, ptosis, and proptosis was noted, while best-corrected VA remained stable.

Conclusions: THS is a rare neuro-ophthalmologic disorder. Diagnosis can be made clinically with support from CT and corticosteroid response, preventing unnecessary morbidity

Abstract No.: 202210

Transient Optic Perineuritis: A Rare Harbinger of Graves' Disease

First Author: Fadhilah ZAINOL ARIFFIN

Co-Author(s): Dian Nadia ABU TALIB, Jemaima CHE HAMZAH, Nurul Ain MASNON

Purpose: To highlight a rare case of autoimmune related optic perineuritis (OPN) that resolved spontaneously without steroid treatment in Graves' disease.

Methods: Case report.

Results: A 60-year-old woman presented with two episodes of left central blurring of vision over two weeks duration associated with ocular discomfort during eye movement. On examination, right eye was visual acuity was 6/9, and counting fingers on the left, associated with a grade 3 relative afferent pupillary defect (RAPD) and diminished optic nerve function tests (ONFT). The left eye appears proptosed with slight limitation on elevation. There was presence of inferior scleral show with lid retraction and lid lag on the left eye, with no demonstrable signs of active anterior segment inflammation. Fundus examination of the left eye showed optic disc swelling with the presence of optociliary shunt. Blood investigations were unremarkable except thyroid function test which revealed hyperthyroidism. Magnetic resonance imaging (MRI) confirmed the diagnosis of left OPN, showing enhancement of the optic nerve sheath and prominent cerebrospinal fluid (CSF) space surrounding the nerve. A diagnosis of optic perineuritis secondary to Graves' disease was made thus, treatment for hyperthyroidism commenced. Despite the absence of corticosteroid treatment, the patient demonstrated spontaneous clinical improvement of the left visual functions. Visual acuity, RAPD and ONFT returned to baseline with resolution of left optic disc swelling.

Conclusions: Patients with Graves disease may rarely present with OPN. Spontaneous recovery in autoimmune-related OPN is possible highlighting the importance of individualized management and cautious observation especially when the underlying cause remains unidentified after extensively investigated.

Abstract No.: 200170

Turning the Tide in Pediatric Optic Neuritis: A Rare Case of Myelin Oligodendrocyte Glycoprotein Antibody-Associated Disease

First Author: Nomula Sathwik REDDY

Co-Author(s): Siddharam S JANTI, Hari Kumar S, Raghavendra Rao KOLAVALI

Purpose: To report a rare case of pediatric Myelin Oligodendrocyte Glycoprotein Antibody-Associated Disease (MOGAD) presenting as bilateral optic neuritis, and to highlight the efficacy of early high-dose

corticosteroids and IVIG therapy in restoring visual function.

Methods: A 13-year-old girl presented with a sudden onset of bilateral vision loss, headache, and seizures. Clinical examination revealed bilateral relative afferent pupillary defects and hyperemic optic discs with blurred margins. MRI brain showed T2 FLAIR hyperintensities in the periventricular white matter. CSF analysis showed mild lymphocytic pleocytosis. MOG antibody testing returned positive. The patient was treated with IV methylprednisolone (30 mg/kg/day for 5 days), followed by IVIG (2 mg/kg for 5 days) and a tapering dose of oral steroids.

Results: Initial visual acuity was counting fingers at ½ meter in both eyes. After treatment, vision improved to 6/60 in both eyes, and further improved to 6/6 (right eye) and 6/6 (left eye) at follow-up. Fundoscopy showed complete resolution of optic disc edema. The patient had no relapse during short-term follow-up.

Conclusions: Early recognition and prompt treatment of MOGAD with high-dose corticosteroids and IVIG can result in remarkable visual recovery in pediatric patients. This case emphasizes the importance of considering MOGAD in the differential diagnosis of pediatric optic neuritis.

Abstract No.: 205515

Two Cases of Syphilitic Optic Neuritis Occurring in the Early Stage After Syphilis Infection

First Author: Daisuke NAKAJIMA

Co-Author(s): Rieko FUKUDA, Mayumi KOBAYASHI, Tetsuro OSHIKA, Yoshimi SUGIURA

Purpose: Syphilitic optic neuritis is a rare manifestation, occurring in approximately 0.5–5.1% of syphilis cases, with a median onset of 11 months after infection. We report two cases of optic neuritis that developed relatively early after primary syphilis infection.

