Results: Retinal damage and ganglion cell apoptosis were observed at day 1, worsening by day 7. At day 1, mice displayed anxiety- and depression-like behaviors, including reduced center time ($\downarrow 29.34\%$), fewer open-arm entries ($\downarrow 67.65\%$), and increased immobility ($\uparrow 23.44\%$) (all $P < 0.01$). Neurochemically analyses of the brain revealed reductions in glutamine (Gln)/glutamate (Glu)- γ -aminobutyric acid (GABA) and tricarboxylic acid (TCA) cycle metabolites, with significant decreases observed in the frontal cortex, including Glu₄ ($\downarrow 28.12\%$), Gln₄ ($\downarrow 68.58\%$), GABA₂ ($\downarrow 39.55\%$), aspartate₃ ($\downarrow 54.99\%$), and succinate ($\downarrow 33.36\%$), and in the temporal cortex, including Glx (Gln+Glu)₃ ($\downarrow 16.93\%$), GABA₃ ($\downarrow 41.57\%$), and succinate ($\downarrow 17.52\%$) (all $P < 0.05$). By day 7, most parameters returned to baseline, except for increased Gln₄ in the parietal cortex and GABA₄ in the temporal cortex ($P = 0.001$).

Conclusions: Collectively, our findings revealed transient, synchronized changes in mood and Gln/Glu-GABA and TCA cycle metabolites following RIRI, providing compelling evidence of the eye-brain connection and highlighting the need for timely emotional health management in RIRI-related disorders.

Abstract No.: 204555

Faricimab for Polypoidal Choroidal Vasculopathy: One-Year Ethnically Chinese Subgroup Results From Phase-3b/4 SALWEEN Trial

First Author: Ming **ZHANG**

Co-Author(s): Ruobing **BAI**, Gemmy **CHEUNG**, Timothy Y.y. **LAI**, Philippe **MARGARON**, Anh **NGUYEN DUC**

Purpose: Faricimab, a dual angiopoietin-2/vascular endothelial growth factor-A inhibitor and the first bispecific intraocular antibody, showed rapid/robust disease improvement in Asian PCV (polypoidal choroidal vasculopathy) patients in the SALWEEN (ISRCTN69073386) trial. One-year efficacy, safety, and durability of faricimab in the SALWEEN ethnically Chinese cohort is reported here.

Methods: Ethnically Chinese patients with macular PCV in the SALWEEN trial ($n=49$) received four initial Q4W (every-4-week) doses of faricimab-6.0mg, followed by Q8W/Q12W/Q16W based on W20(week-20)/W24 disease activity assessments. At W44/W48 through W104, patients followed a treat-and-extend-regimen (Q8W–Q20W). The primary endpoint was the change

from baseline in BCVA (best-corrected visual acuity) over W40–W48.

Results: Mean (SD [standard deviation]) baseline ocular characteristics were: BCVA: 63.1(12.6) letters; CST (central subfield thickness): 440.0(198.3) μm . Adjusted mean (95%CI [confidence interval]) changes from baseline in BCVA and CST averaged over W40/W44/W48 were +8.1 (+5.2, +11.1) letters and -117.7 (-159.5, -75.9) μm , respectively. At W48, 75.0% patients had no intraretinal/subretinal fluid (baseline:16.3%). Among patients' eyes with baseline polypoidal lesions confirmed by the central reading center and examined at W48, 59.4% (19/32) had complete closure of polypoidal lesions, and 87.5% had inactive polypoidal lesions. Treatment interval of $\geq$ Q12W was achieved in 87.2% patients at W20/W24/W28 (70.2% of those achieved Q16W) and 76.1% patients at W44/W48 (54.3% of those achieved Q20W). Faricimab is well tolerated through W48 with no new safety concerns.

Conclusions: One-year results from the SALWEEN ethnically Chinese cohort are similar to the SALWEEN one-year primary results and elucidate faricimab's long-term efficacy, safety, and durability in this patient subgroup with PCV.

Abstract No.: 202402

Faricimab for Polypoidal Choroidal Vasculopathy: One-Year Results From the Phase-3b/4 SALWEEN Trial

First Author: Paisan **RUAMVIBOONSUK**

Co-Author(s): Ruobing **BAI**, Gemmy **CHEUNG**, Anh **NGUYEN DUC**, Timothy **LAI**, Philippe **MARGARON**

Purpose: Faricimab, a dual Ang-2/VEGF-A (angiopoietin-2/vascular endothelial growth factor-A) inhibitor, is the first bispecific antibody for intraocular use. W16 (Week-16) results from phase-3b/4, multicenter, open-label SALWEEN(ISRCTN69073386) trial in Asian patients with PCV (polypoidal choroidal vasculopathy) showed rapid/robust disease improvement with faricimab. One-year efficacy, safety, and durability of faricimab in this population will be updated.

Methods: Patients with macular PCV ($N=135$) received four initial Q4W (every-4-week) doses of faricimab 6.0mg, followed by Q8W/Q12W/Q16W based on W20/W24 disease activity assessments. At W44/W48 through W104, patients followed treat-and-extend-based regimens (Q8W–Q20W). Primary endpoint is change from baseline in BCVA (best-corrected visual acuity) over W40–W48.

Results: Mean (SD[standard deviation]) patient age is 68.6 (8.3) years; 63% (85/135) are male. Mean (SD) baseline ocular characteristics are: BCVA: 64.4 (11.3) letters; CST (central subfield thickness): 417.0 (155.2) μm ; polypoidal lesion area: 0.25 (0.26) mm^2 ; total lesion area: 8.1 (6.8) mm^2 . At W16, adjusted mean

(95%CI[confidence interval]) changes from baseline in BCVA and CST were +7.7 (+6.3,+9.1) letters and -142.2 (-157.7,-126.7) μm , respectively. At W16, 80.3% (95%CI:73.8–87.1) patients had no intraretinal/subretinal fluid. Among patient eyes with baseline polypoidal lesions confirmed by the central reading center and examined at W16, 51.0%(51/100) had complete closure of polypoidal lesions, and 86.0% had inactive polypoidal lesions. Faricimab is well tolerated through W16 with no new safety concerns. One-year results, including BCVA-, CST-changes, regressed/inactive polypoidal lesions, treatment durability (Q4W/Q8W/Q12W/Q16W/Q20W interval assignments), and safety will be presented.

Conclusions: One-year results from SALWEEN will elucidate long-term efficacy, safety, and durability of dual Ang-2/VEGF-A inhibition with faricimab in Asian patients with PCV.

Abstract No.: 204527

Four-Year Outcomes of Faricimab in Neovascular Age-Related Macular Degeneration: Safety and Efficacy From the AVONELLE-X Long-Term Extension Trial

First Author: Timothy LAI

Co-Author(s): Ruobing BAI, Arshad M. KHANANI, Shriji PATEL, Veeral SHETH, Yannan TANG

Purpose: We present findings from the two-year, phase-3 AVONELLE-X (NCT04777201) long-term extension trial, evaluating faricimab's long-term safety (primary objective) and efficacy (exploratory objective) in nAMD (neovascular age-related macular degeneration) patients who completed the TENAYA(NCT03823287) / LUCERNE(NCT03823300) trials without treatment discontinuation.

Methods: TENAYA/LUCERNE patients received faricimab-6mg up to Q16W (every-16-weeks) or aflibercept-2mg Q8W. All AVONELLE-X patients received faricimab-6mg up to Q16W using a protocol-defined T&E (treat-and-extend) regimen based on TENAYA/LUCERNE-algorithm. AVONELLE-X had the first 12 weeks of masked monthly visits, followed by open-label study visits required only when faricimab was due, at intervals determined by the T&E-algorithm.

Results: Overall, 1,029/1,188 (86.6%; faricimab-T&E, n=524; faricimab-T&E [prior-aflibercept], n=505) eligible patients enrolled in AVONELLE-X and 868(84.4%) completed AVONELLE-X. Faricimab was well tolerated; only 2.1% discontinued due to AEs (adverse events). AEs were consistent with faricimab's known safety profile; intraocular inflammation occurred in 2.0%, with no cases of retinal vasculitis or retinal occlusive vasculitis. Best-corrected visual acuity remained stable over 2 years, with 75% patients who had $\geq 20/40$ vision at week-48 in TENAYA/LUCERNE maintaining it at the end of AVONELLE-X. Central subfield thickness improvements from TENAYA/

LUCERNE were maintained for an additional 2 years in AVONELLE-X. At the end of 4 years, 78.2% patients were on $\geq$ Q12W faricimab dosing and 63.9% were on Q16W dosing.

Conclusions: AVONELLE-X is the largest nAMD extension study to date. This first report on long-term results with faricimab up to Q16W in nAMD patients confirms its safety, efficacy, and durability over 4 years.

Abstract No.: 204121

Greater Anatomical Improvements With Faricimab vs Aflibercept 8 Weeks After Injections: A TENAYA/LUCERNE Post-Hoc Analysis

First Author: Tai-chi LIN

Co-Author(s): Varun CHAUDHARY, Nicholas DAGINCOURT, Avni FINN, Philippe MARGARON, Shriji PATEL

Purpose: TENAYA/LUCERNE (NCT03823287/ NCT03823300) post-hoc analysis evaluated anatomic outcomes for faricimab vs aflibercept at longer duration after dosing, specifically 8 weeks after each injection during the maintenance phase in treatment-naïve nAMD (neovascular age-related macular degeneration) patients.

Methods: Treatment-naïve nAMD patients (pooled N=1,329) were randomized to faricimab 6.0mg (n=665; Q8W [every-8-weeks] up to Q16W after four initial Q4W doses) or aflibercept 2.0mg (n=664; Q8W after three initial Q4W doses) through a two-year maintenance phase. Changes from baseline in CST (central subfield thickness), maximum PED (pigment epithelial detachment) thickness, and proportion of patients with retinal fluid resolution were compared 8 weeks post-injections#4–#9. All P-values are nominal.

Results: Faricimab-treated patients had greater anatomic improvements at 8 weeks post-injections vs aflibercept-treated patients. Adjusted least square mean changes in CST (95% CI [confidence interval]) were: injection#4 – faricimab (n=621): -176.4 (-183.9,-168.9) vs aflibercept (n=571): -154.2(-161.8,-146.6) μm , $P<0.0001$; injection#9 – faricimab (n=503):-187.6 (-195.6,-179.7) vs aflibercept (n=526): -170.9 (-178.9,-163.0) μm , $P=0.0037$. Adjusted least square mean changes in corresponding maximum PED thickness (95%CI) were: injection#4 – faricimab (n=614): -74.2 (-82.2, -66.2) vs aflibercept (n=568): -57.4 (-65.6,-49.3) μm , $P=0.0038$; injection#9 – faricimab (n=311): -80.2 (-89.4,-71.1) vs aflibercept (n=275): -62.2 (-71.4,-53.1) μm , $P=0.0061$. A higher proportion (95% CI) of faricimab-treated patients had subretinal and intraretinal fluid absence 8 weeks post-injections vs aflibercept-treated patients: injection#4 – faricimab (n=626): 63.4% (59.7%,67.1%) vs aflibercept (n=572): 46.6% (42.6%,50.6%), $P<0.0001$; injection#9 – faricimab (n=502): 64.6% (60.5%,68.6%) vs aflibercept (n=527): 50.3% (46.1%,54.5%), $P<0.0001$.

Conclusions: Faricimab demonstrated greater improvements in CST, maximum PED thickness, and fluid resolution vs aflibercept 8 weeks post-injections during the maintenance phase in TENAYA/LUCERNE, when most faricimab-treated patients were on extended ($\geq$ Q12W) dosing.

Abstract No.: 205932

Herpesvirus-Associated Occlusive Vasculitis Without Retinitis (HOVR)- an Underrecognized Presentation of Viral Uveitis

First Author: Rishika RATHORE

Co-Author(s): Atul ARORA, Vishali GUPTA

Purpose: To describe the clinical features, diagnostic findings, and treatment outcomes of Herpesvirus-associated Occlusive Vasculitis Without Retinitis (HOVR).

Methods: Retrospective case series of 7 patients (12 eyes) with occlusive vasculitis due to HSV, VZV, or CMV. All underwent ultrawide-field fundus photography and fluorescein angiography at presentation. Diagnostic evaluation included PCR from ocular fluids, serum antibody testing, and confocal microscopy when indicated. Treatment consisted of systemic antivirals, oral corticosteroids, and aspirin. Laser photocoagulation was performed for capillary non-perfusion as required.

Results: Seven patients (5 bilateral, 2 unilateral) presented with vision ranging from perception of light to 6/24. Three were immunocompromised (2 HIV, 1 lymphoma). Ocular pain and floaters occurred in two patients each. Prior herpetic disease included anterior uveitis (n=2) and herpes zoster ophthalmicus (n=1). Mean IOP was 18 mmHg (12–30); two required antiglaucoma therapy. Aqueous PCR was positive in five patients (1 HSV, 1 VZV, 3 CMV). Of PCR-negative cases, one had CMV IgG seropositivity, and another had prior herpetic keratouveitis. Confocal microscopy demonstrated CMV-like owl-eye nuclei in one patient. All received systemic antivirals, corticosteroids, and aspirin. Ten eyes required laser for non-perfusion, and one developed neovascularization needing scatter laser. On follow-up, inflammation was controlled in all.

Conclusions: HOVR is a distinct manifestation of herpetic uveitis without retinitis. Recognition and prompt systemic antiviral and corticosteroid therapy can achieve inflammation control and preserve vision, with Fundus fluorescein angiography playing a crucial role.

Abstract No.: 201772

High-Resolution Fluorescein Angiography Generated From Color Fundus Photography Using Deep Learning to Enhance Diabetic Retinopathy Diagnosis and Assessment of Anti-VEGF Therapy

First Author: Rui HUA

Co-Author(s): Xue BAI

Purpose: We developed a deep learning algorithm for high-resolution late Fluorescein angiography (FA) image generation from color fundus photography (CFP) and integrated it with Qwen2.5-Max for comprehensive diabetic retinopathy (DR) management. Additionally, we developed a weakly supervised method to detect fluorescein leakage without manual annotation to evaluate the prognosis of anti-VEGF therapy.

Methods: The Pix2PixHD architecture, enhanced with CBAM and 1/8 downsampling, was trained using a GAN framework. A diagnostic model for proliferative DR (PDR) and diabetic macular edema (DME) was developed, improving accuracy and reliability. The Swin Transformer extended ViT with a hierarchical CNN-like structure for multi-scale feature detection. Integrating SAEM into deep learning models improved image analysis and classification. An anti-VEGF treatment (Faricimab) cohort of DR patients was established.

Results: For CFP-to-FA translation, our 1024×1024-pixel model with CBAM achieved high Vision Transformer (30.08), SSIM (0.8306), and low FID (195.28). For PDR vs NPDR classification, the Swin-Transformer-CBAM-SAEM-Augmix (STCSA) model achieved Accuracy: 0.9710, Specificity: 0.9786, Sensitivity: 0.9285, Precision: 0.9717, F1 score: 0.9712. For DME vs non-DME, it reached Accuracy: 0.8633, Specificity: 0.8434, Sensitivity: 0.8816, Precision: 0.8634, F1 score: 0.8631. Using Qwen2.5-Max, we efficiently obtain image descriptions, diagnoses, and treatment suggestions. Finally, intravitreal administration of Faricimab effectively reduces fluorescein leakage.

Conclusions: Our study optimized Pix2PixHD for efficient CFP-to-FA conversion, offering a non-invasive alternative to traditional FA exams. Furthermore, dual-pathway drug demonstrated superior efficacy in treating retinal edema in DR patients.

Abstract No.: 201010

How Does the Diagnosis of Inherited Retinal Disease Influence Reproductive Decision-Making in Singapore?

First Author: Joanna NG

Co-Author(s): Beau FENNER, Eva FENWICK, Ecosse LAMOUREUX, Netanya SEAH, Anna TAN

Purpose: This cross-sectional study aims to assess factors associated with increased understanding and acceptance of patients with inherited retinal disease

(IRD) towards genetic testing, especially in the context of reproductive interventions.

Methods: This cross-sectional study enrolled adults diagnosed with IRD at the Singapore National Eye Centre (SNEC) and its satellite clinics. Participants completed structured questionnaires to assess understanding of genetic testing, attitudes toward genetic and reproductive interventions, and support for financial subsidies. Statistical analyses involved multivariate logistic regression adjusting for age, gender, ethnicity, family history of IRD, clinical phenotype, and visual acuity. Additionally, we employed stratified analysis to identify factors associated with increased understanding and acceptance.

Results: Of the 216 participants recruited (median age 57.5 years; 85.6% Chinese), retinitis pigmentosa was the most common phenotype (59.7%). Most participants expressed favorable views toward genetic testing (62.5%) and reproductive interventions (56.5% for pre-implantation genetic testing, 58.8% for prenatal testing), although 25.9% reported minimal understanding. Better understanding was independently associated with positive attitudes toward testing and support for its availability and subsidy. Support for PGT and PNT was higher amongst younger, Chinese participants and those with a family history of IRD.

Conclusions: Broadly speaking, Singaporean patients were supportive of genetic testing in all settings, including that of reproductive intervention. Future efforts to increase accessibility, such as implementing telemedicine, expanding genetic counseling services, and providing financial subsidies, could translate this support into meaningful clinical and public health benefits.

Abstract No.: 204406

Hypofluorescent ICGA Spots: Prevalence, Characteristics and Associated Features in Age-Related Macular Degeneration

First Author: Zehua JIANG

Co-Author(s): Hiok Hong CHAN, Chui Ming Gemmy CHEUNG, Kelvin Teo Yi CHONG, Beau FENNER, Noa GILEAD, Chenxi ZHANG

Purpose: To investigate the clinical, structural, and metabolic characteristics associated with late-phase hypofluorescent spots ("Hypospots") on indocyanine green angiography (ICGA) in fellow eyes of unilateral neovascular age-related macular degeneration (nAMD) patients.

Methods: We analyzed fellow eyes of patients with unilateral nAMD enrolled in the Asian AMD Phenotyping Study. Based on multimodal images (color fundus photography [CFP], fluorescein angiography, ICGA, optical coherence tomography [OCT], and

OCT angiography [OCTA]), eyes were classified as Homogenous, Hypospots (hypofluorescent spots $\geq 100 \mu\text{m}$ without corresponding OCT or CFP changes), or Drusen/Reticular Pseudodrusen (RPD). Ocular (visual acuity, intraocular pressure, axial length, subfoveal choroidal thickness, choroidal vascular hyperpermeability, choriocapillaris density) and systemic (demographics, smoking, comorbidities, serum lipids) data were collected. Intergroup comparisons and multivariate logistic regression were performed to identify systemic and ocular factors associated with hypospots, and incident nAMD during follow-up was evaluated.

Results: Of 267 patients screened, 142 eyes were included (mean age 70.8 ± 8.2 years; 70.4% male; 90.1% Chinese), comprising 49 Homogenous (34.5%), 46 Hypospots (32.4%), and 47 Drusen/RPD (33.1%). In the Hypospots group, 52.2% of spots were within the central 3 mm and 47.8% beyond; sizes ranged 100–500 μm , visible from 10–20 minutes on late-phase ICGA. Compared to the Homogenous group, Hypospots had lower total cholesterol (4.31 vs 4.56 mmol/L, $p = 0.039$), lower triglycerides (1.28 vs 1.61 mmol/L, $p < 0.001$), shorter axial length (23.52 vs 24.32 mm, $p = 0.047$), greater choroidal thickness (262.3 vs 227.8 μm , $p = 0.080$), and similar choriocapillaris density (62.7% vs 61.9%, $p = 0.337$), with incident nAMD rates of 0.0% vs 4.1% ($p = 0.94$). Compared to Drusen/RPD group, Hypospots were younger (68.4 vs 75.5 years, $p < 0.001$), had lower cholesterol (4.31 vs 4.84 mmol/L, $p = 0.028$), higher use of lipid-lowering medication (56.5% vs 29.2%, $p = 0.009$), better visual acuity (0.17 vs 0.29 logMAR, $p = 0.012$), greater choroidal thickness (262.3 vs 183.0 μm , $p = 0.006$), higher choriocapillaris density (62.7% vs 58.7%, $p = 0.008$), more frequent polypoidal choroidal vasculopathy (PCV) subtype (78.3% vs 29.2%, $p < 0.001$), and lower incidence of nAMD (0.0% vs 22.9%, $p < 0.001$).

Conclusions: Late-phase ICGA hypofluorescent spots were common in fellow eyes of unilateral nAMD and were associated with systemic lipid alterations and PCV, with OCTA confirming they reflect impaired Bruch's membrane-retinal pigment epithelium (BrM-RPE) transport rather than perfusion defects.

Abstract No.: 202500

Identification and Characterisation of TBX1 as a Novel Candidate Gene for Familial Exudative Vitreoretinopathy

First Author: Liuhui HUANG

Co-Author(s): Sheng CHEN, Yuyao DIAO, Jia LIANG, Luoxian WANG, Peiquan ZHAO

Purpose: Familial exudative vitreoretinopathy (FEVR) is a rare retinal disease with genetic heterogeneity, with known genes accounting for only about 50% of cases. We investigated TBX1 as a novel candidate gene for FEVR and characterized its role in disease pathogenesis.

Methods: Whole-exome sequencing and fundus examinations were performed on 791 FEVR families. In human retinal vascular endothelial cells (HRVECs), lentiviral transfection was transfected to knock down or overexpress TBX1, followed by tube formation and wound closure assays to assess angiogenesis and migration. Transcriptomic changes were analysed by RNA sequencing, with TFBSPred used to predict TBX1 binding sites, and validation performed by real-time PCR and Western blot. Endothelial cell-specific conditional knockout mice (TBX1^{fl/fl} Pdgfr^β-iCre-ER) were generated using the Cre-loxP recombination system and induced with tamoxifen.

Results: Four TBX1 variants (c.928G>A, c.929G>C, c.964C>T, and c.1352A>C) were identified in six FEVR families, all maternally inherited except in Family 1. Clinical features included exudative retinal detachment, retinal folds, peripheral avascular area, and anterior segment abnormalities with onset ranging from 10 months to 9 years. In HRVECs, TBX1 overexpression suppressed wound closure and upregulated HIF3A and VEGFC, whereas knockdown produced opposite effects. The c.928G>A variant further enhanced these changes. TBX1 expression positively correlated with HIF3A and VEGFC protein levels. In vivo, endothelial-specific TBX1 knockout reduced superficial retinal vessel area and tip cell number at postnatal day 3.

Conclusions: TBX1 regulates vascular network formation in HRVECs and contributes to FEVR pathology. The c.928G>A mutation, acting through the TBX1–HIF3A–VEGFC axis, may represent a key pathogenic mechanism.

Abstract No.: 202163

Identifying Microvascular and Neural Parameters Related to Systemic Profiles in Early Type 2 Diabetes With SS-OCTA

First Author: Zhaoxia **ZHENG**

Co-Author(s): Xiaobing **YU**

Purpose: To investigate retinal microvascular and neural changes with swept-source optical coherence tomography angiography (SS-OCTA) in type 2 diabetes (T2DM) with no diabetic retinopathy (NDR), and evaluate their relationships with certain systemic characteristics.

Methods: A total of 113 NDR patients and 61 healthy controls were enrolled in this observational cross-sectional study. Three scan modes, including 6.0-mm macular OCTA, ganglion cell complex (GCC) scan mode, and optic disc OCTA, were performed for all subjects. Relevant OCTA parameters were compared between the two groups, and their discriminative power was determined with receiver operating characteristic (ROC) curves. Correlation and multiple linear regression analysis were performed between OCTA parameters and T2DM-related systemic markers, especially corrected homeostasis model assessment of β-cell

function and insulin resistance (HOMA2-B and HOMA2-IR).

Results: Compared with healthy controls, retinal neural and microvascular parameters were statistically decreased in NDR patients except GCC thickness, and the indicator of radial peripapillary capillaries (RPC) had the highest AUC value (AUC=0.74, P<0.001). C-peptide-related indicators correlated with certain OCTA parameters. Furthermore, multivariate regression analysis determined an independent association between HOMA2-B and OCTA neural and microvascular changes (including GCC and foveal superficial capillaries plexus vessel density), and between HOMA2-IR and RPC density (STD β=-0.29, P=0.001) and RNFL thickness (STD β=-0.24, P=0.009) after adjusting for potential confounders.

Conclusions: Peripapillary parameters, especially RPC, could be a more sensitive and reliable marker of early diabetes. Quantitative analysis demonstrated that OCTA microvascular and neural alterations were affected by T2DM intrinsic mechanisms of decreased β-cell function and insulin resistance.

Abstract No.: 203715

Imaging Characteristics and Longitudinal Follow-Up of Inner Choroidal Fibrosis in Chronic Central Serous Chorioretinopathy

First Author: Saarang **HANSRAJ**

Co-Author(s): Jay **CHHABLANI**, Raja **NARAYANAN**, Niroj **SAHOO**

Purpose: To study Inner Choroidal Fibrosis (ICF) in eyes with chronic central serous chorioretinopathy (CSC) and report long-term changes.

Methods: Records of CSC patients were reviewed to identify eyes with ICF. ICF was divided into morphological types: Type 1 ICF represented hyper-reflective accumulations in the inner choroid without any well-defined margin, while Type 2 ICF represented those with a demarcation line. Clinical and multimodal imaging features were assessed longitudinally.

Results: A total of 39 eyes of 24 patients were identified with ICF. A mean of 1.07 lesions was identified per eye, of which 69% involved the fovea. The patients were followed up for a median period of follow up of 53.4 months. The mean BCVA reduced from (0.68±0.47 logMAR, 20/96) to (0.79 ± 0.45 logMAR, 20/125). Mean BCVA at time of presentation (0.84 logMAR, 20/138 vs 0.52 logMAR, 20/66; p=0.01), as well as at last follow-up (0.89 logMAR, 20/155 vs 0.67 logMAR, 20/94; p=0.07), was worse in eyes with Type 2 ICF as compared to Type 1 ICF. At the last follow-up, complete resolution of CSC was only seen in 5 eyes (12.8% eyes). There was a non-significant decrease in SFCT (456 microns vs 444 microns, p=0.8) and an increase in hypo-fluorescence area on indocyanine green angiography of 4.26 sq. mm over the follow-up

period. Higher duration of follow-up and persistent fluid were associated with an increase in size in ICF on multivariate regression analysis.

Conclusions: ICF in complex CSC was associated with persistent fluid and poor response to therapy.

Abstract No.: 202253

Impact of PDS (Port Delivery Platform With Ranibizumab) in Study Eyes vs Anti-VEGF (Vascular Endothelial Growth Factor) in Fellow-Eyes on Efficacy and Safety Outcomes in Bilateral DME (Diabetic Macular Edema) in Pagoda

First Author: Yi-ting **HSIEH**

Co-Author(s): David **EICHENBAUM**, Jordan M. **GRAFF**, Dominic **HEINRICH**, Robert S. **WIRTHLIN**

Purpose: This post-hoc analysis of Pagoda trial (NCT04108156) in bilateral DME patients randomized to PDS arm compared the efficacy and safety of PDS-100 mg/mL Q24W (every-24-weeks) vs intravitreal anti-VEGF injection in FEs (fellow-eyes) through W112 (week-112).

Methods: Pagoda trial investigated PDS-Q24W vs ranibizumab-0.5mg. This subanalysis comprised PDS-SEs (PDS-treated study-eyes) patients with FE-DME at baseline treated with ≥ 1 intravenous anti-VEGF treatment in FEs (IVT-FE). SEs were anti-VEGF treatment-naïve or had ≥ 6 -month washout; FEs had variable anti-VEGF treatment before study-baseline. Study visits were Q4W; IVT-FE received treatment per the investigator's discretion.

Results: A total of 241 patients from PDS-arm met analysis criteria. Mean (Standard deviation) anti-VEGF injections in IVT-FE through W112 was 12.2 (7.8). In PDS-SE vs IVT-FE, mean best-corrected visual-acuity and central subfield thickness at baseline and W112 were 64.2 vs 69.5 and 74.3 vs 75.2 ETDRS letters, and 497.8 vs 399.1 and 274.5 vs 331.0 μm , respectively. At W112, ≥ 2 -step DRSS (Diabetic Retinopathy Severity Scale) improvement and worsening were 50.2 vs 31.7% and 0.4 vs 4.0% in PDS-SE vs IVT-FE, respectively. Ocular adverse events (endophthalmitis, retinal detachment, vitreous hemorrhage) occurred similarly across PDS-SE and IVT-FE (0.4 vs 0.4%; 0.4 vs 0.8%; 10.0 vs 7.5%, respectively).

Conclusions: In this subanalysis, PDS-SEs and IVT-FEs had similar vision outcomes at W112; however, PDS-treated eyes demonstrated better anatomic control despite unrestricted anti-VEGF availability to FEs. FEs had meaningfully greater DRSS worsening, with similar adverse events in both groups over 2 years.

Abstract No.: 201449

Impact of the Optimization of Surgical Procedure on the Incidence of Endophthalmitis and Associated Patient Outcomes in Port Delivery Platform With Ranibizumab Trials

First Author: Se Joon **WOO**

Co-Author(s): Margaret **CHANG**, Nauman **CHAUDHRY**, Philip **JAYCOCK**, Natasha **SINGH**

Purpose: This retrospective analysis examined the impact of surgical improvements on endophthalmitis incidence and patient outcomes over time in patients receiving PDS (Port Delivery Platform with Ranibizumab) in six clinical trials in the PDS development program from 2016–2024.

Methods: PDS trials include: nAMD (neovascular age-related macular degeneration) – Ladder (NCT02510794), Archway (NCT03677934), Portal (NCT03683251), and Belvedere (NCT04853251); DME (diabetic macular edema) – Pagoda (NCT04108156); DR (diabetic retinopathy) – Pavilion (NCT04503551). Key surgical procedure updates from June 2020 included: traction suture emphasis, atraumatic conjunctiva and Tenon's capsule handling during peritomy and closure, and strict adherence to 3.5mm scleral incision length. Endophthalmitis incidence, vision, and treatment outcomes in all PDS-implanted patients at CCOD (clinical-cutoff-date; Ladder/Archway/Portal:31-January-2024; Belvedere:20-December-2024; Pagoda/Pavilion:15-March-2024) were summarized by implantation before vs after June 2020. Most post-June-2020 implants were in DME/DR studies.

Results: Over 8 years (May 2016 to 2024 CCODs), 1344 patients had received PDS implants (pre-June 2020: n=457, mean follow-up: 4.68 years; post-June 2020: n=887, mean follow-up: 2.45 years). Endophthalmitis was reported in 22 patients (overall incidence: 1.6%) across indications. Endophthalmitis incidence was 2.6% (n=12/457) in patients implanted pre-June-2020, while it was 1.1% (n=10/887) in patients implanted post-June-2020. Before vs after June 2020, outcomes were: lost <5-ETDRS (Early Treatment Diabetic Retinopathy Study) letters or maintained $\geq 20/40$ Snellen: 7/12 vs 7/10; lost ≥ 15 -ETDRS letters: 5/12 vs 1/10; continued PDS-refills: 3/12 vs 8/10.

Conclusions: Overall endophthalmitis incidence in the PDS program over an eight-year period was 1.6%. Implementation of key updates in the PDS development program may be associated with lower endophthalmitis incidence and improved outcomes in endophthalmitis-affected patients.

Abstract No.: 207034

In Vivo Imaging of Cone Photoreceptors in the Human Retina Using a Modified Scanning Ophthalmoscope

First Author: Xinyuan ZHANG

Purpose: This study aimed to evaluate the ability of a modified scanning laser ophthalmoscope (SLO) to visualize the cone photoreceptor mosaic at the central 600 microns of the human retina, providing high-resolution in vivo imaging for assessing retinal health.

Methods: A modified SLO was developed, incorporating ocular aberration correction and enhanced resolution capabilities. A series of 80 images, each with a signal threshold of 400, was captured at 780 nm from five locations within the retina, ranging from 300° nasal to 300° temporal, in 30 healthy volunteers and 20 patients with known retinal conditions. The images were registered with color fundus photos, and cone density and spacing (diameter) within a 60 x 60 µm region of interest were analyzed. These findings were compared to standard data from adaptive optics (AO)-SLO imaging.

Results: The modified SLO provided high-resolution images of the cone mosaic, surpassing conventional imaging techniques. In healthy subjects, the cone density at the foveal center was found to be around 25,000-40,000 cones, aligning with previous histological studies and AO-SLO data. In patients with retinal conditions, cone density variations and irregularities in cone arrangement were clearly detected, which correlated with clinical diagnoses.

Conclusions: The modified SLO, by reducing equipment costs while maintaining high imaging quality, successfully enabled in vivo visualization of cone photoreceptors at the cellular level. This technique offers significant potential for diagnosing and monitoring retinal diseases by providing detailed assessments of cone density and arrangement. The improved imaging capabilities could advance clinical research and enhance patient care in retinal disease management.

Abstract No.: 206894

Injection Frequency Based on Baseline Anatomic Lesion Type in Subfoveal Neovascular Age-Related Macular Degeneration: A HARBOR Post Hoc Analysis

First Author: Vicente Lorenzo CABAUG

Co-Author(s): Steven BLOTNER, Quan HOANG, Jesse JUNG

Purpose: To compare injection frequency across Consensus on Neovascular Age-Related Macular Degeneration Nomenclature (CONAN) lesion types in response to ranibizumab for neovascular age-related macular degeneration (nAMD).

Methods: This post hoc analysis of the Phase III, double-masked, multicentre, randomised, active treatment-controlled HARBOR trial evaluated patients in the pro re nata (PRN) ranibizumab arm. Patients were categorised as Type 1 (T1, n=166), Type 2/mixed 1/2 (T2, n=164), or any Type 3 (T3, n=87). High injection burden was defined as ≥7 injections at Month 12 and 16–24 injections at Month 24. Injection burden was compared across lesion subtypes using chi-square tests, and associations between baseline optical coherence tomography (OCT) features and injection burden were assessed using Spearman's rho correlation.

Results: At Month 12, both T1 and T2 had a significantly higher proportion of eyes with high injection burden compared with T3 (p=0.0005 and p=0.0098), with no difference between T1 and T2 (p=0.34). In T2, haemorrhage correlated with lower burden (r=-0.19, p=0.016), and subretinal fluid (SRF) correlated with higher burden (r=0.19, p=0.024). At Month 24, T1 and T2 again showed higher burden than T3 (p=0.0008 and p=0.033). Pigment epithelial detachment (PED) correlated with higher burden in T1 (r=0.19, p=0.016) and T3 (r=0.24, p=0.024). In T2, haemorrhage showed lower burden (r=-0.21, p=0.007) and SRF correlated with higher burden (0.20, p=0.018).

Conclusions: T3 consistently demonstrated the lowest injection burden at 12 and 24 months. Baseline OCT features, particularly haemorrhage correlating with fewer injections, whereas SRF and PED associate with increased burden, may guide individualized strategies in nAMD.

Abstract No.: 205266

Interventions to Improve Intravitreal Anti-VEGF Adherence and Retinal-Care Attendance: A Systematic Review

First Author: Mohamed SHERIF

Co-Author(s): Eva FENWICK, Ecosse LAMOUREUX, Ryan.E.k. MAN, Anna Cs TAN

Purpose: To identify evidence-based strategies that improve adherence to intravitreal anti-VEGF therapy (IVT) visits and associated medical appointments in chronic macular diseases.

Methods: A systematic review was conducted and reported per Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 guidelines; eligibility followed Population, Intervention, Comparison, Outcomes, and Study design (PICOS). Studies evaluating interventions to enhance IVT adherence and/or associated medical appointments versus usual care were screened. Data on design, intervention, and adherence outcomes were extracted and synthesized qualitatively. Study quality was assessed with the Mixed Methods Appraisal Tool (MMAT, 2018). Study outcomes included IVT adherence/persistence and visit adherence/attendance.

Results: Six studies met the inclusion criteria, with three being randomized controlled trials. Two studies evaluated IVT adherence/persistence: a comprehensive patient-support program that significantly improved 24-month persistence versus usual care and resulted in about two additional injections over 24 months; and a home hyperacuity monitoring app that increased on-time attendance to scheduled injection visits versus matched controls. Four studies evaluated visit adherence/attendance. These comprised SMS reminders, brief point-of-care education seminars, education plus personalized telephone outreach, and a self-monitoring journal. These studies reported increased visit adherence of 14.9% to 28.9% post-intervention (all $P < 0.05$). Overall methodological quality was good (MMAT 2018 mean $\sim 4.3/5$).

Conclusions: Limited, but consistent evidence, suggests that multifaceted, patient-centred strategies, i.e., combining education, digital home-monitoring, and proactive communication, can improve IVT adherence/persistence and retinal care attendance compared to usual care. Larger, well-designed randomized trials using standardized adherence endpoints are needed, including trials that personalize support with patient-reported outcome measures to target individual barriers and enablers.

Abstract No.: 202710

Long-Term Efficacy and Safety of Port Delivery Platform With Ranibizumab in Patients With Neovascular Age-Related Macular Degeneration: Results From the Ladder- and Archway-to-Portal Trials

First Author: Yew Sen **YUEN**

Co-Author(s): Dominic **HEINRICH**, Arshad M. **KHANANI**, John **KITCHENS**, Carl D. **REGILLO**, Natasha **SINGH**

Purpose: Ladder and Archway investigated the PDS (Port Delivery Platform with Ranibizumab) in patients with nAMD (Neovascular Age-related Macular Degeneration). We report follow-up data up to 5 and 7 years.

Methods: Patients were randomised to PDS (Ladder [NCT02510794]: 10, 40, or 100mg/mL refilled pro re nata; Archway [NCT03677934]: 100mg/mL refilled Q24W [every-24-weeks]) or monthly IVT (intravitreal) ranibizumab 0.5mg. On primary study completion, patients were eligible to enter the Portal trial (NCT03683251) to receive PDS 100mg/mL Q24W (PDS Q24W and IVT-to-PDS [IVT-PDS] cohorts). Baseline is defined as day-0 of the primary study.

Results: In the Ladder-to-Portal 100mg/mL cohort (PDS Q24W, $n=59$; IVT-PDS, $n=41$), mean BCVAs (best-corrected visual acuities) at baseline and W320 (week-320) were 70.4 and 63.2 letters for PDS Q24W; 70.6 and 68.4 letters for IVT-PDS. Mean CSTs (central subfield thicknesses) at baseline and W320 were 315.6 and 308.6 μ m for PDS Q24W; 325.8 and 301.7 μ m for

IVT-PDS. In the Archway-to-Portal cohort (PDS Q24W, $n=220$; IVT-PDS, $n=132$), mean BCVAs at baseline and W240 were 74.4 and 67.6 letters for PDS Q24W; 76.3 and 68.6 letters for IVT-PDS. Mean CSTs at baseline and W240 were 308.8 and 306.4 μ m for PDS Q24W; 300.6 and 289.3 μ m for IVT-PDS. PDS treatment was generally well-tolerated over the respective study periods.

Conclusions: Continuous anti-vascular endothelial growth factor treatment via the PDS resulted in maintenance of visual and anatomical long-term outcomes for up to 5 and 7 years in nAMD patients and was generally well-tolerated.

Abstract No.: 205082

Macular Atrophy as a Key Determinant of Three-Year Outcomes in Type 1,2,3 Macular Neovascularization: Bilateral Visual and Fellow-Eye Findings

First Author: Mohamed **SHERIF**

Co-Author(s): Hiok Hong **CHAN**, Gemmy **CHEUNG MING**, Noa **GILEAD**, Antoine **HUANG**, Zehua **JIANG**

Purpose: To compare 36-month macular atrophy (MA) incidence in either eye among patients with unilateral type 3 macular neovascularization (MNV) versus unilateral MNV of other subtypes.

Methods: Prospective cohort of 72 patients (144 eyes) with treatment-naïve unilateral MNV: 24 Type 3, 24 Type 1, and 24 Type 2. Fellow eyes without MNV at baseline were followed for 36 months. Baseline visual acuity (VA; ETDRS letters), central retinal thickness (CRT; μ m), and intravitreal injection (IVT) numbers were recorded. The primary endpoint was MA incidence in the MNV and fellow eyes.

Results: At baseline, Type 3 had lower presenting VA and thicker CRT versus Type 1; fellow-eye VA was similar across groups. At year 1, VA improved in all subtypes but remained lower in Type 3; by year 3, VA converged across groups. CRT decreased in all groups with no between-group differences. IVT burden was comparable. MA incidence was higher in Type 3 than in Type 1 and Type 2 in both MNV eyes (96% vs 46% vs 4%) and fellow eyes (58.3% vs 4.2% vs 4.2%) (all $p < 0.001$). No macular fibrosis occurred in Type 3; 50% of Type 2 developed fibrosis by year 3. Incident fellow-eye MNV occurred in 33%, 21%, and 17% in Type 3, Type 1, and Type 2, respectively. At 36 months, fellow-eye VA was lower in Type 3 (57.9 vs 66.1 and 72.9 letters, $p=0.015$).

Conclusions: Type 3 MNV confers a high bilateral risk of MA and worse fellow-eye vision at 36 months versus other subtypes, supporting vigilant bilateral monitoring and MA-focused follow-up and counselling. In selected patients, emerging complement inhibitors for geographic atrophy may be considered for MA management, but randomized trials specific to Type 3 MNV are needed.

Abstract No.: 202944

Maintenance of Driving Eligibility in Patients With Geographic Atrophy From the GATHER1 and GATHER2 Clinical Trials: A Post Hoc Analysis

*First Author: Kelvin **TEO***

*Co-Author(s): Seenu **HARIPRASAD**; Arshad **KHANANI**, Daniel **KIERNAN**, Ivan **SUÑER**, Jeff **CAI**, Justin **TANG**, Don **LUO**, Ronald **TOTONG**, Nikhil **PATEL***

Purpose: Geographic atrophy (GA) may affect vision, limiting independence. To be eligible to drive, individuals must meet vision criteria. Avacincaptad pegol (ACP) is approved for GA secondary to age-related macular degeneration by the US FDA. This post hoc analysis explored progression to loss of driving eligibility among patients in the GATHER trials.

Methods: GATHER1 and GATHER2 were multicenter, randomized, double-masked, sham-controlled trials with treatment periods of 18 and 24 months, respectively, in patients with non-center-point-involving GA. The proportion of patients who progressed to restrictions or loss of driving eligibility defined as BCVA ≤ 65 letters ($\leq 20/50$) or ≤ 60 letters ($\leq 20/63$) at any post-baseline visit or at 2 consecutive post-baseline visits over 24 months was evaluated in patients eligible to drive at baseline (≥ 75 letters [$\geq 20/32$] or ≥ 70 letters [$\geq 20/40$]) in the pooled GATHER studies.

Results: Among ACP 2mg- and sham-treated patients with baseline BCVA ≥ 75 letters, 12.3% (15/122) vs 20.4% (28/137), respectively, had BCVA ≤ 65 letters at any post-baseline visit; 4.9% (6/122) vs 11.7% (16/137), respectively, had BCVA ≤ 65 letters at 2 consecutive post-baseline visits. Among ACP 2mg- and sham-treated patients with baseline BCVA ≥ 70 letters, 25.0% (47/188) vs 23.7% (51/215), respectively, had BCVA ≤ 60 letters at any post-baseline visit; 21.3% (40/188) vs 25.6% (55/215), respectively, had BCVA ≤ 60 letters at 2 consecutive post-baseline visits.

Conclusions: In this analysis of the pooled GATHER studies, a lower proportion of patients treated with ACP 2mg vs sham progressed to restrictions or loss of driving eligibility, defined as BCVA ≤ 65 letters.

Abstract No.: 205466

Mechanistic Study of PIEZO Mechano-Ion Channel Proteins by Mediating the Wnt/MAPK Signalling Pathway in Myopic Tractional Macular Degeneration

*First Author: Fanwen **JIANG***

*Co-Author(s): Zhuping **XU***

Purpose: Myopic traction maculopathy (MTM), a subtype of myopic macular degeneration, has been linked to dysregulation in the Wnt and Myopic traction maculopathy (MTM) pathogenesis involves Wnt and MAPK signaling pathways. Piezo mechanosensitive

ion channels, which respond to mechanical stress and regulate cellular functions, may contribute to MTM through these pathways. This study examines Piezo expression in human MTM tissues and its functional impact on Müller cells.

Methods: Vitreous and inner limiting membrane (ILM) samples from MTM and idiopathic macular hole (iMH) patients underwent proteomic analysis and immunofluorescence. Mouse retinal sections and human MIO-M1 Müller cells were treated with Piezo agonist Yoda1 or antagonist GsMTx4, and assessed via immunofluorescence, CCK-8, calcium imaging, and Western blot for Wnt/ β -catenin and MAPK/ERK1/2 signaling.

Results: Piezo1 and Piezo2 were expressed throughout the mouse retina. Significantly higher Piezo1 and Piezo2 protein levels were detected in the ILM of MTM patients compared to iMH controls ($P=0.0076$; $P=0.0394$). Proteomics identified differential expression of ALB, SOD1, PXDN, and CDH2, suggesting pathway alterations. In MIO-M1 cells, GsMTx4 enhanced viability and proliferation, while Yoda1 suppressed both. Correspondingly, Yoda1 decreased β -catenin and ERK1/2 expression, whereas GsMTx4 increased their levels.

Conclusions: Piezo channel proteins are expressed in the mouse retina, human ILM, and MIO-M1 cells, with elevated expression in MTM ILM. Activation of Piezo channels promotes calcium influx, inhibits Müller cell proliferation and migration, and suppresses Wnt/ β -catenin and ERK1/2-MAPK signaling. These findings indicate that Piezo-mediated mechanotransduction contributes to MTM pathogenesis by regulating key signaling pathways in response to retinal traction.

Abstract No.: 204254

Mendelian Randomization Analysis of the Causal Associations Between Matrix Metalloproteinases and Age-Related Macular Degeneration

*First Author: Liang **FU***

*Co-Author(s): Zhihe **FU***

Purpose: Age-related macular degeneration (AMD) is a leading cause of blindness in older adults. AMD is associated with extracellular matrix (ECM) dysregulation involving matrix metalloproteinases (MMPs) and tissue inhibitors of metalloproteinases (TIMPs). This study investigated the causal relationships between MMP/TIMP levels and AMD.

Methods: We analyzed data from genome-wide association studies (GWAS) on AMD (FinnGen R10 database) and 18 serum MMPs/TIMPs traits (MMP1-3, 7-10, 12-14, 16, 17, 19, 20, TIMP1-4) (GWAS Catalog database). The primary analysis was based on the inverse variance weighted (IVW) method, with confirmation using the MR-Egger, weighted median,

and weighted mode methods. Sensitivity analyses included MR-Egger, MR-PRESO, Cochran's Q, and the leave-one-out method.

Results: MMP12 was causally associated with an increased AMD risk (IVW: OR 1.14, 95% CI: 1.06-1.23, $P < 0.01$). MMP13 was causally associated with AMD pathogenesis (IVW: OR 0.92, 95% CI: 0.85-1.00, $P = 0.04$). Exposure analyses confirmed robust results for MMP12 and MMP13 without evidence of pleiotropy or outliers. The other MMPs and TIMPs did not show conclusive causal associations with AMD.

Conclusions: This Mendelian randomization study provides strong evidence that MMP12 is a risk factor for AMD while MMP13 is protective, enhancing the understanding of ECM regulation in disease progression and suggesting potential therapeutic targets in ECM homeostasis.

Abstract No.: 206330

Metabolomic Evidence of Altered Energy and Redox Pathways in Central Serous Chorioretinopathy

First Author: Francine **BEHAR-COHEN**

Co-Author(s): Stephanie **DURAND**, Laura **KOWALCZUK**, Emilie **PICARD**, Estelle **PUJOS-GUILLOT**, Min **ZHAO**, Marta **ZOLA**

Purpose: Central serous chorioretinopathy (CSCR) is the fourth leading cause of retinal disease, predominantly affecting middle-aged men and often associated with corticosteroid exposure. Its pathophysiology remains incompletely understood, with conflicting data regarding endogenous glucocorticoid excess. We aimed to identify systemic metabolomic signatures associated with CSCR and explore their relationship with corticosteroid-related pathways.

Methods: We conducted an untargeted serum metabolomic analysis using UHPLC-MS in 60 men with active CSCR (30 acute/recurrent, 30 chronic/complex) and 60 age-matched healthy male controls. Metabolites were processed through standardized workflows with quality controls, annotation against in-house and public databases, and pathway enrichment analysis.

Results: Out of 2,196 robust metabolite features, 722 differed significantly between CSCR and controls (592 downregulated, 130 upregulated). CSCR sera exhibited: (i) decreased medium- and long-chain acylcarnitines, suggesting incomplete fatty acid β -oxidation and possible mitochondrial dysfunction; (ii) downregulation of sphingosine-1-phosphate, kynurenine, glutamic acid, and glutathione metabolism, indicating impaired antioxidant defense; and (iii) marked upregulation of primary fatty acid amides (oleamide, linoleamide, palmitoleamide), implicating sleep and vascular regulation pathways. Pathway analysis revealed alterations in amino acid metabolism (histidine,

tryptophan, phenylalanine, arginine/proline) and aminoacyl-tRNA biosynthesis. These findings do not support systemic glucocorticoid excess in CSCR patients

Conclusions: CSCR is associated with a distinct systemic metabolomic signature characterized by impaired energy and redox metabolism and elevated fatty acid amides. These results suggest inadequate glucocorticoid pathway activation rather than excess, highlighting new avenues for understanding disease mechanisms and potential biomarkers. Validation in independent cohorts is warranted.

Abstract No.: 200205

Multi-Omics Integration With Machine Learning Identified Early Diabetic Retinopathy, Diabetic Macula Edema and Anti-VEGF Treatment Response

First Author: Yuhui **PANG**

Co-Author(s): Hui **CHEN**

Purpose: Identify optimal metabolic features and pathways across diabetic retinopathy (DR) stages, develop risk models to differentiate diabetic macular edema (DME), and predict anti-vascular endothelial growth factor (anti-VEGF) therapy response.

Methods: We analyzed 108 aqueous humor samples from 78 type 2 diabetes mellitus patients and 30 healthy controls. Ultra-high-performance liquid chromatography-high-resolution-mass-spectrometry detected lipidomics and metabolomics profiles. DME patients received ≥ 3 anti-VEGF treatments, categorized into strong and weak response groups. Machine learning (ML) screened prospective metabolic features, developing prediction models.

Results: Key metabolic features identified in the metabolomics and lipidomics datasets included n-acetyl isoleucine (odds ratio [OR] = 1.635), cis-aconitic acid (OR = 3.296), and ophthalmic acid (OR = 0.836) for DR. For early-DR, n-acetyl isoleucine (OR = 1.791) and decaethylene glycol (PEG-10) (OR = 0.170) were identified as key markers. L-kynurenine (OR = 0.875), niacinamide (OR = 0.843), and linoleoyl ethanolamine (OR = 0.941) were identified as significant indicators for DME. Trigonelline (OR = 1.441) and 4-methylcatechol-2-sulfate (OR = 1.121) emerged as predictors for strong response to anti-VEGF. Predictive models achieved R^2 values of 99.9%, 97.7%, 93.9%, and 98.4% for DR, early-DR, DME, and strong response groups in the calibration set, respectively, and validated well with R^2 values of 96.3%, 96.8%, 79.9%, and 96.3%.

Conclusions: This research used ML to identify differential metabolic features from metabolomics and lipidomics datasets in DR patients. It implies that metabolic indicators can effectively predict early disease progression and potential weak responders to anti-VEGF therapy in DME eyes.

Abstract No.: 204845

Neurovascular Parameters of the Retina and Choroid Among Adults With Long COVID-19 Syndrome

First Author: Saritra RAJ

Co-Author(s): Mimiwati ZAHARI

Purpose: We aim to investigate the retinochoroidal parameters among individuals with Long Covid-19 syndrome (persistence of symptoms for 12 weeks and beyond) and thenceforth to correlate findings with neurology.

Methods: In this cross-sectional study, 30 eyes from 60 individuals with Long Covid-19 were tested against age and gender matched 30 eyes from 60 controls who have recovered from Covid-19. The retinal nerve fibre layers (peripapillary and macula), ganglion cell layer, and choroidal thickness were measured using Spectral Domain Optical Coherence Tomography (SD-OCT). Vessel and perfusion densities of the radial peripapillary capillary plexus (RPCP), macula superficial (SCP), and deep capillary plexuses (DCP), and also the choriocapillaries (CC) were assessed using Optical Coherence Tomography Angiography (OCTA). Results were compared between the two groups and also correlated with the presence of cognitive impairment symptoms within the Long Covid-19 group.

Results: Individuals in the Long Covid-19 group displayed a significant reduction in the thicknesses of the retinal nerve fibre layer (peripapillary and macula), ganglion cell layer, and choroid. Vessel and perfusion densities of the superficial and deep retinal capillary plexuses, radial peripapillary capillary plexus, and the choriocapillaries ($p < 0.05$) were also significantly reduced in the Long Covid-19 group. Within the Long Covid-19 group, there were also some significant associations seen with cognitive impairment, whereby the ganglion cell layer appears thicker, and vessel densities appear reduced compared to those without cognitive impairment ($p < 0.05$).

Conclusions: Patients with Long Covid-19 syndrome showed significant reductions in the retinochoroidal neurovascular thicknesses and densities compared to those infected with Covid-19 infection for less than 3 months' duration. There were also significant changes in those Long Covid-19 participants with cognitive impairment. This study suggests that the presence of Long Covid-19 syndrome has the tendency to lead to visual abnormalities.

Abstract No.: 202732

Non-Viral Gene Delivery via Electroporation for Inherited Retinal Diseases Using the Sleeping Beauty Transposon System

First Author: Jiao ZHANG

Purpose: Inherited retinal diseases (IRDs) represent a leading cause of irreversible blindness worldwide,

with limited treatment options available. Gene therapy holds significant promise, but viral vector delivery systems face challenges, including immunogenicity and limited cargo capacity. This study aimed to develop a non-viral gene delivery platform using the Sleeping Beauty (SB) transposon system for electroporation-based transfection of degenerating rd10 retinas, with potential applications in combined retinal prosthesis-gene therapy strategies.

Methods: The SB100X transposase and Venus transposon plasmids (1:16 ratio) were electroporated into rd10 retinas at varying degeneration stages and wild-type controls. Transfection efficiency was evaluated via fluorescence microscopy and immunohistochemistry. Retinal integrity was assessed using FITC-dextran electroporation, histology, and TUNEL apoptosis assays.

Results: Highest transfection efficiency occurred in advanced degeneration stages (P61 and older), exclusively targeting Müller cells. A 31% reduction in plasmid size increased transfection efficiency by 1.5-fold. Electroporation preserved retinal laminar structure, with apoptosis rates in the inner nuclear layer (INL) reduced by half compared to wild-type controls.

Conclusions: This study establishes electroporation-mediated SB transposon delivery as a viable non-viral strategy for targeting late-stage degenerated retinas. The Müller cell-specific transfection pattern suggests potential for neuroprotective factor secretion, while preserved tissue integrity supports compatibility with prosthetic implantation. These findings provide critical preclinical evidence for combined electrogene-prosthetic therapy in IRDs, addressing both genetic correction and neural circuit preservation. Future work will focus on therapeutic transgene delivery and in vivo functional validation.

Abstract No.: 202284

One-Year Prospective Single-Arm Clinical Trial of Switching to Faricimab in Previously Treated Neovascular Age-Related Macular Degeneration With Inadequate Response: The FURGGHORN Study

First Author: Andrew CHANG

Co-Author(s): Geoffrey BROADHEAD, Gemmy CHEUNG, Thomas HONG, Hemal MEHTA, Long PHAN

Purpose: To prospectively examine the effect of switching to faricimab therapy in previously-treated neovascular age-related macular degeneration (nAMD).

Methods: FURGGHORN (ACTRN12623000215628) was a phase IV, prospective, single-arm, open-label, multi-center, investigator-initiated clinical trial. Currently-treated patients showing nAMD disease activity were switched to receive four doses of faricimab 6mg/0.05mL given 4-weekly. From week 12, treatment

intervals in all patients were extended to 8-weekly and modified at subsequent visits according to a treat-and-extend protocol. Changes from baseline in best-corrected visual acuity (BCVA) and central subfield thickness (CST), as well as the proportions of retinal fluid, treatment intervals, and the incidence of adverse events through to week 52, were examined.

Results: One hundred and two eligible eyes, with a mean age of 76 years, were recruited across 12 sites. Baseline BCVA was 72 letters, and baseline CST was 384 μm . Seventy-three eyes switched from aflibercept 2mg, and 29 switched from ranibizumab. At week 52 after switching to faricimab, mean BCVA change was +0.9 letters ($P=0.069$), mean CST change was -75.1 μm ($P<0.001$), and 53% percent of eyes showed absence of both intraretinal and subretinal fluid. Last assigned treatment intervals were 4-weekly, 8-weekly, 12-weekly, and 16-weekly in 43%, 18%, 18% and 21% of eyes, respectively. Anterior chamber inflammation occurred in one eye with no cases of vasculitis or occlusive retinitis.

Conclusions: Switching to faricimab in eyes with disease activity led to improved anatomic outcomes with maintained visual function, allowing extended dosing intervals under a flexible treatment regimen.

Abstract No.: 204277

Optic Nerve Infiltration in the Context of Leukemia

First Author: Wenbo LIU

Co-Author(s): Yumeng LI, Xuan SHI, Wenzhou XIAO

Purpose: To report a rare case series of isolated optic nerve infiltration as the initial manifestation of leukemia relapse, a condition typically associated with a poor prognosis.

Methods: A retrospective analysis was conducted on patients with relapsed leukemia who presented with isolated optic nerve infiltration at Peking University People's Hospital between 2018 and 2024.

Results: Three male patients with a history of acute leukemia showed no definitive evidence of systemic relapse in cerebrospinal fluid (CSF) or bone marrow tests at the initial onset of ocular symptoms. Leukemia patients with optic disc infiltration commonly present with optic disc edema; however, more characteristic findings in these cases include a more fluffy and white swollen optic disc, creamy infiltration, tortuosity of the retinal vessels, aggravated dot and blot hemorrhages. A critical finding was the rapid progression to severe vascular complications, such as central retinal artery occlusion (CRAO) and neovascular glaucoma, which ultimately resulted in no light perception (NLP) in all affected eyes.

Conclusions: Isolated optic nerve infiltration can be the sole and initial sign of leukemia relapse. Its clinical presentation often mimics other conditions, leading

to diagnostic delays. A high index of suspicion, close collaboration with hematologists, and prompt initiation of treatment based on clinical judgment, even in the absence of initial laboratory evidence and radiographic evidence, are crucial to preventing irreversible vision loss.

Abstract No.: 207440

Optical Coherence Tomography Angiography in Smokers Without Systemic Disease: Early Retinal Vasculopathy Before Fundus Changes

First Author: Sri Satviki POSINA

Co-Author(s): Inchara NAGARAJ, Rohith Reddy YEDDULA VENKATA

Purpose: To evaluate early retinal microvascular alterations in systemically healthy smokers using optical coherence tomography angiography (OCTA) and determine its utility in detecting preclinical vasculopathy.

Methods: This hospital-based cross-sectional observational study included 60 participants aged 18–50 years, comprising 30 chronic smokers and 30 age-matched healthy non-smokers. All subjects had best-corrected visual acuity (BCVA) $\geq 6/9$, no systemic or ocular disease, and high-quality OCTA scans (signal strength index ≥ 7). OCTA parameters analyzed included vessel density (VD) and perfusion density (PD) of the superficial and deep capillary plexuses, and foveal avascular zone (FAZ) metrics (area, perimeter, and circularity index).

Results: The deep capillary plexus VD was significantly reduced in smokers ($41.2\% \pm 3.8$) compared with controls ($45.6\% \pm 4.1$, $p < 0.001$). Superficial VD also showed a moderate reduction ($48.5\% \pm 3.2$ vs $50.7\% \pm 3.0$, $p = 0.03$). The FAZ area was larger in smokers ($0.33 \pm 0.07 \text{ mm}^2$) than in controls ($0.27 \pm 0.05 \text{ mm}^2$, $p = 0.01$), while the FAZ circularity index was reduced, indicating early ischemic remodeling. A moderate inverse correlation was observed between pack-years and deep plexus VD ($r = -0.54$).

Conclusions: OCTA detects early retinal microvascular compromise in smokers, even in the absence of systemic disease or fundus changes. Reduced deep plexus vessel density and enlarged FAZ area may serve as sensitive biomarkers of subclinical vasculopathy, potentially preceding clinically detectable retinopathy.

Abstract No.: 203448

Overdose Photodynamic Therapy in the Management of Circumscribed Choroidal Hemangioma

First Author: Iat Fan LAI

Purpose: To evaluate the efficacy and safety of overdose photodynamic therapy (PDT) in the

management of circumscribed choroidal hemangioma (CCH).

Methods: A prospective study was conducted on 10 patients (10 eyes) with symptomatic CCH who underwent overdose PDT treatment. Verteporfin was administered intravenously at an overdose of 8 mg/m², followed by laser application at 689 nm with a fluence of 50 J/cm². Patients were monitored for tumor thickness, visual acuity, and complications over a mean follow-up period of 12 months.

Results: PDT resulted in a significant reduction in tumor thickness, with a mean decrease of 1.8 mm ($p < 0.01$). Visual acuity improved by ≥ 2 lines in 80% of patients, remained stable in 20%, and showed no decline. Subretinal fluid resolved completely in 90% of cases within 3 months. No severe adverse events were reported; mild transient visual disturbances were noted in 20% of patients.

Conclusions: Overdose PDT is an effective and safe treatment for circumscribed choroidal hemangioma, leading to significant tumor regression and functional visual improvement with minimal complications. It represents a valuable therapeutic option for preserving vision in affected patients.

Abstract No.: 206328

Overtreatment in Diabetic Macular Oedema: Real-World Consequences of Ambiguous Central Retinal Thickness Definition

First Author: Konstantina **THEODOSAKI**

Co-Author(s): Dominik **FISCHER**, Claire **RUAN**

Purpose: To evaluate the impact of ambiguity in National Institute for Health and Care Excellence (NICE) guidance over different definitions of central retinal thickness (CRT); interpreted as either central subfield thickness (CST) vs central maximum thickness (CMT); on treatment eligibility, outcomes, complications, and cost of care in diabetic macular oedema (DMO) management.

Methods: Single-centre retrospective cohort of 100 consecutively treated DMO eyes receiving aflibercept or faricimab (2022–2024). Exclusion criteria: prior anti-VEGF or non-DMO indications. OCT CST (1mm subfield mean) and CMT (single point maximum) and BCVA were recorded at baseline, 6, and 12 months. Data on treatment burden, including injections, clinic visits, complications, and costs, were extracted. Eyes were stratified into: Group A (CST ≥ 400 μ m and/or ≥ 5 -letter loss) and Group B (CMT ≥ 400 μ m with CST < 400 μ m). The primary outcome was overtreatment proportion (Group B among treated eyes), with secondary outcomes being BCVA gain, complication rate, and costs.

Results: Of 100 eyes, 63 (63%) were in Group A and 37 (37%) in Group B. Optimal response at 6 months was significantly higher in Group A (80.95% vs 51.35%,

$p=0.0038$). Mean BCVA gain was +7 vs 0 ETDRS letters at 12 months ($p<0.005$). Despite significantly lower baseline BCVA in Group A (67.0 vs 75.0, $p=0.0001$), final BCVA at 12 months was comparable (74.3 vs 75.0). Group B accounted for 38% of injections and 35% of appointments, had double the complication rate (2/63 vs 4/37) (including one tractional retinal detachment), and incurred ~£190k in potentially avoidable costs in 6 months.

Conclusions: Ambiguity in CRT ≥ 400 μ m definition caused 37% overtreatment when using CMT instead of CST to initiate treatment. This was linked to inferior response, negligible vision gain, increased complications, and substantial avoidable costs. The refined guideline clarification to CST is expected to reduce overtreatment without compromising outcomes. Despite starting with significantly worse baseline vision, Group A achieved equivalent outcomes at 12 months, supporting the use of CST as a measure of the structural criterium of CRT ≥ 400 μ m.

Abstract No.: 204395

PULSAR Extension: Aflibercept 8 mg Outcomes at 156 Weeks in Choroidal Neovascularization and Polypoidal Choroidal Vasculopathy

First Author: Chui Ming Gemmy **CHEUNG**

Co-Author(s): Youxin **CHEN**

Purpose: To evaluate aflibercept 8 mg outcomes over 156 weeks in neovascular age-related macular degeneration (nAMD) patients, grouped by choroidal neovascularization (CNV) type or polypoidal choroidal vasculopathy (PCV) in PULSAR Extension.

Methods: In PULSAR (NCT04423718), patients were randomized 1:1:1 to aflibercept 8 mg every 12 (8q12) or 16 weeks (8q16), or 2 mg every 8 weeks (2q8), post 3 monthly injections. At W96, patients could enter a 1-year extension through W156. The 2q8 group switched to 8 mg at 12-week intervals (2mg->8mg); 8q12/8q16 groups continued 8 mg at last-assigned intervals (8mg group). Dosing intervals were adjusted from W100 (8–24 weeks) per disease activity. Outcomes, by baseline CNV type or ICGA-confirmed PCV, included best-corrected visual acuity (BCVA) and central subfield retinal thickness (CRT) at W156.

Results: Of 625 patients, 58.4%, 20.0%, 19.8% and 20.3% had CNV in Type 1, Type 2, Mixed, and ICGA-confirmed PCV, respectively. In 2mg->8mg, improvement of BCVA letters from baseline to W156 were Type 1: 64.1 to 68.6; Type 2: 50.3 to 56.5; Mixed: 56.4 to 64.5; PCV: 58.7 to 69.2. In 8mg, these BCVA letter improvements were Type 1: 64.2 to 68.3; Type 2: 54.9 to 58.1; Mixed: 57.1 to 59.0; PCV: 56.8 to 61.9. CRT decreased across CNV types. In 8mg group, 38.7–52.2% of patients had last-assigned dosing interval ≥ 20 -week.

Conclusions: Aflibercept 8 mg sustained BCVA and CRT improvements through 156 weeks support extended dosing in nAMD regardless of CNV type and the presence of PCV.

Abstract No.: 204150

PULSAR Extension: Comparable Outcomes With Reduced Treatment Burden in nAMD Patients Switching From Aflibercept 2 mg to 8 mg

First Author: Gavin TAN

Co-Author(s): Sergio LEAL, Andrea SCHULZE, Xin ZHANG, Sandrine ZWEIFEL

Purpose: To evaluate long-term outcomes in neovascular age-related macular degeneration (nAMD) patients switching from aflibercept 2 mg to 8 mg through 156 weeks in the PULSAR Extension.

Methods: In the Phase 3 PULSAR trial (NCT04423718), treatment-naïve nAMD patients were randomized to receive aflibercept 8 mg every 12 (8q12) or 16 weeks (8q16), or aflibercept 2 mg every 8 weeks (2q8), each after three monthly doses. Patients completing the 96-week main phase could enter a 1-year open-label extension. Those in the 2q8 arm switched to aflibercept 8 mg at Week 96 with a 12-week dosing interval (2mg→8mg group), while 8q12 and 8q16 groups continued their assigned intervals. From Week 100, dosing intervals could be adjusted (8–24 weeks) based on disease activity. Analyses were exploratory.

Results: For the 2mg→8mg group (n=208), the mean best-corrected visual acuity (BCVA) was 66.9 letters at Week 96, 66.7 at Week 100, and 65.1 at Week 156. Mean central retinal thickness (CRT) was 285.2 µm, 263.6 µm, and 274.8 µm, respectively. The proportion without intraretinal and subretinal fluid was 61.8% at Week 96, 74.9% at Week 100, and 64.4% at Week 156. Patients received a mean of 12.8 injections (baseline to Week 96) and 4.7 injections (Week 96–156). No new safety signals were observed.

Conclusions: Switching to aflibercept 8 mg maintained BCVA and CRT, improved fluid control at Week 100, and reduced injection frequency through Week 156, without new safety concerns.

Abstract No.: 204812

Pain Control After Intravitreal Injections: Comparison of Topical Nepafenac 0.3%, Tetracaine 2% and Tetracaine 0.5%

First Author: Andrea SILITONGA

Purpose: Pain after intravitreal injections (IVI) can affect patients' experience and compliance. We prospectively evaluated topical nepafenac 0.3% or tetracaine 2% to reduce ocular discomfort after IVI and compare it to the commonly used topical anesthetic tetracaine 0.5%.

Methods: A cross-sectional study. Participants were randomized to receive either a single drop of tetracaine 0.5% (control group), nepafenac 0.3%, or topical tetracaine 2%. Pain was assessed using the Numeric Pain Rating Scale that ranged from 0 to 10 (horizontal pain scale).

Results: There are 49 patients in the control group (tetracaine 0.5%), 44 patients in the nepafenac 0.3% group and 55 patients in the tetracaine 2% group. Numeric Pain Rating Scale scores at 6 and 12 hours after IVI were lower in the tetracaine 2% group (1.582 ± 0.357 and 0.545 ± 0.262 , respectively) compared to the control group (1.653 ± 0.378 and 0.816 ± 0.278 , respectively) and nepafenac. Although the tetracaine group reported lower pain scores compared to the control and nepafenac group, the difference was not statistically significant (6 hours, p-value = 0.859; 12 hours, p-value = 0.377).

Conclusions: Tetracaine 0.5%, Nepafenac 0.3% and Tetracaine 2% were effective in reducing pain up to 12 hours after IVI. Tetracaine 2% was associated with lower pain scores compared to tetracaine 0.5% and nepafenac 0.3% but not statistically significant. Additional studies are needed to determine the most effective and cost-efficient method to reduce pain after IVI.

Abstract No.: 201898

Persistent Avascular Retina in Retinopathy of Prematurity - Ultra Wide Field Imaging Features and Long-Term Sequelae

First Author: Simar Rajan SINGH

Co-Author(s): Rishika RATHORE

Purpose: To describe the presentation, ultra-wide field (UWF) imaging features, and long-term sequelae in eyes with persistent avascular retina (PAR) secondary to retinopathy of prematurity (ROP).

Methods: This cross-sectional study included patients greater than three years of age with a history of prematurity presenting to a tertiary care centre and diagnosed with PAR (>2DD) secondary to ROP. All patients underwent ophthalmic examination and UWF fundus photography. UWF fluorescein angiography (UWF-FA) was performed to delineate PAR. Family screening was done for all to rule out FEVR.

Results: The study included 58 eyes of 31 patients with a mean age of 9 years (range 3 – 30 years). Thirteen (41.9%) patients presented with low vision incidentally detected at school, 8 (25.8%) had a sudden decrease in vision due to rhegmatogenous retinal detachment, and 7 (22.5%) were detected on fundus screening prior to refractive surgery. Only 12 (38.7%) had previously been screened for ROP, and 4 had received anti-VEGF injection without any subsequent laser treatment. Fundus findings included vitreous veils (62%), straightening of arcades (62%), vascular tortuosity

(51.7%), lattice (55.1%), epiretinal membrane (13.8%), tractional retinal detachment (10.3%) and vitreous hemorrhage (5.1%). UWF-FA done in 54 (93.1%) eyes demonstrated >6 clock hours of PAR in 82% eyes. Laser of PAR was done in 40 eyes, and surgery for retinal detachment in 8 eyes.

Conclusions: Spontaneously regressed ROP can be associated with PAR, which can lead to long-term sequelae. Timely screening and treatment of PAR may help in preventing vision loss in these eyes.

Abstract No.: 201621

Persistent Diffuse Photoreceptor Disorganization

First Author: Miaoling LI

Purpose: To characterize persistent diffuse photoreceptor disorganization (PDPD), a newly recognized retinal disorder, and establish diagnostic criteria differentiating it from similar outer retinopathies.

Methods: This retrospective observational case series included 14 patients (21 eyes) with subacute vision loss, unremarkable fundus, and persistent diffuse photoreceptor disorganization on OCT, from 2020-2025. Medical records, multimodal imaging (OCT, fundus autofluorescence [FAF], fluorescein angiography [FA], indocyanine green angiography [ICGA]), and visual function (electroretinography [ERG], visual field) findings were analyzed.

Results: Patients (mean age 30.7 years) presented with subacute vision loss (mean BCVA 0.9 LogMAR, range, 2.0-0.2). Seven patients (50%) had bilateral involvement. Infectious uveitis and known retinal dystrophy mutations (via whole-exome sequencing) were excluded. Fundus, FAF, and ICGA were largely unremarkable. OCT revealed blurred/rough ellipsoid zone (EZ) and absent interdigitation zone (IZ) in the posterior pole of all eyes (including fovea in 100%, periphery in 92.9%). The RPE layer was preserved. Outer retina thickness was significantly thinner in involved eyes compared to fellow eyes (118.3 vs. 147.6 μm , $p=0.008$). FA showed peripheral venous leakage in 75% of eyes. Full-field ERG indicated reduced amplitudes (normal latency, scotopic/photopic), and visual fields showed significant defects. Eleven patients received immunosuppressive therapies. Over 17 months, OCT abnormalities persisted, outer retina thickness slowly decreased, and visual acuity remained stable with no significant improvement.

Conclusions: PDPD is characterized by subacute, diffuse, and persistent photoreceptor disorganization with largely unremarkable fundus, distinct from other outer retinopathies. Visual prognosis is generally poor, necessitating further research into pathogenesis and treatment.

Abstract No.: 201618

Persistent Placoid Maculopathy (PPM): Lichen-Like Lesions Growing Between Retinal Pigment Epithelium and Bruch's Membrane

First Author: Miaoling LI

Purpose: To report the novel imaging findings in PPM from the first case series of Asian subjects.

Methods: Patients with PPM from 2013 to 2023 were included retrospectively. Medical records and multimodal images from each visit were analyzed.

Results: Twenty-one eyes of 16 patients were included. The mean age was 61 years old. PPM lesions were unremarkable on CFP, autofluorescence, and FA. Hypofluorescent spots with a lichen-like appearance presented in all phases of ICGA, which were most prominent in the late phase and presented in a fused (71%) or clustered (29%) pattern. The hypofluorescence correlated with the lesions between the RPE and Bruch's membrane (BM) with moderate reflectivity on OCT, and the thickness ranged from slit-like to mound-like. The intensity of hypofluorescence sometimes varied in the same eye and correlated with the thickness of sub-RPE lesions on OCT. No abnormal blood flow signals were detected in either the sub-RPE space or choriocapillaris slab of OCTA across the PPM lesions. Ten eyes of 7 patients were followed up (median, 26 months). During follow-up, the lichen-like lesions spread and migrated slowly without changing the plane patterns of the first visit and were limited to sub-RPE growth. Ten eyes (9 eyes in the fused pattern, 1 eye in the clustered pattern) had secondary CNV.

Conclusions: PPM lesions were located in the sub-RPE space. Spreading and migration between the RPE and BM may account for their unique lichen-like appearance and progression pattern.

Abstract No.: 205167

Phase I Safety and Efficacy Topline Results of Subretinal Gene Therapy FT-002 for X-Linked Retinitis Pigmentosa

First Author: Ruifang SUI

Co-Author(s): Rongping DAI, Xiaoxu HAN, Xinyan LI, Weihong YU, Xuan ZOU

Purpose: To investigate the safety and efficacy of FT-002, a novel rAAV (Recombinant Adeno-associated Virus) vector containing codon-optimized hRPGORF15 (Human Retinitis Pigmentosa GTPase Regulator ORF15) gene developed by Frontera Therapeutics, in participants with RPGR-associated XLRP (X-linked Retinitis Pigmentosa).

Methods: In an open-label, dose escalation Phase I study (CTR20222868), male participants at 18~45 years of age with RPGR-associated XLRP were enrolled to receive FT-002 at a dose of 1.0×10^{11} or 2.0×10^{11} vg/

eye via unilaterally subretinal injection. The safety and efficacy of FT-002 were evaluated within 52 weeks.

Results: Six participants were enrolled in Phase I with follow-up for 52 weeks. FT-002 demonstrated a good safety profile, with no DLT (Dose-Limiting Toxicity) or FT-002-related SAE (Serious Adverse Event). At Week 52, the BCVA (Best Corrected Visual Acuity) of participants who received FT-002 at 2.0×10^{11} vg/eye improved by an average of 8.3 letters from baseline, with 2/3 (66.7%) achieving a gain of ≥ 5 letters. Additionally, the National Eye Institute Visual Function Questionnaire (NEI VFQ-25) scores showed a mean improvement of 14.139 points from baseline. Moreover, OCT (optical coherence tomography) revealed an increase in EZ (ellipsoid zone) width of 0.022 mm compared to baseline, marking the first reported reversal of EZ width reduction, which suggests slowed disease progression in XLRP.

Conclusions: FT-002 is safe and holds great promise to be an effective treatment for participants with RPGR-associated XLRP.

Abstract No.: 208340

Prediction of the Risk for Developing Diabetic Retinopathy Based on Blood Molecules and Retinal Features

First Author: Huiqian **KONG**

Co-Author(s): Jiahui **CAO**, Chunran **LAI**, Honghua **YU**, Xiayin **ZHANG**

Purpose: Diabetic retinopathy (DR) has rapidly become the leading blinding eye disease threatening the working population. We aimed to explore molecular biomarkers and retinal features and build prediction models of DR.

Methods: Participants from UK Biobank were recruited from 2006 to 2010, and prospectively followed up until 2021. We divided the enrolled population according to the full-course DR into 5 groups: no diabetes mellitus (no DM), prediabetes (pre DM), diabetes mellitus (DM), non-proliferating diabetic retinopathy (NPDR), and proliferating diabetic retinopathy (PDR). The molecular biomarkers evaluated at baseline includes 7 lipids and 8 proteins, while the retinal features were measured by Optical coherence tomography (OCT). The associations between molecular biomarkers and retinal features were performed by correlation analysis. A predictive model of DR was constructed using both retinal features and molecular biomarkers.

Results: The study included 3,953 participants (2095 [53.0%] female), with a mean age (SD) of 47.3 (5.8) years. Apo A, Apo B, HDL, and LDL were associated with retinal nerve fiber layer (RNFL), ganglion cell layer (GCL), and inner nuclear layer (INL) in full-course DR (all r range from 0.5 to 1 0.5, $p < 0.05$). Protein biomarkers, including albumin, total protein, and creatine, showed significant correlation with GCL and RNFL in pre DM, DM, NPDR, and PDR groups compared to the no DM

group (all $p < 0.05$). The Area Under Curve (AUC) of the DR prediction model based on the combination of molecular biomarkers and retinal features is 0.790 (95%CI:0.711-0.847), $p < 0.01$, which is higher than the prediction models based on molecular biomarkers or retinal features alone.

Conclusions: Molecular biomarkers were associated with retinal features during the full-course DR. DR prediction model based on the combination of molecular biomarkers and retinal features presented a higher AUC, suggesting a possible strategy for early diagnosis of DR.

Abstract No.: 202049

Predictors of Diabetic Macular Oedema Development in Type 2 Diabetes: The Importance of Glycaemic Control and Systemic Inflammation

First Author: Linh **DO**

Co-Author(s): Charisse **KUO**, Stuti **MISRA**, Odunayo **MUGISHO**, Rinki **MURPHY**, Rachael **NIEDERER**

Purpose: To investigate predictors of diabetic macular oedema (DMO) in patients with type 2 diabetes mellitus (T2DM), focusing on hyperglycaemia, glycaemic variability, and systemic inflammation.

Methods: This is a retrospective, hospital-based longitudinal study. Of 603 charts reviewed, 125 patients with T2DM without DMO were included and followed from 2012 to 2022. Hyperglycaemia and glycaemic variability were recorded using HbA1c measurements, adjusted standard deviation (SD), and coefficient of variation (CV). White blood cell (WBC) counts, metabolic comorbidities, and medication use were tested as predictors of DMO development using univariate Cox proportional hazards followed by multivariate regression and Kaplan–Meier curves.

Results: Among 125 patients (49.6% male; mean diabetes duration 13.42 ± 7.81 years), DMO developed in 42 (33.6%) over a mean follow-up of 4.97 ± 3.04 years. Predictors of DMO development were mild or moderate DR at baseline, higher HbA1c ($p = 0.005$, HR = 1.045), lower neutrophil counts ($p = 0.024$, HR = 0.396), but not HbA1c variability (adjusted SD: $p = 0.646$; CV: $p = 0.982$). Only dipeptidyl peptidase-4 (DPP-4) inhibitor use reduced risk ($p = 0.004$), whereas other metabolic medications and comorbidities were not associated.

Conclusions: Higher HbA1c levels and lower neutrophil counts are associated with increased risk of DMO in T2DM, highlighting the role of glycaemic control and systemic inflammation. These findings pave the way for future therapeutics targeting systemic immune response in DMO prevention.

Abstract No.: 202499

Predictors of Extended Treatment Interval in DME Diabetic Macular Edema Patients Treated With Faricimab in the Phase-3 YOSEMITE/RHINE Trials

First Author: Anna TAN

Co-Author(s): Aude AMBRESIN, Bianca S. GERENDAS, Kara GIBSON, Ming YANG

Purpose: This YOSEMITE/RHINE post-hoc analysis evaluated baseline characteristics and treatment response as treatment interval predictors in faricimab-treated DME (diabetic macular edema) patients.

Methods: In YOSEMITE/RHINE(NCT03622580/ NCT03622593), 1891 patients were randomized 1:1:1 to faricimab-6.0mg per personalized T&E (treat-and-extend) interval, faricimab-6.0mg Q8W (every-8-weeks), or aflibercept-2.0mg Q8W doses through week-100. In faricimab-T&E arm, treatment intervals were adjusted (Q4W-Q16W) based on pre-specified CST (central subfield thickness) and BCVA (best-corrected visual-acuity) criteria. Twenty-one baseline characteristics and nine treatment responses (week-16 and year-1) were evaluated as treatment interval predictors at year-1 and year-2 by univariate/ multivariable analyses. All P values are nominal.

Results: Every 50-µm decrease in baseline-CST had greater odds of achieving Q16W vs shorter intervals at year-1 (Q16W vs Q4W: OR [odds ratio]=2.95; Q16W vs Q8W: OR=1.73; Q16W vs Q12W: OR=1.75, all P<0.0001) and year-2 (Q16W vs Q4W: OR=1.74, P<0.0001). Every 50-µm CST-decrease from baseline to week-16 increased the odds of achieving Q16W vs shorter intervals at year-1 (Q16W vs Q4W: OR=2.13; Q16W vs Q8W: OR=1.27; Q16W vs Q12W: OR=1.30, all P<0.05) and year-2 (Q16W vs Q4W: OR=1.75, P<0.0001). Anti-vascular endothelial growth factor treatment-naïve patients at baseline had greater odds of achieving Q16W interval at year-1 (Q16W vs Q4W: OR=2.56; Q16W vs Q8W: OR=2.17, both P<0.01). Additional volumetric fluid data will be presented.

Conclusions: Select baseline characteristics and early treatment response were associated with extended treatment intervals at year-1/year-2 among faricimab-treated DME patients, suggesting earlier disease control with faricimab may improve long-term durability and outcomes.

Abstract No.: 206365

Preoperative Educational Video Viewing Is Associated With a Reduced Incidence of Subconjunctival Hemorrhage Following Intravitreal Anti-VEGF Injection

First Author: Fang ZHENG

Co-Author(s): Xiaoyun FANG

Purpose: To assess whether preoperative viewing of an educational procedural video reduces the incidence and severity of subconjunctival hemorrhage (SCH) following intravitreal anti-VEGF injections (IVI), and improves patient experience.

Methods: In this surgeon-blind randomized controlled trial (NCT07002372), treatment-naïve patients scheduled for their first IVI were prospectively enrolled and randomized to either an intervention group (video viewing) or a control group (no video). All participants completed the State-Trait Anxiety Inventory-State (STAI-S) before and after the injection. SCH incidence and area were assessed via standardized post-injection photographs analyzed using ImageJ software. Additional outcomes included patient-reported pain and satisfaction scores, heart rate, procedure time, and physician-rated patient cooperation.

Results: A total of 108 patients were enrolled; 103 completed the study. Baseline demographics were similar between groups. SCH occurred in 21/51 (41.2%) patients in the intervention group versus 36/52 (69.2%) in the control group, though SCH area did not differ significantly. Logistic regression analysis revealed that the use of anticoagulant medication was positively associated with the occurrence of SCH, whereas watching an educational video prior to IVI was negatively associated with SCH. Anxiety scores decreased post-procedure in both groups. In the intervention group, anxiety decreased modestly after video viewing. Patients rated the video as helpful for understanding (8.75/10), calming nerves (8.44/10), and improving cooperation (8.55/10). No significant differences were observed in pain scores, heart rate, procedure time, or surgeon-rated cooperation.

Conclusions: Preoperative procedure video viewing is a simple, low-cost, and convenient approach to enhance both patient experience and the safety of IVI.

Abstract No.: 208620

Prevalence of Psychiatric Disorders in Chinese Patients With Age-Related Macular Degeneration

First Author: Raymond Lai-man WONG

Co-Author(s): Wing Yi Chilli LAU, Fiona LUK, Shaheeda MOHAMED, Simon Ka-ho SZETO, Carolyn Ka-wing WONG

Purpose: To determine the prevalence of psychiatric disorders in Chinese patients with age-related macular degeneration (AMD), identify clinical correlates,

and assess the effectiveness of the 12-item General Health Questionnaire (GHQ-12) and Hospital Anxiety and Depression Scale (HADS) in detecting psychiatric morbidity.

Methods: This cross-sectional study recruited consecutive Chinese AMD patients attending an ophthalmology clinic over six months. Data collected included demographics, medical and psychiatric history, ophthalmological details, and subjective visual disability. GHQ-12 and HADS scores were obtained. All subjects underwent the Structured Clinical Interview for DSM-IV Axis I Disorders (SCID) to identify psychiatric disorders.

Results: Among 132 recruited subjects, point prevalences of psychiatric morbidity and depressive disorder were 17.4% and 12.9%, respectively. Visual disability was significantly correlated with both current psychiatric disorder and current depressive disorder. Receiving Comprehensive Social Security Allowance (CSSA) and poor visual acuity were possible correlates of current depressive disorder. The GHQ-12, using 4-point Likert scoring at a cutoff of 10/11, provided optimal sensitivity and specificity for detecting psychiatric morbidity. HADS-D and HADS-A at cutoffs 2/3 and 3/4, respectively, demonstrated good psychometric properties for screening depressive and anxiety disorders.

Conclusions: Psychiatric morbidity and depressive disorders are common among Chinese AMD patients. Identifying significant correlating factors and establishing optimal cutoff thresholds for GHQ-12 and HADS can assist ophthalmologists in early detection of psychiatric morbidity and facilitate timely referral to psychiatric services.

Abstract No.: 201781

Proteome Profiling in Vitreous Reveals the Targets and Potential Signaling Pathways of Angiopoietin-2

First Author: Yan **SHAO**

Purpose: To investigate the intraocular role of Ang-2 by preoperative intravitreal injection of faricimab in patients with proliferative diabetic retinopathy (PDR) and to clarify the molecular mechanisms underlying the therapeutic effects of faricimab.

Methods: Patients with vitreous hemorrhage secondary to PDR received preoperative intravitreal injection of faricimab (dual Ang-2/VEGF inhibitor) or aflibercept (VEGF inhibitor). Vitreous humor samples were collected during vitrectomy and subjected to label-free LC-MS/MS proteomic profiling. Differentially expressed proteins were identified, followed by gene set enrichment analysis (GSEA), and protein-protein interaction (PPI) network construction. Key targets were further validated by quantitative assays.

Results: A total of 351 vitreous proteins were identified, among which 42 were differentially expressed between the two groups. Faricimab markedly reduced Ang-2 levels (~1500-fold) and significantly downregulated TIE2-associated signaling proteins, including KDR (VEGFR2), HMGB1, and F2, while upregulating immune-regulatory proteins such as C1QC and RAB10. Enrichment analysis revealed Ang-2/TIE2 involvement in angiogenesis, extracellular matrix organization, oxidative stress response, and inflammation. GSEA further demonstrated modulation of mTOR, VEGF, Ras, and KEAP1-NFE2L2 signaling cascades. PPI network analysis highlighted F2, APOH, and KDR as central hubs. Validation confirmed suppression of KDR and P4HB in the faricimab group. Faricimab downregulated fibrosis- and inflammation-related proteins including LTBP3, COL6A1, CCL14, and HMGB2.

Conclusions: This study provides the proteomic evidence in human PDR that Ang-2/TIE2 signaling serves as a regulator of intraocular cytokine networks. These findings enrich and clarify the understanding of Ang-2/TIE2 signaling in real-world disease conditions, with implications for improved clinical outcomes in PDR.

Abstract No.: 200620

Real-Life Short-Term Experience of Switching From Other Anti-VEGF Therapy to Faricimab in Patients With Refractory Macular Edema Secondary to Retinal Vein Occlusion in China

First Author: Sun **YAOYAO**

Co-Author(s): Qi **HUIJUN**

Purpose: This retrospective, case series study is to evaluate real-world outcomes of faricimab in Chinese patients with persistent macular edema secondary to retinal vein occlusion (RVO).

Methods: This retrospective study analyzed the outcomes after the injections of faricimab in both persistent macular edema secondary to central RVO (CRVO) and branch RVO (BRVO). All patients would be treated with injections of faricimab under the pro re nata (PRN) regimen. Best corrected visual acuity (BCVA), central macular thickness (CMT), intraretinal fluid (IRF), and subretinal fluid were described and analyzed.

Results: Fifty-two eyes of 52 patients met the criteria and were enrolled in the study. Prior to enrollment, patients received an average of 9.16 ± 4.26 anti-VEGF injections, with 18 patients (34.62%) receiving an average of 3.23 ± 1.42 sustained-dexamethasone intravitreal implant. After the switch, patients received an average of 2.97 ± 0.74 injections, with a mean follow-up duration of 25.65 ± 11.87 weeks after IVF. After the third injection, BCVA was significantly improved from 40.13 letters to 46.75 letters, and CMT was significantly decreased from $547.4 \mu\text{m}$ to $216.4 \mu\text{m}$. Of the patients experiencing SRF or IRF at baseline, 78.85% had complete fluid resolution by the end of the follow-

up period. 73.08% of all the patients extended the treatment interval to 12 weeks or longer. No significant systemic and ocular adverse events were observed during the follow-up period.

Conclusions: This study demonstrates that faricimab significantly improves visual acuity and reduces CMT in previously treated RVO-ME patients, with a favorable safety profile.

Abstract No.: 207123

Real-World Comparison of Bevacizumab Innovator (Avastin) and Bevacizumab Biosimilar (Bevatas) for Retinal Vascular Diseases in a Private Eye Hospital of Western Nepal

First Author: Roshija **KHANAL RIJAL**

Co-Author(s): Amrit **BANSTOLA**

Purpose: To compare treatment frequency, visual and anatomical outcomes, and safety of Avastin versus its Bevatas, in retinal vascular diseases, and to evaluate the role of biosimilars as cost-effective alternatives in a low- and middle-income country like Nepal.

Methods: A retrospective review was performed on 269 eyes with diabetic macular edema, retinal vein occlusion with macular edema, or neovascular AMD treated with intravitreal Avastin (n=174) or Bevatas (n=95) between January 2023 and December 2024 at a tertiary center in Nepal. Outcomes included best-corrected visual acuity (BCVA), central retinal thickness (CRT), injection frequency, and ocular/systemic safety at 12 months.

Results: Baseline characteristics were comparable between groups. At 12 months, mean BCVA gain was +7.8 letters with Avastin and +7.2 letters with Bevatas (p=0.48). Mean CRT reduction was -122 µm vs -120 µm (p=0.82). The average number of injections was 6.4 vs 6.1 (p=0.09). Rates of ≥2-line VA improvement were 62.6% and 60.0%, respectively. Safety outcomes were similar, though mild ocular inflammation occurred slightly more often with Bevatas (3.3% vs 1.3%, NS). No systemic adverse events were observed.

Conclusions: Avastin and Bevatas demonstrated equivalent efficacy, treatment burden, and safety in retinal vascular diseases. In an LMIC setting such as Nepal, Bevatas represents a cost-effective and practical alternative to innovator Avastin, supporting its role in expanding access to anti-VEGF therapy.

Abstract No.: 201824

Real-World Effectiveness of Faricimab in Chinese Patients With Neovascular Age-Related Macular Degeneration: 3-Month Results From the Farseeing Study

First Author: Chenjin **JIN**

Co-Author(s): Xiaorong **LI**, Kun **LIU**, Xinjun **REN**, Xun **XU**

Purpose: The Farseeing study (NCT06439576) is a non-interventional real-world study conducted in 50 sites in China, collecting primary data of approximately 1000 patients with neovascular age-related macular Degeneration (nAMD), diabetic macular edema (DME), or macular edema secondary to retinal vein occlusion (RVO) to assess the effectiveness and safety of faricimab. Here, we report the first interim analysis in nAMD patients.

Methods: This interim analysis included data from April 2024 to January 2025 and included nAMD and polypoidal choroidal vasculopathy (PCV) patients from 22 sites. Management was as per usual care, with no mandated scheduled visits or imaging protocol requirements. Visual acuity (VA), central subfield thickness (CST), and the proportion of eyes with retinal fluid were evaluated at baseline and 3 months. Incidence of safety events was collected with any duration of follow-up. Descriptive analyses were performed.

Results: A total of 79 nAMD patients (87 eyes) were included in this analysis. Mean VA (standard deviation [SD]) change from baseline to month 3 was +2.4 (12.7) letters in switched eyes with nAMD, the mean CST (SD) change was -56.01 (138.31) µm, and the investigator-determined subretinal fluid (SRF) and intraretinal fluid (IRF) decreased. Similar results were observed in switched eyes with PCV.

Conclusions: The results of the cohort of nAMD patients in the Farseeing study will show the real-world effectiveness and safety of faricimab in the treatment of nAMD patients in China, and the relevant data of PCV patients will also provide a treatment reference for this high-incidence subtype.

Abstract No.: 203464

Real-World Efficacy and Safety of Aflibercept 8mg in Australian Patients With Neovascular Age-Related Macular Degeneration: 6-Month Outcomes From the CUREOS Research Network

First Author: Hemal **MEHTA**

Co-Author(s): Geoffrey **BROADHEAD**, Andrew **CHANG**, John **CHANG**, Thomas **HONG**, Long **PHAN**

Purpose: To study the effectiveness of high-dose aflibercept 8mg (HDA) for neovascular age-related macular degeneration (nAMD) in routine clinical practice.

Methods: Multi-centre retrospective audit of nAMD eyes commencing HDA therapy in Australia. Data was collected over a 6-month period, which included: demographics, treatment history, visual acuity (VA), and adverse events (AEs). Optical coherence tomography images were graded for anatomic outcomes, including central subfield thickness (CST) and retinal fluid status.

Results: Of 208 eyes, 44 (21%) were treatment-naïve, and 164 (79%) were previously-treated (switched). Switched eyes received a mean of 4.5 injections in the preceding six months, with aflibercept 2mg in 83% and faricimab in 14% of eyes prior to HDA. In naïve eyes, mean VA and CST changes were +7.8 letters ($p=0.001$) and $-107.1 \mu\text{m}$ ($p<0.001$) after three injections. In active eyes at switch, mean VA change was +1.3 letters ($p=0.074$) and mean CST change was $-24.7 \mu\text{m}$ ($p=0.020$) after three injections. In inactive eyes at switch, mean VA change was -0.5 letters ($p=0.746$) and mean CST change was $+0.3 \mu\text{m}$ ($p=0.728$) after three injections. Six months from switching, 64% of eyes were treated at extended intervals, 2 weeks or more than prior to HDL, with no eyes requiring reduced treatment intervals. There were no serious treatment-related adverse events identified.

Conclusions: In this Australian population, HDA demonstrated favourable visual and anatomic outcomes in nAMD with no new safety signals beyond the clinical trials. Extended treatment intervals were observed in previously-treated eyes, including those switched with active disease.

Abstract No.: 202777

Real-World Evidence on First-Line Treatment Versus Switching to Faricimab for Hyperpermeable Diabetic Macular Edema During Loading Phase

First Author: He-nan LIU

Purpose: Hyperpermeable diabetic macular edema (DME), characterized by intraretinal and subretinal fluid with hyperreflective foci and/or hard exudates, as a remarkable subtype of DME, had a poor response to single-pathway anti-VEGF agents, which was defined as a reduction in central subfield thickness (CST) of $<10\%$ and a gain of <5 ETDRS letters in best-corrected visual acuity (BCVA). The purpose of the investigation is to identify the dual-pathway anti-VEGF agent faricimab as a preferred administration for patients with hyperpermeable DME.

Methods: This is real-world evidence of a retrospective cohort study. The consecutive patients with hyperpermeable DME enrolled in the study were classified into three groups based on the timing of intravitreal faricimab: first-line group, included those eyes who received faricimab as a first-line therapeutic regimen; early-switch group, included those eyes who initially received conventional single-pathway anti-VEGF agents; after exhibiting a poor response

to treatment at 4 weeks, they switched to faricimab immediately; standard-switch group, included those eyes that initially received conventional single-pathway anti-VEGF agents; after exhibiting a poor response to treatment at 12 weeks, they switched to faricimab immediately. All patients were followed up for 52 weeks. The changes in CST and the number of ETDRS letters for BCVA were compared among the groups before and after treatment or switching therapy.

Results: The analysis included 79 eyes, 26 (32.9%), 28 (35.4%), and 25 (31.6%) in first-line, early-switch, and standard-switch groups, respectively. Intragroup comparison. In the first-line group, CST was significantly decreased, and BCVA was significantly improved compared with baseline ($P<0.05$) at 4, 12, 24, and 52 weeks. In the early-switch group: CST was significantly decreased, and BCVA was significantly improved compared with pre-switch values ($P<0.05$) after switching to faricimab at 12, 24, and 52 weeks. In the standard-switch group: CST was significantly decreased, and BCVA was significantly improved compared with pre-switch values ($P<0.05$) after switching to faricimab at 24 and 52 weeks. Intergroup comparison. At 24 weeks and 52 weeks, compared with the standard-switch group, both the first-line group and the early-switch group showed significantly higher Δ CST ($P<0.05$) and Δ ETDRS ($P<0.05$).

Conclusions: For patients with hyperpermeable DME, faricimab should be initiated as early as possible to achieve significant improvements in macular edema and visual function.

Abstract No.: 204123

Real-World Faricimab Outcomes in Neovascular Age-Related Macular Degeneration and Diabetic Macular Edema: The VOYAGER Study

First Author: Voraporn CHAKITMONGKOL

Co-Author(s): Gloria C. CHI, Amanda DOWNEY, Robyn GUYMER, David KARDATZKE, Jörn SCHWEITZER

Purpose: VOYAGER (NCT05476926) is a global, real-world, prospective, five-year observational study in $>5,000$ patients initiating faricimab for nAMD (neovascular age-related macular degeneration), DME (diabetic macular edema), or retinal vein occlusion. Six-month nAMD and DME data are reported; one-year data will be presented.

Methods: Data on VA (visual acuity, ETDRS [Early Treatment Diabetic Retinopathy Study] letters), CST (central subfield thickness), SRF (subretinal fluid), IRF (intraretinal fluid), and safety were analyzed at baseline/month-6/year-1 in treatment-naïve and PT (previously-treated) eyes receiving faricimab from 2022–2024.

Results: nAMD 6-month cohort included 443 (482 eyes) treatment-naïve and 300 (339 eyes) PT patients.

Mean (SD [standard deviation]) VA changes from baseline were +3.6(14.0) and -0.1(10.7) ETDRS letters in treatment-naïve and PT eyes, respectively. Corresponding mean(SD) CST changes were -93.3(123.0) and -26.9(84.5)µm. DME 6-month cohort included 144(187 eyes) treatment-naïve and 101(129 eyes) PT patients. Mean(SD) VA changes were +6.7(14.3) and +0.5(11.8) ETDRS letters in treatment-naïve and PT eyes, respectively. Corresponding mean(SD) CST changes were -126.7(132.8) and -56.2(132.4)µm. SRF and IRF rates were lower at month-6 vs baseline in treatment-naïve and PT nAMD (SRF:30.2% vs 75.8%, 38.4% vs 60.9%; IRF:22.5% vs 52.3%, 29.4% vs 40.8%) and DME (SRF:3.1% vs 28.6%, 17.4% vs 22.4%; IRF:71.0% vs 89.9%, 70.6% vs 70.5%) eyes. Mean(SD) injections for treatment-naïve and PT eyes were 4.2(1.4), 4.2(1.5) for nAMD and 4.0(1.6), 4.0(1.7) for DME. Safety was consistent with faricimab phase-3 trials.

Conclusions: At month-6, VOYAGER study showed clinical benefits of faricimab in real-world nAMD and DME patients, supporting its real-world effectiveness and safety.

Abstract No.: 201407

Real-World Outcomes and Aqueous Humor Cytokine Analysis After Switch to Faricimab in Eyes With Treatment-Resistant Neovascular Age-Related Macular Degeneration

First Author: Han **ZHANG**

Co-Author(s): Jun **LI**

Purpose: To evaluate the short-term functional, anatomic outcomes, and changes in aqueous humor cytokine levels of patients with treatment-resistant neovascular age-related macular degeneration (nAMD) who were converted from aflibercept and/or ranibizumab to faricimab.

Methods: Only eyes treated with at least 3 consecutive injections of aflibercept/ranibizumab spaced 4-6 weeks apart prior to conversion and with at least 2 faricimab injections afterward were considered for inclusion. Best-corrected visual acuity (BCVA; in logarithm of the minimum angle of resolution) and central retinal thickness (CRT) were analyzed before and after the switch. Aqueous humor was collected before and after the switch, and angiopoietin-2 (Ang-2), placental growth factor (PlGF), vascular endothelial growth factor (VEGF)-A, monocyte chemoattractant protein (MCP)-1, and interleukin (IL)-6 levels were measured.

Results: Twenty-seven eyes of 29 patients were included. The mean logMAR visual acuity improved by the second visit after conversion compared to the pre-switch visit ($P = 0.083$). The average CRT significantly improved by the second visit following conversion ($P < 0.001$). Significantly decreased concentrations of VEGF-A and Ang-2 were observed after conversion.

Conclusions: Conversion to faricimab for treatment-resistant nAMD resulted in significant anatomic improvements. Faricimab treatment influenced the concentrations of various cytokines in the aqueous humor.

Abstract No.: 201056

Real-World Short-Term Efficacy Observation of Faricimab in the Treatment of Refractory Wet Macular Degeneration

First Author: Du **JIANTONG**

Co-Author(s): Li **JUN**

Purpose: This study aims to evaluate the short-term efficacy of switching to Faricimab in the treatment of refractory nAMD.

Methods: This is a retrospective study that included previously treated refractory nAMD patients who received 2-5 injections of Faricimab. Baseline data were collected from April 2024 to October 2024, and follow-up data were gathered until April 2025.

Results: This study included 26 participants (31 eyes) with an average age of 73.4 ± 7.7 years, of whom 53.8% were male. At baseline, all patients had previously undergone multiple anti-VEGF treatments, averaging 9.5 ± 5.4 sessions, yet still exhibited visual impairment and anatomical abnormalities, with a mean CST of 433.5 ± 195.5 µm. Over a follow-up period of at least six months, patients received an average of 3.2 ± 1.2 faricimab injections per eye, resulting in 77.4% of affected eyes showing visual improvement, with BCVA increasing by an average of 10.5 ± 11.8 letters. CST decreased by an average of 118.4 ± 139.0 µm, and the proportion of completely dry macular retinal areas increased from 32.3% to 77.4%, achieving 67.7% after the first faricimab injection. Additionally, the study found that in eyes with thicker choroid (submacular choroidal thickness exceeding 225 µm), baseline choroidal vascular index (CVI) was significantly correlated with anatomical outcomes: eyes with lower baseline CVI experienced greater CST reduction following faricimab treatment ($p = 0.001$).

Conclusions: Faricimab can provide significant visual improvement and anatomical enhancement for patients with refractory nAMD, while baseline CVI has certain predictive value for the treatment outcomes in patients with thicker choroid.

Abstract No.: 206411

Reassessing the Antioxidant Paradox: High Dietary PUFA and Vitamin E Linked to Increased Neovascular AMD Risk – a Case-Control Study

First Author: Dewi Fathin **ROMDHONIYAH**
Co-Author(s): Mohammad Eko **PRAYOGO**, Muhammad Bayu **SASONGKO**, Dian Caturini **SULISTYONINGRUM**, Supanji **SUPANJI**, Firman Setya **WARDHANA**

Purpose: The role of dietary nutrients in age-related macular degeneration (AMD) is complex, with an ongoing debate regarding high-dose antioxidant supplementation. This case-control study aimed to evaluate the association between nutritional intake and the risk of neovascular AMD (nAMD).

Methods: A total of 52 treatment-naïve patients with neovascular AMD (nAMD) and 50 control subjects were recruited from ophthalmology clinics at tertiary hospitals. Diagnosis was confirmed by a retinal specialist following a comprehensive assessment, including slit-lamp examination, dilated non-stereoscopic colour fundus photography, and spectral-domain optical coherence tomography (OCT). Dietary data were collected using both a semiquantitative food-frequency questionnaire and a 24-hour recall. The association between nutrient intakes and AMD risk was determined through multivariable-adjusted logistic regression analysis, employing Firth's penalised likelihood method to account for the modest sample size.

Results: Analysis of 24-hour recall data revealed significantly higher intakes of protein ($p = 0.007$), fat ($p = 0.015$), polyunsaturated fatty acids (PUFAs) ($p < 0.001$), and vitamin E ($p = 0.004$) in nAMD patients compared to controls. In the multivariable-adjusted logistic regression analysis using Firth's penalised likelihood method, the highest tertile of PUFA intake was associated with a 7.2-fold increase in the odds of nAMD (95% CI 2.3–23.1, $p = 0.001$), while the highest tertile of vitamin E intake was associated with a 4.3-fold increase (95% CI 1.3–14.0, $p = 0.02$), both compared to the lowest tertile.

Conclusions: This study suggests that a higher dietary intake of PUFA and vitamin E is associated with increased odds of nAMD. These findings challenge conventional views on the role of antioxidant nutrients. While requiring validation in prospective studies, these results emphasise the need for personalised nutritional approaches in AMD management rather than universal supplementation strategies.

Abstract No.: 202790

Redefining Inherited Retinal Disease: Modifier-Driven Variability in EYS- and USH2A-Associated Retinitis Pigmentosa

First Author: Beau **FENNER**
Co-Author(s): Choi Mun **CHAN**, Ranjana **MATHUR**, Jean **NEO**, Mathieu **QUINODOZ**, Carlo **RIVOLTA**, Tien-en **TAN**, Rachael **TANG**

Purpose: Inherited retinal diseases (IRDs) are traditionally viewed as Mendelian disorders with predictable genotype–phenotype correlations. We tested this assumption in two of the most common IRD genes, EYS and USH2A, by asking whether matched genotypes truly yield matched disease expression.

Methods: We prospectively enrolled patients with biallelic EYS- or USH2A-associated retinitis pigmentosa at the Singapore National Eye Centre (2021–2025). Genetic diagnoses were established by whole-exome sequencing. Disease severity was quantified using OCT-derived ellipsoid zone width and a novel principal component analysis (PCA)-based severity score that integrates both structural loss and progression rate to define a continuous disease trajectory.

Results: We analysed 78 individuals ($n = 30$ EYS; $n = 47$ USH2A) from 70 families. Despite matched pathogenic alleles among groups, we observed striking variability in age of onset, EZ width, and progression. In several genotypes, younger individuals were more severely affected than older carriers, and siblings with the same variants diverged markedly in severity. PCA-derived severity scores demonstrated broad dispersion across nearly all genotype-defined groups, indicating that primary alleles explain only a fraction of disease variation. Certain variants (e.g., large EYS deletions) are consistently associated with severe disease, but most genotypes showed unpredictable trajectories.

Conclusions: Our findings challenge the concept of recessive IRDs as monogenic diseases. Instead, they emerge as genetically primed conditions, profoundly shaped by as-yet-unidentified modifiers. This paradigm shift has wide-ranging implications: genetic testing alone cannot provide a prognosis, trial design must account for hidden variability, and the search for modifiers represents a transformative frontier for predictive medicine and targeted therapy across IRDs.

Abstract No.: 202431

Redefining Treatment in Neovascular Age Macular Degeneration: A Systematic Review and Meta-Analysis of Ranibizumab Biosimilars' Safety and Efficacy

First Author: Zahra **ZHAFIRA**

Purpose: This review aimed to evaluate ranibizumab biosimilars (RB) safety and efficacy in neovascular age macular degeneration (nAMD) management.

Methods: We conducted a systematic review and meta-analysis based on PRISMA criteria. Data of RCTs in MEDLINE, Scopus, and ScienceDirect from inception to August 17, 2025, were sought and computed using RevMan 5.4. Efficacy was assessed using mean differences (MD) via the generic inverse variance and inverse variance methods, while safety outcomes were analyzed using Mantel–Haenszel risk ratios (RR) with 95% CIs. Risk of Bias was assessed using RoB 2 for the randomized clinical trials.

Results: A total of 3085 patients (RB group: 1538; control group: 1547) from 5 RCTs suggest that no significant difference in mean BCVA change at 8 and 52 weeks (MD=−0.19, 95%CI=−1.79–1.42, $p=0.82$; MD=−0.96, 95% CI −2.33–0.40, $p=0.17$). Mean lesion area change at 24 weeks was also comparable (MD=−0.07, 95%CI=−0.41–0.27, $p=0.70$). In contrast, RB demonstrated a significant reduction in CNV leakage area at both 24 and 52 weeks (MD −0.10, 95%CI −0.15–−0.05, $p < 0.0001$; MD −0.40, 95%CI −0.45–−0.35, $p < 0.00001$), supporting their anatomical efficacy. Safety analyses revealed no significant differences in the incidence of treatment-emergent adverse events, serious ocular or non-ocular events, or anti-drug antibody development, indicating a favorable and comparable safety profile.

Conclusions: Ranibizumab biosimilars show comparable efficacy and safety, reinforcing their value as cost-effective options to expand access to sustained anti-VEGF therapy.

Abstract No.: 202065

Resveratrol Attenuates Diabetic RGCs Degeneration Through TRIM23-Dependent VDAC1 Ubiquitination and Mitophagy

First Author: Ruohong **WANG**

Co-Author(s): Xufang **SUN**

Purpose: Voltage-dependent anion channel 1 (VDAC1) plays a key role in mitochondrial quality control; however, its function in RGCs degeneration under diabetic conditions remains poorly understood. This study aims to investigate the role of VDAC1 in DR and explore its potential therapeutic target.

Methods: We examined VDAC1 expression in human donor retinal tissues, diabetic mice, and high-glucose-treated SH-SY5Y cells. Using virtual screening and molecular docking, we identified RSV as a potential VDAC1 inhibitor, which was further validated by surface plasmon resonance (SPR) binding assays and RSV-based pull-down experiments. VDAC1-knockdown SH-SY5Y cells were established. The effects of RSV were assessed by RGC survival and mitochondrial quality control. Potential interactors of VDAC1 were profiled by mass spectrometry. TRIM23-VDAC1 interaction along with ubiquitination modifications were confirmed by co-immunoprecipitation. Combination therapy involving RSV and AAV-SNCG-mediated TRIM23

overexpression was applied in both DR and acute ocular hypertension (AOH) models.

Results: VDAC1 was upregulated in RGCs under diabetic conditions. Knockdown of VDAC1 attenuated high-glucose-induced apoptosis. RSV bound to the S102, F103, and K113 pocket of VDAC1 with moderate affinity, enhanced VDAC1 ubiquitination, improved mitochondrial membrane potential, reduced reactive oxygen species (ROS), and facilitated P62/LC3-mediated mitophagy. Mechanistically, RSV promotes the contact of TRIM23 with VDAC1. This molecular engagement is mediated by the RING domain of TRIM23 and the N-terminal (N1-25) peptide of VDAC1, culminating in K27-linked ubiquitination of VDAC1. Combined treatment with RSV and RGCs-targeted TRIM23 overexpression reduced RGCs loss in both DR and AOH models.

Conclusions: Our study identifies VDAC1 as a key target in the degeneration of diabetic RGCs and demonstrates that RSV promotes TRIM23-dependent VDAC1 ubiquitination and mitophagy.

Abstract No.: 207317

Retinal and Choroidal Microvascular Changes in HIV: OCTA Evaluation With CD4 Correlation

First Author: Srishti **KHULLAR**

Co-Author(s): Vikas **AMBIYA**

Purpose: Subclinical microvascular changes in the retina and choroid may occur in HIV-positive individuals even without overt retinopathy. We aimed to evaluate retinal and choroidal microvascular alterations in HIV-positive participants using OCTA, and to explore their correlation with CD4 T-cell counts.

Methods: In this cross-sectional study, 50 HIV-positive individuals on stable antiretroviral therapy (undetectable viral load) and 50 age- and sex-matched healthy controls underwent macular OCTA imaging. Vessel density (VD) and vessel length density (VLD) were computed in segmented retinal (NFLVP, SVP, ICP, DCP) and choroidal layers, along with the foveal avascular zone (FAZ). HIV-positive participants were stratified by CD4 count (< 350 vs. ≥ 350 cells/mm³) to assess immune-status associations.

Results: Compared to controls, HIV-positive individuals demonstrated significantly reduced VD in the superficial vascular plexus (SVP) ($30.95 \pm 8.64\%$ vs. $34.98 \pm 4.70\%$, $p < 0.01$) and significantly elevated choroidal VLD (8.77 ± 0.75 mm/mm² vs. 8.01 ± 1.69 mm/mm², $p < 0.01$). Other retinal layers showed trends toward lower VD/VLD, though not reaching statistical significance. The superficial FAZ area was marginally larger in HIV subjects ($p = 0.08$). Within the HIV cohort, participants with CD4 < 350 cells/mm³ exhibited lower SVP VD (trend, $p = 0.067$) and significantly higher choroidal VLD ($p = 0.032$) than those with CD4 ≥ 350 .

Correlations between CD4 count and OCTA metrics were weak and not statistically significant ($r = 0.21$ for SVP VD, $r = -0.24$ for choroidal VLD).

Conclusions: OCTA reveals early subclinical microvascular alterations in HIV-positive individuals, especially in those with lower CD4 counts. The pattern of reduced superficial VD and increased choroidal VLD suggests vascular remodeling or compensatory changes in immune-compromised states. These findings support the potential of CD4 count as a biomarker for ocular microvascular health in HIV, and underscore the utility of OCTA in detecting vascular dysfunction before overt retinopathy develops.

Abstract No.: 202450

Risk of Retinal Artery Occlusion Progression in Paracentral Acute Middle Maculopathy Without Retinal Vascular Disease

First Author: Hokoru **YOSHIOKA**

Co-Author(s): Takanori **AOKI**, Kentaro **KOJIMA**, Kosaku **NUMA**, Chie **SOTOZONO**, Hiroshi **TANAKA**

Purpose: Paracentral acute macular degeneration (PAMM) shows distinct en face OCT patterns that may reflect disease severity and progression risk. We aimed to classify these morphological patterns and evaluate their clinical significance.

Methods: We retrospectively reviewed 14 cases of PAMM diagnosed between January 2017 and October 2024. En face OCT patterns were classified and correlated with visual outcomes, lesion extent, and progression to retinal artery occlusion (RAO). Cases with a history of retinal vascular disease were excluded.