Methods: We retrospectively reviewed two male patients diagnosed with syphilitic optic neuritis at our institution. Clinical presentation, ophthalmic and imaging findings, laboratory results, treatment, and outcomes were evaluated.

Results: Case 1: A 66-year-old man presented with fever, right ocular pain, and decreased vision. Best-corrected visual acuity (BCVA) in the right eye was 0.4, with optic disc swelling. Goldmann perimetry showed a right central scotoma and enlargement of the left Mariotte blind spot. MRI revealed perineural inflammation of the right optic nerve. Laboratory tests showed elevated inflammatory markers and positive RPR and TPHA. Early syphilis was suspected, and oral amoxicillin therapy was initiated. After one month, BCVA improved to 0.9 with regression of the right central scotoma and normalization of the left field. Case 2: A 50-year-old man complained of one month of

progressive visual decline. BCVA was 0.5 in the left eye with bilateral optic disc edema and left macular edema. Goldmann perimetry revealed a left central scotoma. MRI was unremarkable. Blood tests were positive for RPR and TPHA, confirming syphilitic optic neuritis. Oral amoxicillin therapy was initiated, and vision gradually improved.

Conclusions: We encountered two cases of syphilitic optic neuritis occurring relatively early after primary syphilis infection. Syphilis should be considered a potential cause of optic neuritis.

Abstract No.: 205782

Unmasking Ocular Myasthenia Gravis in a Patient With Longstanding Thyroid Eye Disease

First Author: Dianita Veulina GINTING

Co-Author(s): Antonia Kartika INDRIATI, Rusti Hanindy SARI, Niluh Putu Ayu Dewi WARDHANI, Prettylla YOLLAMANDA

Purpose: To report a rare coexistence of thyroid-associated ophthalmopathy (TAO) and ocular myasthenia gravis (OMG), emphasizing the diagnostic challenges and importance of recognizing dual pathology.

Methods: A review of clinical history, ophthalmic findings, laboratory investigations, imaging, and treatment response in a patient with TAO and OMG.

Results: A 57-year-old woman was diagnosed with hyperthyroidism in 2021 and treated with thiamazole and propranolol. She later presented with blurred vision in the left eye. On examination, best-corrected visual acuity (BCVA) was 0.8 OD and 1/300 OS. Bilateral ptosis with compensatory frontalis activity was observed, along with exophthalmos predominantly in the left eye (Hertel: 22–112–23), restricted ocular motility, and mature cataract OS. Stare and ice pack tests were positive. Thyroid function tests (FT4, T3, TSHS) were within normal limits. Computed tomography of the orbits revealed bilateral exophthalmos characterized by enlargement of orbital fat compartments without significant extraocular muscle belly or tendon involvement, consistent with Type 1 fat-predominant TAO. Serology showed positive acetylcholine receptor antibody. The patient was diagnosed with mild inactive TAO, OMG, mature senile cataract OS, and pseudophakia OD. Cataract extraction OS was performed, resulting in postoperative BCVA improvement to 0.8. Medical management with pyridostigmine 60 mg three times daily produced marked improvement in ptosis and ocular motility.

Conclusions: This case highlights the coexistence of TAO and OMG, a diagnostic challenge in patients presenting with fluctuating ptosis and diplopia. Comprehensive evaluation and confirmatory testing are essential for accurate diagnosis. Timely recognition

with adequate management can significantly improve visual function and quality of life.

Abstract No.: 205261

Utility of 15-Minute VEP in Mild Optic Neuritis Diagnosis: Case Report of a Young Cricketer

First Author: Prasan **WARNAKULA**

Co-Author(s): Thilina **MUNASINGHE**, *Rythmi* **RAGUNATHAN**, *Dushyantha* **WARIYAPOLA**

Purpose: To highlight the diagnostic value of the 15-minute Visual Evoked Potential (VEP) study in detecting subtle conduction delays of the optic nerve in a case of mild optic neuritis with otherwise normal clinical and laboratory findings.