Results: The median age was 73 years (IQR, 61.75-79), and 10 patients (71.4%) were male. Median interval from symptom onset to presentation was 3 days (IQR, 0.5-8.5). Progression to complete RAO within 24 hours occurred in 2 patients (14.3%). Three distinct en face patterns were identified: perivenular fern-like ($n=5$), globular ($n=3$), and mixed patterns ($n=6$). Five cases (35.7%) demonstrated diffuse lesion distribution, while 9 cases (64.3%) showed sectoral involvement. The two cases progressing to RAO shared poor initial visual acuity and diffuse patterns. Initial visual acuity was significantly worse in diffuse patterns, often involving the macula, than in sectoral patterns (0.52 vs -0.02 , $p=0.025$). Both CRAO cases within 24 hours exhibited diffuse perivenular fern-like patterns, suggesting this morphology may predict higher ischemic progression risk.

Conclusions: En face OCT pattern classification in PAMM provides valuable prognostic information. PAMM with diffuse involvement indicates increased risk for progression to severe retinal ischemia. Such cases may warrant closer monitoring and early intervention.

Abstract No.: 200305

Role of Insulin-Like Growth Factor-1 (IGF-1) & Postnatal Growth Failure in ROP In Babies Weighing <1500 Grams

First Author: Amit Kumar **DEB**

Co-Author(s): Sandip **SARKAR**

Purpose: Low postnatal serum IGF-1 levels and slow postnatal weight gain are associated with severe ROP in many Western studies. However, similar studies in the Indian cohort of preterm babies are limited. The objective of this study was to determine the role of IGF-1 and postnatal growth failure (PNGF) in predicting ROP in babies <1500 grams in a south Indian cohort.

Methods: A total of 329 preterm neonates were screened for ROP. Babies screened for ROP were categorized based on the highest ROP stage in either eye. Weekly serial birth weight was estimated & growth was monitored using growth charts; growth failure was diagnosed based on the Z score. Blood samples for IGF-1 were collected between 30 and 33 weeks for each baby.

Results: The median IGF-1 levels were lower in the babies with any stage ROP (18.82 ng/ml) than in no ROP (28.81 ng/ml) ($p=0.002$). On logistic regression analysis, PNGF was independently associated with ROP development with an odds ratio of 2.07 (CI 1.04-4.11). The area under the curve of the receiver operating characteristic for both IGF-1 levels and postnatal weight gain was >0.5 , implying good diagnostic accuracy in predicting ROP.

Conclusions: The current study results show that low IGF-1 and PNGF are additional important risk factors for ROP development. This study is the first to estimate serum IGF-1 levels in preterm babies to establish ROP risk in an Indian cohort.

Abstract No.: 200408

Role of Triggering Receptor Expressed on Myeloid Cells-1 (TREM-1) in the Prognostic Evaluation in Bacterial Endophthalmitis

First Author: Joveeta **JOSEPH**

Co-Author(s): Md Hasnat **ALI**, Sreyasi **MAITI**, Dhanwini **RUDRAPRASAD**

Purpose: Infectious endophthalmitis is a sight-threatening intraocular infection requiring rapid and accurate diagnosis, particularly in culture-negative cases. This study explores the potential of soluble Triggering Receptor Expressed on Myeloid Cells-1 (sTREM-1) and sTREM-2 as biomarkers through transcriptomic and protein analysis.

Methods: Transcriptomic profiling of C57BL/6 mice with *Pseudomonas aeruginosa* endophthalmitis identified immune-related gene expression changes at 24h post-infection (p.i). Following this, ELISA-based quantification of sTREM-1 and sTREM-2 was conducted

on 62 vitreous samples, including 30 culture-positive, 17 culture-negative, and 15 non-infectious cases. ROC analysis was used to assess the diagnostic performance of these biomarkers and correlated with clinical severity.

Results: Transcriptomic analysis revealed significant enrichment of immune pathways, including ILs and T-cell receptor signalling. Notably, Trem1 was highly upregulated, while Trem2 was downregulated, suggesting differential immune activation. ELISA analysis demonstrated that sTREM-1 levels were significantly elevated in bacterial endophthalmitis ($p < 0.001$; cutoff >446.72 pg/mL), with strong correlations to disease severity. In contrast, sTREM-2 levels were markedly suppressed across infected groups. ROC analysis showed sTREM-1 had high sensitivity ($>90\%$) and specificity ($>90\%$) for differentiating infection, including culture-negative cases, while sTREM-2 alone had limited diagnostic power.

Conclusions: Our findings establish sTREM-1 as a promising biomarker for bacterial endophthalmitis, particularly in culture-negative cases, while sTREM-2 appears to play a regulatory role in inflammation. The strong correlation between sTREM-1 levels and disease severity highlights its potential as both a diagnostic and prognostic marker.

SPECTRUM: Early Data From a Global Real-World Study of Aflibercept 8 mg in Neovascular Age-Related Macular Degeneration

First Author: Andrew CHANG

Co-Author(s): Helmut ALLMEIER, Clare BAILEY, Varun CHAUDHARY, Zoran HASANBASIC, Martin KIRCHNER, Clemens LANGE, Paolo LANZETTA, Tobias MACHEWITZ, Marion R. MUNK, Hassiba OUBRAHAM, Xin ZHANG

Purpose: To present early results from the global Phase 4 SPECTRUM study of aflibercept 8 mg in patients with neovascular age-related macular degeneration (nAMD).

Methods: SPECTRUM (NCT06075147) is an ongoing, 24-month, prospective observational study. In the treatment-naïve (TN) and previously treated (PT) nAMD cohorts, patients aged ≥ 50 years who have been prescribed aflibercept 8 mg by their physician are eligible for enrollment. Data are collected during routine visits. All analyses are exploratory.

Results: In the TN nAMD Week 8 analysis (first ~ 100 patients with a visit and visual acuity [VA] assessment at Week 8), the mean change (observed cases) from baseline (BL) in VA was $+3.2$ letters ($n=114$; BL, 60.1 letters), and the mean central retinal thickness (CRT) change was -115 μm ($n=72$; BL, 367 μm). In the PT nAMD Month 6 analysis (first 150 patients to complete Month 6), the mean change (last observation carried forward) from BL in VA was -0.7 letters ($n=148$; BL,

63.0 letters), and the mean CRT change was -31 μm ($n=115$; BL, 320 μm).

Conclusions: These interim SPECTRUM analyses provide early insights into real-world outcomes in patients with nAMD.

Abstract No.: 208387

Seasonal Variations of Central Retinal Artery Occlusion

First Author: Chi Lik AU

Purpose: To systematically review the existing literature on seasonal variations in the incidence of central retinal artery occlusion (CRAO) and present the primary data of seasonal variations in Hong Kong from the HORA study.

Methods: A comprehensive literature search was performed across databases, including PubMed, Google Scholar, and relevant ophthalmic journals, for studies published up to October 2025 examining seasonal or monthly patterns in CRAO incidence. Keywords included «central retinal artery occlusion,» «CRAO,» «seasonal variations,» «incidence by season,» and «environmental factors.» Studies were included if they reported on CRAO specifically; those focused solely on retinal vein occlusion or general stroke without CRAO data were excluded. Data extraction focused on study design, sample size, incidence patterns, statistical analyses, and correlations with weather or pollution variables

Results: The review identified limited but high-quality evidence on seasonal variations in CRAO, with one major retrospective study dominating the findings. In a 15-year analysis of 432 CRAO cases from a German tertiary center, significant monthly ($p=0.025$) and seasonal ($p=0.008$) variations were observed, with peak incidence in February (adjusted cumulative incidence: 50.61) and winter (131.51), and lowest in June (23.34) and summer (84.37). Winter incidence was 1.55 times higher than summer. Weak to moderate inverse correlations were found with temperature (Spearman's $\rho \approx -0.15$ for average, minimum, and maximum temperatures; $p < 0.05$) and positive correlations with air pollutants, including NO_2 ($p < 0.01$) and $\text{PM}_{2.5}$ ($p \approx 0.05$), but not PM_{10} , O_3 , precipitation, or atmospheric pressure. Annual CRAO cases remained stable (21–40/year), with no long-term trends. Older literature primarily addressed general CRAO epidemiology or retinal vein occlusion, with no pre-2023 studies directly reporting significant seasonal patterns in CRAO incidence. Related stroke literature suggests analogous winter peaks in cerebral ischemic events, potentially extending to CRAO as a retinal stroke equivalent.

Conclusions: Current evidence indicates that CRAO incidence exhibits pronounced seasonal variation, peaking in winter and correlating with colder

temperatures and elevated air pollution levels. These findings underscore the need for heightened clinical awareness during high-risk seasons and further prospective, multi-center studies

Abstract No.: 207422

Seeing the Invisible: OCTA Reveals Subclinical Ischemia and Predicts Visual Outcomes in Diabetic Eyes Without Retinopathy Undergoing Cataract Surgery

First Author: Rohith Reddy YEDDULA VENKATA

Co-Author(s): Sreedeeep AMARAVADI, Harshitha C, Sasankadhar Reddy MUDUMALA, Sri Satviki POSINA, Sangeetha T

Purpose: To uncover hidden retinal microvascular alterations using optical coherence tomography angiography (OCTA) in diabetic eyes without clinical retinopathy undergoing cataract surgery, and to determine whether these preoperative biomarkers predict postoperative vision.

Methods: This prospective study enrolled 194 type-2 diabetic eyes (>5 years duration) with visually significant cataract but no fundus signs of retinopathy. All underwent standardized small-incision cataract surgery or phacoemulsification. Pre- and 30-day postoperative OCTA 3×3 mm scans quantified superficial/deep plexus vessel density (VD) and foveal avascular zone (FAZ) area. Best-corrected visual acuity (BCVA, logMAR) was measured. Paired t-tests compared vascular parameters; Pearson correlation assessed associations between baseline OCTA metrics and postoperative BCVA.

Results: OCTA revealed silent microvascular rarefaction preoperatively, invisible on clinical examination. Following surgery, VD showed a robust increase in both plexuses (mean gain +5.6%, $p < 0.01$) and FAZ area contracted significantly (mean -0.04 mm^2 , $p < 0.05$). Baseline FAZ was a strong negative predictor of BCVA improvement ($r = -0.52$, $p < 0.001$), and lower deep plexus VD correlated with limited visual gain ($r = -0.48$, $p < 0.01$). Eyes with healthier preoperative microvasculature achieved near-normal visual acuity despite identical surgical technique.

Conclusions: OCTA not only detects the undetectable but also forecasts who will see best after surgery — offering a paradigm shift in preoperative counseling and individualized surgical planning for diabetics without retinopathy. Routine OCTA integration could transform visual prognostication and elevate pre- and postoperative care standards.

Abstract No.: 203385

Senescence-Induced Endothelial-to-Mesenchymal Transition Accelerates the Subretinal Fibrosis in Neovascular Age-Related Macular Degeneration

First Author: Yinhao WANG

Purpose: Subretinal fibrosis remains a severe vision loss in neovascular age-related macular degeneration (nAMD). Cellular senescence and endothelial-to-mesenchymal transition (EndMT) have been implicated in nAMD pathogenesis. We tend to explore the association between senescence and EndMT in subretinal fibrosis.

Methods: We analyzed single-cell RNA sequencing data to investigate the role of senescent choriocapillary endothelial cells (CapECs) in subretinal fibrosis. In vitro assays were performed to validate the link between senescence and EndMT. We utilized Brown-Norway rats and INK-ATTAC mice with laser-induced subretinal fibrosis to evaluate the therapeutic effects of senolytic treatment (dasatinib plus quercetin, D+Q) or selective clearance of p16INK4A-positive cells. Additionally, young (2–3 months) and old (18 months) C57BL/6J mice were compared to assess the influence of aging on EndMT and fibrosis.

Results: CapECs in nAMD exhibited elevated SenMayo GSVA scores, and upregulated differentially expressed genes (DEGs) were enriched in senescence and mesenchymal transition pathways. A higher proportion of senescence-like CapECs (17.68%) was observed in nAMD, which also showed increased mesenchymal scores and TGFB1 expression. Senescent endothelial cells in laser-induced fibrotic models and bleomycin/doxorubicin-treated human umbilical vein endothelial cells underwent enhanced EndMT. Early intervention with D+Q or removal of p16INK4A-positive cells markedly reduced subretinal fibrosis and restored retinal function. Furthermore, endothelial cells from old mice exhibited heightened EndMT and more severe subretinal fibrosis compared to those from young mice.

Conclusions: Our study demonstrates that accumulation of senescent endothelial cells promotes subretinal fibrosis via EndMT in nAMD. Targeting these cells represents a promising therapeutic strategy for mitigating fibrosis-associated vision loss.

Abstract No.: 203398

Serum Pro-Brain Natriuretic Peptide Levels Correlate With Retinal Photoreceptor Ellipsoid Zone Disruption in Proliferative Diabetic Retinopathy

First Author: Shivani CHATURVEDI

Co-Author(s): Levent AKDUMAN, Sandeep SAXENA

Purpose: Serum pro-brain natriuretic peptide (BNP) is a 32-amino-acid polypeptide hormone that has receptors

in the human retina, suggesting a role in maintaining the structural integrity of the retina. Correlation between serum pro-BNP levels and ellipsoid zone (EZ) integrity was evaluated in proliferative diabetic retinopathy (PDR).

Methods: A tertiary care center-based, cross-sectional, prospective study investigated 108 consecutive subjects aged between 40 and 65 years: controls, no diabetic retinopathy (NoDR), non-proliferative diabetic retinopathy (NPDR), and proliferative diabetic retinopathy (PDR) (n=27 each). Same-day analysis of blood samples for BNP levels was done on the Roche Elecsys cobas e 411 machine. EZ was evaluated on spectral-domain optical coherence tomography (SD-OCT). The caliper function was used to measure the EZ defect. Pearson correlation analysis was performed.

Results: Mean serum pro-BNP levels for controls, NoDR, NPDR, and PDR were 14.07 ± 11.51 , 27.35 ± 11.81 , 280.44 ± 106.13 , and 122.33 ± 43.66 pg/ml, respectively. Mean central subfield thickness (CST) for controls, NoDR, NPDR, and PDR were 248.65 ± 35.95 , 259.25 ± 50.04 , 329.70 ± 65.78 , and 394.60 ± 150.22 microns, respectively. Mean best corrected visual acuity (BCVA) for controls, NoDR, NPDR, and PDR were 0.31 ± 0.18 , 0.37 ± 0.13 , 0.68 ± 0.49 , and 1.19 ± 0.43 , respectively. EZ integrity was maintained in controls and NoDR groups. Mean EZ defect values in NPDR and PDR groups were 779.50 ± 121.50 and 1914.40 ± 291.15 μ m, respectively ($p < 0.001$). Serum pro-BNP levels had a significant negative correlation with EZ defect significant ($r = -0.417$, $p < 0.05$).

Conclusions: This novel research highlights that serum pro-BNP levels correlate significantly with EZ integrity and BCVA in PDR, playing a key role in its preservation.

Abstract No.: 205029

Short-Term Efficacy of Switching to Faricimab in Patients With Conbercept-Resistant Wet Age-Related Macular Degeneration

First Author: Sanhua XU

Co-Author(s): Xinbang MAO

Purpose: To evaluate the changes in the NEI-VFQ-25 score, visual and structural outcomes of faricimab in patients with conbercept-refractory wet age-related macular degeneration (wAMD).

Methods: To evaluate the changes in the NEI-VFQ-25 score, visual and structural outcomes of faricimab in patients with conbercept-refractory wet age-related macular degeneration (wAMD).

Results: In relation to the baseline (B0), the NEI-VFQ-25 score for general health and vision status, difficulty level during activities, reflections of the vision problems, and total mean scores increased significantly at B1, B2, and B3 ($P < 0.05$). Compared with the baseline (B0), the patients' BCVA and CMT showed significant improvements at B1, B2, and B3 (P

< 0.05), while the maximum PED height significantly improved at B3 ($P < 0.05$). BCVA (logMAR), CMT, and maximum PED height decreased from B0 to B3, and the IOP fluctuated within the normal range. Notably, the preoperative PED of 9 eyes was completely resolved at B3. A strong positive correlation was observed between CMT and maximum PED height at B0, B1, B2, and B3. Additionally, BCVA exhibited a strong positive correlation at different time points. No intraoperative or postoperative complications were reported among the 14 eyes.

Conclusions: Switching from conbercept to faricimab has a significant anatomical effect in eyes with wAMD, and treatments appear to be effective short-term treatment options. There is a trend towards greater visual improvements and reductions in CMT with faricimab.

Abstract No.: 206307

Sliding Conjunctival Seal for Intravitreal Injections

First Author: George LIU

Co-Author(s): Christopher LIU

Purpose: Feasibility study of implementing a sliding conjunctival seal to provide immediate protection to the scleral entry site for intravitreal injections. Repeated injections for wet macular degeneration and macular oedema require different methods to reduce the risk of infectious endophthalmitis (Povidone Iodine, injector wearing mask, not talking, clean technique, clean room, eye shield, patient not wearing mask; topical antibiotic no longer used). We propose a sliding conjunctival seal to further mitigate the risk of infection. A literature search of "intravitreal injections" AND "endophthalmitis" yielded no relevant results associated with conjunctival seals.

Methods: Retrospective review of 300 injections. 1. Mark 3.5 or 4 mm (pseudophakic/phakic eyes) with callipers before injection; 2. Slide or displace the conjunctiva sideways or towards the cornea by 2 to 3 mm; 3. Inject intravitreal solution adjacent to the calliper mark, thus avoiding injection through thin compressed sclera; 4. Allow conjunctiva to slide back so conjunctival and scleral entry sites are no longer aligned, thus providing an immediate physical seal against microbial entry.

Results: Technique achieved in 288 injections. In some eyes, there was conjunctival immobility. No cases of endophthalmitis were recorded. See the video with sound for illustration.

Conclusions: A sliding conjunctival seal may be a good method to guard against post-injection microbial entry in intravitreal injections. Care should be taken not to inject through the calliper mark as the sclera there would have been indented, compressed, thinned, and less able to close following injection. There should be

a reduction of post-injection endophthalmitis. A large-scale study is required to demonstrate efficacy.

Abstract No.: 206172

Small Intracellular Vesicles Outperform Small Extracellular Vesicles in Uptake, Drug Delivery, and Retinal Neuroprotection

First Author: Xiaomin ZHANG

Co-Author(s): Hui ZHANG

Purpose: Small extracellular vesicles (sEVs) have been widely studied for their therapeutic potential, but intracellular vesicles (sIVs), naturally present within cells, remain largely unexplored. This study aimed to establish isolation protocols for sIVs, characterize their molecular and functional properties, and evaluate their therapeutic potential compared with sEVs.

Methods: We developed standardized methods to isolate sIVs from multiple cell types. Their size, yield, and uptake efficiency were analyzed using in vitro and in vivo models. Multi-omics profiling, including proteomics, miRNA analysis, and lipidomics, was performed to identify molecular signatures. Therapeutic efficacy was assessed in a mouse model of retinal degeneration, and drug-loading studies were conducted to test the delivery efficiency of lipophilic compounds.

Results: Compared with sEVs, sIVs were smaller, yielded higher quantities, and showed enhanced uptake. Proteomic analysis revealed enrichment of endoplasmic reticulum and Golgi-associated proteins, while miRNA signatures highlighted links to intracellular membrane systems. Lipidomics indicated elevated phosphatidylcholine and phosphatidylethanolamine levels. Umbilical cord MSC-derived sIVs reduced endoplasmic reticulum stress and delivered neuroprotective factors in retinal degeneration. sIVs also demonstrated superior drug-loading capacity and efficient retinal delivery of lipophilic molecules.

Conclusions: sIVs exhibit distinct molecular profiles, enhanced bioactivity, and strong therapeutic potential compared with sEVs. Their ability to carry neuroprotective factors and improve drug delivery positions them as promising candidates for future therapeutic applications.

Abstract No.: 207055

Spectral-Domain OCT Features of Vision-Threatening Rhino-Orbito-Cerebral Mucormycosis

First Author: Ankur SINGH

Co-Author(s): Preeti DIWAKER

Purpose: To characterise vitreoretinal changes on spectral-domain OCT (SD-OCT) in vision-threatening rhino-orbito-cerebral mucormycosis (ROCM) and correlate in vivo imaging with histopathology.

Methods: Consecutive eyes with vision-threatening ROCM underwent examination, serial colour fundus photography, and SD-OCT at baseline and follow-ups. Central macular and inner, outer, and total retinal thickness were measured 1 mm nasal to the fovea. Two masked graders assessed layer integrity, reflectivity, hyperreflective foci, vitreous inflammation, posterior hyaloid changes, and outer-retinal “optically empty” spaces. In exenterated eyes, histopathology evaluated necrosis, lamellar disruption, inflammatory infiltrate, mucor hyphae, and vascular invasion.

Results: Fifteen eyes showed diffuse retinal whitening and boxcarring. Baseline SD-OCT demonstrated inner-retinal thickening with hyperreflectivity, loss of inner-retinal/outer-plexiform lamination, increased outer-retinal thickness, external limiting membrane disruption, and vitreous cells/haze. Early follow-up revealed reduced inner-retinal thickness with persistent hyperreflectivity; outer-retinal ill-defined, optically empty necrotic spaces and hyperreflective foci appeared, with widespread ELM/photoreceptor disruption. By last follow-up, all eyes exhibited further retinal thinning with collapse of necrotic spaces, posterior hyaloid thickening/partial detachment, inner-retinal fibrous scarring, and chorioretinal scarring with RPE hyperplasia. Quantitatively, macular and inner, outer, and total retinal thickness decreased over time ($p < 0.05$), with the greatest decrease in the inner retina. Histopathology confirmed choroidal/retinal necrosis, lamellar disorganisation, neutrophilic infiltrate, mucor hyphae, and thrombotic angioinvasion.

Conclusions: SD-OCT reveals a characteristic ischaemic signature in ROCM—diffuse inner-retinal hyperreflectivity with lamination loss and early vitreous inflammation—evolving to thinning, scarring, and RPE change. Combined with histopathology, findings implicate early retinal infarction from thrombotic angioinvasion with subsequent inflammatory remodelling, supporting SD-OCT for early recognition and prognostication.

Abstract No.: 201634

Study on the Efficacy of Faricimab in the Treatment of Refractory Wet Age-Related Macular Degeneration

First Author: Wei

Purpose: Evaluate the efficacy of intravitreal injection of Faricimab in the treatment of refractory nAMD patients.

Methods: Twenty patients with refractory nAMD who had previously undergone multiple ineffective treatments with VEGF were selected for intravitreal injection of Faricimab once at the ophthalmology department of Nanjing University of Chinese Medicine Affiliated Hospital from April 27, 2024, to May 31, 2024. The BCVA, macular retinal thickness, CST, CCT, and outer retinal thickness were evaluated before

treatment (T1), 1 week after treatment (T2), 1 month after treatment (T3), 2 months after treatment (T4), and 3 months after treatment (T5). The height and area of the highest point of PED, as well as the area of neovascularization (NA).

Results: Twenty eyes received treatment compared with before treatment, showed statistical significance one week after treatment; At the first month after treatment, BCVA ($P<0.001$), PED height ($P=0.043<0.05$), and NA ($P=0.023<0.05$) showed statistical significance; At the second month after treatment, BCVA ($P<0.001$), CST ($P=0.015<0.05$), MRT ($P=0.024<0.05$), and NA ($P=0.03<0.05$) showed statistical significance; At the third month, BCVA ($P<0.001$) and CST ($P=0.01<0.05$) PED height ($P<0.001$), PED area ($P=0.023<0.05$). It has statistical significance during the follow-up period; all patients did not experience ocular or systemic complications.

Conclusions: Faricimab provides a new treatment option in refractory nAMD patients.

Abstract No.: 204935

Study on the Relationship Between Continuous Glucose Monitoring Metrics and Retinal and Choroidal Blood Flow Density in a Normoglycemic Population

First Author: Yinchun **SHEN**

Co-Author(s): Yan **JIANG**, Kun **LIU**

Purpose: To evaluate the association between continuous glucose monitoring (CGM)-derived glucose variability indicators and OCTA parameters in normoglycemic individuals.

Methods: A total of 218 individuals at high risk for T2DM diagnosed with normal glucose tolerance (NGT) according to OGTT results were divided into the normal glucose fluctuation (NGF) group and the abnormal glucose fluctuation (AGF) group according to the mean amplitude of glycemic excursions (MAGE). The differences of FAZ, blood flow density in the retina and choroid, retinal thickness, choroidal thickness, RNFL thickness and GCL thickness between the two groups were analyzed. Generalized linear model analysis was utilized to identify risk factors.

Results: Compared with NGT participants with NGF, those with AGF had reduced blood flow density in the parafoveal nasal ($P=0.002$) and parafoveal superior ($P=0.025$) superficial layer and in the central deep layer ($P=0.047$). In the choroid, the volume of large vessels (CVV) and the volume area ratio of large vessels (CVV/a) in the central ($P=0.013$, $P=0.012$), parafoveal temporal ($P=0.048$, $P=0.049$), and parafoveal nasal ($P=0.010$, $P=0.011$) sides were decreased in the AGF group. In populations with AGF, parafoveal temporal ($P=0.003$) and parafoveal superior ($P=0.005$) retinal thickness; central macular ($P=0.011$), central (0.010), parafoveal superior ($P=0.045$) and parafoveal nasal ($P=0.006$)

choroidal thickness; parafoveal temporal RNFL thickness ($P=0.025$) and parafoveal temporal ($P=0.002$), parafoveal superior ($P<0.001$) and parafoveal inferior ($P<0.001$) GCL thickness were all decreased. In NGT individuals, MAGE, LAGE, family history of diabetes, SBP and HbA1c were identified as possible risk factors to predict the development of disease.

Conclusions: The research discovered that greater glucose variability is associated with decreased blood flow density, and taking proactive steps to address glucose variability early could alleviate the global burden of diabetes and its related complications.

Abstract No.: 207167

Subclinical Retinal Dysfunction in Type 2 Diabetes: Insights From Multifocal Electroretinography and Optical Coherence Tomography

First Author: Ankur **SINGH**

Co-Author(s): Shivansh **BANSAL**

Purpose: To evaluate whether multifocal electroretinography (mfERG)—alone and combined with spectral-domain optical coherence tomography (SD-OCT)—detects subclinical functional and structural retinal changes in type 2 diabetes mellitus (T2DM) without clinically evident retinopathy, and to explore associations with HbA1c.

Methods: Prospective observational study including 64 T2DM eyes without retinopathy and 64 matched healthy controls. mfERG assessed N1/P1 implicit times (IT) and P1 amplitudes across standardized retinal regions. SD-OCT measured foveal, parafoveal, and perifoveal thickness (10 ETDRS regions), including inner/outer/total retina 1 mm nasal to fovea. Multivariable regression adjusted for age, sex, and HbA1c.

Results: Compared with controls, T2DM eyes showed delayed IT for N1 and P1 in temporal regions ($P<0.05$) and reduced P1 amplitude ($P<0.01$). SD-OCT demonstrated thinner retina at the fovea (213.8 ± 19.8 vs 220.0 ± 18.8 μm ; $P<0.05$), temporal parafovea (320.9 ± 13.7 vs 324.0 ± 12.8 μm ; $P<0.05$), and temporal perifovea (276.4 ± 29.7 vs 284.8 ± 14.7 μm ; $P<0.05$). On regression, HbA1c $> 8.5\%$ independently correlated with reduced temporal perifoveal thickness ($P<0.01$), after adjusting for age and sex.

Conclusions: mfERG—alone and with SD-OCT—identifies subclinical retinal dysfunction and thinning in T2DM without clinical retinopathy, with a temporal predilection and thickness loss associated with poor glycaemic control. These biomarkers may support earlier risk stratification and prompt metabolic optimization to delay or prevent diabetic retinopathy progression.

Abstract No.: 204684**Sustained Hydrogel-Delivered Anti-Galectin-3 Therapy Disrupts Pathological Angiogenesis in Diabetic Retinopathy***First Author: Ziyi ZHOU**Co-Author(s): Tianfang CHANG, Guorui DOU, Yusheng WANG, Tianhao YUAN*

Purpose: Pathological angiogenesis is a hallmark of vision-threatening diabetic retinopathy (DR). This study aims to elucidate the role of microglia-derived Galectin-3 (Gal3) in promoting abnormal vessel growth and to develop a novel hydrogel targeting microglial Gal3 and endothelial Notch signal as a combined therapeutic strategy with anti-VEGF towards DR.

Methods: Using single-cell RNA sequencing of human fibrovascular membranes and murine OIR models, we identified Gal3 from activated microglia as a key mediator of pathological angiogenesis through competitive binding to Jag1 and inhibition of Notch signaling. We further engineered a sustained-release photocurable hydrogel for intravitreal delivery of a Gal3-neutralizing antibody, evaluating its effects on vascular pathology.

Results: Gal3 was significantly upregulated in activated retinal microglia under ischemic conditions. Mechanistically, secreted Gal3 bound to the Notch ligand Jag1 on endothelial cells, competitively inhibiting Notch signaling—a critical pathway for maintaining vascular quiescence. This disruption enhanced endothelial glycolytic metabolism and increased proliferation, leading to excessive angiogenesis. Intravitreal delivery of anti-Gal3 via hydrogel effectively restored Notch signaling, suppressed endothelial activation, and markedly reduced pathological neovascularization and vaso-oblivation in OIR mice, with sustained drug release and therapeutic effect beyond one week.

Conclusions: Our findings establish microglial Gal3 as a potent promotor of retinal angiogenesis through glycosylation-dependent interference with Jag1-Notch signaling in DR. The hydrogel-based anti-Gal3 delivery system offers a promising translational strategy, synergizing with anti-VEGF therapies to address refractory neovascularization and restore vascular homeostasis.

Abstract No.: 204599**Switching to Faricimab or High-Dose Aflibercept for Neovascular AMD: Impact on Injection Interval in a Real-World Cohort***First Author: Zachary ANGUS**Co-Author(s): Zhi LEE, Sukhpal SINGH SANDHU, Robyn TROUTBECK, Sanjeeva WICKREMasinghe*

Purpose: To compare changes in injection interval (primary outcome), best-corrected visual acuity (BCVA) and central subfield thickness (CST) (secondary

outcomes) in neovascular age-related macular degeneration (nAMD) patients switched to faricimab or 8mg high-dose aflibercept (HDA) from alternative anti-VEGF agents. Both agents have shown promise in extending treatment intervals, but real-world comparative data in previously treated eyes are limited.

Methods: This was a multi-centre retrospective observational cohort study. Eligible eyes had a diagnosis of nAMD and at least three anti-VEGF injections, both pre- and post-switch. Fifty-eight eyes of 50 patients switched to faricimab, and 42 eyes of 38 patients switched to HDA. Injection intervals were compared by averaging the final three intervals pre- and post-switch.

Results: Patients in the HDA and faricimab group were initially treated with 2 mg aflibercept (83% vs 91%), faricimab (14% vs 0%), ranibizumab (2% vs 7%), or brolucizumab (0% vs 2%) ($p = 0.017$, Chi-Squared Test). Both cohorts achieved similar significant extension of treatment intervals: faricimab $+1.21 \pm 1.81$ weeks ($p < 0.001^*$) and HDA $+1.20 \pm 2.34$ ($p = 0.002^*$) weeks. CST decreased similarly with both agents: faricimab $-24 \pm 94\mu\text{m}$ ($p = 0.005^*$) and HDA $-25 \pm 47\mu\text{m}$ ($p = 0.001^*$). BCVA significantly improved in the HDA cohort by $+3.2 \pm 7.5$ letters ($p = 0.014^*$), whereas a non-significant decline was observed in the faricimab cohort -1.9 ± 7.2 letters ($p = 0.078^*$). The faricimab group had significantly longer follow-up pre-switch (4.1 ± 2.5 years vs 3.1 ± 3.0 years, $p = 0.009^*$) and post-switch (1.1 ± 0.2 vs 0.8 ± 0.2 years, $p < 0.001^*$). * Wilcoxon Signed-Rank Test ^ Welch's T-Test

Conclusions: Switching to faricimab or high-dose aflibercept was associated with similar modest but statistically significant extension of injection intervals and improved anatomical outcomes in previously treated nAMD patients. High-dose aflibercept was additionally associated with improved BCVA. These findings support their role in reducing treatment burden, though prospective studies with longer follow-up are warranted.

Abstract No.: 205207**Targeted Micronutrient Supplementation in Managing Vitreous Floaters: Clinical Data and Practitioner Insights***First Author: Franziska WEIGLEIN**Co-Author(s): Thomas KAERCHER, John NOLAN, Warren ROCHE, Ulrich WELGE-LÜSSEN*

Purpose: Floaters are a common cause of visual disturbance. Non-invasive treatment options are limited. Here we summarize clinical evidence on the effectiveness of a targeted micronutrient complex (VitroCap®), which contains L-lysine, citrus extract, vitamin C, grape seed extract, and zinc, and conducted a survey with eye care professionals in Germany and Austria regarding its practical use.

Methods: Five clinical studies were evaluated: two observational trials (Kaercher 2013, Sobol 2018), two case-control studies (Marchenko 2015, Varganova 2019) – supplementation for 3 months, and one randomized, double-blind, placebo-controlled trial (FLIES, Ankamah 2021) – supplementation for 6 months. More than 500 patients were treated overall across these studies. Outcomes included subjective visual disturbance, quality of life, and objective floater area measured by OCT. A post-hoc effect size analysis quantified benefits in FLIES. Additionally, 96 eye care professionals participated in a survey on clinical experience with the micronutrient complex.

Results: Across studies, 65–88% of patients reported improvement. In FLIES, visual disturbance scores decreased significantly (3.90 ± 1.56 to 2.10 ± 0.79 ; $p < 0.001$), with OCT showing an 18% reduction in floater area ($p < 0.001$). Effect size analysis demonstrated medium-to-large benefits. Among professionals surveyed, 83.1% rated the complex as helpful or extremely helpful; 96.9% reported no side effects. A therapy duration of six months was commonly recommended.

Conclusions: Clinical evidence and practitioner experience support targeted micronutrient supplementation as an effective, safe, and non-invasive option for managing vitreous floaters.

Abstract No.: 206239

The Differential Expression and Domination of VEGFA121 in Proliferative Diabetic Retinopathy, Retinal Vein Occlusion, and Wet Age-Related Macular Degeneration: A Comparative Analysis of Vitreous VEGFA Isoforms

First Author: Raka Kurnia **RAMADHAN**

Co-Author(s): Dewi Kartikawati **PARAMITA**, Supanji **SUPANJI**

Purpose: To identify, quantify, and correlate the expression of VEGFA121, VEGFA165, and VEGFA189 protein isoforms in the vitreous of patients with proliferative diabetic retinopathy (PDR), retinal vein occlusion (RVO), and wet age-related macular degeneration (wet AMD), and to compare their expression with a non-angiogenic control group.

Methods: This cross-sectional study analyzed 22 vitreous samples, obtained through vitrectomy procedures, from patients with PDR ($n=8$), RVO ($n=3$), wet AMD ($n=4$), and rhegmatogenous retinal detachment as a non-angiogenic control ($n=7$). The three VEGFA isoforms were detected using Western blotting with a polyclonal anti-VEGFA antibody specific to all three isoforms, followed by densitometric analysis using ImageJ for expression quantification. Data were analyzed using one-way ANOVA, fold change analysis, and Pearson correlation tests.

Results: VEGFA121 and VEGFA165 isoforms were identified in all groups, while VEGFA189 was not detected. VEGFA121 and VEGFA165 expression was significantly higher in all disease groups compared to controls ($p < 0.05$), with no significant differences between angiogenic retinal disease groups. VEGFA121 was the predominant isoform in PDR, RVO, and wet AMD. A strong positive correlation between VEGFA121 and VEGFA165 was found only in the PDR group ($p=0.025$).

Conclusions: VEGFA121 and VEGFA165 are differentially expressed in angiogenic retinal disease compared to non-angiogenic controls, with VEGFA121 being the dominant isoform. A positive correlation was found only between VEGFA121 and VEGFA165 expression in PDR patients. These findings may provide a basis for developing more isoform-specific anti-VEGF therapies.

Abstract No.: 203563

The Effects of Different Anti-VEGF Drugs on Choroidal Neovascularization-Related Macular Atrophy in Pathological Myopia

First Author: Yu **MAO**

Co-Author(s): Yue **QI**

Purpose: To observe the efficacy of intravitreal injection of different anti-VEGF drugs on choroidal neovascularization (CNV)-related macular atrophy in pathological myopia.

Methods: This retrospective study included patients with CNV-related macular atrophy associated with pathological myopia who were treated in our hospital from January 2018 to July 2023. The patients were divided into two groups: group A (Ranibizumab, 18 eyes) and group B (Conbercept, 20 eyes). Both groups received 3+PRN regimen. The changes in area of CNV-related macular atrophy, BCVA, refractive error, and axial length before and 1 year after treatment were compared.

Results: Before treatment, there were no significant differences in the area of CNV-related macular atrophy, BCVA, refractive error, and axial length between the two groups ($P > 0.05$). After 1 year of treatment, both groups showed significant improvement in the BCVA (LogMAR). However, there was no significant difference between the two groups (0.77 ± 0.40 vs. 0.60 ± 0.46). In group A, the area of CNV-related macular atrophy increased from 7.21 ± 5.88 mm² to 14.93 ± 9.93 mm² after 1 year's treatment, showing a statistically significant difference ($p < 0.001$). While in group B, the atrophic lesion area was 5.63 ± 4.16 mm² to 7.73 ± 5.82 mm², with no significant difference ($P=0.198$). The expansion of the atrophic lesion area was smaller in group B than that in group A (group A 7.72 ± 6.24 mm² vs. group B 2.10 ± 1.90 mm²), and the difference was statistically significant ($P < 0.001$).

Conclusions: Compared with small molecule monoclonal antibody-based anti-VEGF drugs, fusion protein-based anti-VEGF drugs may have a better impact on the occurrence and development of PM-CNV-related macular atrophy.

Abstract No.: 205109

The Mongolian Medicine GuRiGuMu-13 Mitigates Ferroptosis in Retinal Ganglion Cells in Glaucoma via Activation of the NRF2/HO-1 Pathway

First Author: Minggao QIN

Co-Author(s): Qiuli ZHANG

Purpose: This study aims to analyze the targets of active substances in rat serum containing GRGM-13 and their relationship with ferroptosis pathways, and to further explore the mechanism of GRGM-13 in preventing RGC ferroptosis using in vitro and in vivo glaucoma models.

Methods: To analyze active ingredients from rat serum containing GRGM-13, UPLC-Q-TOF-MS/MS technology was utilized. Network pharmacology and bioinformatics methods were used to identify drug targets related to ferroptosis in glaucoma. HE staining and immunofluorescence were used to evaluate the in vivo effects of GRGM-13. The evaluation of cell ferroptosis in vitro involved a series of ferroptosis-related markers, including intracellular Fe²⁺ levels, lipid ROS, GSH levels, MDA levels, and the expression levels of related proteins. The role of the Nrf-2/HO-1 pathway was validated using Nrf-2 inhibitors or Si-Nrf2, and lipid metabolism differences were analyzed using UPLC-Q-TOF-MS/MS.

Results: In the rat serum with GRGM-13, 49 active components and 885 active substance targets were identified. After cross-matching glaucoma DEGs with ferroptosis-related genes, 80 glaucoma-related ferroptosis genes were identified, primarily involving key targets such as NFE2L2 and HMOX-1. In vivo and in vitro experiments showed that GRGM-13 inhibited ferroptosis in glaucoma and RGCs and activated the NRF2/HO-1 pathway. GRGM-13 affected lipid metabolism in RGCs, with the main pathways including alpha-linolenic acid, linoleic acid, and lysophosphatidylcholine.

Conclusions: This study confirmed the protective effect of GRGM-13 against ferroptosis in the optic nerve in glaucoma through activating the Nrf-2/HO-1 pathway. Our findings offer improved theoretical insights for using GRGM-13 in glaucoma treatment.

Abstract No.: 201873

To Study the Correlation of Corneal Hysteresis and Ocular Blood Flow in Retinal Vein Occlusion

First Author: Priya SHARMA

Co-Author(s): Mohd SHADAB

Purpose: To study the correlation of corneal hysteresis and ocular blood flow in retinal vein occlusion and to evaluate its potential risk in patients with retinal vein occlusion.

Methods: This cross-sectional study included 44 cases of retinal vein occlusion (22 BRVO and 22 CRVO) and 22 age- and gender-matched controls. Corneal hysteresis was analyzed using the Ocular Response Analyser (ORA), and colour Doppler imaging (CDI) was used to assess ocular blood flow in the central retinal artery, central retinal vein, and superior ophthalmic artery.

Results: The mean corneal hysteresis was lower in cases compared to controls. Statistically significant correlations were found between corneal hysteresis and superior ophthalmic artery peak systolic velocity, superior ophthalmic artery end-diastolic velocity, and superior ophthalmic vein resistive index. The correlation coefficients were -0.253 ($p = 0.040$), -0.295 ($p = 0.020$), and 0.317 ($p = 0.015$), respectively.

Conclusions: This study demonstrates a correlation between corneal hysteresis and ocular blood flow in retinal vein occlusion. The lower value of corneal hysteresis on ORA or the higher value of resistive index in ocular blood vessels on CDI can be considered as a risk factor for developing retinal vein occlusion disease. This study provides new insights into the pathophysiology of retinal vein occlusion and may help in the early detection and management of the disease.

Abstract No.: 204083

Transforming Geographic Atrophy Care: A Systematic Review and Meta-Analysis on Pegcetacoplan's Efficacy and Safety

First Author: Zahra ZHAFIRA

Co-Author(s): Ari DJATIKUSUMO, Anindita SHAQIENA

Purpose: This study aimed to assess the efficacy and safety of pegcetacoplan in advancing the management of geographic atrophy (GA).

Methods: This study was reported based on PRISMA criteria. The literature search was conducted in databases such as MEDLINE, Scopus, and ScienceDirect. RevMan 5.4 was used to provide pooled estimates for mean differences and risk ratios with 95% confidence intervals. A random effect model was used based on the heterogeneity level. Risk of Bias was assessed for each study using RoB 2 for the RCT.

Results: Pegcetacoplan significantly reduced the progression of GA lesion area compared with control (MD =1.18, 95%CI:0.1-2.26, $p=0.03$). A small but

significant increase of treatment-emergent adverse events (TEAEs) occurred in the pegcetacoplan group (RR=1.42, 95%CI:1.21–1.67, $p=0.02$). Significant increase specifically occurs in ocular TEAEs (RR=1.39, 95%CI:1.22-1.59, $p<0.00001$), while non-ocular TEAEs showed no significant difference (RR=1.09, 95%CI:0.99-1.19, $p=0.08$). Notably, patients receiving pegcetacoplan had a higher risk of developing new-onset exudative AMD (RR=3.60, 95% CI:1.92-6.77, $p<0.0001$).

Conclusions: Pegcetacoplan has been proven to be effective in slowing GA progression, though its use is tempered by increased ocular adverse events, particularly new-onset exudative AMD, warranting its need for continued evaluation.

Abstract No.: 206332

Twelve-Month Efficacy of Photobiomodulation in Early and Intermediate Dry Age-Related Macular Degeneration

First Author: Kelvin **TEO YI CHONG**

Co-Author(s): Enrico **BORRELLI**, Adriano **CARNEVALI**, Giulia **COCO**, Sibel **DEMIREL**, Giuseppe **GIANACCARE**, Murat **HASANREISOĞLU**, Claudio **IOVINO**

Purpose: To assess the anatomical and functional efficacy and safety of photobiomodulation (PBM) in early/intermediate dry age-related macular degeneration (dAMD) over 12 months in a European multicenter, randomized, double-masked, sham-controlled trial.

Methods: A total of 138 eyes from 78 classified only as AREDS 2–3 dAMD patients were randomized 1:1 to PBM or sham using the eye-light® device. PBM included two cycles of yellow (~590 nm) and red (~625 nm) light, twice weekly. Sham received a demo mode delivering <30% of PBM energy. Patients underwent BCVA (ETDRS), fundus imaging, and SD-OCT to measure mean drusen volume (MDV) at baseline, 6, and 12 months. Adverse events and tolerability were recorded. Multilevel mixed-effects regression analyzed treatment-time interactions, adjusting for age, sex, and AREDS category.

Results: At 12 months, MDV decreased in PBM ($-0.03 \pm 0.05 \text{ mm}^3$) versus an increase in sham ($+0.02 \pm 0.04 \text{ mm}^3$; $p<0.001$). BCVA improved in PBM ($+1.31 \pm 6.7$ letters) and declined in sham (-2.62 ± 7.1 letters), with a between-group difference of +3.75 letters ($p=0.0001$). Four sham eyes developed macular neovascularization versus none in PBM ($p=0.044$). Adverse events were mild, including transient warmth (18.1%) and dry eye-like symptoms (8.7%), with no retinal phototoxicity.

Conclusions: PBM significantly reduces mean drusen volume and improves visual function in early/intermediate dAMD, with excellent safety, supporting its role as a promising non-invasive therapeutic option.

Abstract No.: 207063

Twelve-Month Real-World Outcomes of Aflibercept 8mg in Diabetic Macular Edema: A Swiss Retina Research Network Report

First Author: Tahm **SPITZNAGEL**

Co-Author(s): Aude **AMBRESIN**, Justus **GARWEG**, Katja **HATZ**, Gabor Mark **SOMFAI**, Sandrine **ZWEIFEL**

Purpose: We aimed to evaluate the effectiveness and safety of intravitreal Aflibercept 8mg (Afl8) in patients with treatment-naïve and pretreated diabetic macular edema (DME) in a real-world setting.

Methods: In this retrospective study, we included patients in 13 Swiss Centers, receiving Afl8 for one year. Primary outcomes were changes in visual acuity (VA), center point retinal thickness (CRT), central subfield thickness (CST), treatment intervals, and adverse events (AEs). Secondary outcomes included injection number, fluid persistence, and treatment adherence.

Results: We enrolled 156 eyes (124 patients) with DME, including 42 (26.9%) treatment-naïve and 114 (73.1%) pretreated eyes. VA improved from 72.9 to 77.7 ETDRS letters in naïve eyes ($p=0.006$), and from 73.9 to 75.4 letters ($p=0.094$) in pretreated eyes. CST decreased in both groups (naïve: $448.9 \mu\text{m}$ to $320.0 \mu\text{m}$, $p<0.001$; pretreated: $336.6 \mu\text{m}$ to $310.2 \mu\text{m}$, $p=0.047$). At 12 months, 27% of naïve and 38.1% of pretreated eyes were fluid-free. Mean treatment interval reached 15.3 weeks in naïve eyes and extended from 7.6 to 13.0 weeks in pretreated eyes ($p<0.001$). No AEs occurred in naïve eyes; pretreated eyes showed three cases of non-infectious intraocular inflammation (1.9%), two acute IOP rises, and one vitreous hemorrhage.

Conclusions: Aflibercept 8 mg showed significant visual gains in treatment-naïve and modest improvements in pretreated eyes. Safety was favorable, with only rare cases of mild inflammation. Taken together, Aflibercept 8 represents a promising approach to improve outcomes while lowering treatment burden.

Abstract No.: 205811

UWF-SS-OCTA Imaging and ImageJ-Based Geometric Analysis of Choroidal Features Across Clinical Stages of Diabetic Retinopathy

First Author: Zhenping **LI**

Co-Author(s): Yuqing **LAN**

Purpose: To investigate changes in choroidal and retinal parameters across different clinical stages of DR and their associations with DR progression and visual acuity.

Methods: A cross-sectional study. This study included five groups: NDR, mild non-proliferative DR (mNPDR), severe non-proliferative DR (sNPDR), proliferative DR (PDR), and a healthy control group. Choroidal and retinal parameters were compared among the five groups, and their associations with DR staging and

visual acuity were explored. UWF-SS-OCTA images were analyzed using ImageJ software to obtain choroidal and retinal vascular geometric parameters such as fractal dimension, diameter, and tortuosity. For five-group comparisons, Welch's ANOVA analysis of variance was used, followed by Games-Howell post hoc tests. Correlation analyses were performed using generalized linear mixed models (GLMM) and ordinal logistic regression analysis.

Results: This section included 250 NDR eyes, 228 mNPDR eyes, 199 sNPDR eyes, 225 PDR eyes, and 268 healthy control eyes. Compared to the control, NDR, and mNPDR groups, sNPDR and PDR groups exhibited significantly reduced choriocapillaris density ($47.75 \pm 1.76\%$, $48.41 \pm 1.05\%$, $47.7 \pm 1.51\%$, $46.23 \pm 2.06\%$, $45.41 \pm 2.71\%$), LMCV vascular density ($54.4 \pm 4.84\%$, $54.84 \pm 4.32\%$, $54.46 \pm 4.19\%$, $53.13 \pm 5.56\%$, $51.63 \pm 5.9\%$), CVI ($41.84 \pm 3.23\%$, $41.36 \pm 3\%$, $40.85 \pm 2.77\%$, $39.78 \pm 3.73\%$, $38.8 \pm 3.72\%$) (all $P < 0.05$), SCP fractal dimension (1.8354 ± 0.0245 vs 1.8298 ± 0.0216 vs 1.8199 ± 0.0201 vs 1.8107 ± 0.0275 vs 1.8134 ± 0.0371) (all $P < 0.05$). The LMCV diameter initially decreased and then increased across the five groups ($150.90 \pm 8.75 \mu\text{m}$, $149.03 \pm 8.79 \mu\text{m}$, $149.75 \pm 8.83 \mu\text{m}$, $153.14 \pm 9.43 \mu\text{m}$, $156.93 \pm 8.84 \mu\text{m}$, $P < 0.001$). The intergroup differences in LMCV fractal dimension and LMCV tortuosity were not statistically significant. Multivariate ordinal logistic regression analysis indicated that DR severity was negatively correlated with CVI ($\beta = -0.157$, $P < 0.001$), while multivariate GLMM analysis showed that LogMAR visual acuity was negatively correlated with CVI ($\beta = -0.037$, $P < 0.001$).

Conclusions: As DR progresses, choroidal perfusion progressively declines, and the choroidal vascular network is gradually disrupted, possibly due to choroidal vascular occlusion. Choroidal vascular dilation in sNPDR and PDR may mirror changes in retinal vasculature. Choroidal perfusion decline may play a role in DR progression.

Abstract No.: 208548

Unveiling Safety Signatures of Aflibercept: A Multimethod Pharmacovigilance Analysis of the FDA Adverse Event Reporting System Database

First Author: Junhong LI

Co-Author(s): Binbin DAI, Bin ZHAO

Purpose: Aflibercept, a key anti-VEGF therapy for neovascular eye diseases, lacks a large-scale real-world safety evaluation. This study uses the FDA Adverse Event Reporting System (FAERS) to comprehensively analyze and characterize aflibercept's safety profile beyond clinical trials.

Methods: We analyzed all adverse event (AE) reports associated with aflibercept from January 2013 to December 2022. To ensure robust and reliable signal detection, we implemented a multi-method approach

employing four distinct disproportionality algorithms: Reporting Odds Ratio (ROR), Proportional Reporting Ratio (PRR), Bayesian Confidence Propagation Neural Network (BCPNN), and Multi-item Gamma Poisson Shrinker (MGPS). Signals were comprehensively assessed at both the System Organ Class (SOC) and Preferred Term (PT) levels.

Results: From the FAERS database, 17,310 aflibercept-related adverse event reports were identified. The most frequent System Organ Classes were general disorders and administration site conditions, eye disorders, nervous system disorders, injury/procedural complications, and infections. Major Preferred Terms included endophthalmitis, retinal pigment epithelial tear, lens extraction, intraocular lens implant, vitreous haze/opacities, blurred vision, and vitreous hemorrhage. Severe outcomes were notable, with death (42.4%), hospitalization (8.0%), and disability (6.4%) most reported, occurring more often in females and those aged > 60 years.

Conclusions: This large-scale pharmacovigilance investigation provides a refined and updated safety profile for aflibercept. Our findings extend beyond the established risks, revealing significant signals in system organ classes not currently emphasized in the prescribing information. This evidence calls for heightened clinical vigilance regarding potential systemic and neurological adverse events and underscores the necessity for further prospective studies to validate these associations and optimize patient risk management strategies.

Abstract No.: 201248

Update on Faricimab for Diabetic Macular Edema: New Clinical Features of Eyes in the RHONE-X Long-Term Extension Study

First Author: Toshinori MURATA

Co-Author(s): Kara GIBSON, Cheryl JONES, Ian PEARCE, Veeral SHETH, Dawn A. SIM

Purpose: Faricimab has demonstrated vision gains, anatomic improvements, and extended durability in DME (diabetic macular edema), with a comparable safety profile to aflibercept. We present updated findings from the phase-3 RHONE-X trial (NCT04432831) evaluating faricimab's long-term safety (primary objective) and efficacy (exploratory) in DME patients who completed the two-year, phase-3 YOSEMITE/RHINE trials.

Methods: Patients receiving faricimab-6.0mg Q8W (every-8-weeks), personalized T&E (treat-and-extend)-dosing, or aflibercept-2.0mg Q8W in parent trials received faricimab-6.0mg up to Q16W T&E (per pre-specified vision and anatomic criteria) for an additional 2 years in RHONE-X. The first 16 weeks had masked monthly visits, followed by T&E-interval-based study visits.

Results: Of the 1,474 patients, 81.7% completed RHONE-X. Robust vision gains/improved central subfield thickness from parent trials were maintained. After 4 years of faricimab treatment, >90% patients achieved DME absence, regardless of original treatment. First DME absence (90th-percentile) was reached 12–15 months earlier, with fewer injections with faricimab vs. aflibercept in parent trials. At parent trial end, fewer faricimab-Q8W (-10.3%; nominal $P=0.0026$) and T&E (-7.8%; nominal $P=0.0251$) patients had hard exudates vs. aflibercept. By the RHONE-X end, the differences in hard exudates were similar (nominal $P>0.55$). After 4-years, 80% patients had extended $\geq$ Q12W and >50% qualified for Q20W dosing. Volumetric analysis will be presented.

Conclusions: RHONE-X, the largest DME extension study, maintained faricimab's efficacy and durability from parent trials. Aflibercept-treated patients during parent trials demonstrated further reduction in hard exudates after faricimab-T&E in RHONE-X, suggesting improved vascular stability and disease control with faricimab.

Abstract No.: 206952

Visceral Adiposity Indices (AIP, LAP, CVAI) Surpass Traditional Lipids in Diabetic Kidney Disease Prediction: Divergent Associations With Retinopathy

First Author: Yanchun **ZHANG**

Co-Author(s): Yuemeng **SUN**, Li **ZHANG**

Purpose: To analyze the associations between visceral adiposity indices and the risk of diabetic kidney disease (DKD) and diabetic retinopathy (DR), and to compare their predictive utility against traditional lipids in community-based type 2 diabetes (T2DM).

Methods: This cross-sectional study enrolled 1,467 T2DM patients from 14 Chinese community centers. Visceral adiposity was evaluated by Atherogenic Index of Plasma (AIP), Lipid Accumulation Product (LAP), and Chinese Visceral Adiposity Index (CVAI). Dose-response relationship was modeled via restricted cubic splines (RCS) analysis. Diagnostic performance was compared using DeLong's test. Subgroup interactions were tested for age, sex, BMI, and hypertension status.

Results: Among 1,467 T2DM patients, DKD prevalence was 61.6% ($n=904$) and DR prevalence 33.1% ($n=485$). Patients with DKD had significantly higher AIP, LAP, and CVAI versus non-DKD patients (all $p<0.01$), whereas no associations existed with DR. AIP, LAP, and CVAI increased progressively with KDIGO stages ($p<0.01$). RCS revealed linear association between DKD and AIP (OR=1.036 per 0.1-unit increase; $p<0.001$), while nonlinear associations with LAP (threshold: 42.34; $p=0.001$) and CVAI (threshold: 130.73; $p=0.012$). For diagnostic performance, CVAI provided optimized specificity versus conventional lipids, while LAP showed balanced sensitivity and specificity. CVAI predicted

DKD exclusively in females (OR=2.05, 95%CI:1.52-2.76; $p<0.001$), hypertensives (OR=1.86, 95%CI:1.34-2.57; $p<0.001$), and older adults (OR=1.66, 95%CI:1.25-2.21; $p<0.001$), with significant interactions for sex ($p=0.008$) and hypertension ($p=0.047$).

Conclusions: Visceral adiposity indices (AIP, LAP, CVAI) outperformed traditional lipids in DKD risk stratification. CVAI demonstrated age-, sex-, and hypertension-specific predictive advantages but showed no associations with DR risk.

Abstract No.: 201602

Visual and Anatomical Improvements Over 12 Weeks With OCS-01 Eye Drops in Patients With Diabetic Macular Edema From the Phase 2/3 DIAMOND-Stage 1 Trial

First Author: Timothy **LAI**

Co-Author(s): David S. **BOYER**, Arshad M. **KHANANI**, Sabri **MARKABI**, Quan Dong **NGUYEN**

Purpose: To evaluate the efficacy and safety of OCS-01, a special formulation of dexamethasone eye drop, for treating diabetic macular edema (DME) in Stage 1 of the DIAMOND study.

Methods: DIAMOND is a prospective Phase 2/3, 2-stage, double-masked, randomized, multi-center trial. A total of 148 patients were randomized, with 100 patients having OCS-01 and 48 patients having a vehicle. Primary and secondary endpoints included mean change in best-corrected visual acuity (BCVA) ETDRS letter score at Week 6 compared to baseline, mean change in central subfield thickness (CST) at Weeks 6 and 12, and the proportion of patients with a ≥ 3 -line BCVA gain at Weeks 6 and 12.