Methods: A 20-year-old cricketer presented with blurred vision in the right-eye for six days. There was no Relative Afferent Pupillary Defect(RAPD). Bilateral anterior and posterior segment examinations were normal. FBC, ESR and CRP levels were within normal ranges. Given the normal results from these investigations, a VEP study was performed

Results: The Pattern VEP1.0 degree study showed bilateral P100 amplitudes and implicit times within normal range. However, the 15-minute study revealed a delay in P100 implicit time with normal amplitude levels in the right-eye. Compared to the left-eye, P100 amplitudes were reduced in the right-eye, while the left-eye had normal P100 amplitudes and implicit times. These electrophysiological findings indicated mild to moderate conduction delay in the right optic nerve, suggesting a diagnosis of right-eye optic neuritis.

Conclusions: The VEP study identified subtle conduction delays in the right optic nerve, confirming the optic neuritis diagnosis. This highlights the importance of VEP in detecting even mild optic neuritis and the diagnostic workup for patients with unexplained visual symptoms, particularly when other tests return normal results.

Abstract No.: 207150

Visual Disturbances With Headache: When an Intracranial Tumor Comes in Mind

First Author: Elisa **YOPITASARI**

Purpose: To highlight the importance of suspecting an intracranial tumor in patients with visual disturbances and accompanying headache.

Methods: A case report of a 36-year-old woman who had months of visual disturbances and unexplained headache.

Results: The patient complained of 6 months of unimproved visual disturbances and mainly left-sided headache after some previous visits to internists and ophthalmologists. Initial assessment showed visual acuity of RE 20/100 and LE 4/60. The best corrected

visual acuity of the right and left eyes is 20/20 and 20/60, respectively. There was left eye RAPD, decreased colour vision and contrast sensitivity mainly on left eye and limitation on the peripheral visual field that showed homonim hemianopia pattern. Other external, ocular motility, and fundus findings were within normal limits. Further anamnesis of the unmarried woman revealed an amenorrhea condition for 8 months with decreased levels of pituitary hormones after visits to a gynaecologist. CT Scan with contrast showed a 38x45x56 millimeter-sized intrasellar mass with intrasellar and suprasellar extension and homogeneous enhancement after contrast. She was then referred to the Neurosurgery Department and had a transcranial tumor resection and histopathologic examination that revealed a pituitary adenoma. Multi-disciplinary management with a gynaecologist and an endocrinologist was involved post-surgery.

Conclusions: Uncorrected blurred vision accompanied by chronic headache might suggest an alarming condition of an intracranial tumor. Thorough examination of other ocular and systemic symptoms, along with a multi-disciplinary workup, should be done to determine the most definitive treatment to prevent more devastating compressive effects.

Abstract No.: 202363

Visual Outcome of Paraocular Dexamethasone Treatment in Non-Arteritic Anterior Ischemic Optic Neuropathy: Case Report

First Author: Jing **LI**

Purpose: Nonarteritic anterior ischemic optic neuropathy (NAAION) is a prevalent vascular disease that often leads to significant visual acuity loss in patients. Systemic steroids and intravitreal triamcinolone injection are associated with a range of side effects.

Methods: In this report, we present two cases of NAAION patients who underwent parabolbar injection of dexamethasone (5 mg) every 3 days for a duration of 5 weeks. These patients demonstrated substantial visual acuity improvement without experiencing any adverse effects.

Results: Based on our case report, dexamethasone parabolbar injection appears to be a safe and effective intervention for NAAION patients, offering a potential alternative to systemic glucocorticoids and intravitreal triamcinolone injection as a therapeutic approach.

Conclusions: The administration of dexamethasone through parabolbar injection offers new possibilities for treating NAAION in the acute phase. The significant visual benefits observed in this case report provide hope for patients suffering from this blinding disease. Dexamethasone parabolbar administration may serve

as an alternative therapy to systemic glucocorticoids and intravitreal triamcinolone injection.

Abstract No.: 205685

When Hormonal Whispers Ignite Neurological Storms

First Author: Shreya BHADANI

Co-Author(s): Manisha CHOUDHARY, Srinidhi N, Shrutakirti PARIDA, Somyashree SAMAL, Aanchal SINGHAL

Purpose: To present a rare case of neuromyelitis optica spectrum disorder (NMOSD) in a young woman, potentially precipitated by hormonal fluctuations

Methods: 26-year-old woman presented with progressive diminution of vision in left eye for 1.5 months, preceded by neck pain, vomiting, and weakness. She had history of oral contraceptive use for two years, discontinued six months earlier, followed by spontaneous abortion at six weeks of gestation. On examination, left eye BCVA was counting fingers at 2 meters, with Grade 3 RAPD and sensory exotropia. Fundus evaluation revealed optic nerve pallor in left eye, while right eye was normal. Neuroimaging demonstrated T2 hyperintensities with contrast enhancement involving left optic nerve, optic chiasma, and bilateral optic tracts. Cervical spine MRI showed patchy hyperintensities extending from C2 to C4. Serum aquaporin-4 antibody was positive, while MOG antibody was negative. Visual evoked potential revealed prolonged P100 latency in left eye. Other autoimmune markers were negative, except for borderline elevated anti-Ro.

Results: Diagnosis of seropositive NMOSD with sensory exotropia was established. Patient received intravenous methylprednisolone followed by tapering course of oral steroids, calcium and PPI supplementation. Due to poor visual response, intravenous immunoglobulin was administered, after which therapy was escalated to Rituximab. At 2-week follow-up, no significant visual improvement was observed.

Conclusions: NMOSD may present unilaterally and carries poor visual prognosis despite aggressive therapy. Hormonal factors, including pregnancy and contraceptive use, may serve as potential disease triggers. Early recognition, timely initiation of immunosuppressive therapy, and interdisciplinary management are critical to reduce the risk of irreversible visual and neurological disability.

Abstract No.: 206823

When Optic Neuritis Isn't What It Seems: A Case of Ocular Syphilis

First Author: Fanda Aviesta MINHALINA

Co-Author(s): Lukisiari AGUSTINI

Purpose: Ocular syphilis in individuals with HIV can occur at any stage of infection and may cause severe

visual impairment. Its broad clinical spectrum often mimics other inflammatory ocular conditions, including optic neuritis, leading to delayed diagnosis.

Methods: A 28-year-old woman presented with a one-month history of progressive bilateral blurred vision, beginning in the right eye and later affecting the left. Best-corrected visual acuity was 6/21 (right eye) and 6/15 (left eye). Color vision was markedly reduced in the right eye (2/38) while normal in the left (38/38). Fundoscopy revealed bilateral hyperemic discs with blurred margins. Optical coherence tomography (OCT) showed disc edema with increased peripapillary retinal nerve fiber layer thickness and a lamellar macular hole, characterized by irregular foveal contour and an intraretinal hyporeflective cavity, with preserved outer retinal layers.

Results: In this case, she was initially treated with intravenous methylprednisolone (250 mg four times daily for 5 days), with partial improvement. Two weeks later, she developed a maculopapular rash on the palms and soles. Serologic tests confirmed secondary syphilis (TPHA 1:2560, reactive VDRL/RPR), and HIV testing was positive (CD4 count 405 cells/ μ L). Intravenous Penicillin G was administered thrice weekly. At two-month follow-up, visual acuity and color vision improved significantly. Repeat OCT demonstrated spontaneous resolution of the lamellar macular hole with restoration of foveal architecture.

Conclusions: Beyond emphasizing early recognition and treatment to prevent irreversible visual loss, it also illustrates a rare instance of spontaneous resolution of a lamellar macular hole following appropriate therapy, making this an unusual presentation of ocular syphilis.

Abstract No.: 202872

When Ptosis Points to the Pituitary: Pituitary Apoplexy Presenting As Isolated Third Nerve Palsy

First Author: Yi Lin CHUA

Co-Author(s): Mahani BINTI MASTOR, Penny Poi Wah LOTT, Woan Shian SEE, Cheun-seng WONG

Purpose: To describe a rare presentation of pituitary apoplexy where the initial manifestation was isolated oculomotor (third cranial) nerve palsy.

Methods: Case report.