Results: Early improvement in mean BCVA was observed with OCS-01 versus vehicle at Week 6 (7.2 vs 3.1 letters, $p=0.007$), and Week 12 (7.6 vs 3.7 letters, $p=0.016$). A higher proportion of patients in the OCS-01 group achieved a ≥ 3 -line BCVA gain at Week 6 (25.3% vs 9.8%, $p=0.025$) and Week 12 (27.4% vs 7.5% $p=0.009$). A significant reduction in mean CST was observed in OCS-01 vs Vehicle at Week 6 (-63.5 vs +5.4 μm , $p<0.001$), and persisted at Week 12 (-61.6 vs -16.0 μm , $p=0.004$). OCS-01 was well-tolerated with no unexpected adverse events, and none of the SAEs reported were deemed to be related to the study drug.

Conclusions: The results from these analyses show OCS-01 met its primary and secondary endpoints with significance.

27-Gauge MIVS-Assisted Scleral Fixation of Intraocular Lens: An AS-OCT Guided Study

First Author: Manasi TRIPATHI

Co-Author(s): Ashish MARKAN

Purpose: To evaluate the outcomes of 27-gauge microincision vitrectomy surgery (MIVS)-assisted scleral fixation of intraocular lenses (SFIOL) using anterior segment optical coherence tomography (AS-OCT).

Methods: This retrospective study included 36 patients undergoing 27G MIVS-assisted SFIOL implantation. Preoperative data, including best-corrected visual acuity (BCVA), intraocular pressure (IOP), endothelial cell count, and surgical indications, were recorded. Postoperatively, BCVA, IOP, and endothelial cell count were assessed at 3 months. Additionally, postoperative ASOCT was performed to assess IOL tilt, decentration, and distance of the IOL from the posterior iris surface. Surgical complications were documented.

Results: The mean IOL tilt was 3.58 ± 0.57 degrees, IOL decentration was 0.22 ± 0.47 mm, and IOL to posterior iris distance was 0.76 ± 0.66 mm. At three months, BCVA significantly improved from 0.85 ± 0.53 log MAR to 0.38 ± 0.38 log MAR ($p = 0.03$). Hyperopic shift (MRSE: $+1.14 \pm 0.62$ D) correlated strongly with increased distance of IOL from the posterior iris surface. Complications included early postoperative IOL tilt ($n=4$, requiring refixation), vitreous hemorrhage ($n=3$, resolving spontaneously), and choroidal detachment ($n=2$, resolving with corticosteroids).

Conclusions: The 27G MIVS-assisted SFIOL technique demonstrates favorable outcomes with minimal IOL tilt and decentration. The technique offers a safe and effective alternative for scleral fixation, optimizing surgical efficiency and patient outcomes.

Abstract No.: 205502

A Minimal Air-Fluid Exchange Technique for Office-Based Management of Post-Vitrectomy Vitreous Hemorrhage

First Author: Xuhui YU

Co-Author(s): Jun CHEN

Purpose: Post-operative vitreous hemorrhage may occur after pars plana vitrectomy (PPV). In-office air-liquid exchange may be an option for these patients.

Methods: A modified two-needle method of air-fluid exchange in the office is introduced. A 29-gauge needle is inserted 3.5-mm posterior to the limbus at 6 o'clock. A second 29-gauge needle with a 5mL syringe filled with sterile air is inserted 3.5-mm posterior to the limbus in the superotemporal quadrant or superonasal quadrant. The plunger of the air-filled syringe is pushed

while the liquid of the vitreous cavity flows out of the 6 o'clock needle drop by drop, and the flow rate of the fluid changes with the injection pressure.

Results: The method approximates the conditions of air-fluid exchange in vitrectomy, and the air injection and liquid outflow are balanced by pressure naturally.

Conclusions: The modified two-needle method is an easy, safe, and effective in-office air-fluid exchange for the treatment of Post-Vitrectomy Vitreous Hemorrhage.

Abstract No.: 201834

A Novel Surgical Approach for Macular Schisis Associated With Optic Disc Pit

First Author: Zhao Jie CHU

Co-Author(s): Hong Fang YONG

Purpose: Report on modified surgical technique for the treatment of optic disc pit.

Methods: Case Report with Surgical Video. Modified vitrectomy with fovea-sparing ILM peeling and wet biologic amniotic membrane packing for optic disc pit-associated maculopathy. Case Presentation: A 25-year-old female presented to the outpatient clinic with a 1-year history of blurred vision in the left eye. Best-corrected visual acuity (BCVA) was 0.2 in the affected eye. Fundus examination revealed an inferotemporal optic disc pit in the left eye, while optical coherence tomography (OCT) demonstrated macular edema and schisis. Surgical Intervention: The patient underwent 25G vitrectomy combined with fovea-sparing internal limiting membrane (ILM) peeling, followed by optic disc packing with wet biologic amniotic membrane and air tamponade.

Results: At the 6-month postoperative follow-up, optical coherence tomography (OCT) revealed a hyperreflective filling material within the optic disc pit, indicating successful graft placement. Macular edema had resolved significantly, and best-corrected visual acuity (BCVA) improved to 0.3 in the left eye.

Conclusions: The wet-state biologic amniotic membrane serves as a standardized graft material with high safety profile and excellent surgical maneuverability, while selective ILM peeling preserves foveal integrity. The combination of wet biologic amniotic membrane grafting and fovea-sparing ILM peeling represents a promising modification to macular schisis associated with optic disc pit.

Abstract No.: 204955

Advantages of Robotic Assistance Over a Manual Approach in Retinal Intravascular Injection

First Author: Weihong YU

Co-Author(s): Junqi CHEN, Zhangwanyu WEI

Purpose: To compare the success rate and stability of robot-assisted versus manual retinal intravascular injection.

Methods: We performed retinal intravascular injections in ex vivo (15 porcine eyes per group) and in vivo (6 porcine eyes per group) models. Surgeons executed the procedure using a master-slave robotic system (experimental group) or manually (control group). We recorded the success rate, instrument stability duration, total procedure time, and intraoperative complications.

Results: In the in vivo experiment, the success rate was significantly higher in the robotic group compared to the manual group ($p = 0.047$). No significant difference in success rate was observed between the two groups in the ex vivo experiment. The robotic group demonstrated greater needle tip stability and maintained a longer stable injection duration than the manual group.

Conclusions: Robot-assisted retinal intravascular injections demonstrated a higher success rate and greater stability, enabling a prolonged duration of stable injection.

Abstract No.: 206133

Alteration of Tear Metabolomics and Proteomics Profiling in Infants With Retinopathy of Prematurity

First Author: Zixin FAN

Co-Author(s): Xiaofeng LU, Peiling WEI, Shuo YANG, Guoming ZHANG

Purpose: The purpose of this study was to investigate the characteristics of metabolomic and proteomic profiles in the tears from infants with retinopathy of prematurity (ROP) and further define noninvasive biomarkers.

Methods: This prospective study included 94 eyes from 47 premature infants. Tear samples from 23 infants with ROP (15 treatment-requiring ones [ROP (t)] and 8 non-treatment-requiring ones [ROP (nt)]) and 24 infants without ROP were collected with Schirmer strips after topical anesthesia. Detailed fundus examination upon pupil dilation was conducted, with data on demographics and birth history recorded. Untargeted tear metabolomic analysis based on ultra-performance liquid chromatography-mass spectrometry and proteomic analysis based on data-independent acquisition mass spectrometry were performed.

Results: Adjusted by sex, postmenstrual age, gestational age, and birth weight, among 145 metabolites quantified, 3,5-di-tert-butyl-4-hydroxybenzaldehyde, caffeine, and trehalose were identified to be upregulated in the tears from infants with ROP when compared to those from premature infants with non-ROP, whereas uric acid, dihomoy-linolenic acid, nootkatone, pyridoxal, ornithine, 6-keto-prostaglandin F1 alpha, adenosine, and tetrahydrocortisol were downregulated (all adjusted false discovery rate [FDR adj] < 0.05). Nine and one dysregulated metabolites were further found in the ROP (t) and ROP (nt) subgroups, respectively. The dysregulated tear metabolites were fundamentally related to vitamin B6, purine, caffeine, arginine, and starch and sucrose metabolism pathways. Besides, 94 differentially expressed proteins in tear fluid were identified between infants with ROP and premature infants with non-ROP, including 29 downregulated proteins and 65 upregulated proteins. These proteins were associated with inflammation, retinal homeostasis, coagulation, and angiogenesis. The 6-keto-prostaglandin F1 alpha obtained the best performance in classifying premature infants with and without ROP (area under the curve [AUC] of 0.893 [range = 0.800–0.986], $P < 0.001$).

Conclusions: Dysregulated tear metabolites and proteins in ROP might be noninvasive biomarkers that potentially serve as complementary screening tools.

Abstract No.: 206552

Anatomical and Functional Outcomes of Conventional Scleral Buckling, Segmental Buckling, and Radial Buckling for Uncomplicated Retinal Detachments

First Author: Aarush

Co-Author(s): Rohan CHAWLA, Avneet KAUR, Vinod KUMAR

Purpose: To compare anatomical and visual results of conventional scleral buckle (with encircage), segmental circumferential buckling, and radial buckling for uncomplicated retinal detachments.

Methods: This retrospective interventional case-control study included patients who underwent conventional scleral buckling (CB), segmental buckling (SB) and radial buckling (RB) for retinal detachments with proliferative vitreoretinopathy (PVR) grade $< C$. Patients who completed a minimum follow up period of 12 months were enrolled with follow-up examinations scheduled on the first post-operative day and 1, 3, 6 and 12 months after surgery. Anatomical success was defined as retinal reattachment at 12 months without additional procedures. Metamorphopsia and aniseikonia were assessed with M-CHARTs and the New Aniseikonia Test, respectively.

Results: A total of 139 eyes were enrolled, including 75 in group CB, 46 in group SB, and 18 in group RB.

Single operation success rates at 12 months were 67/75 eyes (89.3%) in the CB group, 42/46 eyes (91.3%) in the SB group, and 15/18 eyes (83.3%) in the RB group. There was no significant difference in the final best corrected visual acuity (BCVA) between the three groups; however, eyes with macula-on detachments displayed a trend towards better visual gain. Refractive error shift was noted to be maximum in CB group [Mean change in spherical equivalent (Δ SE): -1.875 ± 2.97 D], followed by SB group (Mean Δ SE: -1.09 ± 0.91 D) and least in RB group (Mean Δ SE: -0.625 ± 0.59 D, $p < 0.001$). No significant differences were noted regarding metamorphopsia and aniseikonia in the three groups. However, eyes that underwent external drainage of subretinal fluid displayed worse metamorphopsia and aniseikonia scores ($p < 0.05$).

Conclusions: Scleral buckling has an exceptional success rate for managing uncomplicated retinal detachments, irrespective of the different techniques in our study. However, conventional buckling with encirclage is associated with a pronounced myopic shift. Vision gain post-surgery is a direct function of the preoperative macular status, whereas external drainage of SRF is associated with retinal displacement leading to metamorphopsia and aniseikonia.

Abstract No.: 202001

Application of Foldable Capsular Buckle in the Treatment of Rhegmatogenous Retinal Detachment

First Author: Hua **YAN**

Purpose: Rhegmatogenous retinal detachment (RRD) is a blinding eye disease caused by retinal break formation, which leads to fluid accumulation in the subretinal space and subsequent separation of retinal layers. Current primary treatment methods include scleral buckling (SB), pars plana vitrectomy (PPV), and pneumatic retinopexy (PR). Although PPV is widely used, it often carries complications such as cataract and disrupted intraocular oxygen metabolism due to intraocular tamponade. This study evaluates the foldable capsular buckle (FCB), a novel external surgical device, as a treatment for RRD.

Methods: The FCB is constructed from medical silicone and consists of a capsule, drainage tube, and valve. Preoperative break localization was performed using a three-dimensional constructive method. The folded capsule was inserted via a small incision and inflated with saline to create an indentation ridge supporting the retinal break. A multicenter clinical trial across 22 centers in China, since July 2019, has included nearly 200 patients with RRD.

Results: The FCB effectively supported breaks within 3-disc diameters, including cases challenging for conventional external surgery. This technique provides a minimally invasive external alternative for large-break RRD cases that would otherwise require PPV,

proving particularly suitable for children, young adults, pregnant women, highly myopic patients, and those with inferior, nasal, or horseshoe-shaped breaks.

Conclusions: The FCB technique provides a minimally invasive external alternative to PPV for certain RRD cases, expands the indications for external surgery, improves visual prognosis, and reduces complications. It demonstrates broad clinical application potential.

Abstract No.: 205633

Case-Control Study on Risk Factors for Developing Early Choroidal Detachment After Diabetic Vitrectomy

First Author: Umesh **CHANDRA BEHERA**

Purpose: We aimed to elucidate the associations of early postoperative choroidal detachment (PCD) occurrences with attributable preoperative and intraoperative factors after diabetic vitrectomy.

Methods: All consecutive eyes undergoing 23G transconjunctival pars plana vitrectomy for proliferative complications of diabetes were included. The eyes that developed PCD within two weeks of surgery were compared with eyes without PCD for risk identification.

Results: Ninety-two eyes satisfied the inclusion/exclusion criteria. The mean age and duration of diabetes in the study subjects were 54.6 ± 9.7 years and 11.8 ± 6.6 years, respectively. PCD was noted in 32.61% of eyes; most resolved spontaneously by 2 weeks (93%). The odds of PCD were higher in older subjects (> 70 years), longer diabetes duration (> 10 years), and intraoperative lasers (> 500 spots). The odds of PCD increased proportionally with the number of laser spots ($p = 0.006$).

Conclusions: Postoperative choroidal detachment in diabetic vitrectomy may be noted in approximately one-third of the eyes but typically resolves spontaneously. Limiting the number of endo laser spots may reduce their occurrence.

Abstract No.: 204163

Changes in Fixation Stability and Location After Internal Limiting Membrane Surgical Technique for Macular Hole Repair: A Prospective Study

First Author: Jin **MA**

Co-Author(s): Yuanjie **QIAN**, Renchun **WANG**

Purpose: This study aimed to evaluate the impact of the internal limiting membrane (ILM) surgical technique on postoperative fixation stability and the spatial relocation of the preferred retinal locus (PRL), particularly focusing on the PRL-to-foveal center distance. Additionally, the study examined the relationship between PRL displacement, preoperative fixation patterns, and macular hole (MH) diameter.

Methods: In this prospective interventional study, 126 patients (105 eyes) with idiopathic MH underwent 25G pars plana vitrectomy (PPV) with the ILM surgical technique of simple ILM peeling, ILM flap inverting, and filling technique. Based on preoperative optical coherence tomography (OCT) measurements, patients were stratified into three groups: Group A (<300 μ m, 36 eyes), Group B (300–600 μ m, 44 eyes), and Group C (>600 μ m, 46 eyes). High-resolution OCT and MP-3 microperimetry were conducted preoperatively and at 1, 3, 6, 9, and 12 months postoperatively to evaluate PRL displacement. Secondary outcomes included fixation stability (BCEA 1-SD, 2-SD, 3-SD), macular sensitivity, and MH closure configuration. Statistical analysis included the Shapiro–Wilk test, Friedman test, Wilcoxon signed-rank test, and Spearman correlation.

Results: By 12 months postoperatively, all groups demonstrated a significant reduction in PRL–foveal center distance ($p < 0.05$), reflecting a centripetal PRL shift. Fixation stability improved significantly ($p < 0.05$), while macular sensitivity, initially reduced at 1 month, gradually recovered. PRL centripetal shift showed a significant positive correlation with both preoperative fixation pattern and MH diameter ($p < 0.001$).

Conclusions: ILM flap techniques facilitate anatomical MH closure and significantly enhance fixation function, as evidenced by improved fixation stability and centripetal PRL realignment. The trend of PRL movement toward the horizontal papillomacular bundle was significant. These results highlight the value of fixation metrics as functional indicators in postoperative evaluation and support the refinement of surgical approaches and outcome assessments in MH repair.

Abstract No.: 208395

Characterization of Retinotomy and Bleb Formation in Subretinal Gene Therapy for Inherited Retinal Disease and Age-Related Macular Degeneration

First Author: Xiaodong **SUN**

Purpose: Consistent delivery is critical to gene therapy potency. We evaluated an optimized subretinal injection protocol across multiple centers and surgeons in LCA and nAMD, and discussed the rationale for key delivery parameter selection.

Methods: Retrospective review of subretinal injection in thirteen patients from a single-center investigator-initiated trial (IIT) to develop an optimal protocol (including retinotomy selection, bleb monitoring, IOP and reflux management). This protocol was then implemented in registered trials by surgeons across multiple centers to evaluate delivery performance in gene therapy for LCA and nAMD. Surgical procedure–related adverse events and technical performance metrics were used to evaluate

delivery performance. Retinotomy selection and bleb propagation were visualized for further reference.

Results: Under the optimized protocol, 203 injections in 64 patients with LCA and nAMD achieved rapid, targeted delivery. Surgical time decreased by 26.2%, and single-bleb formation time by 88.9%. Common TEAEs were conjunctival hyperemia (64.1%) and transient IOP decrease (40.6%). One moderate retinal detachment resolved with treatment. Most events resolved spontaneously. With intraoperative IOP lowering, single injections achieved high bleb success (98.8% LCA; 94.1% nAMD). For LCA, 4–5 retinotomies (15–20 psi) are recommended; for nAMD, 2–3 (30–35 psi), with MI-OCT monitoring to prevent macular detachment.

Conclusions: By optimizing retinotomy selection, monitoring bleb bias, and managing IOP and reflux, our surgical procedures accelerated surgical speed, maintained delivery consistency, and achieved a low burden of procedure related adverse events comparing with international scale. Discussion of the key features of the optimal procedure provides practical reference for refining a broadly applicable multicenter protocol in the future.

Abstract No.: 207289

Chronic Myeloid Leukaemia Mimicking As Retinal Vascular Occlusions and Neovascular Glaucoma

First Author: Nikita **CHAUDHARY**

Co-Author(s): Vishal **SANJAY JADHAV**

Purpose: We present a cohort of case series of treating naïve Chronic Myeloid Leukaemia masquerading as Central retinal vein occlusion and neovascular glaucoma.

Methods: Three patients presenting with an acute onset of visual loss, two of them were diagnosed initially to have Central retinal vein occlusion, and one as neovascular glaucoma, are described.

Results: Initial fundus examination of 2 patients revealed bilateral extensive retinal haemorrhages, cotton wool spots, vascular sheathing, and macular edema, suggestive of central retinal vein occlusion. While another patient presented with high intraocular pressures (IOP), haem admixed hypopyon, neovascularisation at the iris, retinal haemorrhages, and was diagnosed to have neovascular glaucoma. Diligent fundus examination in all 3 cases, however, revealed the presence of Roth spots. Subsequent investigations identified marked leucocytosis on peripheral blood smear and Philadelphia chromosome (BCR-ABL) detection. Treatment with imatinib and intravitreal ranibizumab and dexamethasone implant resulted in the resolution of the leucocytosis, significant improvement in the retinal haemorrhages and macular edema, as well as control of IOP in respective patients.

Conclusions: This case series emphasizes the importance of keeping masquerades as a differential for retinal vascular occlusions and highlights the importance of comprehensive systemic workup to ensure accurate systemic diagnosis and appropriate life-saving management.

Abstract No.: 200604

Clinical Characteristics and Prognostic Factors Influencing Visual Outcomes in Intraocular Foreign Bodies: A 10-Year Multiethnic Tricenter Retrospective Study

First Author: Derrick Jun Quan CHUAH

Co-Author(s): Azhan AZMAN, Shahidatul Adha MOHAMAD, Maizan YAAKUB

Purpose: Intraocular foreign bodies (IOFB) represent a significant subset of ocular trauma; however, current local data remains limited. This study aimed to provide an update on the clinical characteristics and prognostic factors influencing visual outcomes following vitrectomy for IOFB removal in Malaysia.

Methods: Medical records of 186 patients, out of 355 cases of IOFB removal at three Malaysian public vitreoretinal centers between 2014 and 2023, were selected and retrospectively reviewed.

Results: Most patients were male (98.4%) and of Malay ethnicity (53.2%), with a mean age of 35.8 ± 13.9 years. Hammering and nails were the most common injury mechanism (45.2%). Most IOFBs were metallic (81.7%), with a mean size of 4.2 ± 2.8 mm, entering via the cornea (61.3%) and lodging in the retina (61.3%), predominantly extramacular (57.0%). Secondary clinical features included cataract (75.8%), retinal tear (54.8%), vitreous hemorrhage (40.3%), and endophthalmitis (32.3%). Primary vitrectomy within 3 days of injury was performed in 28.5% patients, while the remainder underwent primary wound repair pre-vitrectomy. At presentation, 75.9% had visual acuity (VA) worse than 6/60; postoperatively, 54.8% regained VA better than 6/60. Poor final VA was significantly associated with poor presenting VA, macular involvement, preoperative retinal detachment, and postoperative complications, for example, glaucoma and retinal detachment (all $p < 0.05$).

Conclusions: IOFB imposes a substantial clinical burden in Malaysia. Identifying high-risk prognostic features and ensuring timely intervention are crucial to improve visual outcomes. Strengthened workplace safety protocols remain essential to reduce the incidence of IOFBs and their long-term visual impact.

Abstract No.: 202438

Clinical Efficacy Observation of Intravitreal Injection of Tissue Plasminogen Activator Combined With Anti-VEGF in the Treatment of Acute Submacular Hemorrhage Secondary to Neovascular Age-Related Macular Degeneration

First Author: Jianing WANG

Co-Author(s): Xiaobing YU, Yue ZHANG, Zhaoxia ZHENG

Purpose: To observe the efficacy and safety of intravitreal injection of tissue plasminogen activator (tPA) combined with anti-VEGF in the treatment of acute submacular hemorrhage (SMH) secondary to nAMD.

Methods: Retrospective clinical study. Patients diagnosed with acute SMH secondary to nAMD. They were divided into two groups: Patients in group A received intravitreal injections of anti-VEGF drugs, and patients in group B received intravitreal injections of tPA 0.1ml/100ug combined with anti-VEGF drugs. All patients were followed up in the ophthalmology clinic at 1 month, 3 months, and 6 months after treatment. BCVA, macular central retinal thickness (CRT), and macular central retinal volume of the patients at each follow-up were recorded.

Results: A total of 38 patients were included in this study. Both groups' BCVA were higher than before treatment, but only group B had a statistically significant ($P=0.046$). The CRT and retinal volume of both groups of patients decreased significantly ($P < 0.001$). However, the degree of subretinal hemorrhage reduction in group A after treatment was less than that in group B, the reduction rate was lower, and the decline trend was also slower.

Conclusions: Intravitreal injection of tPA combined with anti-VEGF therapy is a more rapid, simple, safe, and effective treatment for acute SMH secondary to nAMD. It can improve visual function in patients with nAMD secondary to acute SMH and is more effective in achieving the displacement of subfoveal blood accumulation in the macula.

Abstract No.: 210124

Clinical Performance of Nanopore Targeted Sequencing for Diagnosing Endophthalmitis

First Author: Dalan JING

Purpose: Rapid identification of pathogenic bacteria in the vitreous and/or aqueous humor of patients with acute clinical diagnosis of endophthalmitis via nanopore sequencing technology.

Methods: We recruited a total of 12 patients (12 eyes) who were diagnosed with endophthalmitis at an ophthalmic outpatient clinic from January 2022 to October 2022. Clinical evaluation is conducted in the order of consultation, symptom evaluation, physical

sign evaluation, and ophthalmic special examination, all of which are completed by the same experienced clinical physician. Finally, 19 aqueous humor and/or vitreous samples were obtained via anterior chamber wash, vitreous tap, and vitrectomy. The samples were separated for cultivation, biochemical drug sensitivity identification, and targeted nanopore sequencing (NTS), and the results of nanopore sequencing were validated via Sanger sequencing.

Results: In patients with endophthalmitis, NTS can identify infected pathogens within 8–12 hours. Six samples (31.6%) were subjected to culture-based diagnosis, while NTS revealed the presence of pathogenic microorganisms in 19 samples (100%), of which bacteria and fungi were detected in three samples. A total of 19 samples were subjected to Sanger sequencing, of which 16 (84.2%) tested positive, including 6 culture-positive samples and 10 culture-negative samples, of which 5 (26.3%) were positive for two bacterial genera. In culture-positive cases, there is a high-quality match between culture and targeted nanopore sequencing.

Conclusions: NTS can quickly detect pathogenic bacteria in samples from patients with endophthalmitis. Moreover, the use of vitreous and/or aqueous humor for the NTS has potential. NTS is a promising diagnostic platform for endophthalmitis, especially for mixed infections and culture-negative cases.

Abstract No.: 206444

Clinical Profile and Surgical Outcomes of Acute Postoperative Candida Cluster Endophthalmitis

First Author: Naresh Babu **KANNAN**

Co-Author(s): Vignesh **ELAMURUGAN**, Veerasasari Jawahar **SATYA BABU**, Muthukrishnan **VALLINAYAGAM**

Purpose: To study the clinical profile and surgical outcomes of Candida pelliculosa cluster endophthalmitis following cataract surgery in twelve eyes.

Methods: A cluster of twelve eyes of ten patients with endophthalmitis, after uncomplicated phacoemulsification with IOL implantation, was referred. Core vitrectomy with intraocular lens (IOL) explantation and intravitreal injection of Vancomycin, Ceftazidime, and Voriconazole was done. The explanted IOL-bag complex and vitreous samples were sent for microbiology. Minimum follow-up was three months.

Results: The mean interval from surgery to presentation was 28.03 days. Presenting symptoms were mild pain, redness and minimal visual diminution. Mean presenting best corrected visual acuity (BCVA) was 20/40 (0.3 LogMAR). Mild congestion and keratic precipitates in all. Three eyes had infiltrates in the corneal tunnel. Fluffy capsular plaque, IOL deposits, and severe vitritis in all eyes, with a string of pearls in

two eyes. There was no retinitis. Silicone oil was not used as a tamponade. Explanted IOL-bag complexes were culture positive for Candida pelliculosa. IOLs used were monofocal from the same manufacturer. All other consumables were culture-negative. Mean post-operative BCVA was 20/60 (0.48 LogMAR), which was unaltered at three months. No statistically significant difference was found between initial presenting BCVA and final BCVA ($p=0.718$).

Conclusions: Candidal postoperative endophthalmitis presents with a relatively delayed onset with innocuous signs. Presentation with deceptively good baseline visual acuity should not cause dismissal of the diagnosis, and a high index of suspicion must be maintained. Prompt vitrectomy with explantation of the IOL provides excellent visual rehabilitation.

Abstract No.: 205603

Clinical Study on the Efficacy of Anti-VEGF Therapy Combined With Triamcinolone Injection for Diabetic Macular Edema

First Author: Bo **QIN**

Co-Author(s): Deshuang **LI**, Dongcheng **LIU**

Purpose: To investigate the efficacy and safety of anti-VEGF therapy combined with intravitreal triamcinolone injection in patients with diabetic macular edema.

Methods: Prospective study. Sixty-seven patients (67 eyes) with DME were enrolled and randomly assigned to either the aflibercept group or the aflibercept plus TA group using a random number table. Patients received monthly intravitreal aflibercept injections or aflibercept combined with intrafascial triamcinolone (TA) injections for 3 consecutive months. The following parameters were observed and compared between groups before treatment and after each treatment: best-corrected visual acuity (BCVA), central macular thickness (CMT), length of retinal inner layer disorganization (DRIL), height of subretinal fluid (SRF), number of hyperreflective foci (HRF), area of foveal avascular zone (FAZ), superficial vascular density (SVD), and deep vascular density (DVD).

Results: (1) Visual acuity improved significantly in both the aflibercept group and the aflibercept plus TA group compared to baseline. Comparison between the two groups showed no statistical significance after the first treatment ($P = 0.17$), statistical significance after the second treatment ($P < 0.05$), and marked statistical significance after the third treatment ($P < 0.01$). (2) Mean choroidal thickness (CMT) decreased significantly in both the aflibercept group and the aflibercept plus TA group compared to baseline. Intergroup comparisons showed significant differences after the first and second treatments ($P < 0.01$), but no significant difference after the third treatment ($P = 0.73$).

Conclusions: (1) After treatment, the apixaban plus TA group demonstrated superior outcomes compared to the apixaban group in terms of BCVA improvement, DRIL reduction, SRF reduction height, and HRF reduction count. (2) Although no statistically significant difference in CMT thickness was observed between groups after the final treatment, the aflibercept plus TA group achieved a more rapid reduction in CMT thickness in DME patients at an earlier stage. This facilitated better restoration of retinal interlayered structures and yielded superior retinal anatomical benefits.

Abstract No.: 202301

Clinical Characteristics of Familial Exudative Vitreoretinopathy in a Large Cohort of Southwest China

First Author: Yiliu YANG

Co-Author(s): Fang LU

Purpose: To establish a clinical database for familial exudative vitreoretinopathy (FEVR) in Southwest China and analyze its clinical characteristics.

Methods: A retrospective study was conducted using clinical data from FEVR patients admitted to our hospital over the past 10 years. Disease staging and distinctive clinical features were analyzed.

Results: A total of 592 eyes from 296 patients were included. Males outnumbered females by approximately 2:1. Stage 1 and 2 eyes all showed increased retinal vascular branching. Notably, 35.6% of stage 1 and 44.4% of stage 2 eyes exhibited tortuous anastomotic vessels, most frequently in the temporal retina ($P < 0.05$). In stage 3 eyes, the mean macular-to-disc distance was 4.5 (4.0, 5.0) disc diameters. Across all stages, 5.1% of patients had monocular involvement, 21.6% showed an interocular difference ≥ 3 stages, and 21.6% had bilateral advanced disease (stage 4–5). Visual impairment and blindness increased significantly in stages 3–5 ($P < 0.05$). Surgical intervention was performed in 49.5% of stage 3, 58.6% of stage 4, and 78.7% of stage 5 eyes. Additionally, 17.2%, 19.8%, and 33.3% of eyes in stages 3, 4, and 5 underwent two or more treatments, respectively.

Conclusions: FEVR is not rare in Southwest China. Advanced stages severely affect vision. While most early-to-mid stage patients stabilize with treatment, stage 5 often requires multiple surgeries with limited functional improvement.

Abstract No.: 204112

Comparative Efficacy of Subretinal Versus Intravitreal T-PA Injection in the Surgical Management of Submacular Hemorrhage

First Author: Xiang MA

Co-Author(s): Cong MA, Naiwen ZHANG

Purpose: To evaluate the clinical outcomes of pars plana vitrectomy (PPV) with subretinal t-PA injection compared to intravitreal t-PA injection in patients with submacular hemorrhage (SMH).

Methods: A retrospective study was conducted. Group A underwent PPV, internal limiting membrane (ILM) peeling, subretinal t-PA injection (38/41G), intravitreal gas tamponade, and anti-VEGF therapy. Group B received intravitreal t-PA injection, gas tamponade, and anti-VEGF therapy. Best-corrected visual acuity (BCVA) and central subfield thickness (CST) were compared at 4–6 months postoperatively.

Results: Both groups achieved significant displacement of hemorrhage. However, Group A demonstrated superior outcomes in BCVA improvement at 5 and 6 months, as well as significantly reduced CST values at 4–6 months. Subretinal t-PA injection reduced the frequency of postoperative anti-VEGF treatments. In a subset followed for 6 months, baseline BCVA (16.36 ± 9.19 letters) improved to 64.91 ± 13.64 , and baseline CST ($656.95 \pm 98.60 \mu\text{m}$) decreased to $261.82 \pm 15.89 \mu\text{m}$.

Conclusions: Both intravitreal and subretinal t-PA effectively displace submacular hemorrhage, but PPV with subretinal t-PA provides better visual and anatomical outcomes with reduced need for anti-VEGF therapy. Surgical strategy should be individualized based on hemorrhage onset, extent, and severity, with optimal timing at 7–10 days post-hemorrhage. Careful postoperative monitoring remains essential.

Abstract No.: 203949

Corneal Stromal Lenticule Transplantation for Covering Macular Hole During Vitrectomy

First Author: Wenting DING

Co-Author(s): Yongping HU, Di LI, Xiaoxiao QIAN, Yile XU

Purpose: To describe an innovative surgical technique for pathologic myopia and macular holes accompanied by retinal detachment using allogeneic corneal stromal lenticule transplantation combined with pars plana vitrectomy.

Methods: The allogeneic corneal stromal lenticule was harvested through small incision lenticule extraction (SMILE) and stored at -30°C in advance. After pars plana vitrectomy, an allogeneic corneal stromal lenticule was thawed, trimmed into approximately $60 \mu\text{m}$ thick and $100 \mu\text{m}$ larger than the macular hole and transferred to cover the macular hole through the

troc. Autologous whole blood was dripped to seal the corneal stromal lenticule. The vitreous cavity was then filled with perfluoropropane (C3F8) or sterile air.

Results: The technique was performed on three eyes of three patients. The mean postoperative follow-up period was 77.3±50.0d. Postoperatively, the macular hole of all eyes was restored. All patients' visual acuities also improved. No complications occurred during the follow-up period.

Conclusions: The innovative corneal stromal lenticule transplantation technique provides convenient operations, less surgical invasion, effective results, and reliable safety for macular hole repair during follow-up time.

Abstract No.: 203111

Delayed Closure of Idiopathic Macular Hole Following Vitrectomy and Superior Internal Limiting Membrane Flap Coverage

First Author: Yanhua CHU

Purpose: To investigate the clinical characteristics of delayed closure of idiopathic macular holes following vitrectomy with superior internal limiting membrane coverage and gas tamponade.

Methods: A retrospective analysis was conducted on 85 cases of idiopathic macular hole treated with vitrectomy combined with inferior ILM peeling and superior ILM flap coverage, along with air tamponade at our institution from October 2022 to November 2024. Delayed closure was defined as hole closure occurring only after complete gas absorption. Visual acuity changes were defined as an improvement of ≥2 lines on the Snellen chart. Comparative analysis of clinical characteristics was performed between the study groups.

Results: The hole closure rate was 100%. Delayed closure occurred in 9 cases (10.59%), with a mean disease duration of 12.97 weeks, postoperative best-corrected visual acuity (logMAR) of 0.48±0.17, and hole closure time ranging from 21 to 67 days (mean 38.4 days). No significant differences were observed in the macular hole index and drawbridge index between the two groups. ILM wrinkling was observed in 7 cases (77.78%) in the delayed closure group, compared to 40.74% in the non-delayed closure group.

Conclusions: ILM wrinkling may serve as the primary cause of delayed closure in IMH, independent of the size and configuration of the MH.

Abstract No.: 205570

Dissociated Optic Fibre Layer (DONFL): Diagnostic Methods and Correlation With Surgical Techniques

First Author: Yui Yan Veronica LI

Co-Author(s): Sunny AU

Purpose: DONFL is a structural change seen as retinal dimpling on fundus photos or arcuate macular striae on ophthalmoscopy. It has been postulated to be due to the traction of ILM peeling in vitreoretinal surgeries, causing damage to Muller cells, or resulting from the macular healing and reorganization processes. Primary endpoint: To understand how various surgical techniques correlate with the incidence of DONFL. Secondary endpoint: To understand current diagnostic methods for DONFL.

Methods: A literature review was conducted via PubMed on 23/9/2025 with keywords 'DONFL diagnosis', 'DONFL imaging', 'DONFL surgery', 'DONFL ERM', and 'DONFL macular hole'. For the primary endpoint, studies with primary data on the incidence of DONFL and the comparison between surgical techniques were extracted. For the secondary endpoints, we included studies which mention the diagnostic method used for DONFL. Case reports were excluded.

Results: Optical Coherence Tomography (OCT) was used in 13 studies (n=1076) of which Spectral-domain OCT was most common (n=605). Fundus photographs were used in 10 studies (n=460). A combination of OCT and fundus photographs was used in 3 studies (n=387). Adaptive optics scanning laser ophthalmoscope (AO-SLO) was used in 1 study (n=17). ILM peeling correlated with DONFL incidence (OR=111, p<0.001, n=482). The correlation with the ILM peeling technique, such as the forceps pinch-peel technique, diamond dusted membrane scraper or a combined technique, was not statistically significant (p>0.05). The use of conventional microscopy correlated with DONFL incidence compared to three-dimensional heads-up vitrectomy (OR=1.98, p<0.05, n=534). The use of intravitreal gas tamponade correlated with DONFL incidence (OR=2.33, p=0.038, n=296). The correlation with combined phacovitrectomy (OR=1.50 p=0.16, n=830), the use of Indocyanine green (OR=2.4; p=0.052, n=296) and a perfluorocarbon bubble (Adjusted OR=0.119, p=0.07, n=296) were statistically insignificant.

Conclusions: ILM peeling and the use of intravitreal gas tamponade correlate strongly with the incidence of DONFL. Three-dimensional heads-up vitrectomy correlates negatively with the incidence of DONFL. OCT remains the most common imaging modality for DONFL.

Abstract No.: 205805
Effects of Inner Limiting Membrane (ILM) Peel on Central Retinal Thickness Following Vitrectomy Surgery for Diabetic Eye Disease: A 12-Month Retrospective Case Series Review

First Author: Ker Yin **TOH**

Co-Author(s): Maheshwar **BAKTHAVATSALU**, Siddharth **SUBRAMANI**, Tun Hang **YEO**

Purpose: To evaluate differences in central retinal thickness 12 months after vitrectomy for diabetic eye disease, comparing patients who underwent inner limiting membrane (ILM) peeling with those who did not.

Methods: Retrospective case review.

Results: Records of 23 patients (13 male, 10 female; mean age 54.7 years) were reviewed, divided into ILM peel (n=8) and no peel (n=15) groups. Patients lacking optical coherence tomography (OCT) within 4 months pre-op or 11–14 months post-op, or with confounding factors such as macular oedema, vitreomacular traction, epiretinal membrane, and fovea involving tractional detachments, were excluded. In the ILM peel group, mean retinal thicknesses were 174 μ m (minimum), 199 μ m (average), and 249 μ m (maximum) preoperatively, and 182 μ m, 201 μ m, and 239 μ m at 1 year, respectively. These changes were not statistically significant ($p = 0.233, 0.123, 0.199$). In the no ILM peel group, preoperative retinal thicknesses were 219 μ m (minimum), 230 μ m (average), and 256 μ m (maximum), compared with 217 μ m, 235 μ m, and 253 μ m at 1 year. These changes were not statistically significant ($p = 0.432, 0.345, 0.276$). Preoperative measurements showed no significant group differences in minimal ($t = 1.56, p = 0.146$), average ($t = 1.74, p = 0.090$), or maximum thickness ($t = 1.92, p = 0.061$). Postoperatively, no significant differences were found in minimal ($t = 0.16, p = 0.878$), average ($t = 0.25, p = 0.803$), or maximum thickness ($t = 0.47, p = 0.636$).

Conclusions: Combining ILM peel during diabetic vitrectomy surgery does not significantly affect the central retinal thickness at 1 year. Further larger studies with visual outcome analyses will be beneficial.

Abstract No.: 202692
Efficacy of Intraoperative OCT-Guided 41G Microneedle Drainage for Drusenoid PED

First Author: Shuai **SHENG**

Purpose: To assess intraoperative OCT-guided 41-gauge retinal microneedle drainage for drusenoid pigment epithelial detachment (PED).

Methods: Thirty eyes with confirmed drusenoid PED (excluding other types via OCTA/angiography) were randomized: Group A (15 eyes) underwent vitrectomy with intraoperative OCT-guided subretinal fluid aspiration using a 41G needle at the PED edge. Group B

(15 eyes) received intravitreal anti-VEGF injections only. Preoperative assessments included BCVA (Snellen), central retinal thickness (CRT), foveal PED height/width (OCT), and PED area (SLO). Outcomes (complete/partial/no resolution based on foveal PED height change) were compared at 6 months, along with BCVA, CRT, and PED dimensions.

Results: Groups had similar baseline characteristics. At 6 months, Group A showed significantly higher complete PED resolution (9 eyes vs. 2 eyes in B) and lower no resolution (1 eye vs. 6 eyes). Differences were statistically significant.

Conclusions: Intraoperative OCT-guided 41G microneedle drainage effectively resolves drusenoid PED, improving BCVA and reducing CRT/PED parameters, potentially mitigating long-term vision loss. Real-time OCT guidance enhances safety, offering a promising new treatment.

Abstract No.: 202192
Efficacy of Vitrectomy Combined With Intravitreal Conbercept for Treatment of Vitreous Hemorrhage in Proliferative Diabetic Retinopathy: A Prospective Cohort Study Based on QILIN I Study

First Author: Mengyu **LIAO**

Co-Author(s): Hua **YAN**

Purpose: To evaluate the efficacy of intravitreal conbercept (IVC) combined with pars plana vitrectomy (PPV) in patients with vitreous hemorrhage (VH) due to proliferative diabetic retinopathy (PDR) in real-world practice.

Methods: This prospective, observational, multicenter cohort study enrolled 561 patients with VH due to PDR from 26 hospitals between August 2022 and June 2024. Participants were assigned to: (1) preoperative IVC (0.5 mg conbercept 3–7 days before PPV), (2) intraoperative IVC (0.5 mg conbercept at PPV completion), or (3) PPV alone as control. The primary outcome was the incidence of early postoperative VH (POVH, 7–30 days). Secondary outcomes included late POVH (30–180 days), best-corrected visual acuity (BCVA), and POVH severity.

Results: Of 425 enrolled participants (425 eyes), 406 completed the 30-day visit, and 341 completed the 180-day visit. Early POVH incidence was 24.0% (preoperative IVC) vs 23.2% (intraoperative IVC), compared to 37.6% (control; $p=0.016$ and $p=0.012$, respectively). Late POVH incidence was 11.9% (preoperative IVC) vs 17.5% (intraoperative IVC), compared to 17.8% (control; $p=0.4109, 0.4661$, respectively). Early POVH was less severe in both IVC groups versus control ($p=0.0067, 0.0304$); late POVH severity was comparable ($p=0.4860, 0.8353$). Mean BCVA improved in all groups without significant intergroup differences.

Conclusions: This QILIN study, with the largest participants to date, demonstrates that preoperative or intraoperative IVC effectively reduces early POVH incidence, rather than late POVH. IVC combined with PPV is effective in managing VH due to PDR. Preoperative IVC may be preferable for patients with more severe baseline cases.

Abstract No.: 202600

Evaluation of Intraocular Pressure Control During Vitrectomy With a Newly Developed Surgical Platform

First Author: Iori **WADA**

Co-Author(s): Yuichiro **ISHIDA**, Motohiro **KAMEI**, Naomichi **OHATA**, Kotaro **TSUBOI**

Purpose: The newly developed UNITY VCS system incorporates an independent irrigation/infusion pump capable of real-time monitoring, enabling stabilization of intraocular pressure (IOP) during fluctuations caused by leakage or infusion changes. This study aimed to evaluate the effectiveness of its IOP control function during vitrectomy.

Methods: Porcine eye models underwent 25- and 27-gauge core vitrectomy. IOP fluctuations with and without IOP control were recorded using an integrated pressure monitoring device. Surgical settings included cut rates of 20,000 and 30,000 cuts/min and a vacuum of 700 mmHg. In addition, comparisons were performed with a widely used vitrectomy platform, the Constellation vision system, under identical conditions.

Results: The IOP control group demonstrated significantly smaller IOP fluctuation amplitudes compared with the no-control group (4.6 ± 2.9 mmHg vs. 13.9 ± 9.5 mmHg, $p = 0.0019$). Recovery time to baseline IOP was also significantly shorter (3.9 ± 3.4 s vs. 16.0 ± 12.8 s, $p = 0.021$). Furthermore, compared with the established platform, the new system exhibited significantly smaller IOP fluctuations (4.6 ± 2.9 mmHg vs. 14.6 ± 0.3 mmHg, $p = 0.0018$). No significant differences were observed between 25- and 27-gauge settings or between cut rates of 20,000 and 30,000 cuts/min.

Conclusions: The IOP control function of the UNITY VCS system effectively minimized intraoperative IOP fluctuations and allowed rapid recovery to baseline values. Compared with an established vitrectomy platform, this system provided superior stability and suggests potential advantages for improving surgical safety and reliability.

Abstract No.: 206396

Evaluation of Prone vs Supine Positioning in Fresh Rhegmatogenous Retinal Detachment Treated With Pars Plana Vitrectomy and Gas

First Author: Vinod **KUMAR**

Co-Author(s): Anushka **AGARWALLA**, Rohan **CHAWLA**, Rajpal **VOHRA**

Purpose: To compare Supine versus Prone positioning in fresh rhegmatogenous retinal detachments (RRDs) treated with vitrectomy and gas tamponade.

Methods: This was a prospective randomized controlled trial of 72 eyes with fresh RRD who underwent 25-gauge vitrectomy. 37 eyes were allotted the supine position, and 35 were allotted the prone position. Cases were evaluated for single surgery reattachment rates, best corrected visual acuity (BCVA), intraocular pressure (IOP), cataract formation, and any complications. The patients were followed up for a period of 3 months.

Results: Both groups had similar demographics, and no significant difference was found between the two groups in terms of the extent of retinal detachment, position, and number of breaks. The anatomical success after single surgery was 97.3% in the Supine group and 94.3% in the Prone group ($p=0.609$). The BCVA at the end of 3 months was 0.44 ± 0.27 in the Supine group and 0.35 ± 0.27 in the Prone group ($p=0.119$) with a significant increase in BCVA preoperatively from 0.11 ± 0.22 and 0.13 ± 0.22 in the Supine and Prone groups, respectively ($p < 0.001$). The IOP in the two groups was comparable at each follow-up. The rates of cataract formation were also similar in the two groups - 60% and 53.8% in the Supine and Prone groups, respectively ($p=1.00$). Complications such as spikes in IOP, epiretinal membrane formation, cystoid macular oedema etc were similar in both groups.

Conclusions: Rates of retinal reattachment were comparable in both groups, showing that supine position is equally safe and effective for adequate tamponade.

Abstract No.: 203887

Fibrin Glue Assisted Vitrectomy for Inferior Retinal Detachment With Inferior Break: A Case Series

First Author: Kiet Phang **LING**

Co-Author(s): Chin Sern **CHAN**, Choon Teng **CHAN**, Wee Min **TEH**, Wilson Jun Jie **WONG**

Purpose: Inferior rhegmatogenous retinal detachment (RRD) presents a significant surgical challenge. Achieving a lasting tamponade of inferior breaks often requires prolonged postoperative positioning with silicone oil or gas, which delays visual recovery and increases morbidity. This case series explores the use of fibrin glue as an adjuvant to air tamponade in

managing inferior RRD, aiming to circumvent the need for prolonged tamponade.

Methods: We included 9 eyes of 9 patients who had inferior retinal detachment during the period of December 2023 to June 2025. All 9 patients were treated with 25-gauge pars plana vitrectomy and the application of fibrin glue (Artiss, Baxter) into the break under air after laser photocoagulation.

Results: The median age of patients was 45.2 (range, 15-70) years, and the median duration of symptoms was 14 (range, 3-90) days. Air tamponade was used in 4 eyes (44.4%), and 6 patients (66.7%) did not require head posturing post-operatively. 8 out of 9 patients achieved primary anatomical success, and 1 patient required a second surgery at 2 weeks. All 9 (100%) showed a clear improvement in visual acuity. 2 out of 4 phakic eyes developed cataract, and 1 patient developed epiretinal membrane.

Conclusions: The adjunctive use of fibrin glue to secure inferior retinal breaks appears to be a safe and highly effective technique, allowing for the use of short-acting air tamponade instead of prolonged gas or silicone oil. This technique facilitates rapid visual rehabilitation, and it represents a promising option for complex inferior retinal detachments, though larger comparative studies are warranted.

Abstract No.: 206166

Foldable Capsule Body Scleral Buckling Technique Under Indirect Ophthalmoscopy: a Novel Technique for Treating Relatively Posterior Retinal Breaks

First Author: Hong WU

Co-Author(s): Yan CHENG, Xinyu LIU, Zaoxia LIU, Xiaomeng ZHANG

Purpose: To describe a foldable capsule body (FCB) scleral buckling technique under indirect ophthalmoscopy for treating rhegmatogenous retinal detachment (RRD) with relatively posteriorly located breaks. It overcomes the limitation of conventional scleral buckling, which cannot address posterior pole breaks and solely relies on pars plana vitrectomy (PPV), thereby offering a more precise, minimally invasive, and refractive-function-preserving alternative for such RRDs.

Methods: The novel technique was conducted on 2 cases (2 eyes) diagnosed with RRD. During surgery, the FCB was inserted into a pre-set scleral tunnel. Under indirect ophthalmoscopy, the balloon position and inflation were adjusted to ensure the hole was positioned on the balloon buckle. Postoperative laser photocoagulation was applied around the breaks. The balloon was removed after retinal reattachment was achieved.

Results: Postoperative retinal reattachment was observed in 2 eyes. During follow-up, the visual acuity

improved, with no changes in refractive status and visual function.

Conclusions: This novel technique represents a breakthrough in the treatment of posterior pole hole-related RRD compared to conventional scleral buckling, addressing challenges previously manageable only by PPV. It allows precise intraoperative localization of retinal breaks and improves the primary surgical success rate. Moreover, it is minimally invasive, straightforward to perform, and eliminates the requirements for scleral cryotherapy or subretinal fluid drainage. Importantly, the surgery has minimal impact on visual function and refractive status. It offers a more accurate and practical alternative for patients with posteriorly located retinal breaks who are unsuitable for conventional scleral buckling.

Abstract No.: 202605

Gene Therapy for Bietti Crystalline Corneoretinal Dystrophy: A Phase 1/2 Clinical Trial

First Author: Xiaorong LI

Purpose: We report the initial findings from the first phase 1/2 clinical trial (NCT05832684) evaluating the safety and efficacy of ZVS101e in BCD patients.

Methods: In this phase 1/2, open-label, single-arm study, eleven patients with BCD were enrolled and assigned to phase 1 (dose-escalation, low: 7.5×10^{10} vg/eye, n=3; medium: 1.5×10^{11} vg/eye, n=3; high: 2.2×10^{11} vg/eye, n=1) and phase 2 (dose-expansion, low dose, n=4) to receive a single subretinal injection of ZVS101e in the worse eye. Oral prednisone was given from 3 days before the subretinal injection and continued for 12 days. Safety was assessed by monitoring adverse events and dose-limiting toxicity. Efficacy was evaluated using best-corrected visual acuity (BCVA), visual function questionnaire (VFQ-25), optical coherence tomography (OCT), and multi-luminance mobility testing (MLMT).

Results: Over 365 days of follow-up, ZVS101e showed a favourable safety profile, with no dose-limiting toxicities or drug-related serious adverse events. The mean change in BCVA from baseline was -0.28, -0.08, and 0 LogMAR for the low, medium, and high dose groups, respectively (equivalent to improvements of 14, 4, and 0 letters). In the low-dose group, 50% (3/6) of participants had a visual acuity improvement of ≥ 15 letters, with a maximum improvement of 34 letters. Functional assessments, including the multi-luminance mobility test (MLMT) and the Visual Function Questionnaire-25 (VFQ-25), along with retinal structure, demonstrated consistent improvements.

Conclusions: These results highlight ZVS101e's therapeutic potential for BCD, supporting further clinical development.

Abstract No.: 201928

Immediate Sequential Bilateral Vitreoretinal Surgery for Management of Advanced Retinopathy of Prematurity

First Author: Simar Rajan SINGH

Co-Author(s): Deeksha KATOCH, Manu SHARMA

Purpose: To determine the safety and efficacy of immediate sequential bilateral vitreoretinal surgery (ISBVS) in advanced Retinopathy of prematurity (ROP).

Methods: This retrospective, interventional study included infants who underwent ISBVS under general anaesthesia for advanced ROP at a tertiary care institute in Northern India between June 2021 and January 2025, with a minimum follow-up of 3 months. Three-port vitrectomy was done. Both eyes were operated on in the same anaesthesia session. Outcomes in terms of systemic / ocular complications and anatomical success were noted.

Results: Fifty-five eyes of 28 babies underwent ISBVS during this period. There were 19 (67.86%) males with a mean birth weight of 1188±441.625 grams and a mean period of gestation of 29.69±2.516 weeks. Sixteen (29.09%) eyes had stage 4A, 36 (65.45%) eyes had stage 4B, 2 (3.64%) eyes had stage 5, and 1(1.81%) had Vitreous haemorrhage. Lens-sparing vitrectomy was performed in 50(90.91%) eyes and lensectomy-vitrectomy in the remaining 5 (9.09%) eyes. Laser photocoagulation was done in all the eyes before surgery, except for stage 5 ROP. Two babies had anaesthesia-related complications, and the procedure was abandoned after surgery on one eye in one baby due to systemic instability. No case of endophthalmitis was noticed. Post-operative ocular complications included hypotony in 2 (3.64%) eyes, choroidals in 1(1.81%), loose blood in 7(12.73%), re-surgery in 4 (7.27%) eyes.

Conclusions: ISBVS is a safe and effective option for treating advanced ROP, which warrants urgent bilateral management without the increased risks of repeated anaesthesia sessions.

Abstract No.: 204111

Impact of Subretinal Balanced Salt Solution Injection on the Removal of Foveal Hard Exudates and Fluid in Patients With Refractory Diabetic Macular Edema

First Author: Xiang MA

Co-Author(s): Cong MA, Naiwen ZHANG

Purpose: To assess anatomical and functional outcomes of subretinal balanced salt solution (BSS) injection during vitrectomy for the removal of foveal hard exudates in refractory diabetic macular edema (DME).

Methods: A retrospective study of 6 patients (7 eyes) with refractory DME treated between March 2021

and May 2023. All underwent vitrectomy with internal limiting membrane peeling, gas/air tamponade, and subretinal BSS injection via 38G cannula. Follow-up was ≥6 months. Outcomes included best-corrected visual acuity (BCVA), central retinal thickness (CRT), and submacular hard exudate area.

Results: Patients were all female, with a mean age of 64.2 years, and had prior panretinal photocoagulation and cataract surgery. Significant clearance of foveal hard exudates was observed at 1, 3, and 6 months postoperatively. At final follow-up, 85.7% of eyes showed BCVA improvement ≥3 lines, with mean LogMAR VA improving from 0.97 ± 0.23 to 0.51 ± 0.31. Mean CRT changed from 189 ± 53 µm to 218 ± 53 µm. No recurrence of hard exudates or macular edema was detected.

Conclusions: Subretinal BSS injection during vitrectomy is a safe and effective adjunct for clearing foveal hard exudates in refractory DME, leading to visual improvement and stable anatomical outcomes. This approach may be considered in persistent DME with extensive exudates.

Abstract No.: 207287

Individualized Treatment Approach for Acute NAION: Visual Outcomes of 27-Gauge Microincision Vitrectomy Surgery in Patients With Peripapillary Wrinkles

First Author: Shuo SUN

Co-Author(s): Xiaorong LI

Purpose: To assess the potential therapeutic efficacy of 27-gauge microincision vitrectomy surgery (MIVS) in patients with acute NAION presenting with peripapillary wrinkles (PPWs).

Methods: In this prospective, nonrandomized, controlled study, acute NAION patients within 1 month of onset were classified based on swept-source optical coherence tomography (SS-OCT) findings into two groups: those with PPWs (n=33) and those without PPWs (n=13). Within the PPWs group, 21 patients underwent 27-gauge MIVS, while 12 received drug treatment. All 12 patients without PPWs received drug treatment. Visual outcomes were evaluated at 1 week, 2 weeks, and 1 month. Peripapillary vascular density was additionally assessed using optical coherence tomography angiography (OCTA). Safety was evaluated by adaptive optics scanning laser ophthalmoscopy (AOSLO).

Results: At the end of follow-up, 18 patients with PPWs who underwent MIVS, 12 with PPWs who received drug treatment, and 12 without PPWs who received drug treatment completed the study. Patients with PPWs undergoing MIVS showed significantly greater improvements in BCVA, MD, and VFI at all follow-up intervals compared with those receiving drug therapy alone. Moreover, patients without PPWs

treated with drugs achieved significant visual gains at 1 month, outperforming the PPWs+drug group. At 1 month, OCTA revealed a significant recovery of peripapillary vascular density in the PPWs+MIVS group compared with others. AOSLO assessments revealed no postoperative structural damage to photoreceptors or retinal nerve fiber layers.

Conclusions: Our findings suggest that 27-gauge MIVS could provide both visual and vascular benefits in acute NAION patients with PPWs, while medical therapy may be more effective in those without PPWs.

Abstract No.: 201665

Innovation in Action: First Sutureless Buckling–Vitreotomy for Retinal Detachment in PNG

First Author: Muhammad IMRAN

Purpose: To study the surgical outcome of sutureless scleral buckling with vitrectomy in patients with advanced combined detachment.

Methods: A patient presented with vasculitis-induced combined retinal detachments for 5 years. The patient had a funnel configuration detachment due to anterior proliferation. There was peripheral anterior PVR, which reflected the indication for advanced vitrectomy. We decided to perform the scleral buckling by the tunnel technique. We applied band, performed vitrectomy, and also did some peripheral retinotomies to cut the subretinal fibrotic bands.

Results: On the next day follow-up, the retina was flat. Her corrected vision was counting fingers, and she was able to walk independently.

Conclusions: If we modify the technique and use a sutureless technique for scleral buckling, then it would be the optimal management and of course a more time-saving technique

Abstract No.: 204439

Internal Limiting Membrane Flap Versus Conventional Peeling for Idiopathic Full-Thickness Macular Holes: A Registry Analysis of 2990 Eyes

First Author: Zi JIN

Co-Author(s): Fred K. CHEN, Rohan ESSEX, Adrian T. FUNG, Mohammad A. HONARDOOST, Ee Lin ONG

Purpose: The internal limiting membrane (ILM) flap technique was introduced to treat large (>400 μ m) full-thickness macular holes (FTMHs). Controversy exists regarding the benefits of the ILM flap compared to conventional peeling. To address this, we used a binational registry database to assess the anatomical and functional outcomes of the ILM flap in idiopathic FTMHs.

Methods: A retrospective cohort study was performed using the Australian and New Zealand Society of Retinal Specialists (ANZSRS) Registry between October 2006 and November 2023. Patients underwent either ILM flap (ILM-F) or conventional ILM peeling (ILM-P). The outcome measures were hole closure rate and best corrected visual acuity (BCVA) change at 3 months. Propensity score weighting and multivariable regression analysis were performed to adjust for baseline characteristics and covariates (surgeon grade, lens status, and follow-up duration).

Results: A total of 2990 eyes from 2905 patients were included (mean age 69 ± 9 years). 119 eyes underwent ILM-F and 2871 underwent ILM-P. The median hole size was 300 μ m (IQR, 200–422 μ m). On weighted multivariable regression analysis, ILM-F showed higher odds of hole closure compared to ILM-P (OR = 2.97, 95% CI: 1.08 – 8.20, $p = 0.04$). No significant difference in BCVA gain was observed at 3 months ($p = 0.08$). The effects of ILM-F compared to ILM-P were consistent across hole size groupings: small/medium (≤ 400 μ m), large (401–550 μ m), and X-large + (>550 μ m).

Conclusions: Although ILM-F was more effective than ILM-P in achieving FTMH closure, it provides no additional visual acuity benefit.

Abstract No.: 208169

Intraoperative Fluorescein Angiography-Guided Optimization of Preoperative Anti-VEGF Timing in Proliferative Diabetic Retinopathy: A Randomized Controlled Trial

First Author: Ruolan LING

Co-Author(s): Jie LI, Siyu QUAN, Xi WANG, Jie ZHONG

Purpose: To assess the optimal preoperative time of intravitreal injection of anti-VEGF agents for proliferative diabetic retinopathy (PDR).

Methods: This study was exploratory in nature. Patients were randomly assigned to three groups based on the timing of preoperative intravitreal anti-VEGF therapy: Group A (3 days preoperatively), Group B (7 days preoperatively), and Group C (14 days preoperatively). Intraoperative fluorescein angiography (IOFA) was used to observe the number and size of retinal neovascularization. Subsequently, participants were managed at the clinician's discretion and scheduled for a 3-month follow-up visit.

Results: A comparative analysis of intraoperatively observed neovascularization (NV) demonstrated significant differences in both NV count and size across the groups. Group A exhibited a mean NV count of 2.30 ± 1.72 and an NV size of 2.92 ± 3.33 Papillary Diameter (PD), whereas Group B showed markedly reduced values (0.95 ± 1.10 for count and 0.72 ± 0.81 PD for size), and Group C similarly displayed lower measurements (1.05 ± 1.47 for count and 1.00 ± 1.73 PD for size). Compared to Group A, Group B achieved

a 58.7% reduction in NV count ($p = 0.005$) and a 75.3% reduction in NV size ($p = 0.003$), while Group C demonstrated a 54.3% decrease in NV count ($p = 0.009$) and a 65.8% decrease in NV size ($p = 0.008$). However, no statistically significant differences were observed between Group B and Group C in either NV count ($p = 0.828$) or NV size ($p = 0.687$).

Conclusions: Quantitative analysis demonstrated that intravitreal injections administered at 7-day and 14-day preoperative intervals achieved significantly greater regression in both neovascularization number and size compared to the 3-day protocol.

Abstract No.: 206454

Intravitreal tPA for Sub-Internal Limiting Membrane Hemorrhage in Pediatric Acute Myelocytic Leukemia: A Novel Therapeutic Strategy

First Author: Aoxiang **WANG**

Co-Author(s): Yu **TIAN**

Purpose: This study aimed to evaluate the safety and efficacy of intravitreal tissue plasminogen activator (tPA) for sub-internal limiting membrane (sub-ILM) hemorrhage in pediatric acute myelocytic leukemia (AML) patients and explore its potential as a minimally invasive alternative to traditional pars plana vitrectomy.

Methods: A retrospective case series included 3 pediatric AML patients (4 eyes) with sub-ILM hemorrhage confirmed by optical coherence tomography (OCT) and fundus examination, all presenting with visual acuity $\leq 20/200$ and leukemic retinopathy. Intravitreal tPA (20 μg in 0.1 mL sterile solution) was administered under topical anesthesia, with 1–2 injections per eye (mean 1.25). Post-injection management included supine positioning and prophylactic antibiotics.

Results: Follow-up from January to December 2024 (median 5 months) showed all 4 eyes achieved significant visual recovery: best-corrected visual acuity improved from finger counting/hand motion to $\geq 20/30$ within 1 month. Near-complete hemorrhage resolution occurred in 3 eyes after 1 injection, with 1 eye resolving after a second injection. OCT confirmed sub-ILM fluid resolution and retinal architectural restoration. No intraocular or systemic complications were observed.

Conclusions: Intravitreal tPA is a safe and effective minimally invasive treatment for pediatric AML-related sub-ILM hemorrhage, enabling rapid visual recovery without general anesthesia. This approach may serve as a first-line alternative to invasive procedures, though larger prospective studies are needed to confirm long-term outcomes.

Abstract No.: 206262

LUMIDENT: Do It Yourself Construction and Real-World Efficacy in Relation to Scleral Thickness

First Author: Prithvi **CHANDRAKANTH**

Co-Author(s): Shishir **VERGHESE**

Purpose: To evaluate the efficacy of Lumi-Indent, a novel do-it-yourself scleral indenter with integrated illumination, compared to conventional methods in enhancing examination quality and user satisfaction during retinal evaluations.

Methods: A prospective, randomised study over 10 months in a tertiary eye hospital involving 100 patients during vitreoretinal surgery. Lumi-Indent was created by inserting an endoilluminator (light source) into a disposable hypodermic needle cap, secured with sterile tape. The Lumi-Indent was used for scleral indentation at all quadrants to check for visibility of peripheral retina (score 1–4). Scleral Thickness Was Measured At All 4 Scleral quadrants using ASOCT at the Superior/Inferior/Nasal/Temporal areas and was compared to the transilluminated area. The results were compared, and analyses were done using SPSS and Microsoft Excel

Results: The results indicated 62.7%-normal scleral thickness, 11.4%-increased thickness, and 26%-less than normal thickness. Among cases, normal thickness Scores 1 to 4 were distributed 12%, 25%, 33%, and 30%, respectively. In increased scleral thickness -6%, 18%, 35%, 41%, reduced scleral thickness -23%, 38%, 21%, 18%. Quadrant-wise analysis: superior sclera scored 24%, 32%, 41%, 3%; temporal quadrant -15%, 34%, 39%, 12%; inferior quadrant -12%, 27%, 34%, 27%; nasal quadrant -19%, 36%, 38%, 7%. According to the above statistics, the order of scleral transillumination was found to be Superior>Nasal>Temporal>Inferior. Pre-op assessment with AS-OCT can be done to predict if scleral transillumination can be performed efficiently during VR surgery.

Conclusions: This pioneering clinical study using LUMIDENT is the first to compare scleral thickness with transillumination intensity during retinal examination. Lumident can be used by the surgeon as an illuminated scleral indenter without the help of an assistant for peripheral base shaving and for endolaser easily in cases with lower scleral thickness, which can be assessed preoperatively using ASOCT.

Abstract No.: 204280

Long-Term Outcomes Beyond 5 Years of Lens Capsular Flap Transplantation in the Management of Refractory Macular Hole

First Author: Mingyang **WANG**

Co-Author(s): Shipeng **GUO**, Dian **JIAO**, Jie **PENG**, Peiquan **ZHAO**

Purpose: To evaluate the visual and anatomical outcomes over five years following lens capsular flap

transplantation (LCFT) for the treatment of refractory macular hole (MH).

Methods: This retrospective series included 19 eyes with refractory MHs treated with LCFT between 2015 and 2019, followed for more than 5 years. Assessments included best-corrected visual acuity (BCVA), optical coherence tomography (OCT), fundus photography, and macular integrity assessment (MAIA) microperimetry. Lens Capsular Flap (LCF) thickness was measured in cases with clear delineation.

Results: Mean follow-up was 89.0 ± 13.5 months. At the last follow-up, 17 eyes (89.5%) achieved complete MH closure, one partial closure, and one MH recurrence. Median MH diameter was $1102 \mu\text{m}$. Mean logMAR BCVA improved significantly from 1.85 preoperatively to 1.32 at the last follow-up ($P=0.007$) and remained stable compared with 18 months postoperatively ($P=0.74$). OCT revealed subfoveal LCF structure in all patients and demonstrated gradual integration of the lens capsular flap (LCF) with surrounding tissue, with thickness remaining stable over time ($P = 0.308$). Five eyes developed hyperreflective subretinal scars, but BCVA was not significantly different from eyes without scarring. No immune rejection or ocular inflammation occurred. Eleven patients completed MAIA microperimetry, whereas only 2 eyes were able to complete the test preoperatively. Microperimetry revealed lower sensitivity in LCFT-treated regions but preserved function in the surrounding retina, with paracentral fixation commonly adopted.

Conclusions: LCFT provides durable MH closure and sustained visual improvement over 5 years. Subretinal LCF remains stable, with preserved peripheral retinal function despite localized scarring, supporting LCFT as a long-term effective treatment for refractory MH.

Abstract No.: 201412

Longitudinal Multi-Omics Profiling of Aqueous Humor Deciphers the Dual Therapeutic and Pro-Fibrotic Effects of Anti-VEGF Therapy in PDR.

First Author: Huang YUJUAN

Purpose: Preoperative anti-vascular endothelial growth factor (VEGF) therapy in proliferative diabetic retinopathy (PDR) can paradoxically worsen fibrovascular contraction, a significant clinical challenge. Since the molecular drivers are poorly understood, the dual molecular effects of anti-VEGF therapy were systematically investigated in this study.

Methods: Paired aqueous humor samples were prospectively collected from 25 PDR patients, categorized as either vitreous hemorrhage (VH; $n=13$) or VH with tractional retinal detachment (VH+TRD; $n=12$). An intersection analysis was performed to identify molecules significantly altered in both baseline (VH+TRD vs. VH) and post-treatment comparisons.

Results: Enrichment analysis implicated extracellular matrix and TGF- β pathways at baseline, and VEGF and inflammatory pathways post-treatment. Thirty-eight significant molecules were identified. Three «aggravation-type» molecules exhibited changes that worsened pathological dysregulation: CAST (upregulated, $P=0.030$), GALNS (downregulated, $P=0.046$), and 3-Hydroxypropanoic acid (downregulated, $P<0.001$). The remaining 35 molecules demonstrated an «improvement-type» pattern.

Conclusions: This study identifies distinct proteo-metabolomic signatures underlying the dual effects of preoperative anti-VEGF. The aggravation-type molecules, particularly CAST, GALNS, and 3-Hydroxypropanoic acid, provide a mechanistic basis for adverse fibrotic responses and potential biomarkers for risk stratification.

Abstract No.: 204516

Lyophilized Human Amniotic Membrane Covering for Macular Hole Retinal Detachment in High Myopia: A Randomized Clinical Trial

First Author: Wei LIN

Co-Author(s): Xiaoyan LIN, Yong WEI

Purpose: To evaluate the efficacy and safety of lyophilized human amniotic membrane (LhAM) covering for macular hole retinal detachment (MHRD) associated with high myopia.

Methods: This prospective randomized controlled trial enrolled 40 patients (40 eyes) with MHRD secondary to high myopia. Participants were randomly assigned to receive either LhAM covering (LhAM group, $n=20$) or internal limiting membrane peeling (ILM group, $n=20$). The AM group received C3F8 gas tamponade, while the ILM group received silicone oil tamponade. The outcomes included retinal reattachment rate, macular hole closure rate, visual improvement, and complications.

Results: Ultimately, 37 patients completed follow-up and were included in the efficacy analysis (18 eyes in the LhAM group and 19 eyes in the ILM group). The macular hole closure rate was significantly higher in the LhAM group compared to the ILM group (88.9% vs. 31.6%, $P < 0.001$). Both groups achieved high rates of retinal reattachment (94.4% in the LhAM group vs. 94.7% in the ILM group, $P = 1.00$). At 6 months postoperatively, there was no significant difference in BCVA between the groups (LhAM group: 1.49 ± 0.43 LogMAR vs. ILM group: 1.57 ± 0.38 LogMAR, $P = 0.54$). The incidence of elevated intraocular pressure was 5.6% (1/18) in the LhAM group and 36.8% (7/19) in the ILM group ($P = 0.042$).

Conclusions: For eyes with MHRD due to high myopia, LhAM patching resulted in a significantly higher macular hole closure rate and a lower risk of

postoperative ocular hypertension compared to ILM peeling with silicone oil tamponade. It is a promising technique that eliminates the need for secondary surgery to remove silicone oil.

Abstract No.: 208668

Macular Buckling Combined With Inverted Internal Limiting Membrane Flap Technique and Air Tamponade in the Treatment of Macular Hole Retinal Detachment in High Myopia

First Author: Qi ZHANG

Purpose: The study aims to assess the efficacy of integrating macular buckling (MB) with pars plana vitrectomy (PPV), the inverted internal limiting membrane (ILM) flap technique, and air tamponade in treating macular hole retinal detachment (MHRD) in patients with high myopia.

Methods: This retrospective study included sixty-two eyes from sixty-two consecutive patients diagnosed with highly myopic MHRD. The participants were categorized into two groups: the PPV group (n=34) and the combination group (n=28). Best-corrected visual acuity (BCVA), axial length (AL), progression of myopic maculopathy (MM), rates of macular hole (MH) closure, and retinal reattachment were assessed and compared.

Results: The mean follow-up duration was 14.13±2.57 months. The combination group demonstrated a significantly higher rate of MH closure compared to the PPV group (79.41% vs. 100%, P=0.011). Retinal reattachment was successfully achieved in 100% of eyes in the combination group following the initial surgery, in contrast to 70.59% in the PPV group (P=0.002). The combination group demonstrated a significantly greater improvement in BCVA compared to the PPV group (P<0.001). The mean MM stage in the PPV group increased from 2.12±0.69 to 2.38±0.92 (P=0.031). The combination group exhibited no significant progression of MM postoperatively.

Conclusions: The integration of MB with the inverted ILM flap technique and air tamponade seems to enhance both MH closure and retinal reattachment rates, along with notable improvements in BCVA among patients with highly myopic MHRD.

Abstract No.: 201895

Macular Hole Closure by Internal Limiting Membrane Flap Without Gas Tamponade Versus Conventional Surgery

First Author: Ka Ho SZETO

Co-Author(s): Vivian HUI, Julia LAM, Mohamed SHAHEEDA, Chi Wai TSANG, Ken TSANG, Amy YU

Purpose: To compare the effectiveness and safety of the novel internal limiting membrane (ILM) flap with

no gas tamponade technique and conventional surgery in repairing macular hole (MH).

Methods: Retrospective study of consecutive patients with OCT-confirmed full-thickness MH who underwent MH repair surgery by either conventional surgery or the ILM flap with no gas tamponade technique at the Hong Kong Eye Hospital from November 1, 2021, to July 31, 2024.

Results: Ninety-three eyes from 93 patients were included in the study, of which 51 eyes underwent MH repair with conventional surgery, and 42 underwent the ILM flap with no gas tamponade technique. The MH closure rates were comparably high in both groups (94.1% vs. 95.2%; P = 0.812). Visual acuity was significantly better in the no gas tamponade group at postoperative week 1 (1.48 vs. 0.84; P < 0.001) and month 1 (0.87 vs. 0.73; P = 0.048). There were no significant differences in VA by postoperative months 3 (0.54 vs. 0.49; P = 0.281) and 6 (0.41 vs. 0.47; P = 0.991). In multivariate analysis, the rate of foveal gliosis was lower in the no gas tamponade group (20.0% vs. 4.9%; P = 0.043).

Conclusions: The ILM flap with no gas tamponade technique could achieve a high MH closure rate comparable to conventional surgery. This novel technique was associated with significantly better vision in the first month of the postoperative period, as well as a lower rate of foveal gliosis. These results demonstrated the feasibility of repairing MH without gas tamponade and warrant further prospective study.

Abstract No.: 201620

Macular Hole Retinal Detachment Repair Without Gas Tamponade – a Proof-of-Concept Case Series

First Author: Vivian HUI

Co-Author(s): Julia T.w. LAM, Shaheeda MOHAMED, Simon K.h. SZETO, Chi Wai TSANG, Ken K. TSANG, Amy H.y. YU

Purpose: To describe a surgical technique for macular hole retinal detachment repair in highly myopic eyes using a temporal internal limiting membrane (ILM) flap without the need for gas tamponade.

Methods: A retrospective single-centre case series from August 2024 to August 2025. Patients with myopic macular hole (MH) with retinal detachment who underwent pars plana vitrectomy with a temporal ILM flap without gas tamponade were included. Main outcome measures include anatomical closure of MH, retinal attachment, visual improvement, and rate of post-op complications.

Results: Six eyes were included. Mean spherical equivalent and axial length were 12.4D (range: -6.5D to -17.25D) and 30.21mm (range: 28.95 mm to 30.72 mm), respectively. Complete anatomical closure of MH and retinal attachment was achieved in all eyes. 16.6%,

60%, 100% and 100% of eyes achieved improvement in visual acuity at week 1, 1-month, 3-month, and 6-month, respectively. One eye developed vitreous hemorrhage, which resolved spontaneously. None of the cases had a reopening of the MH or redetachment.

Conclusions: This novel surgical technique provides proof of concept that gas tamponade may not always be necessary in the surgical repair of macular hole retinal detachment in highly myopic eyes.

Abstract No.: 206305

Management of Aphakia in the Absence of Capsular Support: Outcomes in a Scottish Patient Cohort With the Carlevale (Soleko) IOL

First Author: Juan Lyn **ANG**

Co-Author(s): Manjit **MEHAT**

Purpose: To report the clinical outcomes of the use of a specially designed scleral fixated intraocular lens, the Carlevale intraocular lens (Carlevale IOL, Soleko, Italy) for the correction of aphakia in the absence of capsular support of variable etiology.

Methods: This is a single-centre retrospective case series study. A prospectively maintained database of patients undergoing Carlevale (Soleko) lens fixation at a tertiary centre from December 2020 to December 2024 was analysed. Procedures were performed by four consultant vitreo-retinal surgeons (MM, HB, AK and CG). Descriptive statistical analysis was performed on patient demographics, indication for surgery, surgical technique, complications, and pre- and post-operative best corrected visual acuity (BCVA) and intra-ocular pressure (IOP). Paired-samples t-test assessed mean difference between pre- and post-operative best corrected visual acuity BCVA and IOP.

Results: Forty-five eyes from 43 individual patients (15 females, 28 males) with mean age 73.6 (± 14.7) with a mean follow-up of 15 months were included in the analysis. The most common indication was dislocated IOL (22.4%, n=21), followed by subluxed IOL and aphakia (each 22.2%, n=10) then subluxed crystalline lens (6.7%, n=3). One patient had decompensating cornea secondary to anterior chamber IOL (2.2%, n=1). Mean pre-operative BCVA was logMar 1.30 (± 0.70), with mean post-op BCVA 0.55 (± 0.57). There was a statistically significant improvement in BCVA (0.76 ± 0.83 , $p < 0.001$). There was a drop in IOP (2.8 ± 7.9 , $p = 0.041$). In four cases, there was haptic rupture requiring use of further IOL(s). 7 eyes required a further surgical procedure(s).

Conclusions: Carlevale (soleko) lens fixation represents a safe and reliable method to manage aphakia without capsular support, demonstrating a statistically significant improvement in BVCA.

Abstract No.: 201103

Microbiological Analysis of Vitreous Sample in Endophthalmitis Patients at a Tertiary Eye Care Hospital in Bangladesh

First Author: Shah Md Rajibul **ISLAM**

Co-Author(s): Quazi Sazzad **IFTEKHAR**, Mominul **ISLAM**, Omar **JAFARULLAH**, Lutfullahil **KHABIR**

Purpose: This study was planned to determine the microbiological organisms of endophthalmitis patients (vitreous sample) attending a tertiary eye care hospital.

Methods: A prospective longitudinal study was undertaken from July 2022- December 2022. All patients underwent a thorough history, clinical examination, and appropriate investigations. After a clinical diagnosis of endophthalmitis was reached, pars plana vitrectomy was performed, and vitreous tap was sent for microbiological analysis. The microbiological reports were collected, and the patients were monitored on follow-up.

Results: Out of 223 patients with endophthalmitis, the majority, 100 (44.8%), were aged 50 years or older. Most were male, 134 (60.1%). The male-to-female ratio was 1.5:1. 89 (39.9%) were culture positive and included bacteria 61 (27.4%), fungus 26 (11.7%), and both 2 (0.9%). The most common bacteria identified were *Pseudomonas* sp. 20 (31.7%), followed by *Staphylococcus aureus* 13 (20.6%), *Staphylococcus epidermidis* 11 (17.5%), and *Bacillus* 10 (15.9%). The commonest fungi identified were *Candida* 12 (42.9%) and *Fusarium* 9 (32.1%). *Staphylococcus pneumoniae* was significantly higher in those less than 18 years (14.3%). *Pseudomonas* sp. was significantly higher in female patients (46.2% vs 21.6%). *Candida* was significantly higher in the age group 19-50 (83.3%).

Conclusions: The study concluded that total culture positivity was 39.9%, which included bacterial (27.4%), fungal (11.7%), and mixed organisms (0.9%). The most common bacterial organisms identified were *Pseudomonas* sp., *Staphylococcus aureus*, *Staphylococcus epidermidis*, and *Bacillus* in postoperative endophthalmitis. The most common fungal organisms identified were *Candida* and *Fusarium* in postoperative endophthalmitis.

Abstract No.: 200189

Near-Real Surgical Specimens (NRSS): A Novel Platform for Standardized Assessment of Suprachoroidal Drug Delivery

First Author: David **ALMEIDA**

Co-Author(s): Vinit **MAHAJAN**

Purpose: This study presents Near-Real Surgical Specimens (NRSS), an engineered platform replicating the biomechanical properties of human ocular tissue for standardized evaluation of SC drug delivery.

Methods: NRSS ocular models were fabricated with biomimetic materials calibrated to human tissue characteristics. Suprachoroidal injections (100 μ L) were performed using a standardized protocol and compared to published cadaveric data. Real-time imaging enabled visualization of injection dynamics. Quantitative metrics, including coverage, reproducibility, and tissue-device interactions, were assessed. Pathology-specific NRSS variants (high myopia and hypertensive choroidopathy) were evaluated to determine the effect of disease states on SC distribution.

Results: NRSS models exhibited SC coverage of 35.1% $\pm$ 2.4%, consistent with cadaveric data (33.3% $\pm$ 5.9%) but with significantly reduced variability (coefficient of variation: 6.8% vs. 17.7%). Injections displayed the known circumferential-before-posterior spread pattern. Real-time visualization revealed temporal distribution dynamics and center-of-mass migration.

Conclusions: The NRSS platform enables standardized, reproducible assessment of SC drug delivery and overcomes key limitations of cadaveric models. Its real-time imaging and customizability for disease states offer novel insights for therapeutic optimization, device development, and surgical training.

Abstract No.: 201679

Optical Coherence Tomography Angiography Analysis of Macular Perfusion After Rhegmatogenous Retinal Detachment Repair: A Systematic Review and Meta-Analysis

First Author: Amer **AWAN**

Co-Author(s): Abdullah **AHMED**, Fiza **SHAHEEN**

Purpose: To systematically evaluate and synthesize evidence regarding macular perfusion changes following rhegmatogenous retinal detachment (RRD) repair using optical coherence tomography angiography (OCTA).

Methods: A comprehensive search of major databases was conducted from the inception to November 2024. Studies comparing OCTA parameters between RRD eyes post-repair and control eyes were included. The analysis included foveal avascular zone (FAZ) area, foveal vascular density (FVD), parafoveal vascular density (PFVD), perfusion density in choriocapillaris (CC), and best-corrected visual acuity (BCVA). Data were analyzed separately for macula-ON and macula-OFF groups.

Results: Twenty studies comprising 686 RRD eyes (231 macula-ON, 455 macula-OFF) and 686 control eyes were analyzed. In macula-OFF cases, FAZ area remained significantly enlarged post-repair in both superficial capillary plexus (SCP) (0.06 mm², 95% CI: 0.02-0.09) and deep capillary plexus (DCP) (0.12 mm², 95% CI: 0.04-0.19). FVD showed no significant differences in either group. PFVD demonstrated a significant reduction in DCP for both macula-ON (-1.38%, 95%

CI: -2.72 to -0.05) and macula-OFF (-2.82%, 95% CI: -5.02 to -0.63) groups. CC perfusion density showed a significant reduction post-repair (-2.39%, 95% CI: -4.56 to -0.22). Postoperative BCVA improved significantly in macula-OFF cases (0.79 logMAR, 95% CI: 0.37 to 1.21) but showed no significant change in macula-ON cases.

Conclusions: The enlarged FAZ area, reduced PFVD, and CC perfusion density suggest lasting changes in the retinal microvasculature post-repair. It demonstrates persistent alterations in macular perfusion parameters following RRD repair, particularly in macula-OFF cases.

Abstract No.: 200470

Outcomes of Diabetic Vitrectomy and Factors Affecting the Outcomes: A Prospective Observational Study

First Author: Amit Kumar **DEB**

Co-Author(s): Sandip **SARKAR**

Purpose: Limited literature is available on predictors of diabetic vitrectomy. Most available studies are retrospective. Hence, we conducted this prospective study to evaluate the short-term outcomes (6 months) of diabetic vitrectomy and assess the predictors.

Methods: Eyes undergoing diabetic vitrectomy were classified under the following 5 categories: Non-clearing VH (group I), Non-clearing VH with minimal TRD (group II), Progressive FVP c EMTRD (group III), MTRD (group IV), Combined TRD/RRD (CRD) (group V). Intra-op findings were documented for each case along with a review of the surgical video. Post-operatively, patients were followed up for 6 months.

Results: A total of 76 patients were recruited. Primary anatomical success: 69/76 (90.78%). Final success: 74/76 (97.36%). Mean Log MAR BCVA: 1.07 $\pm$ 0.66. Vision at 6 months: 6/60 or better=40/76, Less than 6/60=36/76, 6/24 or better=27/76. On multinomial logistic regression analysis, non-usage of pre-op anti-VEGF agents, silicone oil tamponade, > 2 quadrants of TRD, and residual retinal traction after surgery maintained significant association with poor visual outcomes, with an Odds ratio > 2 or higher for each parameter.

Conclusions: Pre-op laser and use of anti-VEGF agents were associated with good outcomes in diabetic vitrectomies, while > 2 quadrants of TRD, disc pallor, and iatrogenic breaks were associated with poor outcomes.

Abstract No.: 200791**Outcomes of Early Vitrectomy in Vitreous Haemorrhage (VH) Secondary to Proliferative Diabetic Retinopathy (PDR) – a Prospective Study***First Author: Manjot KAUR**Co-Author(s): Dr Madhu KUMAR*

Purpose: To evaluate the visual outcomes, to assess the incidence of rebleeding and to analyse the impact of vitrectomy on the progression of PDR (NVE and FVP leading to TRD).

Methods: After obtaining informed consent and approval from the ethics and scientific committees, fifty diabetic patients aged over 18 years, with visual acuity ranging from PL to ETDRS logMAR 0.3 (equivalent to Snellen's 20/40, 6/12) due to VH secondary to PDR were enrolled. Preoperative variables included age, gender, duration of diabetes, HbA1c levels, visual acuities, and IOP at initial and follow-up visits. Patients underwent pars plana vitrectomy (PPV) within two weeks of presentation, and intraoperative complications were documented. Postoperative follow-up visits at 1 (± 1) week, 4 (± 4) weeks, 12 (± 4) weeks, and 24 (± 4) weeks to monitor postoperative complications in the study eye, along with the progression rate of DR in the contralateral eye according to the ETDRS classification.

Results: The mean HbA1c level was 8.66% (± 1.45). Post-operative complications were minimal, with a 2% incidence of complications at 1(± 1) week and 8% incidence at 12(± 4) weeks. The incidence of rebleeding at 4(± 4) weeks was 2% and at 12(± 4) weeks was 8%.

Conclusions: In the MIVS era, the complication rate of small-gauge 3-port pars plana vitrectomy has significantly reduced. A single surgical sitting of vitrectomy helps prevent blindness, decreases time spent with reduced VA, and is a non-inferior treatment modality as compared to delayed vitrectomy, and also reduces follow-up visits for additional PRP.

Abstract No.: 204917**Outcomes of Vitreoretinal Surgery for Complications and Macula-Threatening Bullous Retinoschisis in X-Linked Retinoschisis***First Author: Licong LIANG**Co-Author(s): Fang LU, Kaiqin SHE*

Purpose: To evaluate the outcomes of vitreoretinal surgery in patients with X-linked retinoschisis (XLRS) complicated by vitreous hemorrhage (VH), retinal detachment (RD), macular hole, or macula-threatening bullous schisis.

Methods: This retrospective study included 29 XLRS patients (35 eyes) who underwent vitreoretinal surgery at West China Hospital of Sichuan University from 2015

to 2024. All patients underwent pars plana vitrectomy. C3F8 gas or silicone oil (SO) intraocular tamponade was used in different situations. The postoperative rate of retinal reattachment and the best corrected visual acuity (BCVA, LogMAR) were evaluated.

Results: The median age at surgery was 4 years (range, 7 months–10 years). Genetic testing in 28 patients identified 25 RS1 variants, predominantly missense mutations (72%). Complications included RD in 14 eyes (40%), VH in 8 eyes (22.9%), bullous schisis in 12 eyes (34.3%), and macular hole in 1 eye (3%). Among eyes with RD, final retinal reattachment was achieved in 78.6% (11/14). Two eyes developed silicone oil dependence, and one eye developed secondary glaucoma. The retinoschisis cavity may recur or resolve postoperatively. In eyes with macula-threatening bullous schisis, vitrectomy with viscoelastic or C3F8 tamponade preserved a clear central visual axis in 83.3% (10/12), although two eyes developed secondary rhegmatogenous RD. Mean BCVA improved from 1.6 ± 0.7 to 1.3 ± 0.4 logMAR ($P = 0.034$).

Conclusions: Vitreoretinal surgery provides favorable anatomic restoration and modest visual improvement in XLRS eyes with complications or macula-threatening bullous schisis, supporting timely surgical intervention when the macula is at risk.

Abstract No.: 205419**Preoperative Intravitreal Viscoelastic Injection for Surgical Optimization in Rhegmatogenous Retinal Detachment With Choroidal Detachment***First Author: Devesh KUMAWAT**Co-Author(s): Ritweez SAHU, Pradeep VENKATESH, Saurabh VERMA*

Purpose: To evaluate the safety and efficacy of a modified protocol- combining preoperative intravitreal viscoelastic injection (PIVOT) with standard anti-inflammatory therapy, in facilitating vitrectomy in eyes with rhegmatogenous retinal detachment with choroidal detachment (RRD-CD).

Methods: In an ambispective Institute Ethics Committee-approved study, ten eyes of ten patients with RRD-CD (CD reaching till the equator in ≥ 1 quadrant) were managed at a tertiary eye-care center between December 2024 and June 2025. 1% sodium hyaluronate (Healon™ PRO) was injected intravitreally until IOP became digitally normal, one day post-baseline, and at a median of one day (range: 1-4days) before vitrectomy, along with preoperative topical difluprednate, cycloplegics, and oral corticosteroids (if not contraindicated). Outcome measures were intraocular pressure (IOP), cumulative CD height (on B-scan ultrasonography), injection-related adverse events, and intraoperative complications. Data were analyzed using the paired t-test, the Wilcoxon test, and the Pearson correlation.

Results: The mean age of patients was 50.6 ± 11.4 years. Mean IOP increased significantly from 4.75 ± 2.05 mmHg at baseline to 10.0 ± 3.34 mmHg on the day of surgery ($p=0.001$). Cumulative CD reduced significantly from 15.82 ± 4.88 mm to 5.49 ± 6.01 mm ($p=0.003$), with complete resolution in 4 cases. No injection-related adverse events were observed. Port placement with a standard 25G system was uneventful in 9/10 eyes. Vitrectomy could be safely completed in all eyes. Adequate oil fill could be achieved in all eyes.

Conclusions: PIVOT combined with anti-inflammatory treatment may be a safe and effective strategy in managing RRD-CD. It improves IOP, reduces CD, and optimizes intraoperative conditions without delaying surgery. Larger studies with control groups are advised to validate these findings.

Abstract No.: 200465

Prevalence and Risk Factors Associated With Progression and Regression of Type 2 Prethreshold Retinopathy of Prematurity

First Author: Mojtaba HEYDARI

Co-Author(s): Mohammadkarim JOHARI

Purpose: To investigate the frequency and risk factors associated with the progression and regression of type 2 retinopathy of prematurity (ROP) among preterm infants in southern Iran.

Methods: In a retrospective cohort, a total of 1,214 infants underwent ROP screening at the Poostchi ROP Clinic between March 2021 and April 2022; 62 infants with type 2 prethreshold ROP were classified into the finally regressed and progressed groups. Clinical characteristics and risk factors associated with the risk of regression and progression were assessed.

Results: Among the final cohort, 43 infants experienced spontaneous regression of ROP, while 19 progressed to type 1 ROP. No significant differences were observed in birth weight or gestational age between the two groups. Male gender was more prevalent among those progressing to type 1 ROP (28% vs 58%, $p=0.024$). Univariate analysis identified longer duration of mechanical ventilation (6.74 ± 4.27 vs 11.24 ± 7.02 , $p=0.047$), higher oxygen consumption (11.85 ± 8.89 vs 19.89 ± 9.39 , $p=0.042$), and history of sepsis (9.50% vs 26.40%, $p=0.047$) as significant predictors of ROP progression. Infants with lower gestational age ($p=0.041$), longer NICU admission ($p=0.014$), and prolonged mechanical ventilation ($p=0.035$) exhibited delayed regression of ROP. Conversely, shorter durations until progression to treatment were noted in infants with prolonged NICU admission ($p=0.021$) and higher oxygen consumption ($p=0.048$).

Conclusions: Tailored screening strategies considering factors such as mechanical ventilation, oxygen consumption, gestational age, and weight gain are crucial for optimizing outcomes in patients with ROP.

Abstract No.: 202488

Prophylactic Buckling in Retinal Capillary Hemangioblastoma (RCH): Early Intervention to Prevent Progression and Complications

First Author: Shivayan SRIVASTAVA

Co-Author(s): Shorya AZAD

Purpose: To report a case of retinal capillary hemangioblastoma (RCH), a condition associated with von Hippel-Lindau (VHL) disease, highlighting the importance of early detection and timely intervention.

Methods: A 29-year-old female presented with a history of diminution of vision in the right eye (RE) for 3 years. The patient had a history of laser treatment in the RE. Systemic history was unremarkable. Visual Acuity (VA) in the RE was no light perception, and 6/9 in the LE. Examination revealed total hyphema in the RE, and B scan ultrasound was suggestive of a disorganized globe. Fundus examination of the LE showed multiple small orange-reddish lesions with dilated feeder and draining vessels, consistent with RCH. The diagnosis was confirmed, and a comprehensive systemic workup for VHL was carried out, which revealed a simple renal cyst and multiple pancreatic cysts. Laser photocoagulation was performed for all RCHs in the LE.

Results: At 1-month follow-up, traction was noted associated with one of the RCHs. Due to the traction and exudation over the lesion, prophylactic scleral buckling with cryotherapy was performed in the LE. Postoperative day 1 (POD1) assessment revealed increased exudation and a decrease in BCVA, and a course of steroids was given. At the 1-week follow-up, subretinal fluid (SRF) had resolved with maintained BCVA.

Conclusions: This case underscores the early onset of RCH and its association with VHL disease. It emphasizes the importance of early detection and timely intervention to prevent further visual deterioration in patients, particularly those with pre-existing vision loss in the other eye.

Abstract No.: 205355

Real-World Outcomes of Faricimab in AMD, DMO, and RVO: Functional, Anatomical, and Retreatment Analyses

First Author: Nishant Vijay RADKE

Co-Author(s): Ya CHAN, Miaoli LIN, Jiaying LIU, Snehal Nishant RADKE

Purpose: To evaluate the real-world effectiveness of faricimab across neovascular AMD, diabetic macular edema (DMO), and retinal vein occlusion (RVO), focusing on anatomical, functional, and retreatment outcomes

Methods: This retrospective study included 53 eyes (AMD/PCV $n=19$, DMO/DR $n=16$, RVO $n=18$). Visual acuity (VA, logMAR) and central retinal thickness (CRT,

microns) were analyzed using ANCOVA and ordinary least squares (OLS) regression, adjusting for baseline values, age, sex, and prior treatment status. Pairwise comparisons between disease groups were performed using Tukey HSD when the global test was significant. Time to first retreatment was assessed with Kaplan–Meier analysis and Cox proportional hazards modeling. In addition, inter-injection intervals (Tx1–Tx2 and Tx2–Tx3) were analyzed for differences across disease groups using the Kruskal–Wallis test, followed by pairwise Mann–Whitney U tests with Holm correction where appropriate.

Results: OLS regression demonstrated baseline CRT as the strongest predictor of Δ CRT ($p < 0.001$), and baseline BCVA as the strongest predictor of Δ BCVA ($p = 0.001$). Prior treatment status predicted Δ CRT ($p = 0.007$) but not Δ BCVA ($p = 0.057$). ANCOVA revealed no significant differences in Δ CRT between disease groups ($F = 1.38$, $p = 0.263$), while Δ BCVA differed significantly ($F = 4.32$, $p = 0.019$), with RVO patients showing greater functional gains than AMD/PCV (Tukey $p = 0.023$). Kaplan–Meier curves indicated shorter time to retreatment for DMO/DR patients; Cox modeling confirmed this, with DMO/DR patients more likely to require earlier injections than AMD/PCV ($HR = 2.18$, $p = 0.047$). Kruskal–Wallis testing of inter-injection intervals showed no difference for Tx1–Tx2 ($p = 0.584$) but a significant group effect for Tx2–Tx3 ($p = 0.037$), with DMO eyes having shorter intervals than RVO (Mann–Whitney U, Holm-corrected $p = 0.009$).

Conclusions: Faricimab improves both anatomical and functional outcomes across retinal diseases, with the largest functional gains in RVO. Baseline factors and prior treatment influence response, and retreatment intervals vary by disease, highlighting the need for individualized dosing strategies in real-world practice.

Abstract No.: 207260

Relentless Infectious Necrotizing Scleritis Secondary to Phthiriasis Palpebrarum

First Author: Nikita **CHAUDHARY**

Co-Author(s): Vishal **SANJAY JADHAV**

Purpose: To discuss clinical diagnosis and treatment of a case of relentless infectious necrotizing scleritis secondary to Phthiriasis palpebrarum.

Methods: A case of painful red eye diagnosed as diffuse nodular scleritis was approached and investigated with progressive and persistent scleral thinning and inflammation.

Results: The patient developed severe necrotizing scleritis, characterized by marked scleral thinning and uveal tissue exposure. Systemic investigations for infective, autoimmune disorders were largely inconclusive, suggesting a localized reaction rather than a systemic process. Eventually, a detailed ophthalmological examination revealed a lice in the

sclera in the advanced stages of the disease. The lice were meticulously removed, histopathologically proven as Phthiriasis palpebrarum, and the site was thoroughly irrigated. Treatment with systemic antibiotics and removal of the causative agent led to resolution of the inflammation, although residual scleral thinning persisted.

Conclusions: This case highlights that incidental lice infestation within the sclera, though rare, can trigger refractory necrotizing scleritis.

Abstract No.: 202697

Retinal Vascular Reconstruction for Branch Retinal Vein Occlusion

First Author: Shuai **SHENG**

Purpose: To evaluate the feasibility and efficacy of retinal vascular reconstruction (RVR) for treating branch retinal vein occlusion (BRVO).

Methods: Ten patients diagnosed with BRVO by clinical and imaging examinations were enrolled. Five patients received anti-VEGF therapy (intravitreal injections), while the other five underwent RVR. Treatment outcomes and macular edema recurrence were compared between the groups.

Results: In the RVR group ($n = 5$), significant improvement was observed in 4 patients (3 complete resolution, 1 partial resolution) with no macular edema recurrence. In the anti-VEGF group ($n = 5$), improvement occurred in 2 patients (1 complete resolution, 1 partial resolution) with no recurrence. A statistically significant difference in treatment efficacy was found between the groups ($P < 0.05$).

Conclusions: Retinal vascular reconstruction is a safe and effective treatment for BRVO, demonstrating significantly better outcomes than anti-VEGF therapy in this pilot study. This approach holds promise for clinical application but requires further validation with larger sample sizes to confirm long-term efficacy and safety.

Abstract No.: 205571

Saudi Arabian Retinopathy of Prematurity Telemedicine Program: 6-Year Results

First Author: Saleh **AL AMRO**

Co-Author(s): Sami **ALGHAMDI**, Sulaiman **ALSULAIMAN**

Purpose: To report the 6-year results of the Saudi Arabian retinopathy of prematurity telemedicine program (SAROP), which was established with the goal of eradicating ROP blindness in the Kingdom of Saudi Arabia (KSA).

Methods: Premature infants with a birth weight (BW) of 1500 g or less and/or gestational age (GA) of 32 weeks or less were screened for ROP using digital wide-angle fundus cameras placed in all 32 level 3 neonatal intensive care units (NICU), Ministry of Health, covering every part of this large country (2.2 million square

kilometres area). Fundus photos were uploaded to the SAROP server, which were then evaluated and reported by retina specialists. Detailed reports were electronically sent back to referring NICUs with management plan.

Results: In 6 years, a total of 6,238 premature infants were screened. ROP was found in 1,683 infants (27%). Stage 3 was seen in 477 infants (28%). Among the participants, 407 infants (24%) received treatment; the majority received anti-vascular endothelial growth factor (VEGF) intravitreal injections, while a few received laser ablative treatment. 26 infants received retreatment. No infants developed advanced ROP.

Conclusions: SAROP is a large ROP telemedicine program. The prevalence of ROP in KSA is 27% in infants of 1500 g or less BW. Treatment was needed in 24% of infants with ROP. No cases of ROP blindness were seen in NICUs participating in SAROP over 6 years.

Abstract No.: 206309

Selective Micropulse Individual Retinal Therapy for the Treatment of Central Serous Chorioretinopathy Based on the Navigation Technology

First Author: Pavel **VOLODIN**

Co-Author(s): Elena **IVANOVA**

Purpose: To evaluate the results of selective micropulse individual retinal therapy (SMIRT) for the treatment of central serous chorioretinopathy (CSCR) based on the navigation technology and with the selection of parameters by autofluorescence testing.

Methods: This study has been conducted on 61 patients (61 eyes) aged 36 to 58 years with acute CSCR and transparent optical media. The patients were divided into 2 groups. In group 1 (31 eyes), CSCR was treated using the SMIRT technology on a Navilas 577s laser system. Micropulse mode (50-100 μ s, 2.4-4.7%, 10 ms, 100 μ m, 0.4-1.9 W) was used for treatment, in which, according to computer modelling, selective destruction of the retinal pigment epithelium occurs with minimal damage to the chorioretinal complex. The parameters were selected for each patient by preliminary testing and evaluation of the results according to shortwave autofluorescence data (488 nm). Laser applications were applied close to each other, completely covering the points of leakage according to fluorescence angiography. Group 2 (30 eyes) was a control group; laser treatment was not performed. Follow-up observations were performed at 1, 3, 6, 12, and 24 months.

Results: Complete resorption of subretinal fluid was determined in all cases in group 1 and in 10 eyes (33.3%) in the control group in 1 1-year follow-up. In group 1, best-corrected visual acuity (BCVA) increased from 0.85 ± 0.02 to 0.98 ± 0.02 ($P < 10^{-8}$), and retinal sensitivity increased from 24.34 ± 0.33 dB to 29.15 ± 0.17

dB ($P < 6 \cdot 10^{-6}$) in 1 year. In group 2 (control) BCVA decreased from 0.84 ± 0.02 to 0.77 ± 0.03 and retinal sensitivity increased insignificantly from 25.09 ± 0.32 dB to 25.32 ± 0.72 dB in 1 year.

Conclusions: The navigation treatment of CSCR using the SMIRT technology with the selection of parameters by AF testing can be used for points of leakage in the fovea.

Abstract No.: 202573

Subretinal Injection of RRG001, an AAV8-Based Anti-VEGF Gene Therapy at the End of Vitrectomy for Unstable Proliferative Diabetic Retinopathy: An IIT Trial

First Author: Xiaorong **LI**

Purpose: This study evaluates RRG001, a novel AAV8-based gene therapy engineered for sustained intraocular anti-VEGF expression with a single subretinal injection, administered adjunctively during vitrectomy in PDR patients requiring further anti-VEGF therapy

Methods: In this single-center, open-label trial (NCT06412224), six patients with PDR were recruited to receive a single subretinal injection of RRG001 in one eye (study eye) at one of two dose levels immediately following standard PPV. Of the six participants, one was vitrectomy-naïve and characterized by extensive neovascularization in the retina and optic disc, along with the presence of an epiretinal membrane; two had persistent macular edema after prior vitrectomy; and three had recurrent PVH. Participants were followed for 24 weeks to assess preliminary safety and tolerability. Key efficacy endpoints included visual acuity, disease progression, and the need for rescue therapy

Results: RRG001 was well tolerated. No treatment-related serious adverse events (SAEs), deaths, or clinically significant intraocular inflammation occurred. All patients showed improved visual acuity postoperatively, which was sustained through Week 24. The three patients with baseline «hand motion» vision achieved gains of ≥ 52 ETDRS letters. No disease progression was detected, and no rescue therapy was required in any patient during the study. Central retinal thickness (CRT) in eyes with baseline macular edema markedly decreased and remained stable following PPV and RRG001 injection.

Conclusions: The combination of PPV and a single subretinal injection of RRG001 exhibited a favorable safety profile and promising preliminary efficacy, supporting further investigation in larger, controlled trials.

Abstract No.: 200499**The 1-Step vs. 2-Step Subretinal Injection Trial (1,2-SIT): A RCT Comparing Drug Reflux Following Subretinal Injection***First Author: Matthew **SIMUNOVIC****Co-Author(s): Rhuen **CHOW**, Zeid **MADANAT**, Khin Thida **OO**, Perach **OSAADON**, Zak **PRIME**, Emily **SHAO**, Lay Khoon **TOO**, Tun **YEO*****Purpose:** To compare sub-retinal drug retention following 1- or 2-step sub-retinal injection (SRI).**Methods:** Patients with sub-macular hemorrhage from age-related macular degeneration were randomised to undergo SRI of tissue plasminogen activator (50µg/0.1mL) with sodium fluorescein (NaFl, 10µg/0.1mL) as an optical label either as a 1-step (n=6) procedure, in which the drug defines the sub-retinal space, or as a 2-step (n=6) procedure, in which balanced salt solution first defines the sub-retinal space, following vitrectomy. Patients underwent 20% sulfurhexafluoride and bevacizumab injection at the end of surgery. Fluorophotometry on the intraocular fluid was used to estimate drug reflux. Patients received monthly anti-VEGF treatment; the final follow-up was at 12 weeks. The primary outcome was drug reflux. Secondary outcomes included surgery duration, change in VA, final VA, final foveal thickness, and change in foveal thickness. This approach's applicability to gene- and cell therapy was assessed by quantitative PCR to determine AAV yields, and its effects on retinal progenitor cells (RPCs) were evaluated using a viability assay.**Results:** Reflux was 4.8±3.1% (mean±SEM) for 1-step SRI and 3.9±0.9% for 2-step SRI (no significant difference in means; P=0.0155 for difference in variance). There was no significant difference in any of the secondary outcomes. NaFl did not affect AAV titers or RPC viability.**Conclusions:** NaFl can track subretinal therapeutics quantitatively, and 2-step SRI is preferable to 1-step SRI to ensure consistency in drug delivery.**Abstract No.: 204109****The Administration of T-PA via the Central Retinal Artery Using a 48G Needle With Acupuncture Therapy for CRAO***First Author: Xiang **MA****Co-Author(s): Cong **MA**, Naiwen **ZHANG*****Purpose:** To evaluate the safety and efficacy of intra-arterial tissue plasminogen activator (t-PA) delivered via a 48G microneedle, combined with standardized acupuncture, in treating acute central retinal artery occlusion (CRAO).**Methods:** Forty-one patients (41 eyes) were prospectively assigned to t-PA alone (n=5), acupuncture alone (n=27), or combined therapy (n=9). Acupuncture

targeted 15 peri-ocular and distal points daily for 4 weeks (extendable to 3 months). Outcomes included best-corrected visual acuity (BCVA, logMAR), visual evoked potential (VEP) P100 latency/amplitude, and central retinal artery peak systolic (PSV) and end-diastolic velocities (EDV) at baseline, 1 month, and 6 months.

Results: Baseline BCVA was hand-motion or worse across groups. At 6 months, combined therapy achieved a mean BCVA of 0.40 ± 0.08, significantly surpassing t-PA (0.25 ± 0.07) and acupuncture (0.18 ± 0.05) alone (P < 0.001). P100 latency improved from 152 ± 18 ms to 113 ± 12 ms with amplitude rising to 7.8 ± 1.6 µV, exceeding single-therapy gains (P < 0.05). Combined therapy also yielded marked hemodynamic improvements: PSV increased from 5.6 ± 1.4 to 12.3 ± 2.5 cm/s and EDV from 1.8 ± 0.6 to 4.5 ± 1.1 cm/s (P < 0.001). Safety outcomes were favorable, with no severe complications; transient ocular hypertension (<5%) resolved with topical treatment.**Conclusions:** Microneedle-guided intra-arterial t-PA with acupuncture accelerates reperfusion, enhances visual and electrophysiological recovery, and maintains excellent safety. This integrative approach may represent a promising therapeutic option for CRAO.**Abstract No.: 204729****The Concept of Temporary Myopic Traction Maculopathy Resolution: A Case Series and Long-Term Follow-Up of 12 Patients***First Author: Ka Hin Gabriel **LI****Co-Author(s): Veronika **MATELLO**, Barbara **PAROLINI**, Tommaso **PELLEGRINO*****Purpose:** To describe the long-term natural progression of 12 highly myopic eyes with myopic traction maculopathy (MTM) that initially demonstrated apparent improvement, followed by recurrence.**Methods:** A series of 400 eyes were referred for macular buckle treatment to our centre from January 2008 to June 2025. Long-term data were available for 286. Among them, 12 patients who had optical coherence tomography (OCT) proof of prior spontaneous or post-vitrectomy improvement of MTM were retrospectively reviewed. OCT findings and visual outcomes were retrieved and analysed.**Results:** All 12 eyes of 12 patients showed proof of MTM recurrence after spontaneous (9 eyes) or post-vitrectomy (3 eyes) improvement. The mean best-corrected visual acuity (BCVA) at MTM improvement and recurrence were 0.346 ± 0.36 logMAR and 0.855 ± 0.34 logMAR, respectively. The average time interval from MTM improvement to recurrence was 27.44 ± 37.5 months for the treatment-naïve group and 84 ± 25.92 months for the vitrectomy group.**Conclusions:** Spontaneous or post-vitrectomy improvement of MTM only represents a temporary

relieve. Recurrence can be observed in the long-term and is likely driven by the progressive nature of posterior staphyloma with persistent perpendicular traction. This highlights the importance of long-term OCT monitoring for patients with MTM, more specifically at least 2 years to judge the effect of spontaneous modification of the vitreoretinal interface or at least 7 years to judge the efficacy of any treatment. Vitrectomy only temporarily relieves the perpendicular traction exerted by the vitreous whereas treating the staphyloma can permanently halt the progression of MTM.

Abstract No.: 203176

The Effect of Vitreous Surgery for Familial Exudative Vitreoretinopathy

First Author: Zhao XIQUAN

Purpose: To retrospectively analyze the clinical effect of vitreous surgery for the treatment of stage IV familial exudative vitreoretinopathy.

Methods: Retrospective analysis of 27 cases (32 eyes) of clinical diagnosis of stage IV FEVR undergoing vitreous surgery. A total of 17 eyes were found to have retinal tears and iatrogenic tears, and 5 eyes had elevated retinal protrusions that required external scleral drainage of subretinal fluid. Patients with retinal holes should undergo drainage of subretinal fluid from the retinal hole, reattachment of the retina, and laser photocoagulation to seal the hole and non-vascular areas of the retina. 13 eyes were filled with gas, and 19 eyes were filled with silicone oil. All patients were observed for more than 6 months after surgery.

Results: In 17 eyes with stage IV disease without retinal tears or iatrogenic tears, the retina was well reattached after surgery. Of the 15 eyes with retinal tears (including iatrogenic), 9 had good retinal reattachment, and 6 were silicone oil-dependent.

Conclusions: The prognosis of vitreous surgery for patients with FEVR stage IV without retinal breaks is good, while the prognosis for patients with retinal breaks and iatrogenic retinal breaks during surgery is poor. During FEVR vitrectomy, it is essential to minimize the occurrence of iatrogenic holes.

Abstract No.: 201518

The GLOW Study: Real-World Use of the "Glowport"—Illuminated Vitrectomy Cannulas

First Author: Shishir VERGHESE

Co-Author(s): Prithvi CHANDRAKANTH

Purpose: To evaluate the real-world clinical impact and surgical utility of the Glowport, an illuminated vitrectomy trocar cannula, by assessing procedural efficiency, surgeon experience, and device performance through a comprehensive scoring system during routine vitreoretinal surgeries.

Methods: This multicenter, retrospective study included 508 eyes undergoing three-port pars plana vitrectomy (PPV) performed by seven vitreoretinal surgeons over a one-year period. The Glowport—a novel, 3D-printed phosphorescent ring fitted onto standard vitrectomy cannulas—was used selectively to enhance trocar visibility during instrument exchanges under mesopic (low-light) conditions. Objective efficiency was measured as time to task completion, with comparisons made between cases performed with and without the Glowport. Subjective surgeon feedback on visualization, ergonomics, and workflow integration was collected via standardized questionnaires. Safety outcomes and adverse events were closely monitored. The device's performance was further assessed using the Retina Surgery Adapted Quality Score (AQS), a weighted scoring system based on visualization, safety, ergonomics, durability, and cost-benefit considerations.

Results: Glowport-assisted surgeries showed a significant reduction in instrument exchange time (mean 4.2 vs. 11.4 seconds, $P < 0.05$), greatly improving procedural efficiency. Surgeons unanimously reported superior visibility, increased confidence, and reduced intraoperative challenges, with no device-related complications. The AQS scores confirmed outstanding visualization, safety, and cost-effectiveness, as well as reliable glow retention and sterilization durability.

Conclusions: Glowport's innovative, cost-effective design transforms vitrectomy workflow under low-light conditions and earned strong surgeon endorsement. Its exceptional safety, performance, and high AQS scores position Glowport as a significant advance for retinal surgery.

Abstract No.: 205556

The Impact of Preoperative Choroidal Detachment on Short-Term Surgical Outcomes in Highly Myopic Macular Hole Retinal Detachment

First Author: Yi CAI

Co-Author(s): Enzhong JIN, Heng MIAO, Xuan SHI

Purpose: To evaluate the impact of choroidal detachment on short-term surgical outcomes in highly myopic macular hole retinal detachment (MHRD) and to discern the risk factors associated with macular hole (MH) closure.

Methods: A retrospective analysis was carried out on 104 highly myopic MHRD eyes that underwent vitrectomy and intraocular tamponade. Patients were stratified according to the presence or absence of preoperative choroidal detachment. Demographic data, preoperative ocular parameters, and postoperative outcomes were compared. Logistic regression analysis was employed to identify risk factors for MH closure.

Results: No significant differences were observed in age or disease duration between groups. Preoperative

visual acuity was inferior in the choroidal detachment group (2.19 ± 0.70 LogMAR vs. 1.78 ± 0.60 LogMAR, $P = 0.013$), and preoperative intraocular pressure (IOP) was significantly lower (9.05 ± 3.73 mmHg vs. 13.18 ± 4.15 mmHg, $P < 0.001$). Postoperatively, the choroidal detachment group demonstrated worse vision outcome (1.52 ± 0.49 LogMAR vs. 1.22 ± 0.38 LogMAR, $P = 0.004$) and a substantially higher rate of rescue therapy (28.6% vs. 3.6%, $P = 0.002$). The rate of MH closure was comparable between groups (41.0% vs. 42.9%, $P = 1.000$). Logistic regression identified advanced age ($\beta = 0.099$, $P = 0.001$) and lower preoperative IOP ($\beta = -0.132$, $P = 0.031$) as favorable factors for MH closure.

Conclusions: Choroidal detachment exerts an adverse impact on postoperative visual acuity and is associated with a significantly higher rate of rescue surgical intervention. Younger age and higher preoperative intraocular pressure (IOP) may impede MH closure.

Abstract No.: 201172

The Natural History of Symptomatic Epiretinal Membranes

First Author: Tsun Tat Victor **CHAN**

Co-Author(s): Mary **HO**, Andrew Chun-yue **MAK**, Alvin **YOUNG**

Purpose: Idiopathic epiretinal membrane (ERM) has a low progression rate in subjects with good visual acuity (VA). However, the natural history of symptomatic ERM (e.g. significant metamorphopsia or reduced vision) remains unclear. This study aims to evaluate the natural history of symptomatic ERM and identify predictors of visual decline.

Methods: We identified consecutive subjects with symptomatic ERM awaiting surgery. Only one eye from each subject was included. Visual decline was defined as a decrease in VA of ≥ 0.3 LogMAR units from the baseline. Optical coherence tomography (OCT) scans were evaluated for central macular thickness, Govetto's ERM staging, and qualitative characteristics. Independent t-tests were used to compare continuous variables. The associations between OCT features and visual decline were assessed using logistic regression.

Results: After excluding 79 patients, 309 eyes with symptomatic ERM were evaluated, including 62 eyes in stage 1, 99 eyes in stage 2, 103 eyes in stage 3 and 45 eyes in stage 4. At presentation, mean VA was 0.41 ± 0.24 for stage 1, 0.42 ± 0.26 for stage 2, 0.49 ± 0.28 for stage 3, and 0.72 ± 0.33 for stage 4. The VA showed no significant difference from ERM stage 1 to stage 3, until the development of DRIL. After a mean follow-up of 43.4 months, 104 eyes (33.7%) experienced visual decline, at a mean rate of 0.16 ± 0.15 LogMAR per year. Among 189 eyes with follow-up OCT scans, ERM staging progressed in 31 eyes. We did not identify any OCT features predictive of visual decline.