Results: A 39-year-old male with no prior medical history presented with a three-day history of left ptosis, diplopia, blurred vision, and throbbing headache. Examination revealed complete left-eye ptosis and dilated pupil with impaired efferent pupillary function. Extraocular movement showed limitation of elevation, depression, and adduction over the left eye. Visual acuity, fields, and anterior/posterior segment examinations were unremarkable. The remaining cranial nerves and neurological functions were intact. Magnetic resonance imaging showed

a 2.7-cm lobulated solid–cystic sellar lesion with haemorrhage, calcification, peripheral enhancement, and mass effect compressing the optic chiasm and partially encasing the left cavernous internal carotid artery. The patient underwent transsphenoidal excision with neurosurgical collaboration. Intraoperatively, the lesion was soft, greyish, moderately vascular, and haemorrhagic. Histopathology confirmed a pituitary adenoma with chromophobic to weakly acidophilic cells, haemorrhage, infarction, mild pleomorphism, and an intermediate proliferative index (Ki-67 ~20%). Immunohistochemistry demonstrated growth hormone and follicle stimulating hormone positivity, consistent with infarcted pituitary adenoma. The diagnosis of pituitary apoplexy was established based on clinical, radiological, and pathological findings. Unfortunately, the patient developed postoperative pulmonary embolism and succumbed.

Conclusions: This case illustrates a rare neuro-ophthalmic presentation of pituitary apoplexy manifesting initially as isolated oculomotor nerve palsy. Prompt recognition of such atypical features is essential to facilitate early diagnosis and intervention, potentially reducing ocular morbidity and life-threatening systemic complications.

Abstract No.: 201023

When the Eyes Speak: Optic Disc Swelling as a Clue to POEMS Syndrome

First Author: Deying **YU**

Co-Author(s): Sabrina **ABU HASSAN ASAARI**, Kelvin **CHONG HAN NGIE**, Yi Wen **LIM**

Purpose: To report a rare case of POEMS syndrome with bilateral optic disc swelling.

Methods: Case report

Results: A 33-year-old gentleman presented with progressive peripheral neuropathy, recurrent falls and weight loss. He denied experiencing blurring of vision or headache. Best corrected visual acuity was 6/6 bilaterally with normal optic nerve function tests. Fundoscopy revealed bilateral optic disc hyperaemia with sectoral oedema. A comprehensive workup revealed he fulfilled both major diagnostic criteria. Demyelinating sensorimotor polyneuropathy was detected on nerve conduction studies and EMG, whereas monoclonal plasma cell disorder was identified by presence of monoclonal IgG Lambda paraprotein (M-protein 3.8g/L), and elevated vascular endothelial growth factor (VEGF) at 1200pg/mL (> 700pg/mL). Minor criteria present included sclerotic bone lesions (ribs and humerus), hepatosplenomegaly, endocrine abnormalities (elevated TSH), hypogonadism (low testosterone, elevated prolactin) and monoclonal gammopathy on bone marrow biopsy. These findings, together with systemic features, led to a diagnosis of POEMS syndrome. He was initiated on chemotherapy with Bortezomib, Lenalidomide and Dexamethasone

(VRD) under haematology. Supportive ophthalmic management started with oral acetazolamide, while co-management with endocrine and rehabilitation was established for blood glucose monitoring, hormonal panels and bone protection measures. Over 4-6 weeks, his disc parameters improved on Optical Coherence Tomography (OCT). His visual function remained preserved throughout treatment.

Conclusions: POEMS syndrome is a rare cause of bilateral optic disc swelling with polyneuropathy. Early recognition and multidisciplinary interventions are essential to prevent irreversible neurological and visual complications.

Abstract No.: 203980

mtDNA12811 Mutation Causing Leber Hereditary Optic Neuropathy: A Case Report

First Author: Nian **TAN**

Co-Author(s): Yanru **CHEN**, Xunwen **LEI**

Purpose: Leber hereditary optic neuropathy (LHON) is a genetic disorder caused by mitochondrial DNA (mtDNA) mutations. This paper reports a case of LHON caused by the m.12811 T>C mutation, summarizing the clinical presentation, disease characteristics, and treatment.

Methods: Retrospective case study.

Results: Mitochondrial mutation gene testing confirmed the presence of the m.12811 T>C mutation, establishing the diagnosis of LHON. The patient's father was wild-type, while her brother also carried the mitochondrial DNA mutation. Treatment included idebenone tablets, cytidine diphosphate choline sodium capsules, and methylcobalamin tablets. Currently, the patient exhibits RAPD (+) in the left eye, left eye visual acuity HM/10cm, right eye corrected visual acuity 1.0, and limb muscle strength grade 5. Regular outpatient follow-ups are scheduled to monitor disease progression.