Conclusions: There was a significant rate of progression in symptomatic ERM, which might require closer monitoring or earlier intervention.

Abstract No.: 205031

The Significance of Baseline Foveal Ectopia in Primary Idiopathic Epiretinal Membrane

First Author: Stephanie **WU**

Co-Author(s): Paul **BASSETT**, Christopher **GO**, Cherlin **LEE**, Teresa **SANDINHA**, David **STEEL**, Yalin **ZHENG**

Purpose: To investigate the extent, direction, association and prognostic value of foveal ectopia in patients with unilateral idiopathic epiretinal membranes (iERMs), as assessed relative to the fellow unaffected eye.

Methods: Two-centre retrospective, consecutive case series of unilateral ERMs who underwent standardised vitrectomy and membrane peel. Foveal location in the operative eye was assessed with respect to the fellow normal eye pre- and post-operatively using optical coherence tomography and scanning laser ophthalmoscope images. The extent of macular pucker was graded using the Govetto grading scheme. Multivariate linear regression was used to analyse variables associated with baseline and postoperative visual acuity (VA).

Results: 167 eyes of 167 patients were included. The mean age was 68.3 years. The mean pre-operative VA was 0.51 logMAR and the mean central macula thickness (CMT) was 465.5 μ m. 41% were male, and 72% were phakic at baseline. Pre-operatively, the fovea was displaced more temporally (122.64 μ m) and inferiorly (8.70 μ m) compared to the fellow eye. Pre-op foveal position and CMT were significantly correlated with pre-op VA, whilst pre-operative VA, pre-op foveal position, iERM stage, and CMT were all significantly associated with post-operative VA. A 100 μ m increase in CMT was also significantly associated with a 12% increase in post-foveal displacement.

Conclusions: Baseline foveal ectopia was associated with both baseline and postoperative visual acuity independent of other measures. Further investigation of its utility as a novel biomarker of surgical outcome should be considered.

Abstract No.: 204883

The Silent Shift: Macular Thickness Alterations After Uncomplicated Phacoemulsification — Insights From a Prospective Cohort Study

First Author: Divya GOYAL

Co-Author(s): Nitika BERI, Pramod SAHU, Ankur SINGH, Tavishi SINGHAL, G.k. DAS

Purpose: To study changes in macular thickness after uncomplicated phacoemulsification surgery using optical coherence tomography.

Methods: A total of 120 patients aged 50–70 years without pre-existing systemic or ocular disease, following complete ophthalmological examination, were included in the study. OCT measured preoperative macular thickness in patients undergoing uneventful phacoemulsification with posterior chamber IOL implantation. Operative time (OT), effective phacoemulsification time (EPT), and phacoemulsification energy (PE) were recorded. Post-surgery macular thickness & postoperative BCVA were recorded on the 1st postoperative day, 1st month, 3rd month, and 6th month.

Results: In this study of 120 patients, mean age was 60.77 ± 6.88 years; central macular thickness increased from $241.43 \pm 19.87 \mu\text{m}$ preoperatively to $258.55 \pm 15.95 \mu\text{m}$ on POD1, $257.02 \pm 19.70 \mu\text{m}$ at 1 month, $257.60 \pm 14.95 \mu\text{m}$ at 3 months, and $255.03 \pm 19.21 \mu\text{m}$ at 6 months (all $p < 0.001$). Significant increases were also observed in the superior quadrant at 1 month ($p=0.03$), nasal quadrant at 1 month ($p=0.03$), and temporal quadrant at 3 months ($p=0.03$). Central macular thickening at 6 months was positively correlated with operative time ($r = 0.263$, $p = 0.004$), phaco time ($r = 0.290$, $p = 0.001$) & phaco energy ($r = 0.336$, $p < 0.001$).

Conclusions: Shortened surgical time, reduced ultrasound energy, and the use of femtosecond laser-assisted cataract surgery, which requires minimal ultrasound energy, are key strategies to lower the risk of pseudophakic cystoid macular edema following uncomplicated phacoemulsification.

Abstract No.: 203454

Visual and Structural Changes Following Subtenon Stem Cell Therapy in a Patient With Dry Age-Related Macular Degeneration: A Case Report

First Author: Shahzoda JURAKHONOVA

Purpose: Dry age-related macular degeneration (AMD) remains a major cause of irreversible vision loss, with no approved therapies capable of restoring photoreceptor function. Regenerative treatments, such as stem cell therapy, are under investigation for their potential to slow progression and support

retinal recovery. This case highlights partial visual and anatomical improvement following sub-Tenon stem cell therapy in a patient with intermediate-stage dry AMD.

Methods: A 51-year-old woman with Charcot-Marie-Tooth disease and amblyopia presented with progressive visual decline over two years. Optical coherence tomography (OCT) of the left eye revealed multiple drusen, perifoveolar thinning, and disruption of the ellipsoid zone and retinal pigment epithelium, consistent with intermediate-stage dry AMD. Best-corrected visual acuity (BCVA) was 0.4 (OS) and 0.3 (OD). In July 2024, she underwent pyramidal Alloplant therapy (subcutaneous implantation of allogenic biomaterial) at an external center. Four months later, in November 2024, she received a sub-Tenon injection of placenta-derived mesenchymal stem cells (2.5 mL) in the left eye. Daily supplementation with OcuVit Forte and omega-3 was prescribed post-treatment.

Results: At 7-month follow-up, BCVA improved to 0.7 (OS). OCT showed localized thickening in perifoveolar areas and a stable foveal structure. Visual field testing demonstrated increased sensitivity in the left eye. No complications were observed. The right eye remained anatomically stable but functionally limited due to amblyopia and early lenticular changes.

Conclusions: This case suggests that sub-Tenon stem cell therapy may contribute to localized visual and structural improvement in intermediate-stage dry AMD. Controlled studies are needed to evaluate its long-term safety and therapeutic potential.

Abstract No.: 205596

Vitrectomy Combined With Dexamethasone Sustained-Release Implant Injection for Residual Macular Edema Following Surgery for Macular Epiretinal Membrane

First Author: Bo QIN

Co-Author(s): Yijie LU

Purpose: To investigate the efficacy and safety of using a sustained-release dexamethasone implant during surgery, combined with 25G vitrectomy and pre-retinal membrane peeling, in patients with idiopathic macular epiretinal membrane.

Methods: A retrospective analysis was conducted on patients with idiopathic macular pucker. Some patients underwent 25G-puncture vitrectomy and internal limiting membrane peeling (the “control group”), while the remaining patients received 25G-puncture vitrectomy and internal limiting membrane peeling combined with dexamethasone implant (the “DEX group”). Best-corrected visual acuity was assessed using Snellen visual acuity ratios. Anatomical outcomes (macular center thickness and total macular volume) were analyzed via spectral-domain optical coherence tomography.

Results: (1) Macular epiretinal membrane: Preoperative OCT and multifocal ERG can predict prognostic markers for macular epiretinal membrane surgery. (2) After 6 months of follow-up, best-corrected visual acuity significantly improved in both groups, and macular thickness significantly decreased in both groups. Finally, at the last follow-up, total macular volume significantly decreased in both groups, showing similar trends.

Conclusions: The long-acting dexamethasone sustained-release implant used during macular epiretinal membrane surgery is a potent anti-inflammatory agent demonstrating significant efficacy in the eyes of patients following vitrectomy.

Translational Research in Ophthalmology

A Mosquito Proboscis-Inspired Cambered Microneedle Patch for Ophthalmic Regional Anaesthesia

First Author: Sun XUEQUAN

Purpose: Considering the certain limitations (e.g., pain, the requirement of skilled professionals, or slow passive diffusion) of conventional delivery methods of local anesthetics, developing alternative strategies that offer minimally invasive yet therapeutically effective delivery systems is of great concern for ophthalmic regional anesthesia.

Methods: In this study, a rapidly dissolving cambered microneedle (MNs) patch, composed of poly(vinylpyrrolidone) (PVP) and hyaluronic acid (HA) and served as a delivery system for lidocaine(Lido) in local anesthesia, was developed taking inspiration from the mosquito proboscis's ability to extract blood unnoticed. The lidocaine-containing MNs patch (MNs@Lido) consisted of 25 microneedles with a four-pronged cone structure (height: 500 μ m, base width: 275 μ m), arranged in a concentric circle pattern on the patch, and displays excellent dissolubility for effective drug delivery of Lido.

Results: After confirming good cytocompatibility, MNs@Lido was found to possess adequate rigidity to penetrate the cornea without causing any subsequent injury, and the created corneal pinhole channels completely self-healed within 24 h. Interestingly, MNs@Lido exhibited effective analgesic effects for local anesthesia on both heel skin and eyeball, with the sustained anesthetic effect lasting for at least 30 min.

Conclusions: These findings indicate that the mosquito proboscis-inspired cambered MNs patch provides rapid and painless local anesthesia, overcoming the limitations of conventional delivery methods of local

anesthetics, thus opening up new possibilities in the treatment of ophthalmic diseases.

Abstract No.: 205124

A Novel Fixation Ring Integrated Suprachoroidal Space Micro-Shunt Implantation System for Glaucoma

First Author: Chan ZHAO

Purpose: To develop a novel ab externo suprachoroidal space (SCS) micro-shunt implantation system for glaucoma.

Methods: We engineered an ab externo SCS micro-shunt implantation system following viscoelastic expansion of the SCS with our novel resistance-sensing injector. Two delivery paradigms with 4 different micro-shunt designs were incrementally developed and tested in a steroid-induced ocular hypertension rabbit model: (i) wire-guided insertion of polyethersulfone (PES) tubes (smooth and retention-ring variants) and (ii) in-situ release of nickel–titanium (NiTi) micro-shunts (helical tube design and straight tube with integrated fixation ring design).

Results: In rabbits, wire-guided smooth PES tubes showed satisfactory IOP reduction but a 28% dislocation rate. The wire-guided retention-ring PES variant reduced dislocation to 16.7%, but it led to increased malposition. The in-situ release approach using the helical NiTi prototype disappointingly showed low implantation success (20%). Encouragingly, the straight NiTi tube with an integrated fixation ring demonstrated stable placement, accurate positioning, and effective IOP control. Version 2 (outer diameter 0.2 mm; distal segment 0.5/1.0/2.0/2.5 mm) achieved 100% implantation success with 0% dislocation and no corneal touch or hypotony during 4-week follow-up; the 1.0-mm and 2.5-mm distal segments variants provided the most consistent efficacy, with 83.3% (15/18) achieving $\geq 20\%$ IOP reduction. Finite-element and benchtop tests demonstrated more efficient outflow compared to straight tube without fixation ring.

Conclusions: Our novel fixation ring integrated NiTi micro-shunt implantation system enables safe, rapid, sutureless, and multi-mechanistic IOP control and suggests potential for durable outcomes.

Abstract No.: 206092

Anti-Adhesive Tough Silk/Hydrogel Composites for Symblepharon Treatment

First Author: Renjian HU

Co-Author(s): Xiuming JIN

Purpose: In this work, we developed a novel anti-adhesion composite from fabric-reinforced double network hydrogels for the treatment of symblepharon after alkali burn, which realized the combination

of stable mechanical strength and good tissue anti-adhesive ability.

Methods: In this study, based on the radical polymerization of double network hydrogel and strong interaction with enhanced silk fiber, we present here a specific composite for the treatment of symblepharon. Tensile tests were performed to verify its mechanical properties. Owing to the enhancement of the silk fiber, the composite is tough enough to sustain the surgery process. Cell adhesive and toxicity tests showed that the composite with a super-hydrophilic surface endowed it with reliable cell isolation towards target sites and great biocompatibility. Besides, the conjunctival alkali burn model of rabbits was employed to evaluate the anti-adhesion efficacy of the composite. The composite graft showed good anti-tissue adhesion properties.

Results: In summary, we developed a novel anti-adhesion composite from fabric-reinforced double network hydrogels for the treatment of symblepharon after alkali burn, which realized the combination of stable mechanical strength and good tissue anti-adhesive ability. Our composites could effectively prevent the formation of symblepharon, which shows a great potential for wider clinical treatments of relieving tissue adhesion.

Conclusions: The composite is easily handled, biocompatible, conducive to mass production, and most importantly, tissue anti-adhesion to satisfy the clinical requirements for anti-adhesion graft materials. Therefore, our composite material exhibits great potential to be used as an anti-adhesion material not only in ocular surface disease but also in more extensive tissues.

Abstract No.: 208277

Associations of Polymorphisms in FCGR2B, FRMD4B and VPS13B With Immunoglobulin G4- Related Ophthalmic Disease: A Territory-Wide Cross-Sectional Study

First Author: Kenneth Ka Hei LAI

Co-Author(s): Guy Lj CHEN, Kelvin CHONG, Pancy Os TAM, Clement THAM, Yuyao WANG, Alvin L YOUNG

Purpose: The aim is to study the genetic susceptibility of immunoglobulin G4-related ophthalmic disease (IgG4-ROD) by evaluating associations between IgG4-ROD and selected single-nucleotide polymorphisms (SNPs) previously reported in IgG4-related disease (IgG4-RD).

Methods: Cross-sectional, case-control genetic association study. Ninety-four biopsy-proven IgG4-ROD patients and 529 age-, sex-, and ethnically matched healthy controls were recruited from the Hong Kong IgG4-ROD territory-wide cohort. Eighteen candidate SNPs across 14 genes previously associated with IgG4-

RD were selected from the literature and genotyped in all participants using TaqMan assays.

Results: Three SNPs demonstrated associations with IgG4-ROD. The strongest association was observed for rs1340976 in FCGR2B, which conferred a protective effect (OR = 0.40; 95% CI = 0.28–0.57; $P = 5.30 \times 10^{-7}$) and remained significant in both males and females after multiple testing correction. In contrast, rs9831516 in FRMD4B (OR = 0.69; 95% CI = 0.49–0.96; $P = 0.0302$) and rs10955197 in VPS13B (OR = 1.34; 95% CI = 1.025–1.77; $P = 0.0325$) showed nominal significance and were limited to males.

Conclusions: This study identifies FCGR2B as a genetic locus associated with susceptibility to IgG4-ROD, supporting a role for B cell regulation in pathogenesis. While FRMD4B and VPS13B showed nominal associations. The absence of associations with other IgG4-RD loci highlights potential genetic heterogeneity between organ-specific manifestations.

Abstract No.: 204893

Augmented Reality-Based Pathway-Specific Dichoptic Therapy Compared With Conventional Occlusion in Adult Amblyopia

First Author: Yulian ZHOU

Co-Author(s): Xinyan DUAN, Yige GAO, Shuyang GUO, Yazhu QIAN, Wen WEN, Peng ZHANG, Chen ZHAO

Purpose: Dichoptic training has shown promising performance in restoring visual function in amblyopes beyond the critical period in the laboratory. However, the treatment outcome is variable and indeterminate in actual clinical and neuroscientific practice. In this study, we introduced a novel dichoptic therapy for adult amblyopia that leverages an augmented-reality (AR) technique to selectively enhance parvocellular pathway function, based on neural deficits of amblyopia in monocular processing and binocular interactions revealed in our previous work.

Methods: This single-center prospective nonrandomized study enrolled adults with unilateral amblyopia assigned to two parallel groups, who received home-based treatment (patching or AR-based dichoptic training) for 2 hours per day over a 24-week period. Visual functions were assessed at baseline and week 1/4/12/24 after treatment, including best-corrected visual acuity at distance and near, uncrowded/crowded VA with single tumbling E target, contrast sensitivity, binocular rivalry, and phase combination, using visual psychophysical methods.

Results: We enrolled 27 patients in the training group and 21 patients in the patching group in this study. During 24 weeks of home-based dichoptic training with wearable AR glasses, participants demonstrated high at-home treatment adherence (78.7%±22.3% cumulative time of prescribed totals), with marked improvements in monocular visual functions of

the amblyopic eye, binocular functions, and neural activities biased to the parvocellular pathway. Compared to conventional occlusion therapy, this pathway-specific, AR-based dichoptic therapy generally enables more rapid and pronounced functional gains.

Conclusions: AR-based pathway-specific dichoptic therapy targeting the selective deficits in the parvocellular pathway represents a promising therapeutic strategy for improving visual outcomes in adults with amblyopia.

Abstract No.: 202669

Bacterial-Synthetic Biomimetic Cornea for Scarless Regeneration of Large-Scale Corneal Defects

First Author: Liyin **WANG**

Co-Author(s): Jing **ZHAO**, Xingtao **ZHOU**

Purpose: Corneal transplantation faces challenges such as donor shortage and the difficulty in matching the physicochemical and biocompatible properties of artificial corneal materials with those of the human cornea. This study aimed to develop a novel bioengineered cornea using bacterial nanocellulose (BC) to address these limitations.

Methods: Dialdehyde bacterial nanocellulose (DBC) was synthesized using a bacterial synthesis system combined with aldehyde modification. Surface modification with human lenticule microparticles (L) and Celastrol (Cel) yielded a custom-sized bacterial-engineered bio-cornea (DBC@L-Cel). The transmittance and mechanical properties were assessed subsequently. In vitro, the effects of DBC@L-Cel on the major cellular components of the cornea were investigated through immunofluorescence, flow cytometry, and transcriptome sequencing of corneal epithelial cells and stromal cells. In vivo, a rabbit model with a large-diameter corneal defect was treated with DBC@L-Cel to evaluate its efficacy in promoting corneal regeneration.

Results: DBC@L-Cel exhibited a high light transmittance of 91.91% and mechanical properties comparable to those of the human cornea. In vitro, modification with L and sustained release of Cel reduced stromal fibrosis by inhibiting the AGE/RAGE pathway and promoted epithelial proliferation and adhesion by upregulating the Wnt/ β -catenin pathway. In a rabbit model of large-area corneal defect, transplantation of DBC@L-Cel significantly enhanced the repair and regeneration of both the corneal stroma and epithelium, enabling rapid and scarless reconstruction of damaged corneal tissue.

Conclusions: These findings show that DBC@L-Cel is a potential alternative material for corneal transplantation to achieve rapid scar-free corneal regeneration.

Abstract No.: 200310

Bioengineered Intravitreal Stem Cell Factor Enables Long-Lasting Neurovascular Repair in Chronic Retinal Ischemia

First Author: Xi **CHEN**

Purpose: Retinal ischemia underlies vision loss in diseases such as ocular ischemic syndrome, diabetic retinopathy, glaucoma, and vascular occlusions. Effective neurovascular-targeted therapies remain lacking. We investigated a bioengineered intravitreal formulation of stem cell factor (SCF) to protect retinal structure and function in a chronic ischemia model by modulating the neurovascular unit (NVU).

Methods: Recombinant SCF was incorporated into a thermosensitive hydrogel (SCF-HG), forming a sustained-release depot after intravitreal injection. SCF-HG retained >90% bioactivity over four weeks in vitreous-mimetic conditions. Brown Norway rats underwent bilateral common carotid artery occlusion, followed by a single intravitreal injection of SCF-HG (200 ng SCF) or hydrogel control. Retinal function (ERG, light/dark box, optokinetic tracking), structure (ONL thickness, Brn3a⁺ RGCs, synaptic markers), and NVU integrity (CD31 angiography, GFAP/Iba1 staining) were evaluated over 28 days. Bulk RNA-seq and qRT-PCR analyzed Wnt pathway activation.

Results: SCF-HG sustained therapeutic SCF levels in vivo. Treated eyes preserved ONL thickness (+35%, $p < 0.001$) and Brn3a⁺ RGCs (+60%, $p < 0.001$), enhanced synaptic density (+45%, $p < 0.01$), and maintained interneuron populations. Functional improvements included 2.3-fold higher ERG amplitudes, 50% reduction in light avoidance, and 32% gain in spatial acuity. NVU integrity improved with 42% vascular recovery and 52% reduction in glial activation. Transcriptomics revealed activation of the Wnt7a/b-Lrp5-Lgr5 axis.

Conclusions: The SCF-HG platform enables sustained intravitreal delivery and restores neurovascular function in chronic retinal ischemia. This bioengineered therapeutic holds translational potential for ischemic retinal disease treatment.

Abstract No.: 202394

Cis- and Trans-Regulatory Factors Independently Shape Phenotypic Heterogeneity of Retinitis Pigmentosa

First Author: Cong **CUI**

Co-Author(s): Ayaka **DAN**, Dexin **MENG**, Shigeru **SATO**, Takumi **TATENO**, Motokazu **TSUJIKAWA**

Purpose: Retinitis pigmentosa (RP) shows striking clinical heterogeneity even among patients carrying identical pathogenic mutations, but the genetic basis of this variability remains poorly defined. Although modifier effects have long been hypothesized, direct in vivo validation has been lacking. Using a transgenic zebrafish model carrying the human rhodopsin S334X

mutation, we aimed to dissect cis- and trans-regulatory contributions to RP phenotypic variation and provide mechanistic insights into disease heterogeneity.

Methods: Rod photoreceptor survival was quantified in multiple generations of S334X transgenic zebrafish. Whole-genome sequencing, PCR genotyping, RT-qPCR, and luciferase assays were performed to characterize potential cis-regulatory variants. Segregation analysis and statistical modeling were applied to evaluate trans-acting modifiers.

Results: Two distinct mechanisms modulating RP severity were identified. A benign subline displayed markedly attenuated degeneration fully linked to the S334X allele. Targeted sequencing revealed a unique 3-bp insertion upstream of the transgene, acting as a cis-regulatory variant that significantly reduced rhodopsin expression, confirmed by RT-qPCR and luciferase assays. Unexpected segregation of severe-like phenotypes within this benign line followed a Mendelian 1:1 ratio, independent of the transgene, strongly suggesting a dominant trans-acting modifier. Both cis and trans effects were validated across generations, demonstrating stable inheritance and independent contributions.

Conclusions: This study provides the first in vivo evidence that cis- and trans-regulatory elements can independently and cooperatively shape RP phenotypes in a shared genetic background. These findings highlight the importance of genetic modifiers in clinical heterogeneity and suggest new avenues for personalized management of RP.

Abstract No.: 205826

Correlations of Th1, Th17, and Tfh Cells With Clinical Activity Scores of Thyroid Eye Disease and Euthyroid Graves' Ophthalmopathy Patients

First Author: Tsz Chun Jason **WONG**

Co-Author(s): Hemlata **BISNAUTHSING**, Kam Lung Kelvin **CHONG**, Wai Kit **CHU**

Purpose: Thyroid Eye Disease (TED) is an autoimmune orbital disease. Many immune cells, especially T cells, have been reported to be integral in TED pathogenesis. In this study, we investigated the relationship between various T cell populations and Clinical Activity Score (CAS) in Thyroid Eye Disease (TED) patients, alongside those with Euthyroid Graves' Ophthalmopathy (EGO).

Methods: T helper (Th) 1 cells, Th17 cells, and follicular helper T (Tfh) cells were measured in peripheral blood mononuclear cells (PBMC) of a Chinese cohort of TED and EGO patients. Cell abundance was measured using flow cytometry. CAS was evaluated based on the clinical activity of TED, based on the European Group of Graves Orbitopathy (EUGOGO) classification. Correlations between cell types and CAS were measured by Pearson and a paired t-test.

Results: Twenty patients were recruited in both TED (11, age=48.54±8.73 years) and EGO (9, age=45.22±13.93 years) groups. The abundance of Tfh cells (15.89±2.11%) was significantly higher ($p<0.01$) than Th1 and Th17 cells (6.4 ±0.67%; 1.4±0.25%) in TED. Similarly, Tfh cells (14.38±2.85%) were also significantly more abundant than Th1 and Th17 cells in EGO (6.52±0.76%; 1.66±0.27%). There was no significant correlation between various T cell populations and CAS in both TED (Th1: $r=0.22$, $p<0.74$, Th17: $r=-0.40$, $p<0.11$, Tfh: $r=-0.31$, $p<0.82$) and EGO (Th1: $r=-0.04$, $p<0.46$, Th17: 0.58, $p<0.93$, Tfh: $r=0.39$, $p<0.83$).

Conclusions: There is noticeable elevation of Tfh cells in both TED and EGO groups; however, there is no correlation between various T cell populations and CAS scores.

Abstract No.: 204204

Corvis ST-Derived Biomechanical Markers Predict Early Corneal Endothelial Abnormalities

First Author: Chengjie **FENG**

Co-Author(s): Miaomiao **CHI**, Shaofeng **GU**, Jing **HONG**

Purpose: Early detection and mechanism exploration of idiopathic endothelial compromise remains challenging, while corneal biomechanics offers a novel approach to identify high-risk eyes before irreversible decompensation occurs. This study aimed to investigate the association between corneal biomechanical parameters and endothelial status, identify potential biomechanical markers for early endothelial abnormalities, and explore the biomechanical manifestations of idiopathic endothelial impairment.

Methods: Corvis ST-derived biomechanical parameters and specular microscopy-based endothelial metrics: endothelial cell density (ECD), hexagonality (HEX), and coefficient of variation in cell size (CV) were assessed. Stratified correlation analysis across central corneal thickness (CCT) subgroups and least absolute shrinkage and selection operator (LASSO) logistic regression were applied to explore biomechanical-endothelial coupling and develop a predictive model.

Results: Stiffness parameter at first applanation (SSI), radius of curvature at highest concavity (HCR), length of flattened cornea at second applanation (A2L), time from start until first applanation (A1T), and corrected tomographic biomechanical index (ctBI) differed significantly between normal and abnormal endothelial groups. Stratified analysis revealed the strongest biomechanical-endothelial correlations in mid-range CCT (530–570 μm). A2L was identified as an independent protective factor for endothelium (OR: 0.202, 95%CI: 0.051–0.731, $p=0.018$). Both the biomechanically derived DASC (A2L, DA, SSI, and CCT) model (AUC: 0.711, 95%CI: 0.614–0.808) and the

cTBI score (AUC: 0.683, 95%CI: 0.565–0.800), which was initially developed for keratoconus screening, demonstrated significant discriminative capacity for detecting endothelial abnormalities.

Conclusions: Corneal biomechanics reflect early endothelial alterations. A2L, cTBI, and the DASC model may serve as potential tools for noninvasive risk stratification in elderly patients.

Abstract No.: 204307

Cytosolic Nuclear DNA Drives AMD Progression via 2'3'-cGAMP-Mediated STING Activation and Paracrine Senescence

First Author: Shuo **SUN**

Co-Author(s): Xiaorong **LI**, Haijiang **LIN**

Purpose: To investigate the role of cytosolic nuclear DNA (nDNA) in retinal pigment epithelium (RPE) cells in age-related macular degeneration (AMD), focusing on STING pathway activation and 2'3'-cGAMP-mediated paracrine senescence and inflammation.

Methods: Cytosolic nDNA accumulation was examined in macular RPE cells from AMD donors and controls. DNASE2A-deficient RPE cells were generated using CRISPR/Cas9 to model impaired DNA degradation. Senescence-associated β -galactosidase staining, cytokine assays, and transcriptomic profiling were used to assess cellular responses. STING knockdown determined its role in mediating the senescence-associated secretory phenotype (SASP). Extracellular and intracellular 2'3'-cGAMP levels were quantified, and its uptake via volume-regulated anion channels (VRACs) was tested. Conditioned medium from DNASE2A^{-/-} RPE cells was applied to ARPE-19 cells and macrophages to evaluate paracrine effects. In vivo, conditional Dnase2a^{-/-} mice and subretinal injection of 2'3'-cGAMP in C57BL/6 mice were used to assess retinal structure and function.

Results: AMD macular RPE cells showed increased cytosolic nDNA and elevated 2'3'-cGAMP. DNASE2A deficiency induced nDNA accumulation, RPE senescence, and SASP cytokine secretion, which were reversed by STING knockdown. Conditioned medium from DNASE2A^{-/-} cells promoted senescence and inflammation in RPE and macrophages via STING activation. Chronic exposure to 2'3'-cGAMP induced dose-dependent RPE senescence and SASP, attenuated by VRAC inhibition. In vivo, Dnase2a^{-/-} mice and 2'3'-cGAMP administration caused AMD-like retinal lesions, microglial activation, and complement deposition.

Conclusions: Cytosolic nDNA drives AMD pathogenesis through 2'3'-cGAMP-mediated STING activation, inducing senescence and inflammatory responses in RPE and immune cells. Modulating STING signaling or extracellular 2'3'-cGAMP uptake may offer novel therapeutic strategies.

Abstract No.: 201837

Engineer Circular ADAR-Recruiting RNA Base Editor as a Potential Treatment for Inherited Retinal Diseases

First Author: Liuhui **HUANG**

Co-Author(s): Satheesh **KUMAR**, Guei-sheung **LIU**

Purpose: Approximately 70% of inherited retinal disease (IRD) variants are point mutations that can cause vision loss. We aim to demonstrate precise correction of these variants using a circular guide RNA that recruits the ADAR enzymes.

Methods: A circular ADAR-recruiting RNA (cadRNA) with 200-nt complementary targeting sequences, flanked by autocatalytic ribozymes and containing a central A:C mismatch, was engineered to correct G>A variants. To enhance editing efficiency and enable single-AAV packaging, cadRNA was co-delivered with truncated ADAR1 and validated in HEK293 cells. On- and off-target editing events were quantified by deep sequencing and RNA-seq. Protein restoration was evaluated by flow cytometry (mCherry reporter) or Western blot. RNA-binding protein (RBP) motifs within guide-target regions were annotated using RBPMAP.

Results: Editing efficacy was first validated using a mutant mCherry reporter and benchmarked against CRISPR-Cas13 and the CRISPR-Cas-inspired RNA targeting system (CIRTS). CadRNA achieved 27.7% RNA editing and 33.6% protein rescue, outperforming CIRTS (12.6%; 17.8%) but below CRISPR-Cas13 (69.2%; 51.8%). For pathogenic RPE65 variants, cadRNA reached up to 24.7% editing efficacy with protein recovery. Moreover, cadRNA co-delivered with ADAR1 or truncated ADAR1 improved editing efficiency (3.3-29.7 fold, up to 52.8%), including sites refractory to CRISPR-Cas13 editor. Notably, editing efficiency inversely correlated with RBP motifs on the cadRNA binding region. Extending this approach to a large IRD gene, 45.2% correction of a common human USH2A (c.11864G>A) variant was achieved.

Conclusions: The engineered cadRNA base editor represents a promising strategy for correcting clinically relevant IRD variants.

Abstract No.: 202002

Experimental Research of Human Pluripotent Stem Cells Derived Endothelial Cells (hPSC-ECs) to Repair Choroidal Ischemia

First Author: Yuntao **HU**

Co-Author(s): Meng Da **LI**

Purpose: Choroidal atrophy is a common pathological change closely related to the development of dry age-related macular degeneration (AMD) and pathological myopia. We hope to develop a method to repair choroidal ischemia through stem cell transplantation.

Methods: We induced endothelial cells (EC) from hPSC and established a rat model of choroidal ischemia (CI). hPSC-ECs were transplanted into suprachoroidal space in the CI rats.

Results: We found that hPSC-ECs through the MESP1+ mesodermal progenitor stage express CECs-specific markers and can integrate into choriocapillaris. In a rat model of CI, transplantation of hPSC-ECs into the suprachoroidal space increased choroid thickness and vasculature density. Remarkably, EC transplantation improved the visual function of CI rats.

Conclusions: This work demonstrated that hPSC-ECs could be used to repair choroidal ischemia in the animal model, which may lead to a new therapy to alleviate choroidal atrophy implicated in dry AMD, pathological myopia, and other fundus diseases.

Abstract No.: 200616

First-in-Human iPS Cell Therapy: Ten-Year Follow-Up After Autologous iPS Cell-Derived Retinal Pigment Epithelium Sheet Transplantation for Neovascular Age-Related Macular Degeneration

First Author: Yasuo **KURIMOTO**

Co-Author(s): Masashi **FUJIHARA**, Yasuhiko **HIRAMI**, Michiko **MANDAI**, Daiki **SAKAI**, Sunao **SUGITA**, Seiji **TAKAGI**, Masayo **TAKAHASHI**, Midori **YAMAMOTO**

Purpose: Current treatments for neovascular age-related macular degeneration (nAMD) primarily target pathological neovascularization. However, because retinal pigment epithelium (RPE) deterioration plays a critical role in the disease's pathogenesis, restoring RPE function could provide a curative therapy. We report the 10-year clinical outcomes of the first-in-human autologous induced pluripotent stem (iPS) cell-derived RPE sheet transplantation for nAMD.

Methods: Autologous iPS cells were generated from the patient's skin and differentiated into RPE cells to produce an RPE sheet. Following surgical removal of macular neovascularization (MNV), the RPE sheet was transplanted subretinally. Safety was the primary endpoint, including tumorigenicity, graft failure, or other serious adverse events. Efficacy was evaluated by visual and anatomical outcomes.

Results: The transplanted RPE sheet remained stably engrafted for over 10 years. No tumor formation, graft failure, immune rejection, or other serious adverse events were observed. No recurrence of MNV occurred without any additional anti-vascular endothelial growth factor therapy. The preoperative best-corrected visual acuity of 0.09 was largely maintained. Imaging indicated preservation of photoreceptors and choriocapillaris adjacent to the graft.

Conclusions: This case marks the first-in-human application of iPS cell-derived tissue in a clinical setting, not only for nAMD but also across all medical fields.

The favorable long-term safety and anatomical findings provide strong evidence supporting the feasibility of iPS cell-based regenerative therapy for nAMD and reinforce its broader potential in regenerative medicine.

Abstract No.: 205346

Functional Engraftment of Genome-Edited Retinal Organoid Sheets in a Macaque Model of Macular Degeneration

First Author: Michiko **MANDAI**

Co-Author(s): Ryutaro **AKIBA**, Yingbin **FU**, Akihiro **KAWAI**, Yasuo **KURIMOTO**, Atsuta **OZAKI**

Purpose: The goal of this study was to investigate the functional synaptic integration potential of ON-bipolar cell (BC)-deficient retinal organoids (ROs) derived from human embryonic stem cells (hESC) following transplantation in a macaque model of macular degeneration.

Methods: Islet-1^{-/-} Crx::Venus reporter KhES-1 ROs, which lack ON-BCs, were transplanted into photoreceptor-ablated macular degeneration model of macaque eyes (n=4) in comparison with Islet-1^{+/+} ROs (n=2). Focal electroretinogram (ERG) was conducted during follow-up. After one year, immunohistochemistry (IHC) was performed to assess graft survival, cone ratio, host BC dendrite extension, and host-graft synaptic connectivity. Host-graft synapses were also confirmed by electron microscopy (EM).

Results: Focal ERG showed a significant increase in b-wave in 2 of 4 eyes with Islet-1^{-/-} ROs. All ROs consistently developed PRs with cone ratios of 80±17% and 77±21% in Islet-1^{+/+} and Islet-1^{-/-} grafts, respectively, with the absence of ON-BCs in Islet-1^{-/-} grafts. IHC revealed synaptic contacts between multiple host BC subtypes and CRX::Venus-positive PRs in Islet-1^{-/-} grafts. PKCα, EAAT2, and SCGN-positive host BCs extended dendrites over the graft compared to non-grafted areas. EM confirmed frequent triad synapses in grafted cone pedicles and host ON- and OFF-BC contacting graft PR synapse.

Conclusions: RO transplantation in a macaque model of macular degeneration developed a high ratio of cone PRs. Retracted host BCs regrew dendrites and formed functional synapses with grafted cone PRs, demonstrating plasticity and rewiring potential in primate macula.

Abstract No.: 205232**Generation of Vascularized Retinal Organoids Containing Microglia Based on a V-Bottom Microwell System***First Author: Jiansu CHEN**Co-Author(s): Hon Fai CHAN, Hang CHEN, Yuqin LIANG, Xihao SUN*

Purpose: Retinal organoids (ROs) offer a biomimetic in vitro model for investigating human retinal development and disease. However, current ROs face several limitations, such as the absence of vascular networks and microglial cells (MGs).

Methods: Here, we developed a vascularized retinal organoids (vROs) model by co-culturing vascular organoids (VOs) with ROs in a V-bottom polydimethylsiloxane (PDMS) microwell platform. Through co-culturing for 30 to 120 days, we observed the presence of tubular blood vessels at the center of vROs.

Results: Transcriptomic analysis revealed that the vROs were associated with angiogenesis and immune response. The RT-qPCR validated that the expression levels of genes involved in angiogenesis (TIE1, ANGPT1, ANGPT2, and ECSCR), immune response (C1QC, CD22, TLR2, TLR4, and IRF8), and microglia (AIF1, TMEM119, SPI1, and CSF1R) were significantly higher in the vROs than the ROs. Additionally, we treated VOs lipopolysaccharide (LPS) and the qPCR results showed that LPS stimulation caused a significant increase in the expression of the inflammatory cytokines TNF- α and IL-8 and MG marker AIF1. Interestingly, the expression levels of TNF- α and IL-8 were reduced in PLX5622 (CSF1R inhibitor to deplete MGs) treated VOs. Furthermore, we observed that MGs in VOs migrated and integrated into the vROs as VOs and ROs fused, with the vROs exhibiting responsiveness to inflammatory stimuli. The vROs expressed tight junction protein claudin-5 and displayed similar characteristics to the inner blood-retinal barrier (iBRB).

Conclusions: These vRO models, which incorporate vascular structures and MGs, provide a novel avenue for retinal vascular disease research and hold promise for future clinical applications.

Abstract No.: 204679**Harnessing Apoptotic Vesicles From SHED to Target PD1/PDL1 Immune Checkpoint for Metabolic and Vascular Repair in Ischemic Retinopathy***First Author: Guorui DOU**Co-Author(s): Tianfang CHANG, Yutong JING, Bei LI, Ziyi ZHOU*

Purpose: To evaluate the therapeutic potential of apoptotic vesicles (apoVs) derived from stem cells of human exfoliated deciduous teeth (SHED) in ischemic retinopathy, with a focus on clinical translation and

the novel role of the PD1/PDL1 immune checkpoint in regulating endothelial metabolism and vascular remodeling.

Methods: SHED-apoVs were isolated, characterized, and administered via intravitreal injection in a murine oxygen-induced retinopathy (OIR) model. Retinal vascular changes, neovascularization, avascular area, and visual function were assessed in vivo. In vitro, human umbilical vein endothelial cells (HUVECs) under hypoxia were treated with apoVs, with or without PD1/PDL1 blockade using neutralizing antibodies or shRNA knockdown. Endothelial glycolysis was measured via extracellular acidification rate (ECAR), lactate production, and 2-NBDG uptake.

Results: SHED-apoVs were efficiently internalized by endothelial cells, significantly reducing pathological neovascularization and non-perfusion area in OIR retinas. They promoted deep vascular plexus regeneration and improved electrophysiological function. Mechanistically, apoVs carried PD1, which bound to hypoxia-upregulated PDL1 on endothelial cells, inhibiting anaerobic glycolysis and suppressing angiogenic activation. Blockade of PD1/PDL1 reversed these metabolic and anti-angiogenic effects.

Conclusions: This study highlights SHED-apoVs as a novel, cell-free therapeutic strategy for ischemic retinopathy, leveraging the PD1/PDL1 immune checkpoint to modulate endothelial metabolism and restore vascular integrity. Its translational potential is underscored by bilateral efficacy, dose-dependent response, and absence of systemic toxicity, offering a promising alternative to anti-VEGF therapies.

Abstract No.: 205499**Human Induced Pleuripotent Stem Cells for Corneal Epithelial Formation and Immunobiology of HSV-1 Infective Keratitis***First Author: Bakiah SHAHARUDDIN**Co-Author(s): Komathi SELVARAJAH, Jun Jie TAN, Muhammad Amir YUNUS, Nor Effa Syazuli ZULKAFI*

Purpose: The absence of pertinent human models has constrained our comprehension of HSV-1 pathogenesis in ocular tissues, notwithstanding substantial study efforts. This study presents a novel employment of corneal epithelial-like cells (CECs) from human induced pluripotent stem cells (hiPSCs) to examine HSV-1 infectivity, replication dynamics, and the interactions between virus particles and host cells.

Methods: A stepwise differentiation method modulated by Bone Morphogenetic Protein (BMP) signaling pathway and employed small-molecules, specifically the RBE cocktail, followed by maturation on collagen IV-coated substrates.

Results: This strategy effectively led to hiPSC lineage specification, as evidenced by the strong expression of key biomarkers such as $\Delta Np63$ ($72.37\% \pm 10$) and

PAX6 (72.07% $\pm$ 2), ABCG2 (86.24% $\pm$ 8) and ABCB5 (80.85% $\pm$ 8), and CK3 (67.97% $\pm$ 10) and C12 (87.96% $\pm$ 9). The findings highlight the critical function of the viral immediate-early gene product, infectious cell protein-4 (ICP4), in promoting HSV-1 proliferation and cytopathogenicity within corneal epithelial cells. This model is also useful to demonstrate immunological responses in conjunction with HSV-1 replication, demonstrating increased levels of pro-inflammatory cytokines such as TNF-alpha and antimicrobial peptides Beta Defensin 1 and Beta Defensin 2.

Conclusions: BMP-modulated and RBE-mediated differentiation of hiPSCs on collagen IV-coated plates provides the most effective and scalable method for deriving CECs. This optimized differentiation system positions hiPSC as a platform for studying HSV-1 pathogenesis, immune mechanisms, and potential therapeutic interventions in herpetic keratitis.

Abstract No.: 204179

Human Retinal Organoids Restore Visual Function After Transplantation Into the Transected Optic Nerve

First Author: Yu **GONG**

Co-Author(s): Jiawen **LI**, Weihua **YU**

Purpose: Functional restoration of the adult mammalian vision remains unattainable following complete transection of the optic nerve. In this study, we addressed this challenge by transplanting human retinal organoids into the transection cavity of the optic nerve in adult rats.

Methods: Human retinal organoids were heterotopically transplanted into the intrathecal cavity of rats subjected to complete optic nerve transection. Functional recovery was assessed by optic nerve potentials (ONPs) and visual evoked potentials (VEPs), direct pupillary light reflex (PLR), optokinetic response (OKR), and visual guided behavioral tests at one and three months post-transplantation. Neuroanatomical integration was examined by optical coherence tomography (OCT), anterograde neural tracing, and tissue clearing-based 3D reconstruction.

Results: At one month post-transplantation, 67.5% of animals receiving hROs transplantation exhibited significant recovery of PLR and VEP amplitudes compared with transected controls, along with improved visual discrimination behaviors. These functional improvements were sustained for at least three months. Transplanted hROs survived in the intrathecal cavity and extended human axon-like fibers across the transection site toward central targets. Electrophysiological and neuroanatomical analyses confirmed the functional reconnection of the transected optic nerve, demonstrating reestablished neural pathways from the transplanted retinal organoids to central visual targets.

Conclusions: Our study provides proof-of-concept that heterotopic transplantation of human retinal organoids can repair complete optic nerve transection and restore visual function in adult mammals. The findings highlight a novel and translationally promising therapeutic strategy for severe optic nerve injuries.

Abstract No.: 204895

Hybrid Cell Membrane Coated Nanoparticles for Targeted Therapy of Early Diabetic Retinopathy

First Author: Fan **YANG**

Co-Author(s): Haijun **GONG**, Shurong **GUO**, Yuqing **LAN**, Qihang **ZHOU**

Purpose: Diabetic retinopathy (DR), a complication of diabetes mellitus, requires effective and early intervention to prevent progression. This study evaluated a biomimetic nanoparticle platform for targeted, noninvasive treatment of early DR.

Methods: Hybrid nanoparticles were created by coating poly(lactic-co-glycolic acid) cores with fused membranes from red blood cells (RBCs) and retinal endothelial cells (ECs). The membrane-to-core ratio was optimized to preserve CD47 (immune evasion) and vascular endothelial cadherin (endothelial targeting). Endothelial cell migration and targeting were assessed in vitro. Streptozotocin-induced diabetic rats received intravenous treatment, followed by evaluation of retinal accumulation, vascular leakage, inflammatory markers, and systemic safety.

Results: Nanoparticles demonstrated stability, retained membrane proteins, and showed enhanced endothelial targeting. In diabetic rats, treatment resulted in selective retinal accumulation, decreased vascular endothelial growth factor expression, reduced leakage, and fewer acellular capillaries. Transcriptomic analysis indicated restoration of lysosomal function, lipid metabolism, and tumor necrosis factor-related inflammatory pathways. Systemic lipid profiles were improved without hematological or hepatic toxicity.

Conclusions: Hybrid RBC-EC membrane-coated nanoparticles provided targeted delivery, vascular protection, and favorable safety. This platform represents a promising noninvasive therapeutic approach for early DR.

Abstract No.: 206063

Implementation of an Automated Visual Acuity Test in a Public Hospital in Singapore – a Preliminary Analysis

First Author: Rubin **YONG**

Co-Author(s): David **CHEN**, Victor **KOH**, Zhi Wei **LIM**

Purpose: To evaluate productivity gains from using the self-administered Automated Visual Acuity Test (AVAT)

device for visual acuity (VA) testing in a tertiary hospital ophthalmology outpatient clinic in Singapore.

Methods: The AVAT device was implemented in an ophthalmology outpatient clinic, within the same space allocated for conventional VA testing. A preliminary retrospective analysis evaluated real-world clinical performance pre- and post-deployment (April–June 2024 vs 2025). Data from electronic health records, including the total number of patients requiring VA testing, AVAT utilization rate, VA waiting time, patient experience survey (PES) scores for VA waiting time, and overall clinic satisfaction, were evaluated.

Results: The pre-deployment period (April–June 2024) recorded 8,072 VA tests, while 9,006 tests were conducted post-deployment (April–June 2025). Following implementation, AVAT replaced 39.6% ($\pm 0.21\%$) of daily VA tests, previously performed in manual Snellen chart lanes. The median waiting time for VA testing significantly improved from 8 minutes (IQR 3–19) to 6 minutes (IQR 2–15), representing a 25% reduction (Mann–Whitney U, $Z = -15.2$, $p < 0.0001$). The PES score for waiting time improved by 6.4% (from 43.2% to 49.6%), while overall clinic satisfaction increased by 4.7% (from 83.7% to 88.4%).

Conclusions: In high-volume ophthalmology outpatient clinics, VA testing is an essential functional test and a common bottleneck in the patient journey. AVAT reduces VA waiting time without requiring additional space. With current utilization at 40%, increased adoption could yield further efficiency gains, streamline workflow, increase capacity to accommodate higher patient volumes, and enhance patient experience.

Abstract No.: 204547

In Vitro Cytotoxicity and In Vivo Evaluation of Therapeutic Effect of Kelulut Honey Eyedrop for Dry Eye Therapy

First Author: Shahidatul Adha **MOHAMAD**

Co-Author(s): Nur Karyatee **KASSIM**, Norsuhana **OMAR**, Tuan Nadrah Naim T **ISMAIL** @ T **MANAH**, Kannan **THIRUMULU PONNURAJ**

Purpose: This study evaluates the therapeutic potential of Kelulut honey (KH), derived from Malaysian stingless bees (*Trigona* spp.), as a sustainable and locally sourced alternative for dry eye management. Building on the global precedent set by Manuka honey-based formulations (Optimel), KH offers a unique bioactive profile and ecological advantage.

Methods: In vitro testing was performed using human conjunctival epithelial cells (HConEPiC). KH samples with native pH ranging from 2 to 5 were tested at concentrations from 0.25 to 10 mg/mL, following ISO 10993-5 standards. KH eyedrops (KHED) were subsequently formulated based on the concentration-dependent viability results for further in vivo evaluation involving 18 male New Zealand White rabbits with

induced dry eyes. Subjects are randomized into six groups: negative control, positive control (Hyaluronan Eyedrop), and KHED formulations (0.625%, 12.5%, 25%, 50%). Clinical assessments include Schirmer test, tear break-up time (TBUT), corneal fluorescein staining, and conjunctival impression cytology (CIC). Post-treatment evaluations will include histopathological analysis of the enucleated eyes.

Results: KH concentrations up to 10 mg/mL maintained cell viability above 70% with no cytotoxic reactivity. Mild cytotoxicity at higher concentrations is likely due to the natural high acidity of honey. Ongoing formulation adjustments aim to buffer pH and improve ocular biocompatibility, enhancing patient comfort and therapeutic tolerability.

Conclusions: This study represents a translational initiative to advance KH from laboratory validation toward a clinically viable and safe ophthalmic formulation for dry eye therapy. Preliminary in vivo findings will be presented at APAO 2026.

Abstract No.: 207461

JAK Inhibitor Eye Drops for the Treatment of Non-Infectious Anterior Uveitis: A Randomized, Double-Masked, Active-Controlled, Phase 2 Clinical Trial of VVN461 in China

First Author: Liu **YANG**

Co-Author(s): Hong **DAI**, Lei **FENG**, Bing **JIANG**, Dan **LIANG**, Yanyun **SHI**, Yuqin **WANG**, Meifen **ZHANG**, Xiaomin **ZHANG**, Yihua **ZHU**

Purpose: To evaluate the efficacy and safety of 0.5% and 1.0% VVN461 Solution (JAK1/TYK2 inhibitor) in patients with non-infectious anterior uveitis (NIAU).

Methods: In this phase 2, multicenter, randomized, double-masked study, 83 patients with NIAU were randomized to receive either 0.5% VVN461 ($n=27$) or 1.0% VVN461 ($n=29$) or 1.0% prednisolone acetate (PA) eye drops ($n=27$), 6 times/day (Q2h) for 7 days; QID for 7 days; BID for 7 days; and QD for 7 days. The primary outcome was that the anterior chamber cell grade improved by at least 2 grades from baseline on day 14.

Results: Success rates were 92.6% of 0.5% VVN461, 96.6% of 1.0% VVN461, and 77.8% in PA (within the 90% confidence non-inferiority margin of 17.5%). No safety events of concern were observed.

Conclusions: VVN461 showed a clinically meaningful anti-inflammatory effect, at least as good as the standard of care (PA), in both VVN461 treatment groups. There were no meaningful safety issues with VVN461.

Abstract No.: 208523

LNP Screening for mRNA Delivery in Ocular Disease

First Author: Hao TIAN

Co-Author(s): Kam LEONG

Purpose: To identify lipid nanoparticle (LNP) formulations suitable for ocular mRNA delivery with potential applications in gene therapy.

Methods: Cre mRNA-loaded LNPs were constructed and delivered to mCherry-stop-EGFP reporter retinal pigment epithelial (RPE) cells. Gene expression and editing efficiency were quantified based on the fluorescence conversion ratio. By incorporating different helper lipids and adjusting the component ratios within the formulations, the particle size and surface charge of LNPs were modulated. In vitro screening was then performed to determine the formulations with the highest delivery efficiency in RPE cells.

Results: Screening of 105 formulations revealed that LNPs with an mRNA-to-lipid mass ratio of 20:1–40:1 achieved optimal delivery efficiency. The highest transfection efficiency was observed when the molar ratio of cationic lipids accounted for 5–10% of total lipids, anionic lipids for 10–20%, and neutral lipids for 20–30%. The most effective formulations exhibited particle sizes around 200 nm and zeta potentials ranging from –10 mV to +10 mV. Cationic and neutral lipid-based LNPs showed slightly higher delivery efficiency, while anionic and neutral lipid-based LNPs demonstrated better biocompatibility and lower cytotoxicity.

Conclusions: Our study identified different LNP formulations with optimal in vitro delivery efficiency, providing a valuable foundation for subsequent in vivo screening and therapeutic applications of mRNA-based ocular gene therapy.

Abstract No.: 200188

Liquid Biopsy Proteomics: Revolutionizing Ophthalmic Clinical Trial Design and Drug Development

First Author: David ALMEIDA

Co-Author(s): Vinit MAHAJAN

Purpose: To demonstrate how liquid biopsy proteomics can provide rapid molecular feedback on therapeutic targets and disease pathways, challenging traditional imaging-based trial endpoints in ophthalmology.

Methods: Aqueous humor (AH) liquid biopsies underwent high-resolution proteomic profiling, analyzing approximately 6,000 proteins per sample. This data was integrated with tissue single-cell transcriptomics to determine the cellular origin of identified proteins. The methodology facilitated comprehensive pathway analysis, biomarker discovery,

and evaluation for drug repurposing, including screening against 169 FDA-approved cancer drugs.

Results: Liquid biopsies of AH revealed immunosuppressive proteins, the levels of which changed during intraocular inflammation, and also identified cell-type-specific markers. In diabetic retinopathy, angiogenesis protein profiles were found to be dependent on disease stage. Notably, proteomic biomarkers showed a correlation with clinical trial outcomes in uveal melanoma, where low or absent drug targets were associated with trial failure.

Conclusions: Liquid biopsy proteomics presents a transformative strategy for ophthalmic clinical trials and drug development. It allows for comprehensive pathway analysis from approximately 6,000 proteins per sample, safe and repeatable sampling for longitudinal patient monitoring, and rapid molecular feedback for timely go/no-go decisions. Implementation of this approach could lead to reduced trial costs through improved patient stratification and earlier endpoint detection, while also offering mechanistic insights not available through current methodologies.

Abstract No.: 202222

Molecular Modeling and In Silico Study of the Catalytic Domain of PknB From Ocular Mycobacterium tuberculosis

First Author: Deepak CHOUDHURY

Co-Author(s): Nikita DASH

Purpose: To discover small molecule inhibitors targeting the catalytic domain of PknB, essential for bacterial growth and survival.

Methods: An in silico structure-based drug discovery approach was used to identify potential inhibitors of PknB from Mycobacterium tuberculosis. A total of 646 compounds were retrieved from PubChem. Molecular docking was performed (Lamarckian Genetic Algorithm), focusing on the active site at Val95 (coordinates: 62.467, 4.815, -32.164) via AutoGrid. Each ligand underwent 10 docking runs. Top hits were selected based on binding energy and analyzed for hydrogen bonding and ADMET properties. A molecular dynamics simulation was done for the top molecule using the Gromacs software.

Results: Thirty-four compounds showed strong binding affinity, favorable H-bond interactions, and promising ADMET profiles, suggesting good drug-likeness.

Conclusions: The identified PknB inhibitors may serve as promising anti-tubercular drug candidates, potentially disrupting bacterial growth and survival, offering a novel therapeutic approach against ocular drug-resistant Mycobacterium tuberculosis infections.

Abstract No.: 200781**Monocellular-Pore 3D Printed Scaffolds for Retinal Pigment Epithelial Cell Therapy: Clinical Translation and Impact***First Author: Zengping LIU**Co-Author(s): Dejian HUANG, Gopal LINGAM, Hang LIU, Xinyi SU*

Purpose: Retinal degenerative diseases, such as age-related macular degeneration (AMD), currently lack curative therapies, with retinal pigment epithelial (RPE) cell transplantation emerging as a promising strategy for restoring vision. This study evaluates the clinical translational potential and impact of monocellular-pore 3D-printed scaffolds for RPE cell delivery, comparing them with commercial track-etched polyethylene terephthalate (PET) membranes used in clinical trials.

Methods: Human embryonic stem cell-derived RPE (hESC-RPE) sheets were cultivated on 3D-printed polycaprolactone (PCL) scaffolds engineered with single-cell-sized pores (~10 μ m) and compared with PET membranes. Functional assessments included protein expression, barrier function, permeability, and phagocytosis assays. Safety and biocompatibility were further evaluated via subretinal implantation in porcine (2 months) and rabbit (1 year) models using imaging, electroretinography, and histopathology.

Results: PCL scaffolds with cell-sized pores demonstrated superior RPE monolayer integrity, maturation, and function, with transepithelial electrical resistance and phagocytosis comparable to PET membranes. PCL scaffolds provided enhanced permeability, supporting nutrient exchange post-transplantation. In vivo studies revealed stable retinal structure and function, with no adverse effects or inflammation over extended follow-up. Surgical integration was successful, and scaffold degradation did not impact retinal health.

Conclusions: Monocellular-pore 3D printed PCL scaffolds offer a clinically translatable, biocompatible alternative to current non-biodegradable implants for RPE cell delivery. These findings support their potential to improve outcomes in cell-based retinal therapies and lay the foundation for advancing regenerative strategies in ophthalmology.

Abstract No.: 200210**Multiwalled Mesoporous Silica Constructs "Sunflower-Like" Structures to Promote Stem Cell Migration and Differentiation for Repairing Ectopia Lentis***First Author: Yan LIU**Co-Author(s): Tianhui CHEN, Yongxiang JIANG*

Purpose: Ectopia lentis (EL) is a blinding ocular disorder caused by abnormalities in the zonular fibers. Current surgical interventions are technically challenging and associated with significant complications. This study

aims to explore a novel repair strategy based on stem cells and functionalized nanomaterials to address the limitations of existing therapeutic approaches.

Methods: RNA-seq and Olink proteomics were performed on EL patient ocular tissues/aqueous humor. An amino-modified multiwalled mesoporous silica nanocarrier (mCNT@SiO₂-NH₂) was synthesized. Human BMSCs were adsorbed onto mCNT@SiO₂-NH₂, forming a «sunflower-like» structure (nanocarrier core, radial BMSCs). BMSCs in this structure underwent directional induction using LEC conditioned medium. The nanocarrier's mechanism was probed via multi-omics (RNA-seq, ATAC-seq, scRNA-seq). The mCNT@SiO₂-NH₂/BMSC co-culture was transplanted into rat EL models. Zonular architecture was assessed histologically.

Results: EL patient analyses revealed significantly suppressed extracellular matrix-related gene/protein expression. mCNT@SiO₂-NH₂ co-culture significantly enhanced BMSC expression of zonule-specific proteins FBN1 and MFAP2 post-induction. Multi-omics indicated mCNT@SiO₂-NH₂ activated perinuclear actin cap (F-actin), pMLC, and Nesprin-1, mediating mechanotransduction that drove YAP nuclear translocation and transcriptional activity. Transplantation effectively reconstructed damaged zonular architecture in rats, confirmed histologically.

Conclusions: This study reveals a novel mechanism by which the porous nanomaterial mCNT@SiO₂-NH₂ reprograms BMSC fate via the cytoskeleton-nucleus mechanocoupling pathway (pMLC/F-actin/Nesprin-1/YAP). It successfully achieves BMSC differentiation into zonule-like cells, providing an innovative strategy for stem cell-based therapy to repair complex ocular diseases, such as ectopia lentis.

Abstract No.: 203426**Optic Nerve Sheath Diameter and Retinal Artery Hemodynamics by Color Doppler Ultrasound for Noninvasive Intracranial Pressure Monitoring in Acute Cerebral Hemorrhage***First Author: Zhixin GUAN**Co-Author(s): Li SHOUQING, Liu SHU*

Purpose: To investigate the correlation between optic nerve sheath morphological parameters and central retinal artery hemodynamic parameters with Intracranial Pressure (ICP), this study aims to construct a multiparameter integrated diagnostic model for ICP assessment. Through implementing multidisciplinary collaborative diagnosis and treatment protocols, we further strive to enhance early detection rates of intracranial hypertension in clinical practice.

Methods: In a prospective study, 40 patients with acute cerebral hemorrhage were enrolled, all of whom underwent implantation of intracerebroventricular ICP

transducers for direct intracranial pressure monitoring. Color Doppler ultrasound was utilized to measure optic nerve sheath morphological parameters and central retinal artery hemodynamic parameters in these patients. Statistical analyses were performed using SPSS 27.0 to establish a multiparameter joint diagnostic model.

Results: Intracranial pressure (ICP) demonstrated a strong positive correlation with ONSD ($r = 0.680$, $P < 0.05$) and moderate negative correlations with central retinal artery hemodynamic parameters, including peak systolic velocity ($r = -0.493$) and end-diastolic velocity ($r = -0.422$) (both $P < 0.05$). For detecting elevated ICP (> 15 mmHg), $ONSD \geq 4.45$ mm yielded 79.5% sensitivity and 69.4% specificity. The multiparameter predictive model integrating ONSD and CRA flow metrics achieved superior diagnostic performance, with an overall accuracy of 81.3%, sensitivity of 72.2%, specificity of 93.2%, and Youden's index of 0.654 at a probability threshold of 68.4%.

Conclusions: Color Doppler ultrasound can be used for bedside monitoring of ICP with the advantages of being noninvasive, simple, and reproducible. When the optic nerve sheath diameter is ≥ 4.45 mm, and the predictive probability of the multiparameter combined diagnostic model is $\geq 68.4\%$, the patient should be highly suspected of having elevated ICP.

Abstract No.: 202153

Postprandial C-Peptide to Glucose Ratio as a Promising Systemic Marker of Diabetic Retinopathy in Type 2 Diabetes

First Author: Zhaoxia **ZHENG**
Co-Author(s): Xiaobing **YU**

Purpose: To assess the association between C-peptide-related parameters and diabetic retinopathy (DR) in type 2 diabetes mellitus (T2DM), and find a superior parameter in predicting DR.

Methods: A total of 1,078 T2DM patients were included in this cross-sectional study. Fasting and postprandial C-peptide (FCP and PCP), delta CP, FCP or PCP to glucose ratio (FCGR and PCGR), homeostasis model assessment of β -cell function (HOMA-B), and insulin resistance (HOMA-IR) were compared among different stages of DR. Odds ratios (ORs) of these indices for the presence and severity of DR were estimated after adjusting for confounding factors. Multivariate logistic analysis was performed to evaluate the association between PCGR and DR according to PCGR quartiles. Receiver Operating Characteristics (ROC) curves were generated to determine the discriminative power of DR.

Results: Among C-peptide-related indices, PCGR showed the most significant association with mild and moderate non-proliferative DR (NPDR) (per SD increase, $OR=0.44$, $P<0.001$), and vision-threatening DR (VTDR)

($OR=0.09$, $P<0.001$). When grouped by PCGR quartiles, patients in the lower quartile showed a higher risk of developing DR. PCGR was negatively associated with DR and VTDR independent of confounders (P for trend <0.001). PCGR had high predictive abilities of DR and VTDR ($AUC=0.76$ and 0.83), and also increased the AUC values of the standard model.

Conclusions: Compared with IR, DR was more associated with impaired β -cell function. PCGR could be a promising systemic marker for determining T2DM patients at high risk of developing DR, especially VTDR.

Abstract No.: 200248

Reprogramming of iPSCs to NPCEC-Like Cells by Biomimetic Scaffolds for Zonular Fiber Reconstruction

First Author: Tianhui **CHEN**
Co-Author(s): Yongxiang **JIANG**

Purpose: Ectopia lentis (EL), characterized by impaired zonular fibers originating from non-pigmented ciliary epithelial cells (NPCEC), presents significant surgical challenges and risks of visual impairment. Current treatment via cataract surgery results in loss of lens accommodation and fails to address the fundamental challenge of in situ zonular ligament repair. This study aimed to elucidate EL pathogenesis and develop a regenerative therapeutic strategy targeting zonular restoration.

Methods: Ocular tissues and aqueous humour from EL patients underwent RNA sequencing and Olink high-throughput proteomic analysis. Based on pathogenic insights, we developed biomimetic scaffolds mimicking natural radial zonular fiber microstructure. These scaffolds were utilized to reprogram and directionally differentiate human induced pluripotent stem cells (iPSC) into NPCEC-like cells. The therapeutic efficacy of a single injection of these induced NPCEC-like cells was evaluated in a rabbit EL model, focusing on zonular fiber structural and mechanical restoration.

Results: Transcriptomic and proteomic profiling revealed significant downregulation of key pathogenic genes (FBN1, MFAP2) and upregulation of secretory proteins (IL-12, MMP-1) in EL. While FBN1 and MFAP2 showed high expression in NPCECs, donor scarcity limits NPCEC transplantation. We successfully generated NPCEC-like cells from iPSCs using the novel biomimetic scaffolds. Crucially, a single injection of these cells into the rabbit EL model demonstrated significant restoration and enhancement of mechanical properties within the zonular fiber structures.

Conclusions: Biomimetic scaffold-directed iPSC differentiation yielded NPCEC-like cells, whose single injection restored zonular mechanics in vivo. This iPSC-based regeneration offers a potential alternative to cataract surgery, preserving lens accommodation in EL.

Abstract No.: 205491**Restoration of Conjunctival Lymphatic Vessels With Retinoic Acid following Mitomycin-C–Induced Suppression in a Rat Model***First Author: Hitisha MITTAL**Co-Author(s): Sushmita KAUSHIK, Ritambhara NADA, Surinder S PANDAV, Nusrat SHAFIQ, Faisal T T*

Purpose: To investigate the effect of Mitomycin-C on conjunctival lymphatics and the potential of Retinoic Acid (ec23) to stimulate lymphangiogenesis in rats.

Methods: Twenty-five Sprague-Dawley rats were divided into five groups (n = 5 per group). Right eyes received subconjunctival injections of balanced salt solution, 0.01% Mitomycin-C, 100 nM ec23, 0.01% Mitomycin-C with 100 nM ec23, or 0.1% dimethyl sulfoxide; left eyes served as controls. Eyes were enucleated on postoperative day 14. Conjunctival tissues were stained with Masson trichrome, CD31 (vascular endothelial marker), and D2-40 (lymphatic endothelial marker) to assess fibrosis, vascular, and lymphatic density. Data are expressed as mean $\pm$ standard deviation and compared using the Mann-Whitney U test.

Results: Mitomycin-C significantly reduced conjunctival lymphatic and vascular density ($p = 0.009$). Ec23 alone ($p = 0.008$) or combined with Mitomycin-C ($p = 0.016$) significantly increased lymphatic channel density.

Conclusions: Both conjunctival blood vessels and lymphatic channels contribute to fluid drainage. Mitomycin-C impairs lymphatic development, whereas ec23 promotes lymphangiogenesis at 100 nM. Combining Mitomycin-C and Retinoic Acid may enhance bleb drainage following trabeculectomy, improving postoperative intraocular pressure control.

Abstract No.: 202702**Results From First 100 Participants of the DRMS-India: Variations in Gut Microbiome of People With Diabetic Retinopathy in Asia***First Author: Brijesh TAKKAR**Co-Author(s): Taraprasad DAS, Ankita MADDHESHIYA, Souvik MUKHERJEE*

Purpose: The Diabetic Retinopathy Microbiome Study (DRMS-India) compares variations in gut microbiome in DR in Asia. We present the results of the first 100 participants and compare these with other reports from the Asian region.

Methods: DRMS is an India-wide study involving 17 independent sites and 548 enrolled participants. We recruited healthy people 30 years or older (HC-control) and people with DM with/without DR (cases) in a case-control design. The first-pass morning gut samples were collected and processed for metagenomics sequencing after DNA extraction. Details on lifestyle, dietary, and systemic risk factors of DR were noted.

The microbiome data were analysed for abundance ($>0.5\%$), the alpha (Shanon, Gini, and Richness indices), and the beta diversity (NMDS plot based on Bray-Curtis dissimilarity. Results from the first 100 participants are presented (HC - 26, DM - 33, and DR - 41).

Results: We detected higher alpha diversity in the DR group as compared to that reported from South Central China previously. Beta diversity plots from all studies (DRMS, Southcentral China, Central China, South India) consistently demonstrated gut dysbiosis in DR. At the phyla level, reverse proportions of Actinobacteria (less in DRMS-India than China) and the Firmicutes/Bacteroides ratio (higher in DRMS-India than China). At the general level, Bifidobacterium reduced consistently in the DR group while Ruminococcus increased (DRMS and China). Segatella copri, the commonest species seen in all the groups DRMS cohort, was not reported from China.

Conclusions: There is heterogeneity in gut microbiota data reported across Asia, with a need to consolidate and form a consortium for future preventive therapy.

Abstract No.: 200580**Subconjunctival Injection of Liposomal Tacrolimus (LipoTac) for the Treatment of Allergic Conjunctivitis: Pre-Clinical and Phase I Studies***First Author: Shayne TAN**Co-Author(s): Yu-chi LIU, Jodhbir MEHTA, Tina WONG, Jyh Haur WOO*

Purpose: To develop and evaluate the safety and efficacy of liposomal tacrolimus (LipoTac) in the treatment of vernal keratoconjunctivitis (VKC).

Methods: In-vitro drug-release profiles, 2-year stability, and efficacy tests using a VKC animal model were conducted. Conjunctival tacrolimus levels were compared between 9 rabbits who underwent a single 0.3ml subconjunctival injection of LipoTac and rabbits that received tacrolimus eye drops. 80 mice were randomly allocated into 4 groups (negative control, positive control, LipoTac, and blank liposome injections (LipoBlank)), examined weekly, with immunohistochemical examinations at week 4. Subsequently, a phase 1 clinical trial was conducted on 4 patients with VKC. The patients were followed up for 8 weeks with subjective and objective outcome measures, including the Allergic Conjunctivitis Symptom (ACS) questionnaire, Ocular Symptom Score (OSS), VKC clinical grading, and best corrected visual acuity (BCVA).

Results: In vivo and in vitro testing showed a higher concentration of tacrolimus in the LipoTac group compared to the eye drop group at all time points. The expressions of pro-allergic cytokines IL-4, IL-13, TGF- β 1, and CD40L were all lower in the LipoTac group compared to the positive controls in the mice's eyes.

2-year stability tests showed that there was the least tacrolimus degradation at pH 6.5. First-in-man studies showed significant improvements in OSS and ACS scores, with no change in BCVA. There were no serious adverse events, with undetectable tacrolimus serum levels at all time points.

Conclusions: LipoTac is a safe and effective treatment option for sustained delivery of tacrolimus to treat VKC.

Abstract No.: 208355

Subretinal LX102 Gene Therapy for Neovascular Age-Related Macular Degeneration (nAMD): Preliminary Results of a Randomized, Active-Controlled Phase 2 Trial

First Author: Xiaodong SUN

Purpose: LX102 gene therapy is developed by recombining the AAV2 capsid and the gene coding for VEGF trap. The purpose of this study was to assess the efficacy and safety of 2 higher doses from phase 1 trial compared with Aflibercept (2mg) in participants with nAMD up to 52 weeks.

Methods: In this open-label, randomized, active-controlled phase 2 trial, participants with active CNV secondary to nAMD were assigned (2:2:1) to receive medium-dose (5×10^{10} VG/eye) or high-dose (1.25×10^{11} VG/eye) LX102, or Aflibercept (2 mg). LX102 groups received two Aflibercept injections 4 weeks apart, followed by subretinal LX102. Eyes were monitored for rescue injections based on BCVA, OCT, and fundus findings.

Results: From Dec 21, 2023, to Aug 14, 2024, 49 participants received treatment (19 medium-dose, 19 high-dose, 11 control). Up to Apr 2, 2025, all subjects have been followed up for 24~52 weeks after LX102 administration. LX102 was well tolerated, with no vasculitis, retinitis, choroiditis, vascular occlusion, or endophthalmitis reported. No LX102-related adverse events or rescue injections occurred. By Apr 2, 2025, all were followed for 24–52 weeks. At Week 24, mean BCVA changes in pseudophakic eyes were +2.8 (medium-dose), +9.8 (high-dose), and +5.1 letters (control).

Conclusions: Safety results from phase 2 dose expansion trial evaluating subretinal LX102 injection in nAMD participants were consistent with observations from phase 1 trial, with no clinically determined ocular inflammation in 5×10^{10} VG/eye group. And efficacy results support LX102 gene therapy as a potential treatment option to reduce the burden of frequent anti-VEGF treatments and maintain long-term visual outcomes.

Abstract No.: 202809

Suprachoroidal TA: A Gamechanger for Refractory Macular Edema

First Author: Arjun AURORA

Co-Author(s): Ajay AURORA

Purpose: To evaluate the safety and efficacy of suprachoroidal injection of centrifuged preservative-free Triamcinolone Acetonide (cPFTA) with novel Suprachoroidal Injection Device (SCID) in patients with macular edema due to pathologies including DME, retinal vein occlusion, non-infectious uveitis, and evaluate the long-term efficacy after repeat injections.

Methods: SCITA (Suprachoroidal Injection of Triamcinolone) 0.1ml of cPFTA was given in 60 eyes of 56 patients with a 30G needle using novel-SCID. The angulation of the base plate to the scleral entry was a critical determinant of the correct plane of injection. BCVA, IOP, and CST(SD-OCT) were measured on days (D) 1,7,30,60,90.

Results: SCITA was pain-free, well-tolerated, and there was no retinal/choroidal injury. In 4 eyes, the injection became intravitreal, with patients requiring antiglaucoma medications. Mean baseline CST ($488 \mu\text{m}$) decreased to $240 \mu\text{m}$ at D7; maintained at $230 \mu\text{m}$ (D30) & $262 \mu\text{m}$ (D90). Edema resolution occurred in 66% at D30 & 57% eyes were edema-free at D90. BCVA improved 1 line in 60% & 3 lines in 37% at D30. No eye had increased IOP if there was no intravitreal injection of TA. In two eyes the effect lasted for 7 months.

Conclusions: SCITA using the novel SCID is cheap, safe, effective, and well-tolerated. It requires a learning curve, and angulation of the baseplate to the sclera is critical. Repeated SCITA injections are effective and safe. cPFTA increases the duration of efficacy of TA and can be an alternative to intravitreal injection of Ozurdex.

Abstract No.: 203369

Therapeutic Modulation of the Vitreoretinal Fibrosis Microenvironment Using Engineered Macrophage-Derived Extracellular Vesicles

First Author: Yingjie WANG

Co-Author(s): Yong TAO

Purpose: Vitreoretinal fibrosis is a hallmark pathological feature of proliferative vitreoretinopathy (PVR), which relies on invasive intraocular surgery, retinal detachment, and ocular trauma in the clinic. Accordingly, there is a high demand for developing new and effective pharmacological treatments for such a difficult-to-treat disease.

Methods: Upon initial data mining for depicting the key features of the vitreoretinal fibrosis microenvironment in both PVR patients and model mice, including elevated transforming growth factor $\beta 1$ (TGF $\beta 1$) and M2 macrophage enrichment, we herein designed and

engineered extracellular vesicles that conferred potent anti-fibrotic efficacy against PVR. These extracellular vesicles were derived from M1 macrophages (M1evs) and were conjugated with a TGF β 1 antibody (aT) through an MMP-cleavable linker (cl).

Results: Upon intravitreal injection into the PVR model mice, we observed aT-cl-M1ev (ACE) selectively accumulated in the PVR lesions and aT was cleavably released. By neutralizing TGF β 1 and inhibiting M2 macrophage polarization, the microenvironment was effectively modulated and vitreoretinal fibrosis was diminished. Further incorporating a platelet-derived growth factor receptor antibody via a cl linker, we developed aTP-cl-M1ev (ACEPlus) to treat PVR at an advanced stage and observed a potent benefit in preventing retinal detachment progression, which, notably, was validated with an innovative, patient-derived PVR membrane xenograft model.

Conclusions: Our study thus demonstrated that therapeutic modulation of the vitreoretinal fibrosis microenvironment with the ACE platform was an efficacious alternative to surgical interventions for PVR.

Abstract No.: 204630

Topical Application of Everolimus Attenuates Lens-Induced Myopia Through mTORC1 Suppression

First Author: Rui-heng **ZHANG**

Co-Author(s): Wenbin **WEI**

Purpose: The mechanistic target of rapamycin complex 1 (mTORC1) signaling has been reported to regulate lens-induced myopia (LIM) in guinea pigs. To address the challenge of delivering lipophilic mTORC1 inhibitors to the posterior eye segment, we developed a novel topical ophthalmic formulation of everolimus, a second-generation rapamycin derivative available only orally, and evaluated its anti-myopic efficacy, ocular pharmacokinetics, and safety.

Methods: Vehicle formulations were optimized for delivering everolimus to the RPE-choroid complex. The efficacy of different concentrations of everolimus eye drops was tested in three-week-old male pigmented guinea pigs that underwent LIM. We examined mTORC1 signaling activation, axial elongation, refractive changes, and fundus morphology. Pharmacokinetics was assessed in guinea pigs and New Zealand white rabbits. Ocular safety was evaluated through slit-lamp and fundus examinations, intraocular pressure measurements, and histological analysis.

Results: The optimized formulation of everolimus eye drops (0.001%, 0.01%, and 0.1% w/v) significantly attenuated axial elongation by 0.10 ± 0.03 mm ($P=0.054$), 0.11 ± 0.02 mm ($P=0.001$), and 0.14 ± 0.03 mm ($P=0.001$), respectively. The everolimus eye drops also attenuated fundus tessellation, choroidal thinning, and mTORC1 activation. Peak everolimus concentrations in the RPE-

choroid complex of guinea pigs ranged from 5.6 to 103 ng/g, with a Tmax of 1 hour. In rabbits, 0.005%–0.01% everolimus eye drops achieved concentrations in the RPE–choroid complex comparable to the therapeutic levels in guinea pigs. No corneal, lenticular, retinal toxicity, or intraocular pressure alterations were observed.

Conclusions: This novel ophthalmic formulation effectively delivered everolimus to the posterior segment and inhibited myopia progression, supporting its clinical potential for myopia control.

Abstract No.: 204108

Transplantation of hESC-RPE Cells via Injectable Microfluidic-Templated Microgels for Retinal Regeneration

First Author: Xiang **MA**

Co-Author(s): Ying **WEI**

Purpose: Retinal pigment epithelial (RPE) cells are specialized neural cells essential for vision. Human embryonic stem cell-derived RPE (hESC-RPE) cells show great promise as a therapeutic source for treating retinal degenerative diseases. However, their clinical application is limited by poor transplantation efficiency and low cell viability, largely due to shear stress during delivery and immune clearance by the host.

Methods: To address these limitations, we developed a novel cell delivery platform using microfluidic-templated microgel carriers to enhance the loading and delivery of hESC-RPE cells. These microcarriers, termed Fib@GHMS, consist of a gelatin-methacryloyl/hyaluronic acid-methacryloyl (GelMA/HAMA) core encased in a fibrin shell. Fabricated in a high-throughput and uniform manner, Fib@GHMS enabled robust adhesion and proliferation of hESC-RPE cells and allowed direct subretinal injection via a minimally invasive granular gel format.

Results: Electroretinogram (ERG) analysis revealed significantly enhanced B-wave amplitudes in Royal College of Surgeons (RCS) rats receiving hESC-RPE-loaded Fib@GHMS, indicating improved visual function. Histological evaluation at 8 weeks post-transplantation demonstrated higher retention of transplanted cells, preservation of photoreceptors, and maintenance of the inner nuclear layer compared to control groups.

Conclusions: Our Fib@GHMS-based delivery system significantly improves the therapeutic performance of hESC-RPE cell transplantation, offering a promising strategy for retinal regeneration. This minimally invasive, biomaterial-assisted approach may open new avenues for clinical translation in the treatment of retinal degenerative diseases.

Abstract No.: 202564

Virus-Inspired Nanozymes for Two-Dimensional Biomimetic Penetration and Long-Acting Ferroptosis Inhibition in Treating Dry Eye Disease

First Author: Qingdong BAO

Co-Author(s): Qinghua LI

Purpose: Dry eye disease (DED) has become a global health concern impacting approximately 1.487 billion individuals, yet it remains unresolved. Ferroptosis, a form of non-apoptotic corneal epithelial cell death, has recently emerged as a significant focus in the therapeutic management of DED. However, owing to the corneal epithelial barrier and oxidative stress-inflammation crosstalk, no therapeutic strategy can precisely and sustainably inhibit ferroptosis in DED.

Methods: This study pioneers a transformative paradigm in DED therapy by ingeniously fusing a virus-like hollow mesoporous cerium oxide nanozyme (vHMCe) core-loaded with cyclosporin A (CsA) and surface-functionalized with rabies virus glycoprotein 29 (RVG29) to achieve long-acting ferroptosis inhibition in DED treatment. Structurally, CsA@vHMCe-RVG mimics the roughness and irregularity of viral surfaces, endowing spike-assisted adhesion to corneal epithelial cells.

Results: Functionally, RVG interacts with nicotinic acetylcholine receptors (nAChRs), triggering receptor-mediated transmembrane transport for efficient internalization. The cerium valence cycle and CsA can synergistically block oxidative stress-inflammation interactions to achieve long-acting ferroptosis inhibition in DED. CsA@vHMCe-RVG attains scavenging rates of 95% and 90% for intracellular reactive oxygen species and ferroptosis levels in corneal epithelial cells under continuous hydrogen peroxide stimulation four times.

Conclusions: The integration of biomimetic transmembrane effects and ferroptosis inhibition offers an innovative strategy with significant clinical application potential for DED treatment.

Visual Sciences

Abstract No.: 205113

A Microglia-Dependent Pathological Engram of Amblyopia

First Author: Yixiao FU

Co-Author(s): Yiru HUANG, Minbin YU

Purpose: To investigate microglial alterations in the primary visual cortex (V1) and their role in amblyopia pathogenesis using single-nucleus RNA sequencing

(snRNA-seq) and experimental validation in a long-term monocular deprivation (LTMD) mouse model.

Methods: LTMD spanning the critical period was conducted in mice from postnatal day 19 (P19) to P33. SnRNA-seq was performed on the contralateral V1 at P60. Microglia were depleted in mice using PLX5622. Immunohistochemistry and flow cytometry were used to identify pathological changes of microglia in V1. Two-photon calcium imaging was used to evaluate the tuning properties of excitatory neurons in V1. Optomotor response testing was used to evaluate the visual acuity.

Results: SnRNA-seq identified different classes of neurons and glial cells. Differential gene expression analysis of microglia revealed that LTMD-upregulated genes were enriched for synaptic pruning and inflammation processes, while downregulated genes were involved in synaptic transmission. A microglia subpopulation highly expressing triggering receptor expressed on myeloid cells 2 (TREM2) and synaptic pruning genes increased after LTMD. Immunohistochemistry and flow cytometry confirmed reduced excitatory synapses and increased TREM2 expression in microglia with a more activated state after LTMD. The depletion of microglia during LTMD not only partially rescued synapse density and visual acuity but also restored ocular dominance index with direction selectivity of excitatory neurons in V1.

Conclusions: LTMD leads to an increased TREM2 expression in microglia in the contralateral V1, which may contribute to amblyopia development via excessive synaptic pruning. The microglial elimination partially reverses visual functional deficits caused by LTMD, highlighting the pathogenic role of microglia in amblyopia.

Abstract No.: 206909

A Systematic Review on Alteration of Ocular Surface Microbiome (OSM) Related to Pandemic – COVID-19 and Beyond

First Author: Yan Hei Yannis CHAN

Co-Author(s): Kelvin KI CHONG, Kenneth Kh LAI, Calvin Cp PANG, Clement Cy THAM, Kin Yip YIN

Purpose: The COVID-19 pandemic significantly impacted ocular health, especially disruptions in OSM. This review examines how COVID-19 affects OSM through direct viral effects, post-COVID symptoms and pandemic-induced behavioural changes.

Methods: Five studies were reviewed from PubMed and Web of Science using the keywords: "ocular surface microbiome" and "COVID-19", etc.

Results: SARS-CoV-2 alters OSM significantly ($p < 0.05$), especially the dominant phyla listed below (Spörri et al. 2024), with changes persisting post-recovery. Proteobacteria levels decreased in acute (47.46%) and recovered (48.88%) COVID-19 groups compared

to healthy controls (73.59%), while Actinobacteria, Bacteroidota, and Firmicutes increased significantly. Functional profiling showed heightened membrane transport and prokaryotic activities in the acute-COVID-19 group, while the recovery group exhibited increased cell growth/death and fatty-acid metabolism. These may contribute to ocular diseases like conjunctivitis and dry eye. (Lin et al. 2024) Post-COVID symptoms are linked to microbiome disruption. SARS-CoV-2 may alter the ocular microenvironment, leading to papillary or follicular conjunctival changes, MGD, and evaporative dry eye. (Wan et al, 2022) Behavioural changes also impact OSM. Humans touch their faces 9.5 to 162 times per hour, with one-third involving the eyes, which helps maintain microbiome diversity. Yet mask use reduces spontaneous face-touching frequency and contributes to microbiome dysbiosis. Besides, mask-associated dry eye (MADE) destabilises the tear film and alters microbial homeostasis. (Burgos-Blasco et al, 2022) (Spencer et al, 2021)

Conclusions: This review highlights microbiome changes linked to COVID-19 and pandemic-induced behaviours. Small sample sizes and methodological variability call for standardized, longitudinal studies to elucidate the OSM's role in post-pandemic ocular health.

Abstract No.: 200369

Activation Patterns for Sensory Regions, Laterality, Balance, and Visual Space in Early- and Late-Blind Brains Following Visual-to-Audio Sensory Substitution Training

First Author: Giles **HAMILTON-FLETCHER**

Co-Author(s): Kevin **CHAN**, Matthew **MURPHY**, Amy **NAU**, Patrick **PASZKOWSKI**

Purpose: Sensory substitution devices (SSDs) can translate visual images into patterns of sound. These SSD signals can activate the visual cortex in trained early/late-blind users, but their basic neural processing and 'visual' representation of SSD sounds in the brain remain largely undetermined.

Methods: We trained 6 early-blind (4F, age=60.5±3.1) and 9 late blind (3F, age=60.0±10.1) to interpret SSD soundscapes of horizontal and vertical travelling bars, similar to retinotopic mapping stimuli, and obtained structural and functional brain images using a 3T MRI scanner. We used NORDIC de-noising for functional images alongside standard BrainVoyager preprocessing pipelines and population-receptive field (pRF) analyses. We extracted voxels and their pRF-values (X, Y, RF-size) that represent substituted 'visual'-space, for voxels both exceeding $R>0.2$ and within primary, secondary, and tertiary visual/auditory cortices.

Results: Relative to the late-blind, early-blind participants had significantly more active voxels in the right visual cortex ($p<0.001$, $M=67.2\pm10.5$; $M=24.7\pm21.8$) but not left visual cortex (NS) or left/

right auditory cortices (NS; NS). The ratio of visual: auditory cortex activation was significantly higher ($p=0.036$) for early blind ($M=0.46\pm0.19$) than late blind ($M=0.27\pm0.12$), with a more right-hemisphere lateralized ratio ($p=0.028$; $M=1.58\pm1.11$) than the late-blind ($M=0.74\pm0.29$). Early-blind represented more unique pRF locations ('visual'-space) for voxels in the bilateral visual cortices ($p=0.036$, $M=17.5\pm4.91\%$) than the late-blind ($M=10.9\pm5.66\%$), which was significant for the right visual cortex ($p<0.001$; $M=11.8\pm2.6\%$; $M=4.3\pm1.6\%$) but not the left visual cortex (NS).

Conclusions: Our findings reveal significant differences in cortical activation between early and late-blind participants during SSD learning in specific areas, from visual: auditory cortex balance, to hemispheric laterality, and their representations of substituted visual space.

Abstract No.: 204586

Activation or Overexpression of TASK-3 Protects Retinal Ganglion Cells and Visual Function After Injury

First Author: Jiali **ZHANG**

Co-Author(s): Ruotian **JIANG**, Longqian **LIU**, Yuncheng **LUO**, Xiangyi **WEN**

Purpose: Retinal ganglion cells (RGCs) are located in the innermost layer of the retina, and their axons form the optic nerve, projecting visual signals to the visual cortex center of the brain. Previous studies have shown that the TASK-3 channel is involved in regulating the excitability of RGCs. This study explores whether activating or overexpressing TASK-3 can protect the number of RGCs and rescue visual function after injury.

Methods: RGC injury was performed by optic nerve crush (ONC) surgery. The TASK-3 specific agonist CHET3 was applied on the surface of the eye once a day for one week. TASK-3 activation was tested using patch-clamp electrophysiology. The adeno-associated virus (AAV) approach was used to overexpress TASK-3 in RGCs one week after ONC. RGCs were counted under a fluorescent microscope. Visual function was assessed by the visual cliff test, the visual water maze, and the flash visual evoked potential (f-VEP). The pupillary light reflex (PLR) was used to detect the non-image-forming functions. The quantification of TASK-3 was evaluated by RNAscope.

Results: The CHET3-treated mice retained more RGCs after ONC than the control one, with improved depth perception, visual acuity, contrast sensitivity, and higher f-VEP amplitude. Overexpressing TASK-3 specifically in the RGCs of ONC mice significantly restored visual acuity and contrast sensitivity and enhanced PLR constriction under dim light.

Conclusions: Activating TASK-3 can protect the RGCs from cell death and visual function loss in ONC mice.

Overexpressing TASK-3 specifically in RGCs after ONC injury can restore the image-forming and nonimage-forming behaviors.

Abstract No.: 206753

Acute Effects of Daily Red Wine Consumption on Retinal and Cerebral Blood Flow in Healthy Young Adults and an Animal Model

First Author: Xiaofeng **ZHU**

Co-Author(s): Yi **XU**

Purpose: Acute effects of a daily dose of red wine may cause deterioration of visual function; however, there is limited information on healthy individuals. This study aims to investigate the acute effects of daily red wine consumption on visual function and retinal microvasculature in healthy young adults through a randomized self-controlled design, and to explore the molecular mechanisms using an animal model.

Methods: In a study of healthy young adults, 27 adults with follow-up at baseline, 0.5 h, and 2 h after consuming 300 mL of either red wine or water underwent blood biochemistry, visual function, morphology, and blood flow of retinal and choroidal vasculatures, and cerebral blood flow (CBF) evaluation.

Results: Acute red wine consumption caused abnormal changes in retinal function (mERG) that preceded changes in vision. Macular vessel diameter index (VDI) increased significantly at 0.5 h, but decreased significantly at 2 h, despite increased regional CBF following red wine consumption, which was consistent with increased choroidal thickness and decreased retinal thickness. Animal experiments conducted on Brown Norway rats demonstrated a significant decrease in retinal VDI and vessel area density (VAD) associated with increased ROS production following red wine administration, as well as decreased eNOS and increased ET-1 levels in the retina.

Conclusions: Consequently, red wine consumption caused abnormal changes in retinal function and microvascular constriction in healthy young adults, and an animal model suggested that the underlying mechanism may involve the regulation of eNOS and ET-1 levels in the retina. These findings imply the potential detrimental effects of drinking habits on individuals with retinal ischemic diseases.

Abstract No.: 201064

Altitude-Induced Color Vision Impairment: A Novel Rapid Hue-Discrimination Assay for Acute Hypoxic Exposure

First Author: Yuchen **WANG**

Co-Author(s): Xuemin **LI**, Siru **LIU**

Purpose: To quantify and track acute changes in hue discrimination under simulated high-altitude (3,500–4,500 m) low-pressure hypoxia, and to validate

a new rapid, software-based test that overcomes the portability and time limits of the Farnsworth-Munsell 100-Hue test.

Methods: Fourteen healthy adults with normal color vision in a hypobaric chamber. Eight sequential conditions (ground → 3,500 m → 4,000 m → ... → ground) were tested. Custom “Rapid Hue-Discrimination System” (Toward Pi Ltd.) running on a 14-inch calibrated 120 Hz display. 7 wavelength bands (400–700 nm) tested; minimum hue difference (MHD) resolvable recorded (1 nm precision).

Results: Red light showed the poorest and most variable discrimination (MHD 28.7 → 22.4 nm). Forty minutes of altitude acclimatization significantly improved cyan and purple discrimination (MHD reduced by 20–35 %) but slightly worsened orange and yellow, while other bands remained stable. The overall wavelength-MHD curve preserved the classic pattern with troughs at ~500 nm and ~600 nm and peaks near 550 nm and after 620 nm. The normalized score explained 81 % of MHD variance. Testing time dropped from 25 s per hue on first exposure to 8–10 s thereafter, yielding a total test duration of ~5 min and confirming the tool’s efficiency and robustness.

Conclusions: Acute hypoxia selectively degrades red-light discrimination, while short acclimatization benefits cyan and purple hues. The software-based assay delivers clinically relevant metrics (MHD + score) within ~5 min, feasible for cockpit, alpine, or space environments.

Abstract No.: 206980

Associations Between Low-to-Moderate Alcohol Consumption on Night Vision Performance: A Systematic Review

First Author: Stephany Wing Lam **TAI**

Co-Author(s): Chloe Hei Ching **CHEUNG**, Kelvin KI **CHONG**, Kenneth Ka Hei **LAI**, Calvin Cp **PANG**, Clement Cy **THAM**

Purpose: To investigate how alcohol consumption impairs critical night vision parameters on humans and increases the risk of accidents in low-light conditions.

Methods: A search in PubMed, ScienceDirect, and Ovid Medline identified 14 studies (1959–2023) involving 1,182 subjects across 7 countries, according to PRISMA guidelines. Studies included acute alcohol administration (12 studies) and chronic vs non-alcoholic consumption (2 studies). Participants aged 18–88 with normal or corrected-to-normal visual acuity. Blood alcohol concentrations (BAC) ranged from 0.011%–0.08%; while breath alcohol concentrations ranged from sub-legal limit (0.25mg/L)–0.40mg/L. Testing environments included photopic, mesopic, dark room, and low-illumination conditions. Visual functions tested include contrast sensitivity (10 studies), dark adaptation (3 studies), visual disturbance (3 studies),

glare effects (2 studies), and retinal straylight (3 studies).

Results: Twelve studies consistently report that alcohol intake significantly impairs night vision parameters. Contrast sensitivity was reduced post-alcohol at concentrations as low as BAC 0.043%. Another study found reductions at 4 cpd and angular frequencies 1, 24, 48 cycles/360° ($P<0.05$). In two studies, visual disturbance indices correlated with alcohol ($r^2=0.372$, $P<0.001$) and ($\rho=-0.467$, $P=0.004$). Alcohol affected dark adaptation and glare recovery, with chronic alcoholic drivers exhibiting doubled recovery time versus controls. Retinal straylight increased significantly post-alcohol, contributing to disability glare ($P<0.05$). Retinal-image quality also deteriorated alongside increased objective scatter indices ($P<0.05$).

Conclusions: Alcohol consumption significantly impairs multiple night vision functions even at sub-legal concentrations, affecting performance in outdoor activities, emergency situations, and navigation tasks requiring optimal low-light vision. Future research should establish standardized assessment protocols and investigate protective interventions for alcohol-related visual impairment.

Abstract No.: 201555

Brain Care and Incidence of Age-Related Eye Diseases: A Prospective Study

First Author: Jun YU

Co-Author(s): Li Jia CHEN, Chi Pui PANG, Clement C. THAM, Jason C. YAM, Yuzhou ZHANG

Purpose: The brain care score (BCS) is a novel systemic composite index capturing modifiable determinants of brain care. In this study, we aimed to evaluate the associations of BCS with the incidence of age-related eye diseases and to examine the modifying effects of age and genetic susceptibility.

Methods: In this prospective cohort study, we included 382,221 UK Biobank participants aged 40–69 years without cataract, glaucoma, or age-related macular degeneration (AMD) at baseline. BCS (0–19 points) was derived from physical, lifestyle, and social-emotional factors. Multivariable Cox regression estimated hazard ratios (HRs) for incident cataract, glaucoma, and AMD. Gene–BCS interactions were assessed using polygenic risk scores (PRSs).

Results: Over a median follow-up of 13.37 years, there were 44,033 cataract, 9,280 glaucoma, and 6,754 AMD events. Compared with the lowest BCS quintile, the highest quintile had reduced risks of cataract ($HR=0.89$), glaucoma ($HR=0.92$), and AMD ($HR=0.90$; all P -trend <0.01). Per 5-point BCS increase, protective effects were greater in participants aged 40–50 years, with 22% and 28% lower risks for cataract and glaucoma. Higher BCS partly offset cataract genetic risk

(P interaction <0.001). The joint lowest BCS–highest PRS category conferred the highest risks for each outcome.

Conclusions: Higher BCS is associated with lower risks of cataract, glaucoma, and AMD, particularly in middle-aged individuals and those with high genetic risk. Early improvement of BCS in primary care may help reduce the burden of these eye conditions.

Abstract No.: 204279

Brain-Formed Estrogen Is Required to Stimulate Retina Regeneration in Zebrafish

First Author: Zulvikar Syambani ULHAQ

Purpose: To demonstrate the cellular localization and potential function of AroB in the zebrafish eye.

Methods: Adult male zebrafish were exposed to 17β -estradiol, subjected to retinal injury, and received intravitreal injections of drugs or AroB morpholinos. Proliferating and apoptotic cells were labeled with EdU, BrdU, and TUNEL. Retinal sections underwent immunohistochemistry for key markers, and labeled cells were quantified.

Results: We successfully identified that AroB is not exclusively expressed in Müller glial (MG) cells, but also in interneuronal cells, photoreceptor cells, and lens epithelial cells. Furthermore, the addition of estradiol (E2) increased AroB expression and altered its distribution, resulting in a positive signal located in ganglion cells. We also demonstrated that E2 acts as a neuroprotective and neuroregenerative agent by decreasing the number of apoptotic cells and increasing the number of proliferating cells in the injured retina. In addition, we provide evidence that AroB is involved in stimulating MG cell activation in response to retinal injury.

Conclusions: Altogether, our findings strongly suggest that E2 produced in the eye by AroB, along with its downstream signaling through genomic pathways, mediates the robust regenerative capacity of the zebrafish retina following injury.

Abstract No.: 206258

Cortical Rehabilitation in Neuro-Adaptation Failures Improves Functional Visual Ability After Multifocal Implants: A Randomized Controlled Trial

First Author: Lionel Raj DANIEL RAJ PONNIAH

Purpose: Photoc phenomena, neuro-adaptation failures are major concerns after MFIOs. This study evaluated a patient-specific, visual perceptual learning(VPL) therapy regimen using Gabor patches (grey level gratings, specific for receptive visual fields) for improving vision & contrast sensitivity function(CSF) in patients not satisfied after MF-IOL implantations.

Methods: A prospective, controlled-randomized study. Adults (50-70 yrs) with uneventful MFIOLs, over 24 weeks post-surgery, BCVA worse than 20/40 with sub-optimal Contrast(CSF), complaining about vision quality, were randomized in a 2:1 ratio into Treatment(G1), in which computer-based perceptual therapy using Gabor patches amidst co-linear flankers was employed & Control(G2) arms. The study had 2 phases (screening + treatment). Mid-training (Post 20 sessions), Post 40 training sessions, Post-therapy follow-up by 6 months were evaluated for improvements in BCVA distance & near (ETDRS) & CSF at spatial frequencies of 3, 6,12,18 CPD with FACT sine wave grating, using Friedman tests for repeated measures.

Results: Thirty cases were randomized into a 2:1 ratio into treatment and control arms. Subgroup consisted of 16 Trifocals (PanOptix) and 14 Bifocals (Tecnis). The average improvement after VPL therapy is 2.1 LogMar lines in the Treatment arm ($p<0.0001$), whereas no significant improvements were observed among the controls. Tests for repeated measures showed that 83% subjects improved in Contrast Sensitivity from baseline by over 50% (at spatial freq. of 3,6,12 & 18 CPD) in the Treatment Group(G1, all $p<0.0001$), whereas no significant improvements were observed amongst the controls.

Conclusions: Sequential, post-operative, patient-specific, cortical stimulation improved vision & CSF in patients with dissatisfied Multi Focal-IOL subjects & acts as proof of concept of improving neural connections at cortical levels. The key to optimizing vision following MF-IOLs lies in training the brain to improve neuroadaptation processes. Phaco surgeons could consider this no-side-effect postoperative visual physiotherapy measure after all MF-IOL implantations.

Abstract No.: 204412

Design and Validation of a Transformer-Based Multitask Framework for Forecasting Glaucoma and Time to Disease Onset

First Author: Lijie **PAN**

Co-Author(s): Pheng-ann **HENG**, Hanruo **LIU**, Ningli **WANG**, Xi **WANG**, Jian **WU**, Xikai **YANG**

Purpose: To offer a promising solution for glaucoma detection through the analysis of sequential fundus photography using artificial intelligence (AI).

Methods: In this study, we developed a transformer-based multitask framework designed to predict the onset of glaucoma and estimate the time interval to glaucoma onset. The model utilizes a long-term follow-up dataset and integrates both spatial and temporal information to identify early signs of glaucoma progression. Model performance was assessed using various metrics, including the area under the ROC curve (AUC), accuracy, sensitivity, specificity, and F1 score for glaucoma prediction, as well as RMSE, MAE,

R^2 , and Pearson correlation coefficient (PCC) for time-to-onset prediction.

Results: The transformer-based multitask model demonstrated outstanding performance, achieving an AUC of 0.996, accuracy of 99.2%, sensitivity of 98.0%, and specificity of 99.3%, significantly outperforming other models as well as human ophthalmologists in glaucoma prediction. For the time interval prediction task, the model achieved an RMSE of 2.4384, MAE of 1.6996, R^2 of 0.8466, and PCC of 0.9485, indicating high accuracy in estimating the time to glaucoma onset.

Conclusions: The results highlight the potential of the transformer-based multitask model as a highly accurate tool for both glaucoma prediction and the estimation of the time to disease onset. This AI framework holds significant promise as a complementary tool in clinical practice, offering advancements in glaucoma screening and management, particularly in underserved populations.

Abstract No.: 207300

Development of a Standardized Thai Continuous-Text Reading Chart for Clinical and Research Use

First Author: Tanaporn **WILAI PHUNRATTANA**

Co-Author(s): Suksri **CHOTIKAVANICH**

SUNTHORNYOTHIN, Akarawit **EIAMSAMARNG**,

Piyaphat **JARUNIPHAKUL**, Theerajate **PHONGSUPHAN**, Thanatcha **POOSANAPANYA**

Purpose: To develop and validate standardized Thai continuous-text reading charts for assessing near visual acuity and reading performance in Thai-speaking individuals.

Methods: Fifty-nine Thai participants (20–35 years) with normal vision were enrolled. Sentences were created at a Grade 4 level, each with seven words and 7–9 syllables, paired into 15–17 syllables. Sentences were grammatically reviewed and calibrated using the x-height of the TH SarabunPSK font. Only sentences with corrected words per minute (CWPM) within the mean ± 1 SD were included. Two charts, each with 13 sentence pairs in logarithmic print sizes, were produced. Reading assessments were conducted at 40 cm under standardized luminance. Reliability was assessed using Cronbach's alpha, and inter-rater correlation was measured with Pearson's r .

Results: Of 38 candidate pairs, 26 met the inclusion criteria, yielding a mean reading speed of 239.1 ± 7.6 wpm (95% CI, 236.0–242.2). Cronbach's alpha showed excellent internal consistency (0.975 for 38 pairs; 0.967 for 26 pairs). Test-retest after one week confirmed repeatability (244.5 ± 15.1 wpm). Preliminary comparisons with the English Radner chart showed comparable maximum reading speed and critical print size, further supporting the external validity of the

Thai charts and their alignment with international standards.

Conclusions: The Thai continuous-text reading charts provide a reliable, reproducible, and valid tool for assessing reading performance. With careful linguistic and typographic design, they ensure consistency and cultural relevance. The inclusion of multiple acuity notations (M-units, logMAR, Snellen) enhances international comparability, making the charts applicable in both clinical practice and research, including low-vision rehabilitation and intraocular lens evaluation.

Abstract No.: 206224

Disease and Lifestyle Influences on the Ocular Surface Microbiome: A Systematic Review

First Author: Kin Yip **YIN**

Co-Author(s): Yan Hei Yannis **CHAN**, Kelvin Kl **CHONG**, Kenneth Kh **LAI**, Calvin Cp **PANG**, Clement Cy **THAM**

Purpose: To investigate the disease and lifestyle factors that produce a significant influence on the core Ocular Surface Microbiome (OSM), which comprises seven genera: *Corynebacterium*, *Staphylococcus*, *Acinetobacter*, *Streptococcus*, *Pseudomonas*, *Cutibacterium* and *Bacillus* (Ling et al., 2025).

Methods: This review included 70 studies with 32 pathological and 7 lifestyle factors from PUBMED and Web of Science using keywords “Disease,” “Ocular Surface Microbiome,” and other sources to summarize alterations to the core OSM genera caused by different disease and lifestyle factors.

Results: Twenty-nine out of 32 disease factors (90.6%) and 3 out of 7 lifestyle factors (42.9%) display different degrees of impact on the composition of the core OSM. Notably, for disease factors, dry eye disease, bacterial keratitis, and Steven-Johnson Syndrome significantly increase/decrease ($p < 0.05$) the relative abundance of 6 out of 7 genera in the core OSM. For lifestyle factors, wearing contact lenses is observed to alter the abundance of 5 out of 7 genera significantly in the core OSM. These factors, which produce alterations in multiple genera, are considered to have relatively greater effects on the core OSM. Conflicting results were observed between studies on the same diseases, which might be attributed to differences in methodology.

Conclusions: Although impactful factors have been identified, common limitations, including small sample sizes, hinder the generalizability of these studies. Larger-scale studies with standardized protocols are required in the future to further explore this topic.

Abstract No.: 203571

Dynamic Longitudinal Evaluation of Retinal Optical Coherence Tomography Angiography and Electrophysiology in Acute Hypoxia Exposure

First Author: Xinli **YU**

Co-Author(s): Li **DING**, Deteng **HUANG**, Xuemin **LI**, Yicong **PENG**

Purpose: The purpose of this study was to assess changes in retinal function and structure during acute dynamic hypoxic exposure at high altitude and to identify critical altitude and sensitivity indices for changes in retinal function and structure.

Methods: In this longitudinal study, 21 healthy volunteers were recruited, and their OCTA and ERG were collected at ground level (altitude 1), 3500 m (altitude 2), 4000 m (altitude 3), 4500 m (altitude 4), and back to ground level (altitude 5). Generalized estimating equation analysis was used to compare the differences in OCTA and ERGs at different altitudes. Pearson correlation analysis was used to analyze the correlation between ERGs and OCTA.

Results: Optical coherence tomography angiography (OCTA) revealed that superficial vascular density (SVD) in the inferior and temporal regions of the retina (12–18 mm) significantly increased at 4,000 meters ($P < 0.05$). Both SVD and superficial small vessel density (SSVD) significantly increased (3–18 mm) at 4,500 meters ($P < 0.05$). Concurrent electrophysiological retinal electroretinography (ERG) revealed that at 4,500 meters, the amplitude of the photopic negative response (PhNR) b-wave and photopic flash b-wave significantly decreased ($P < 0.001$). Crucially, superficial perfusion area (3–12 mm) showed a significant positive correlation with the amplitude of light-adapted flash ERG and oscillatory potentials (OPs) ($P < 0.001$), particularly in the upper and lower regions.

Conclusions: These results suggest that altered neurologic function is associated with altered retinal microcirculation and could provide new insights into the progression and determination of HAR. In addition, the density of blood vessels in the inner retinal layer was the first to increase significantly at altitudes above 4000 m, further validating the utility of OCTA as a sensitive biomarker for early HAR detection.

Abstract No.: 205405

Early Processing on Occipital Visual Cortex for Exogenous Attention Based on Eye of Origin Contrast

First Author: Chen **WU**

Co-Author(s): Zhikuan **YANG**, Jinyou **ZOU**

Purpose: Exogenous attentional effects driven by eye-of-origin contrast are demonstrated when attention is captured by a singleton presented to one eye among distractors presented to the other. This phenomenon

has been proposed as a hallmark of the V1 Saliency Hypothesis. We investigated its neural basis using electroencephalogram (EEG) recordings in healthy adults and further examined whether exogenous attention is impaired in patients with intermittent exotropia (IXT).

Methods: We combined electrophysiological and behavioral approaches to examine exogenous attention. Thirty healthy adults underwent EEG recordings while passively viewing arrays of bar stimuli in which a singleton could differ in eye of origin (E), orientation (O), both features (EO), or be absent (uniform baseline, U). Event-related potentials (ERPs) evoked by the singleton were compared with the baseline to identify early attention-related responses. In parallel, we evaluated behavioral performance by assessing visual search accuracy in twenty-five patients with IXT and matched healthy controls.

Results: The attentional effects emerged at 60–90ms post-stimulus, with clear polarity reversals regarding the vertical locations of the stimulus: a significant increase in voltage relative to the baseline condition for the singletons in the lower visual field (E: $t=5.45$, O: $t=7.66$, EO: $t=6.90$; $p < 0.001$) while a significant decrease in voltage relative to the baseline condition for the singletons in the upper visual field (E: $t=-6.13$, O: $t=-3.55$, EO: $t=-4.59$; $p < 0.001$). In behavioral performance, patients with IXT showed no reduction in accuracy under the E condition. In contrast, under the O and EO conditions, IXT patients demonstrated both reduced accuracy and longer reaction times compared with controls.

Conclusions: An early occipital response associated with the exogenous attention by eye of origin, with similar patterns and latency as the response for exogenous attention by orientation, supporting the V1 Saliency Hypothesis. Patients with IXT showed specific attention deficits related to binocular, but not monocular, feature representation. These deficits are likely caused by impairments to V1 binocular neurons in IXT.

Abstract No.: 206223

Effect of Compound Treatment on Lens Gradient Refractive Index

First Author: Kehao **WANG**

Co-Author(s): Masato **HOSHINO**, Barbara **PIERSCIONEK**, Yutian **PU**

Purpose: The eye lens has a gradient distribution of refractive index (GRIN) to help form sharp images on the retina. Distortions to the GRIN can be caused by age-related lens disorders. Studies have shown that pharmaceutical agents can restore the elasticity or transparency of the lens, presenting a promising strategy for treating presbyopia and cataract. This study investigates the effect of these compounds on the lens's optical properties.

Methods: 25-hydroxycholesterol, lipoic acid, and lanosterol were applied both as eye drops to aged C57BL/6J mice and dissolved in medium to incubate enucleated porcine lenses. For the two eyes from the same mouse, one was treated with the compound and the other used as the control. Eye drops were given every 2 days for a total duration of 6 weeks, while lens incubation lasted for 48 hours. All treated lens samples were measured using the synchrotron radiation based Talbot-Interferometer at SPring8 Japan to obtain the three-dimensional distribution of refractive indices.

Results: GRIN profiles were reconstructed using MatLab and different compounds were found to act on lens optical properties in different regions: 25-hydroxycholesterol reduced the local irregularities and sharpen the peripheral steepness of the GRIN profile, lipoic acid increased the width of the central flat region while decrease the thickness of the peripheral region of the GRIN, lanosterol reduced both the width of the central flat region and the peripheral steepness.

Conclusions: Compound treatments can change the lens internal refractive index distribution, reduce the structural discontinuities that cause light scatter and alters the lens optical refractive power.

Abstract No.: 200560

Evaluation of Stereopsis and Fusion in Patients With Vestibular Vertigo

First Author: Muhammad Adri **MOHAMED SHAFIT**

Co-Author(s): Ismail **SHATRIAH**

Purpose: Normal binocular vision is important to retain the visual image on the retina during the vestibulo-ocular reflex, affecting postural stability. Thus, the presence of binocular vision dysfunction in vertigo warrants an evaluation. This study is to compare the means of stereopsis and fusional vergence between patients with vestibular vertigo and control subjects.

Methods: A comparative cross-sectional study was conducted in the Ophthalmology Clinic, Hospital Universiti Sains Malaysia, Kelantan, from January 2019 til February 2021 among patients with vestibular vertigo and the control group. Fifty-seven patients were included in this study, with 57 controls who are in the same age range of 30 to 60 years old. Both groups were evaluated for stereopsis and fusion vergence amplitude once they fulfilled the required criteria. The far and near stereopsis were tested using the M&S Smart System II PC-Plus and the Titmus Test, respectively. Fusional vergence was measured using a prism bar.

Results: Parametric analysis of stereopsis revealed a statistically significant difference in mean stereopsis at near ($p < 0.05$) and an insignificant difference in mean stereopsis at far ($p > 0.05$) between vestibular vertigo patients and the control group. Independent t-test

showed a statistically significant difference in mean fusional vergence measurement ($p>0.05$) between these two groups, which consists of near and far negative and positive fusional vergence for break and recovery point.

Conclusions: There was a statistically significant difference in mean near stereopsis and fusional vergence between patients with vestibular vertigo and the control group. However, there was no significant difference in the mean for far stereopsis.

Abstract No.: 201978

Factors Mediating Alterations in Dynamic Visual Acuity and Color Vision Under Short-Term High-Altitude Exposure

First Author: Jiaying **XIE**

Co-Author(s): Li **DING**, Xuemin **LI**, Ziyuan **LIU**, Yuchen **WANG**

Purpose: To investigate factors mediating alterations in dynamic visual acuity (DVA) and color vision during short-term high-altitude exposure.

Methods: Participants underwent visual function test, including DVA test and color vision test, as well as ocular examinations including optical biometry, IOP, and refractive measurements, ocular surface evaluation, and electrophysiology test at the ground, 3,500m, 4,000m, 4,500m, and at the end of the experiment in a high-altitude complex environment simulation chamber. Correlation analysis, and multilevel mediation analysis combined with a mixed-effects model were constructed to ascertain the factors mediating alterations in visual function among different altitudes.

Results: Correlation analysis showed that DVA and color vision were significantly correlated with several ocular parameters under different settings. Multilevel mediation analysis indicated that for DVA, LLT, TMH, and photopic flash ERG b-wave were identified as significant mediators, with increased LLT, increased TMH and decreased photopic flash ERG b-wave amplitude mediated DVA declined (increased LogMAR). Concerning color vision, IOP, TBUT, TMH, photopic flash ERG a-wave, and photopic flash ERG b-wave were determined as significant mediators, with reduced IOP, TBUT, TMH, and photopic flash ERG a- and b-wave amplitude (absolute value) mediated color vision deterioration (increased nanometer).

Conclusions: LLT, TMH, and photopic flash ERG b-wave were factors mediating alterations in DVA under short-term high-altitude hypoxic exposure. IOP, TBUT, TMH, photopic flash ERG a-wave, and photopic flash ERG b-wave were factors mediating alterations in color vision under short-term high-altitude hypoxic exposure.

Abstract No.: 203582

HOTAIR Interaction With WTAP Promotes PCO Formation via m6A-Dependent THBS1 Expression

First Author: Xi **CHEN**

Co-Author(s): Chenshuang **LI**, Hong **YAN**, Siqi **ZHANG**

Purpose: To explore the role of long non-coding RNAs (lncRNAs) and N6-methyladenosine (m6A) in posterior capsule opacification (PCO) and their underlying mechanisms.

Methods: The localization of lncRNAs and proteins was analyzed using fluorescence in situ hybridization and immunofluorescence staining. RNA m6A quantification, RNA immunoprecipitation, co-immunoprecipitation, MeRIP-seq, MeRIP-qPCR, western blotting, wound-healing, and Transwell assays were applied to elucidate the underlying mechanisms.

Results: The levels of lncRNA HOX transcript antisense intergenic RNA (HOTAIR) and m6A methylation increased significantly during epithelial-mesenchymal transition (EMT) in lens epithelial cells (LECs). HOTAIR promoted EMT and m6A methyltransferase activity but had no effect on methyltransferase activity and was not modified by m6A. Nevertheless, HOTAIR interacted with WT1-associated protein (WTAP), a key m6A writer protein, facilitating WTAP-mediated recruitment of METTL3-METTL14 heterodimers and enhancing m6A modification. The HOTAIR/WTAP complex elevated m6A levels, thrombospondin 1 (THBS1) expression, and EMT in LECs.

Conclusions: lncRNA HOTAIR enhances the assembly of the WTAP/METTL3/METTL14 complex and promotes EMT in LECs by upregulating m6A modification and THBS1 expression. Targeting the HOTAIR/WTAP/THBS1 pathway may prevent or treat PCO.

Abstract No.: 208209

Intraocular Iron Injection Induces Oxidative Stress, Geographic Atrophy-Like Features and Disease-Related Macroglia Activation

First Author: Yingrui **LIU**

Co-Author(s): Ming-ming **YANG**

Purpose: Iron accumulation has been implicated in the pathogenesis of age-related retinal diseases, including age-related macular degeneration (AMD). This study aims to explore the chronic features and mechanisms associated with iron-induced retinal damage in a mouse model.

Methods: Mice were given intravitreal (IVT) ferric ammonium citrate (FAC). Retinal features were analyzed through autofluorescence (AF), bisretinoid quantification, and localization of carboxyethyl pyrrole (CEP), an oxidized adduct associated with AMD. Additionally, quantitative PCR was used to measure

antioxidant and inflammatory responses in the retinal pigment epithelium (RPE) and neural retina.

Results: IVT FAC injection led to progressive RPE death resembling human geographic atrophy. Green AF appeared in photoreceptors, followed by gold AF in rod outer segments, RPE, and subretinal myeloid cells. The green AF signature suggested flavin adenine dinucleotide, while gold AF correlated with increased bisretinoid all-trans-retinal dimers. CEP accumulation was observed sequentially in photoreceptors, RPE, and myeloid cells. RNA-seq revealed upregulation of disease-related microglia (DAM)-specific genes. TREM2 gene deletion inhibited the activation of DAM and phagocytosis of lipid deposits, further exacerbating retinal degeneration.

Conclusions: The findings provide new mechanistic insights into the potential toxicity of retinal iron accumulation in AMD. The mouse model offers a valuable tool for testing therapeutic interventions such as antioxidants, iron chelators, and anti-inflammatory treatments.

Abstract No.: 208215

Iron Chelator Deferiprone Restores Iron Homeostasis and Inhibits Retinal Neovascularization in Experimental Neovascular Age-Related Macular Degeneration

First Author: Yuan **XU**

Co-Author(s): Qian **CHEN**, Xiaodong **CHEN**, Shiya **HUANG**, Shiyang **LI**, Xiang **LIN**, Zuguo **LIU**, Xin **WANG**, Mingyan **WEI**, Shengmei **ZHOU**, Rongrong **ZONG**

Purpose: Retinal neovascularization is a significant feature of advanced age-related macular degeneration (AMD) and a major cause of blindness in patients with AMD. However, the underlying mechanism of this pathological neovascularization remains unknown. Iron metabolism has been implicated in various biological processes. This study was conducted to investigate the effects of iron metabolism on retinal neovascularization in neovascular AMD (nAMD).

Methods: C57BL/6J and very low-density lipoprotein receptor (VLDLR) knockout (Vldlr^{-/-}) mice, a murine model of nAMD, were used in this study. Bulk-RNA sequencing was used to identify differentially expressed genes. Western blot analysis was performed to test the expression of proteins. Iron chelator deferiprone (DFP) was administered to the mice by oral gavage. Fundus fluorescein angiography was used to evaluate retinal vascular leakage. Immunofluorescence staining was used to detect macrophages and iron-related proteins.

Results: RNA sequencing (RNA-seq) results showed altered transferrin expression in the retina and RPE of Vldlr^{-/-} mice. Disrupted iron homeostasis was observed in the retina and RPE of Vldlr^{-/-} mice. DFP mitigated iron overload and significantly reduced retinal

neovascularization and vascular leakage. In addition, DFP suppressed the inflammation in Vldlr^{-/-} retinas. The reduced signals of macrophages were observed at sites of neovascularization in the retina and RPE of Vldlr^{-/-} mice after DFP treatment. Further, the IL-6/JAK2/STAT3 signaling pathway was activated in the retina and RPE of Vldlr^{-/-} mice and reversed by DFP treatment.

Conclusions: Disrupted iron metabolism may contribute to retinal neovascularization in nAMD. Restoring iron homeostasis by DFP could be a potential therapeutic approach for nAMD.

Abstract No.: 210252

Long-Term Phenotypic Characterization of an Adgrv1 Spontaneous Variation Mouse Model: Insights Into Visual and Auditory Dysfunction in Usher Syndrome Type 2

First Author: Lei **ZHANG**

Co-Author(s): Hai-yan **WANG**

Purpose: Usher syndrome (USH) represents the predominant form of syndromic retinitis pigmentosa (RP), characterized by retinal degeneration combined with auditory impairment. While pathogenic variants in ADGRV1 (alternatively designated USH2C) contribute to 5-19% of USH2 diagnoses, comprehensive longitudinal characterization of disease progression in animal models remains limited, especially regarding ocular manifestations.

Methods: This investigation employed a spontaneously generated Adgrv1-deficient mouse strain (Adgrv1^{-/-}) on a C57BL/6J genetic background. Multi-modal analyses encompassed morphological evaluation of sensory tissues, electron microscopic ultrastructural examination (scanning and transmission), molecular characterization through quantitative gene expression and protein localization studies, alongside physiological testing via electroretinography and auditory evoked potentials across developmental timepoints spanning P10 through P20mo.

Results: Cochlea: Hearing impairment manifested early (ABR thresholds elevated by P1mo), with outer hair cell stereocilia degeneration by P10 and spiral ganglion neuron loss by P11mo. Retina: Despite significant Adgrv1 mRNA/protein reduction from P10, retinal morphology remained intact. Ultrastructural disorganization of photoreceptor outer segments emerged at P11mo, followed by functional decline (reduced ERG b-wave amplitude) at P20mo. Specificity: No abnormalities were detected in other organs or hematological parameters.

Conclusions: This study delineates a Adgrv1^{-/-} model with early-onset auditory dysfunction and late-onset retinal degeneration, mirroring human USH2 progression. The delayed retinal phenotype suggests species-specific roles for ADGRV1 in

mechanotransduction, offering a unique tool to study USH2 pathogenesis and therapeutic interventions.

Abstract No.: 208205

METTL3 Governs Diabetic Retinal Vasculopathy Through a CRIP2–VEGF Axis

First Author: Tianyi LUO

Co-Author(s): Ming-ming YANG

Purpose: The epitranscriptomic control of DR vasculopathy remains undefined. CRIP2 has been identified as a transcriptional repressor of VEGF. Here, we dissect how METTL3, the dominant m6A writer, controls this CRIP2–VEGF module in DR.

Methods: Animal and cellular models of DR were generated by AAV- or lentivirus-mediated retinal/endothelial knockdown of METTL3 in streptozotocin-induced T2DM mice, db/db mice, and high-glucose/lactate-stimulated HUVECs. Mechanistic assays included qPCR screening of m6A writers/erasers, immunoblotting of METTL3–CRIP2–VEGF, global m6A dot-blot, dual-IF mapping of endothelial changes, and vascular phenotyping (Evans-blue permeability, H&E, trypsin-digest flat mounts).

Results: METTL3 was the only m6A writer down-regulated in T2DM retinas, coinciding with global m6A loss. High glucose suppressed METTL3 in HUVECs, whereas inflammatory or lactate stress alone elevated it, revealing metabolically driven suppression opposed by inflammatory induction. CRIP2 was reciprocally up-regulated when METTL3 was silenced in vitro and in T2DM retinas. Dual-IF confirmed endothelial co-localisation of METTL3 and its diabetes-induced reduction, paralleled by CRIP2 induction. Retinal Mettl3 knockdown in db/db mice amplified CRIP2 induction, increased microvascular density, and reduced leakage, corroborating the pathway.

Conclusions: Hyperglycaemia silences METTL3, relieving m6A-mediated repression of CRIP2 and thereby dampening VEGF signalling. METTL3 is therefore a negative regulator of DR vasculopathy, whereas CRIP2 represents the first m6A-dependent VEGF repressor.

Abstract No.: 206608

Mechanistic Role of SIRT4-Mediated Deacetylation of Complement Factor B in Age-Related Macular Degeneration

First Author: Cunzi LI

Co-Author(s): Ming-ming YANG

Purpose: To elucidate the role of silent information regulator 4 (SIRT4) in promoting age-related macular degeneration (AMD) by deacetylating complement factor B (CFB) and activating the alternative complement pathway, and to evaluate its potential as a therapeutic target.

Methods: Oxidative stress was induced in ARPE-19 cells with A2E plus blue light, and sodium iodate-induced retinal degeneration was established in wild-type, SIRT4 knockout, and CFB knockout mice. Functional assays included AAV9-SIRT4 overexpression and MSN-125 inhibition of BAX/BAK oligomerization. Molecular and structural changes were evaluated by qPCR, Western blot, Co-IP, HE/TUNEL staining, and electron microscopy.

Results: In both in vitro and in vivo AMD models, CFB expression was elevated, whereas its acetylation level was significantly reduced. Stepwise analysis demonstrated that SIRT4 mediated this deacetylation. Under oxidative stress, SIRT4 translocated from mitochondria to the cytoplasm and directly bound to CFB, as confirmed by co-immunoprecipitation. This interaction promoted deacetylation of CFB and enhanced alternative complement activation, with upregulation of C3, C5, and MAC. Functionally, SIRT4 knockout mice displayed attenuated retinal injury and reduced apoptosis, while SIRT4 overexpression exacerbated damage. Importantly, in CFB-deficient mice, SIRT4 overexpression did not cause further retinal injury, indicating that its pathogenic effect is CFB dependent. Inhibition of BAX/BAK oligomerization blocked SIRT4 cytoplasmic translocation.

Conclusions: SIRT4 promotes AMD progression by translocating to the cytoplasm, deacetylating CFB, and activating the alternative complement pathway. The SIRT4–CFB axis represents a novel mechanism of complement regulation and a promising therapeutic target for AMD.

Abstract No.: 203749

Mecobalamin Promotes Corneal Nerve Regeneration via Wdr81-Mediated Enhancement of Phagocytosis

First Author: Bining ZHANG

Co-Author(s): Shijiu CHEN, Weiyun SHI

Purpose: Corneal neurodegeneration is a key pathological basis for neurotrophic keratopathy (NK). Although recombinant human nerve growth factor (rhNGF) eye drops have been approved for NK treatment, their high cost and strict storage/use requirements limit clinical adoption. This study aims to evaluate the efficacy and mechanism of Mecobalamin (Mec) eye drops in corneal nerve repair and to explore their potential for clinical translation.

Methods: Trigeminal nerve branch transection, alkali burn, and herpes simplex keratitis mouse models were used to compare the effects of topical Mec and rhNGF on corneal nerve regeneration. Nerve repair was assessed via immunofluorescence, corneal nerve function tests, and electrophysiological evaluations. Further mechanistic studies were performed using transcriptomic sequencing, Western blotting, and immunostaining. In addition, a prospective clinical

study was conducted in 12 NK patients who received Mec eye drops for 60 days, with follow-up evaluations.

Results: Topical application of Mec significantly promoted corneal nerve morphological and functional recovery in all three mouse models of NK, with efficacy comparable to rhNGF. Mechanistically, Mec markedly upregulated Wdr81 expression in the trigeminal ganglion and activated non-canonical autophagy pathways, thereby accelerating myelin debris clearance and axonal regeneration. In the clinical study, all patients treated with Mec showed complete corneal epithelial healing within 60 days, with significant improvements in corneal sensitivity and visual acuity, and no adverse effects were observed.

Conclusions: Mecobalamin eye drops effectively promote corneal nerve regeneration, potentially through a Wdr81-mediated non-canonical autophagy pathway. As an approved, stable, and cost-effective drug, Mec demonstrates promising efficacy and translational potential for the treatment of NK.

Abstract No.: 202346

Microglia-Mediated Neuroinflammation Through Autophagy-Related Cell Death in Acute Optic Nerve Injury

First Author: Zijing **HUANG**

Co-Author(s): Shuping **KE**, Jiajian **LIANG**

Purpose: Optic neuropathy is a leading cause of blindness. Autophagy activation has been reported after optic nerve injury, but its role remains unclear. We investigated the involvement of autophagy in the early stages of injury and explored potential therapeutic strategies.

Methods: A mouse optic nerve crush model was established. Autophagy levels were assessed at different time points using electron microscopy and markers LC3 and Beclin-1. The relationship between autophagy and cell death was examined by Beclin-1 co-localization with TUNEL. Receptor-interacting protein 3 (RIP3) knockout mice were used to determine its regulatory role in microglial autophagy-related cell death. The neuroprotective effect of inhibiting this pathway was further evaluated with pharmacological inhibitors.

Results: Autophagy activation peaked one day after injury. Beclin-1 was expressed in retinal ganglion cells (RGCs), microglia, and astrocytes. Excessive autophagy induced cell death specifically in microglia, not in RGCs or astrocytes. RIP3 knockout reduced microglial autophagy-related cell death and attenuated retinal neuroinflammation. In addition, intravitreal injection of the RIP3 inhibitor GSK-872 or the autophagy inhibitor 3-MA decreased RGC loss and improved visual function.

Conclusions: Autophagy-related cell death represents a novel mechanism of microglial activity after optic

nerve injury. Targeting RIP3-mediated autophagy may provide a promising strategy for early intervention in optic neuropathies.

Abstract No.: 205389

Molecular Mechanisms Underlying Bis(2-Ethylhexyl) Phthalate-Induced Dry Age-Related Macular Degeneration: Insights From Network Toxicology, Machine Learning, and Single-Cell RNA Sequencing

First Author: Rui **NIU**

Co-Author(s): Xin **JIN**, Lifei **WANG**, Zhongyang **YAN**, Baoyue **ZHANG**

Purpose: Bis(2-ethylhexyl) phthalate (DEHP), a widely used plasticizer, can affect retinal photosensitivity through long-term exposure. Therefore, this study aimed to investigate the molecular mechanisms of DEHP-induced dry age-related macular degeneration (AMD).

Methods: Dry AMD-associated target genes were retrieved from the GeneCards and OMIM databases; DEHP-interacting targets were identified using the STITCH, SwissTargetPrediction, SuperPred, and SEA databases. Overlapping targets between the two datasets were screened via interaction analysis. Core targets were further identified using LASSO, RandomForest, and SVM machine learning analysis. Their expression patterns and affinity were validated using single-cell transcriptome datasets and molecular docking. These results were validated using PCR and immunofluorescence analysis in cells and animals, and fundus changes in animal models were observed using OCTA.

Results: MAPK14, MCL1, SCARB1, and CTSD were identified as core targets, indicating their important roles in lipids and atherosclerosis, lipid metabolism, and VEGF signaling. Single-cell RNA sequencing confirmed their significant expression in RPE, and molecular docking analysis revealed strong binding affinity between DEHP and these targets. Furthermore, compared with the control group, these core factors were significantly differentially expressed in the Nalo3 animal model and the DEHP animal and cell models ($P < 0.05$). The thickness of the retina and choroid of mice in the DEHP group decreased, the deep blood flow decreased, and DEHP interfered with the lipid metabolism of RPE cells.

Conclusions: DEHP disrupts RPE cell lipid metabolism through MAPK14, MCL1, SCARB1, and CTSD, damaging the retina and choroid and further inducing dry AMD. These findings deepen our understanding of the mechanism of DEHP-induced dry AMD and provide a theoretical basis for the development of potential therapeutic strategies and environmental toxicity assessments.

Abstract No.: 207332**New Compound Heterozygous PEX1 Variants in Heimler Syndrome***First Author: Xiaohu YAN*

Purpose: To report new pathologic variants and retinal and biochemical phenotypes in Heimler syndrome.

Methods: Exon sequencing was used to screen the pathologic variants in a patient with Heimler syndrome. The retinal characteristics and serum metabolome alterations were evaluated.

Results: A scanning laser ophthalmoscope showed that a large area of retinal choroidal atrophy was seen at the posterior pole of the retina, with scattered patchy subretinal pigmentation. Optical coherence tomography showed fovea atrophy accompanied by retinal retinoschisis in the right eye and macular retinoschisis and edema in the left eye. The electroretinogram showed obviously reduced amplitudes of a- and b-waves under photopic and scotopic conditions in both eyes. Visual field tests showed reduced central visual field in both eyes. Exon sequencing was used to identify new compound heterozygous variants, including c.2966T>C and c.1670+1G>T of the PEX1 gene. Non-targeted determination of total lipid metabolites and targeted determination of medium and long chain fatty acids in the serum of the patient and his healthy sibling were tested.

Conclusions: These data identified new compound heterozygous PEX1 variants and expanded our understanding of phenotypes in Heimler syndrome.

Abstract No.: 200143**RP1L1 Variants in Occult Macular Dystrophy: Clinical Signs and Molecular Causes***First Author: Yang PAN**Co-Author(s): Takeshi IWATA*

Purpose: Occult macular dystrophy is a hereditary retinopathy marked by progressive bilateral vision loss despite normal findings on fundus examination, fluorescein angiography, and full-field electroretinography. Its pathogenesis is not yet fully understood, and effective treatments are currently unavailable.

Methods: We performed whole-exome sequencing on 133 samples from 78 OMD pedigrees to identify pathogenic variants. To investigate the effects of the R45W mutation on protein synthesis and trafficking, we generated expression vectors for RP1L1 and R45W. Co-immunoprecipitation with an RP1 vector confirmed their interaction and the impact of R45W. Patient-derived iPSCs were differentiated into photoreceptor-like cells, and RNA-seq was performed to assess mutation effects.

Results: We identified the RP1L1 c.133C>T, p.Arg45Trp (R45W) mutation as the sole pathogenic variant in two families with dominantly inherited OMD. Additionally, five other potentially pathogenic RP1L1 variants were detected. Collectively, these six variants accounted for 33.33% of the pedigrees, with R45W being the most frequent (16.6%). The R45W mutation correlated with earlier disease onset, more severe clinical phenotypes, and abnormal intracellular localization rather than altered expression levels. Functional assays demonstrated that R45W disrupted the intracellular localization of RP1L1 and RP1, leading to reduced cell viability. In induced photoreceptor-like cells derived from OMD patients carrying the R45W mutation, we observed downregulation of the long noncoding RNA MEG3 and the PI3K/Akt pathway, along with upregulation of extracellular matrix organization.

Conclusions: These findings confirm the etiological role of RP1L1 in OMD and offer novel insights into its pathogenesis, potentially guiding future research and therapeutic development.

Abstract No.: 204860**Retinal Pigment Epithelium Dysfunction Induced by Mineralocorticoid Receptor Overexpression***First Author: Min ZHAO**Co-Author(s): Seiki ACHIEDO, Francine BEHAR-COHEN, Sebastien BLED, Frédéric JAISSE, Linxin ZHU*

Purpose: The retinal pigment epithelium (RPE) is essential for retinal homeostasis, and its dysfunction contributes to vision-threatening diseases such as age-related macular degeneration (AMD) and retinitis pigmentosa. RPE cells express the mineralocorticoid receptor (MR). While MR activation has been implicated in inflammation, oxidative stress, angiogenesis, and fibrosis in several blinding retinopathies, its specific role in RPE cells remains unclear. We investigated the effects of MR overexpression in the RPE.

Methods: We generated a transgenic mouse line overexpressing murine MR specifically in RPE cells (BestCreMROE). Retinal morphology (OCT) and function (ERG) were evaluated in BestCreMROE and control mice at 3, 6, and 12 months. Eyes were analyzed by histology and transmission electron microscopy (TEM). Flat-mounted RPE were examined by Phalloidin, Cre, and YAP immunofluorescence.

Results: BestCreMROE mice showed progressive pigmentary changes in the fundus with age. OCT revealed early irregularities in RPE reflectivity, and in aged mice, focal RPE loss with secondary retinal alterations. Aged BestCreMROE mice exhibited reduced ERG amplitudes of scotopic a/b waves and photopic b waves. Histology demonstrated pigment abnormalities, RPE disruption, and migration. TEM revealed rarefaction of RPE apical microvilli, degeneration of basal infolding, and loss of RPE polarization. Flat-

mounts showed hypertrophy and heterogeneity of RPE cells linked to MR overexpression. In these areas, YAP localized predominantly in the cytoplasm, whereas nuclear YAP was preserved in unaffected regions.

Conclusions: MR overexpression in RPE cells disrupts differentiation and polarization, leading to pathological changes that may contribute to retinal degenerative diseases.

Abstract No.: 207835

Short-Term Low-Level Red-Light Therapy for Presbyopia: A Double-Masked, Randomized Trial

First Author: Fan **SONG**

Co-Author(s): Yanxian **CHEN**, Mingguang **HE**, Jijing **LI**, Jian **ZHANG**, Ziwei **ZHAO**

Purpose: To determine whether repeated low-level red-light (RLRL) therapy alleviates asthenopic symptoms and enhances accommodative function in presbyopia over 31 days.

Methods: Double-masked, parallel-group randomized trial in adults with presbyopia and self-reported asthenopia. Participants were allocated 1:1 to RLRL or sham. The primary endpoint was the change in the Computer Vision Syndrome Questionnaire (CVS-Q) score at day 31. Key secondary endpoints included binocular accommodative amplitude (AA), Near Activity Visual Questionnaire (NAVQ) score, habitual near visual acuity, near-addition power, accommodative facility, positive/negative relative accommodation, binocular cross-cylinder response, and AC/A ratio. Continuous outcomes were evaluated with adjusted linear mixed-effects models.

Results: Sixty-four of 66 randomized participants (age 41–62 years) completed follow-up. At day 31, symptom burden decreased more with RLRL than sham (adjusted mean CVS-Q change -2.53 vs -0.78 ; between-group difference -1.75 points; 95% CI -3.10 to -0.39). RLRL also favored improvement in binocular AA (adjusted mean difference 1.09 D; 95% CI 0.37 to 1.82) and patient-reported near-vision difficulty (NAVQ, -8.07 points; 95% CI -14.17 to -1.97). The AA effect was larger among eyes with baseline amplitude >2.0 D (1.33 D; 95% CI 0.32 to 2.34). Other prespecified measures showed no between-group differences at assessed visits. No treatment-related adverse events were observed.

Conclusions: Across one month, RLRL reduced asthenopic symptoms and improved accommodative amplitude in presbyopia, with concurrent gains in near-vision patient-reported outcomes and an acceptable safety profile. Further trials with longer follow-up are warranted.

Abstract No.: 204823

The Efficacy of Individualized Visual Therapy in Children With Attention Deficit Hyperactivity Disorder

First Author: Ye **WU**

Co-Author(s): Longqian **LIU**

Purpose: This study conducts a 12-week vision therapy for children with both attention-deficit/hyperactivity disorder (ADHD) and visual dysfunctions, and analyzes the effectiveness of the vision therapy for improving clinical findings and core symptoms in these children.

Methods: A total of two groups of participants were included: an ADHD group (age: 8.35 ± 1.25 years) and a control group (age: 8.14 ± 1.33 years). The ADHD group underwent 12 weeks of vision therapy; the control group did not receive any therapy. Improvements in clinical findings, core symptoms, social functioning, and reading abilities were compared after 12 weeks of treatment.

Results: After vision therapy, the ADHD group exhibited significant improvements in clinical findings and visual symptoms (all $P < 0.05$). Scores on the Inattention, Hyperactivity/Impulsivity, and total score of the Swanson, Nolan, and Pelham-IV rating scales decreased significantly compared to baseline, with improvements significantly greater than those in the control group (all $P < 0.05$). The ADHD group also showed significant reductions in the School and learning and Social activities domains of the Weiss functional impairment rating scale, with improvements significantly greater than those in the control group (all $P < 0.001$). Moreover, the ADHD group showed significant improvement in reading fluency as compared to baseline ($P < 0.001$), and the improvement was significantly greater than that in the control group ($P = 0.036$).

Conclusions: Vision therapy is effective for improving clinical signs, core symptoms, social functioning, and reading abilities in children with ADHD.

Abstract No.: 200198

The Profile of Retinal Ganglion Cell Death and Cellular Senescence in Mice With Aging

First Author: Shuyi **ZHOU**

Co-Author(s): Xin **BIN**, Tsz Kin **NG**, Wenying **WANG**

Purpose: Older age is a risk factor for glaucoma, in which progressive retinal ganglion cell (RGC) loss leads to visual field defects, irreversible visual impairment, and even blindness. We recently identified the involvement of cellular senescence in RGC cell death post-optic nerve injury. Here, we further aimed to delineate the profile of RGC survival in mice with aging, a physiological process with increasing cellular senescence.

Methods: Longitudinal changes of RGC survival, cellular senescence status, and cell death marker expression were evaluated from 2- to 18-month-old mice. Retinal transcriptomes of young and old mice were also analyzed.

Results: The numbers of senescent cells in the ganglion cell layer (GCL) significantly and progressively increased starting at 8 months of age. Yet, a significant reduction of ganglion cell complex layer thickness began in the 10-month-old mice, and a significant reduction in the number of RGCs began in the 12-month-old mice as compared to the 2-month-old mice. Meanwhile, pyroptosis and ferroptosis markers, as well as cellular senescence-related cell cycle arrest proteins p15Ink4b, p16Ink4a, p21Cip1, and p53, were significantly and progressively increased in GCL. Comparing the 2- and 16-month-old mouse retinas, the differentially expressed genes were involved in the pathways of neurodegeneration, innate immunity, and mitochondrial ATP synthesis.

Conclusions: This study revealed the gradual increase in senescent cells as well as pyroptosis and ferroptosis with progressive RGC reduction in mice with aging. Cellular senescence and the related cell death pathways are potential targets for age-related RGC reduction.

Abstract No.: 202585

Unraveling the Gut-Eye Axis Through Cross-Trait Genomics and Multi-Omics Integration

First Author: Yuelan **GAO**

Co-Author(s): Li Jia **CHEN**, Clement C. **THAM**, Jianming **XU**, Jason C. **YAM**

Purpose: The gut-eye axis (GEA) may underlie comorbidity between gastrointestinal and ocular diseases. This study aims to explore their genetic pleiotropy and pathways regulated by environmental factors and gut microbiota.

Methods: This study integrated large-scale genome-wide association study (GWAS) summary data on five gastrointestinal and eight ocular diseases. Genetic correlations and pleiotropic loci were assessed. Functional and tissue-specific analyses were conducted with functional annotation (FUMA), gene-level analyses (MAGMA), transcriptome- and proteome-wide association studies (TWAS, PWAS). Gene-environment (G×E) interactions were evaluated using UK Biobank data. Bidirectional Mendelian randomization (MR) and mediation analyses assessed the causal and mediating roles of gut microbiota.

Results: Extensive genetic correlations were observed across 40 trait pairs, indicating shared heritability. Functional analyses revealed 366 pleiotropic loci and 603 genes, including 21 loci with shared causality, collectively implicating immune regulation and inflammatory pathways as central mechanisms

between gastrointestinal and ocular diseases. TWAS confirmed 154 pleiotropic genes from the 366 loci, and PWAS identified 11 at the protein level. GXE interactions revealed that 26 pleiotropic variants were modulated by 16 environmental exposures, suggesting lifestyle and psychosocial factors influence genetic risk in 13 gastrointestinal-ocular comorbidities. MR analysis identified five causal links from gastrointestinal to ocular diseases and six in the reverse direction. Mediation analysis indicated that the gut microbiota-related polyamine biosynthesis pathway partially mediates the effect of gastroesophageal reflux disease on diabetic retinopathy.

Conclusions: This study systematically dissects the genetic pleiotropy and environmental networks of the GEA, highlighting key roles for immune-related genes and gut microbiota in gastrointestinal-ocular comorbidity.

Abstract No.: 205237

Visual Perceptual Function Improvement in Patients With Diabetic Retinopathy Trained by Visual Perceptual Learning: A Preliminary Clinical Trial

First Author: Lixia **FENG**

Co-Author(s): Kexin **CAO**

Purpose: Diabetic retinopathy (DR) is a prevalent complication of diabetes, characterized by retinal vascular damage and neurodegeneration, which may ultimately result in blindness. Despite conventional treatments, many patients with DR continue to experience visual impairments. This study aims to evaluate the effectiveness of visual perceptual learning (VPL) in enhancing visual perceptual function in DR patients following conventional treatment.

Methods: Eligible participants were randomly assigned to either the VPL group or the control group, with the VPL group undergoing three months of VPL. Visual function was assessed through grating acuity (GA), first-order motion stimulus (1stM), second-order stationary stimulus (2ndS), second-order motion stimulus (2ndM) perception sensitivity and psychological questionnaires.

Results: The VPL group showed improvements in GA, 1stM, and 2ndS compared to controls. Learning progressed rapidly at first and then slowed, revealing greater enhancement in first-order than second-order tasks, and stronger gains in contrast-modulated versus motion-modulated stimuli. Multivariate analyses identified educational level, hypertension, diabetic tractional retinal detachment (DTRD), foveal avascular zone (FAZ) area and FAZ acicularity index (AI) as predictors of VPL efficacy.

Conclusions: The results suggest that VPL may serve as a potentially effective visual rehabilitation therapy.

Abstract No.: 205170**Visual-Related Sensory Integration Deficits in Autistic Children Without Intellectual Disability: A Pilot Study***First Author: Runting MA**Co-Author(s): Shuli SHEN, Qihao SUN, Mengyi WANG, Xin WANG, Xiao YANG*

Purpose: To explore the visual function and high-level perception in autistic children without intellectual disability (ID) and typically developing (TD) children.

Methods: A cross-sectional pilot study. 5 autistic children without ID (8.43 ± 2.07 years, 100% male) and 7 TD children (10.00 ± 1.41 years, 40% male) were included. All autistic children had a prior clinical diagnosis by the Childhood Autism Rating Scale (CARS). Cognitive ability was assessed via the Chinese version of Wechsler Intelligence Scale for Children, fourth edition (WISC-IV), and all participants had a Full-Scale Intelligence Quotient (FSIQ) above 70. Basic visual function (i.e., accommodation, strabismus, and phoria) and high-level visual perception through Sanet Vision Investigator (SVI) were tested.

Results: For basic visual function, there was no significant difference between the two groups (all $p > 0.05$). However, performance in high-level perception revealed that autistic children showed backwardness in hand-eye coordination. Specifically, autistic children exhibited longer duration in the saccades test assessing visual-auditory integration (autistic: 31.50 ± 3.10 s vs. TD: 26.00 ± 1.60 s, $p = 0.010$), as well as slower reaction times in the go/no-go task (autistic: 2.04 ± 0.16 s vs. TD: 1.50 ± 0.19 s, $p = 0.003$). In addition, the reaction time in the Visual Spatial Memory program also showed a marginal significance (autistic: 2.38 ± 1.31 s vs. TD: 0.98 ± 0.43 s, $p = 0.058$). Within the autistic group, the reaction time of Visual Spatial Memory was correlated with FSIQ ($r = -0.951$, $p = 0.049$) and scores of CARS ($r = 0.990$, $p = 0.010$), respectively.

Conclusions: Autistic children without ID may have deficits in vision-related perception and multisensory integration, while basic visual functions may be intact. The severity of autistic symptoms may be associated with these perceptual impairments. Future studies with a larger sample are valuable.

AI Oculomics as a Biomarker to Predict Long-Term Stroke Functional Outcome

First Author: Kanae **FUKUTSU**

Co-Author(s): Deidre Anne **DE SILVA**, Yao **JIE**, Zengxiang **LI**, Daniel **TING**, Fung Peng **WOON**

Purpose: To evaluate whether long-term functional outcomes after ischemic stroke can be predicted from admission clinical data and fundus photographs.

Methods: In a prospective cohort of ischemic stroke admissions (2005–2007), routine clinical assessments and in-hospital fundus photography were obtained. Functional outcome (modified Rankin Scale, mRS) was assessed at 6 months and at two long-term follow-ups (median 29 and 86 months). The primary endpoint was time to first unfavorable outcome (mRS ≥ 3); others were censored at last follow-up. Variable selection used L1-penalized Cox regression (LASSO) with cross-validation, and performance was evaluated in a held-out test set.

Results: We included 612 patients. Of 215 candidate variables, LASSO retained 33 predictors. On the test set, the model achieved a C-index of 0.691 and time-dependent AUCs of 0.71–0.76 at 1–7 years. Key clinical predictors included diabetes (HR 1.36, 95% CI 1.01–1.83) and prior ischemic stroke (HR 1.95, 95% CI 1.06–3.58). A retinal imaging feature, drusen, also independently predicted unfavorable outcome (HR 1.46, 95% CI 1.03–2.07).

Conclusions: Admission clinical information combined with retinal image-derived features enabled the prediction of unfavorable functional outcomes up to 7 years after ischemic stroke. These findings suggest that ocular factors may have an additional contribution to functional prognostication, over and above standard vascular risk factors.

AI-Orchestrated Workflow for Refractive Surgery and Keratoconus Diagnosis: A Three AI-Agent System for Comprehensive Patient Assessment

First Author: Hatem **ALI**

Purpose: To improve diagnostic accuracy in keratoconus and refractive surgery planning using an AI-orchestrated, multi-AI-agent workflow that integrates multimodal imaging and patient history. Task-specific agents with LLM coordination enhance risk stratification, diagnostic certainty, and individualized treatment planning.

Methods: A retrospective study of 50 keratoconus and refractive surgery cases was conducted using a three-agent, AI-orchestrated workflow. Agents included: (1) General Ophthalmology (patient history, risk factors), (2) Imaging (Pentacam, AS-OCT, epithelial mapping, PTA), and (3) Anterior Segment specialist (diagnosis and surgical planning). Multiple LLMs coordinated task execution. Outcomes were measured as diagnostic accuracy, risk stratification consistency, surgical recommendation reliability, and model variability, benchmarked against general-purpose AI models.

Results: General Ophthalmology Agent: Accuracy of patient history: 84% (LLM range: $\pm 6\%$) Risk factor consistency: 78% (Some misunderstood steroid-induced IOP risk) Pentacam & AS-OCT Agent: Imaging accuracy: 87% (LLM variability: $\pm 5\%$) Detection of keratoconus: 92% (Enhanced in structured models) PTA accuracy: 81% (Borderline values resulted in variation) Anterior Segment Specialist Agent: Agreement on diagnosis: 89% (LLM variability: $\pm 7\%$) Surgery recommendation: 76% (Variability in borderline LASIK cases) Total: 85% accuracy, LLM variation: $\pm 9\%$, best time: 11.2s, worst time: 22.4s. Results emphasize LLM variation, indicating varying models for different agents.

Conclusions: An orchestrated, multi-agent AI workflow enhances diagnostic accuracy and clinical safety in refractive surgery and keratoconus. Task-specific agents consistently outperformed general models for risk stratification and decision-making. Future steps include multicenter validation and EMR integration.

AI-Powered Virtual Eye: Perspective, Challenges and Opportunities

First Author: Yue WU

Co-Author(s): Mingguang HE, Danli SHI

Purpose: The eye, with rich imaging landscape and well-characterized anatomy, serves as an ideal organ for computational modeling. Traditional mechanistic approaches have advanced our understanding of ocular biomechanics, optics, and pharmacokinetics, but remain limited in scale and data integration. Recent breakthroughs in artificial intelligence (AI), imaging, and multi-omics enable a next-generation “virtual eye”, a high-fidelity multiscale digital twin. This work aims to synthesize current progress in computational and AI-based eye modeling and to outline a roadmap for developing an AI-powered virtual eye that unifies mechanistic and data-driven intelligence.

Methods: We systematically reviewed studies on ocular computational models. Literature identified through the database was analyzed thematically to trace the conceptual evolution from mechanistic models to AI-powered systems.

Results: Three major stages were identified: simulation-based mechanistic models grounded in physics and anatomy; data-driven deep learning models learning latent representations from multimodal inputs; and a universal, hierarchical framework of interconnected foundation models integrating multi-scale and multimodal processes. The envisioned virtual eye features multimodal fusion, cross-scale representation, dynamic feedback loops, and real-time adaptability. Potential applications include surgery simulation, personalized treatment, and in silico experimentation. However, several challenges, such as limited interpretability, data processing, ethical and privacy concerns, and the absence of standardized evaluation frameworks, remain to be addressed.

Conclusions: The AI-powered virtual eye represents a transformative paradigm toward precision ophthalmology. By coupling first-principles physics with large-scale data-driven learning, it could serve as both a clinical decision-support system and an in silico laboratory. Achieving this vision will require sustained interdisciplinary collaboration across ophthalmology, bioinformatics, artificial intelligence, and ethics.

Accessible AI for Ophthalmic Care: A Low-Cost Foundation Model Ensemble Pipeline for Eye Disease Prognosis

First Author: Ka Hei NG

Co-Author(s): Hongyang JIANG, Tsz Yu LEE

Purpose: To develop and validate a cost-effective, data-efficient artificial intelligence pipeline that predicts the progression of multiple ophthalmic diseases by leveraging frozen, pretrained ophthalmic foundation models.

Methods: The proposed, disease-agnostic pipeline accepts either color fundus photographs (CFP) or optical coherence tomography (OCT) volumes. Each image is embedded by a frozen foundation model (RETFound or VisionFM), yielding low-dimensional feature vectors. These embeddings are refined through a lightweight multi-head self-attention layer and a supervised contrastive encoder, followed by classification with a compact head (multilayer perceptron). Models built atop each foundation model backbone are ensembled by weighted score averaging. Performance was assessed on two public longitudinal datasets: Harvard-GDP (glaucoma; n=500 eyes) and GRAPE (glaucoma; n=263 eyes). Primary evaluation metrics include area under the receiver operating characteristic curve (AUROC) and area under the precision-recall curve (AUPRC).

Results: Our model demonstrates comparable to improved performance over previously published methods. The weighted average ensemble achieved state-of-the-art AUROCs of 0.943 on HarvardGDP (MD endpoint) and 0.854 on GRAPE (PLR3 endpoint), exceeding both single-backbone baselines and prior fully finetuned models. Notably, the trainable portion comprised only 7–9M parameters versus 302M (RETFound) or 84M (VisionFM) for full model finetuning, significantly reducing computational cost and memory demand.

Conclusions: We present a generalizable, low-cost, data-efficient ensemble pipeline that utilizes frozen ophthalmic foundation models to deliver high-accuracy ocular disease prognostics with minimal training overhead. By lowering compute requirements and carbon footprint, the approach makes personalized, AI-driven eye care more accessible in routine clinical settings.

An Automated Framework Using Large Language Models for Objective Cataract Surgery Skill Assessment

*First Author: Zhongsheng LYU**Co-Author(s): Longhao CAO, Dawei LI, Xuemin LI, Weiqiang QIU, Chen WU*

Purpose: The evaluation of cataract surgery skills in trainees is hindered by its reliance on subjective, time-intensive assessments from senior surgeons. To address this, we developed and validated an automated framework using a multimodal large language model (LLM) to objectively score surgical performance from video. We designed a framework called AI-CAT, which is capable of providing standardized, criteria-based feedback and pinpointing specific procedural deficiencies.

Methods: We established a detailed scoring rubric for the capsulorhexis stage, covering critical domains such as flap initiation, instrument exchange, and capsulorhexis geometry. The assessment was automated using Gemini 2.5 Pro employing a Chain-of-Thought (CoT) prompting strategy. We validated AI-CAT's efficacy by measuring its error detection rate, correlation with expert scores, instrument recognition accuracy, and the fidelity of its qualitative feedback.

Results: From an analysis of 39 high-definition surgical videos, AI-CAT demonstrated high precision, achieving a 99.47% error detection rate and a 97.32% instrument recognition rate. Notably, it identified subtle operative errors beyond the typical threshold of human perception, and its scores showed a strong correlation ($r = 0.94$) with expert assessments. The qualitative feedback was confirmed by surgical experts to be highly accurate and clinically relevant.

Conclusions: This study demonstrates that AI-CAT can objectively and accurately evaluate a critical stage of cataract surgery. This technology offers a scalable solution for standardizing surgical training, reducing the burden on senior surgeons, and providing trainees with precise, actionable feedback, thereby enhancing the educational process.

Abstract No.: 204619**Panel No.: ADV-0062**

An Explainable Artificial Intelligence-Based Approach for Anomaly Detection on Corneal In Vivo Confocal Microscopy Images

*First Author: Ningning TANG**Co-Author(s): Daizai LEI, Fan XU*

Purpose: In vivo confocal microscopy (IVCM) enables detailed assessment of corneal microstructures. However, the multilayered architecture of the cornea makes it difficult to reliably distinguish disease-related changes from normal variability. Current anomaly

detection methods often lack robustness across diverse manifestations. To overcome these limitations, we developed a Transformer-driven framework for detecting abnormalities in IVCM images without reliance on predefined disease labels.

Methods: We constructed an anomaly detection model for identifying disease-related alterations in IVCM images, consisting of three key components: EfficientNet, a multi-scale feature fusion module, and a Transformer encoder. A total of 7,063 images from 95 eyes were analyzed. The model was trained using only normal IVCM images across four corneal layers: epithelium, sub-basal nerve plexus, stroma, and endothelium. During inference, anomaly scores were computed to distinguish pathological from normal images. Explainable anomaly maps were also produced to highlight morphological deviations.

Results: The proposed method achieved areas under the receiver operating characteristic curve (AUCs) of 0.933 on internal validation and 0.917 on an external test dataset. Anomaly scores showed significant separation between normal and pathological images ($p < 0.001$). Visualization confirmed that highlighted regions corresponded to structural abnormalities, suggesting potential imaging biomarkers.

Conclusions: The proposed framework demonstrates high accuracy and interpretability for detecting corneal abnormalities in IVCM images. It reduces annotation burden, improves screening efficiency, and offers a scalable solution for intelligent diagnosis of corneal diseases.

Abstract No.: 206213**Panel No.: ADV-0072**

Antibody-Mediated Immune Responses to Infectious Diseases Causally Associated With Five Ophthalmic Diseases: A Mendelian Randomization Study

*First Author: Liduo PAN**Co-Author(s): Jian DENG, Hui GUO, Yonghao LI, Xiaoyi YU*

Purpose: This study aimed to assess the potential causal relationship between antibody-mediated immune responses to infectious agents and five ocular conditions: chronic iridocyclitis, scleritis, wet age-related macular degeneration (AMD), diabetic retinopathy (DR), and glaucoma.

Methods: We conducted a two-sample Mendelian randomisation analysis utilising GWAS data to assess the causative impacts of antibody-mediated immune responses to 46 pathogens on five ocular disorders, utilising SNPs as instrumental variables. The primary studies included inverse variance weighting, supplemented by sensitivity approaches (MR-Egger, weighted median) and reverse Mendelian

randomisation to evaluate robustness and bidirectionality.

Results: IVW analysis indicated significant associations between specific antibody responses and ocular diseases. Chronic iridocyclitis risk correlated with anti-polyomavirus 2 IgG seropositivity and Epstein-Barr virus (EBV) ZEBRA antibody levels. In wet age AMD, DR, and glaucoma, anti-polyomavirus 2 IgG seropositivity was recognized as a risk factor, whereas EBV EBNA-1 antibody levels exhibited a protective effect. The risk of scleritis was associated with Varicella zoster virus (VZV) glycoproteins E and I antibody levels, while the EBV EBNA-1 antibody demonstrated a protective effect. Moreover, VZV glycoproteins E and I antibody levels were identified as risk factors for wet AMD and DR. Anti-Merkel cell polyomavirus IgG seropositivity and EBV VCA p18 antibody were associated with wet AMD as risk and protective factors, respectively.

Conclusions: This study provides novel evidence for a causal role of immune responses to persistent or reactivated pathogens in a range of ophthalmic diseases.

Abstract No.: 201750

Panel No.: ADV-0048

Application of Automated Grating Visual Acuity Testing in Children Aged 3 to 24 Months

First Author: Yuqing LI

Co-Author(s): Guangqiang WU

Purpose: This study aims to evaluate the effectiveness of automated grating visual acuity testing in children aged 3 to 24 months, measure visual acuity levels in infants and young children across different age groups, establish reference ranges, and explore the clinical value of fully automated assessment technology in pediatric vision screening.

Methods: A prospective clinical study was conducted from June to December 2024, performing automated grating visual acuity tests on infants aged 3 to 24 months. The study included 1,215 infants, of whom 1,066 successfully completed the test and provided valid data, yielding a completion rate of 87.74%. Test data were statistically analyzed by age groups (≤ 2 months, 2–4 months, 4–6 months, etc.), including calculations of mean visual acuity, standard deviation, and percentiles (3rd, 10th, 25th, 50th, 75th, 90th, and 97th percentiles).

Results: The completion rate of automated grating visual acuity testing was 87.74%, indicating high feasibility of this method in the infant population. Significant differences in visual acuity were observed among different age groups ($P < 0.01$), with visual acuity levels gradually improving with increasing age. The study established reference ranges for visual acuity across various age groups (expressed in Snellen

equivalents), including percentile distributions, providing an important basis for clinical assessment.

Conclusions: This study provides reliable reference ranges for vision screening in children aged 3 to 24 months, supporting the clinical promotion and application of automated grating visual acuity testing. Future research could further expand sample sizes and regional scope to optimize reference standards and validate long-term application effects.

Panel No.: ADV-0049

Application of Complex Giant Systems in Ocular Diseases

First Author: Li XUEMIN

Co-Author(s): Li DING, Yi DING, Xinli YU

Purpose: Multiple ocular diseases may result in vision reduction or blindness, often involving a complex interaction of vascular, neural, muscular, and environmental factors. Common clinical single-perspective symptomatic treatment not only delivers limited therapeutic efficacy but also neglects a holistic assessment of disease progression. Therefore, we propose an integrated framework for diagnosis, treatment, and evaluation based on the complex giant system of the eye.

Methods: This study employed biomechanics, haemodynamics, and neuroinformatics to develop a lifespan micro-scale whole-eye viscoelasticity model, a body-head-neck-eye circulation model, and the nerve conduction study. It established a complex, giant systemic model of the body, head, neck, and eye, and explored its applications in various scenarios.

Results: Research indicates that the accommodative function of the eyeball varies with age. Within the Amalric triangular sign syndrome fundus blood flow model, choroidal blood flow velocities generally decrease from normal to pathological regions (1.02×10^{-4} m/s, 1.61×10^{-4} m/s, and 1.08×10^{-5} m/s). Furthermore, studies show that most electroencephalographic channels diminish with increasing altitude, with signal amplitude correlating with the complexity of visual stimulus tasks.

Conclusions: This model not only investigates the multidimensional factors involved in the pathogenesis of multiple ocular diseases but also enables early warning of disease progression and prediction of treatment efficacy.

Artificial Intelligence Model for Detecting Pathologic Myopia and Segmenting Lesions on Fundus Images

First Author: Hieu LE THAI MINH

Co-Author(s): Trung TRAN DINH, Nguyen TRAN DINH KHOI

Purpose: With the rising prevalence of myopia and its associated complications, access to retinal specialists for lesion screening remains limited in many regions. Therefore, this study aims to develop an AI model for the detection of pathological myopia (PM), guided by the META-PM definitions and lesion segmentation on fundus images.

Methods: A dataset of 1,542 myopic fundus images, graded according to the META-PM classification (5 categories) and segmented for lesions (chorioretinal atrophy, retinal hemorrhage, and "Plus" lesions). Fundus images showing myopic maculopathy of Grade ≥ 2 or with at least one "Plus" lesion were classified as PM, while images graded as Grade 0 or Grade 1 without any Plus lesions were classified as non-PM. This dataset was used to train two deep learning models based on CNN architectures: MobileNetV2 (grading) and MANet (lesion segmentation). After training, the models were evaluated by experts on an independent set of 116 fundus images.

Results: The model achieved a sensitivity of 93.06% and a specificity of 90.91% in detecting PM. Kappa coefficient of 0.82. For lesion detection, the sensitivity was 91.9% and the specificity was 88.2%, with an mAP@0.5 of 0.731, a Dice coefficient of 0.84, and an IoU of 0.70. The average analysis time per image was 6.06 seconds, which was 1.38 seconds faster than that of ophthalmologists ($p < 0.001$; 95% CI: 1.05–1.71).

Conclusions: The proposed AI model has the potential to serve as an efficient screening tool for pathological myopia, while also supporting ophthalmologists and healthcare workers in the comprehensive management of myopia.

Abstract No.: 200405

Artificial Intelligence Model for Detection, Grading and Lesion Segmentation of Diabetic Retinopathy on Fundus Images

First Author: Hieu LE THAI MINH

Co-Author(s): Trung TRAN DINH, Nguyen TRAN DINH KHOI

Purpose: To develop an artificial intelligence (AI) model capable of detecting diabetic retinopathy (DR), grading disease severity based on the international classification scale, and segmenting lesions on fundus images.

Methods: The dataset of over 3,700 fundus images was classified into five severity levels of diabetic retinopathy (No DR, Mild NPDR, Moderate NPDR, Severe NPDR, and PDR) and segmented with lesions including hard exudates, soft exudates, microaneurysms, and hemorrhages by the research team. The labeled and preprocessed data were then used to train two deep learning models with CNN architectures: MobileNetV2 (for disease detection and grading) and YOLOv8m (for lesion detection and localization). After training, the models were evaluated on 267 patients (516 images) and compared with ophthalmology specialists to assess performance.

Results: The model achieved a sensitivity of 92.1% and a specificity of 89.3% in detecting referable diabetic retinopathy. The agreement in disease grading reached a Cohen's Kappa of 0.75. For lesion segmentation, the model obtained an F1-score of 80.1% and a mAP@0.5 of 0.768. Among the lesions, hard exudates were detected with the highest accuracy (mAP@0.5 = 0.800), whereas microaneurysms had the lowest detection performance (mAP@0.5 = 0.612). The total evaluation time for all 516 fundus images was 136 minutes with the AI model, compared to 175 minutes by ophthalmologists ($p < 0.001$).

Conclusions: The developed AI model demonstrates high effectiveness in detecting, grading, and segmenting diabetic retinopathy lesions on fundus images. The system shows potential for application in DR screening programs.

Artificial Intelligence-Based Myopia Prediction in Children and Adolescents

First Author: Ying WU

Co-Author(s): Caixia CHAI, Mingxuan LIU, Zhengyuan LIU, Qiyuan TIAN, Lijun ZHANG, Yitong ZHANG

Purpose: To develop and compare multiple machine learning and deep learning models for myopia prediction in children and adolescents, and evaluate the performance of different algorithms in early myopia identification.

Methods: This large-scale cross-sectional study included 65,201 children and adolescents aged 3-18 years from vision screening data. Collected features included bilateral uncorrected and corrected visual acuity, spherical and cylindrical power, corneal curvature, and demographic information like age, gender, and grade level. Nine traditional machine learning algorithms and two deep learning methods (FT-Transformer, TabNet) were used for prediction modeling.

Results: On the test set, the FT-Transformer deep learning model achieved the best performance with 85.32% accuracy, an 87.29% F1-score, and a

93.08% AUC. The top traditional machine learning model, XGBoost, achieved 78.02% accuracy. Feature importance analysis revealed that binocular visual acuity difference, grade level, average visual acuity, corneal astigmatism, and corneal curvature were the most important predictive factors.

Conclusions: Machine learning and deep learning models, especially the FT-Transformer, demonstrate excellent performance in myopia prediction based on large-scale screening data. Key predictive features include binocular visual acuity difference, grade level, visual acuity indicators, and corneal parameters. These models can provide powerful technical support for early myopia screening and precision intervention in children and adolescents.

Automated Detection and Quantification of Intraretinal Microvascular Abnormality (IRMA) on Widefield Swept-Source OCT Angiography (WF SS-OCTA) in Diabetic Retinopathy: Development of Customized AI Deep Learning Model II in the DRIVE Study

First Author: Wenting ZHOU

Co-Author(s): Charmayne Xinyi ANG, Colin Ming Hui GOH, Peiqi LO, Wei Hing SEAH, Gloria Wenjun SONG, Lingyi ZHUANG

Purpose: To evaluate a customized deep-learning algorithm (Model II) for automated intraretinal microvascular abnormality (IRMA) segmentation on widefield swept-source OCT angiography (WF SS-OCTA) and to correlate findings with diabetic retinopathy (DR) severity.

Methods: Sixty-five eyes were imaged with 12 × 12 mm, 1024 × 1024-pixel SS-OCTA. Two independent graders produced pixel-level IRMA annotations; discrepancies were adjudicated by a retinal specialist, yielding 678 references. A multi-scale U-Net with squeeze-and-excitation attention was trained using heavy augmentation and five-fold cross-validation. Confidence-guided preprocessing excluded motion blur and projection artifacts. Pixel-level performance was measured by the F1 score and object-level accuracy, using intersection-over-union (IoU) ≥ 50%.

Results: Model II achieved a pixel-level F1 of 0.51, exceeding published benchmarks (0.29–0.48). Object-level F1 reached 0.71 at IoU ≥ 50 %. Median IRMA counts climbed from 3.3 ± 0.6 in mild and 7.3 ± 3.0 in moderate NPDR to 12.1 ± 11.0 in severe NPDR and 10.7 ± 14.1 in PDR (p < 0.001 overall), yet showed no significant difference between severe NPDR and PDR (p = 0.05), implying replacement of IRMAs by neovascularization or diffuse ischemia.

Conclusions: This CNN-U-Net framework delivers the first widefield benchmark for automated IRMA

segmentation on SS-OCTA. Offering clinically relevant accuracy and resilience to image-quality variations, it reduces manual workload and supports objective DR grading. Integrated with Model I for non-perfusion analysis, it forms a comprehensive, scalable pipeline for biomarker-based decision support and longitudinal DR monitoring across diverse hardware setups and routine workflows.

Benchmarking Performance and Reasoning Capabilities of Large Vision Language Models in Fundus Photos Interpretation

First Author: Wai Chak CHOY

Co-Author(s): Cindy Xinji CAI, Alvin Ty LIU, Sally Shin Yee ONG, Mira Menon SACHDEVA, Yang ZHANG, Ishrat AHMED

Purpose: Recently, there has been an expanding inventory of large language models with increasing ease for clinical applications. We aim to analyse their performance on interpreting fundus photos and detecting specific diagnoses, and investigate the prevalence of hallucinations.

Methods: Fifty images covering the 10 most retinal conditions were included in the study. Responses were generated by Gemini-1.5-flash, GPT-4-turbo, and GPT-4o and graded by 5 fellowship-trained retinal specialists independently for accuracy, relevant signs identification, prevalence of missing signs, irrelevant signs inclusion, and signs hallucinations. Mann-Whitney U test with multiple comparison adjustment was used to compare results from model pairs.

Results: Across all conditions, highest accuracy was noted for GPT-4o (accuracy=40.7%, CI=34.9%-46.6%), followed by GPT-4-turbo (accuracy=37.8%, CI=32.1%-43.6%) and Gemini-1.5-flash (accuracy=14.2%, CI=10.0%-18.3%). Missing signs for diagnosis were most frequently observed for Gemini-1.5-flash. (rate=86.2%, CI=82.1%-90.3%). GPT-4-turbo (rate=62.5%, CI=56.8%-68.3%) and GPT-4o (rate=63.3%, CI=57.5%-69.0%) showed a similar frequency in missing relevant signs. (P=1.0000) Identifying irrelevant signs was observed in 14.5% (CI=10.4%-18.7%), 13.1% (CI=9.1%-17.1%), and 8.7% (CI=5.4%-12.1%) of responses by Gemini-1.5-flash, GPT-4-Turbo, and GPT-4o, respectively. Signs of hallucination were observed in 89.8% (CI=86.2%-93.4%), 60.7% (CI=54.9%-66.5%), and 65.1% (CI=59.4%-70.8%) of responses from Gemini-1.5-flash, GPT-4-turbo, and GPT-4o, respectively. No statistically significant difference was found in hallucination rate comparing GPT-4-turbo and GPT-4o (P=0.710). Hallucination rate was statistically significantly higher comparing Gemini-1.5-flash to either GPT-4-turbo (P<0.0001).

Conclusions: The current study demonstrated the suboptimal performance of language models in

reaching accurate and grounded diagnoses from fundus images. Further enhancement, especially on the explainability of model responses, would be necessary prior to their safe incorporation into clinical practice.

Brain Activity in Different Brain Areas of Patients With Diabetic Vitreous Hemorrhage According to Voxel-Based Morphometry

First Author: Jinyu HU

Co-Author(s): Yi SHAO

Purpose: To elucidate the neuropathological mechanisms underlying diabetic vitreous hemorrhage (DVH) and its correlation with clinical characteristics.

Methods: Twenty-one individuals with DVH (male/female 12/9; mean age 52.29 ± 11.66 y) were selected, alongside 21 appropriately matched controls with diabetes mellitus (DM). Voxel-based morphometry (VBM) techniques were employed to identify aberrant functional regions in the brain. Receiver operating characteristic (ROC) curves were utilized for classification based on the average VBM values of the two groups, and Pearson correlation analysis was conducted to assess the relationship between average VBM values in distinct brain regions and clinical manifestations.

Results: Relative to the DM controls, DVH patients exhibited reduced VBM values in the right superior temporal pole, the right superior temporal gyrus, the right medial orbital frontal gyrus, and the left superior frontal gyrus. Furthermore, ROC curve analysis of these four brain regions in DVH patients demonstrated a high degree of accuracy, as indicated by the area under the curve. The average VBM value in each of these regions exhibited a negative correlation with both the duration of DVH and the score on the Hospital Anxiety and Depression Scale (HADS).

Conclusions: Pathological alterations in four distinct brain regions are observed in patients with DVH, potentially reflecting neuropathological changes associated with this condition.

Can Corneal Epithelial Mapping Predict Postoperative Visual Quality and Patient Satisfaction in Cataract Surgery?

First Author: Gaurav PANDE

Co-Author(s): Abha SHAH, Rohit SHETTY, Vibha SINGH

Purpose: To evaluate how preoperative corneal epithelial mapping impacts postoperative visual quality and patient-reported quality of life (QoL) in cataract surgery patients, using Artificial Intelligence (AI) to identify predictive markers.

Methods: A total of 250 patients underwent pre- and postoperative evaluation, including epithelial mapping (Placido Ocular Coherence Tomography and Ray-tracing based system) and tear biomarker analysis using the BioM Pathfinder kit. Based on epithelial status, Group 1 (n=169) had regular epithelium and Group 2 (n=81) had irregular epithelium. Postoperative assessments included Uncorrected Visual Acuity (UCVA), Patient-Reported Outcomes with LASIK (PROWL) scores, Optical Quality Analysis System (OQAS), and epithelial/corneal higher-order aberrations (HOAs). AI algorithms were applied to identify predictors of visual and QoL outcomes.

Results: UCVA gains were comparable across groups. However, Group 1 had significantly better visual quality and QoL scores (PROWL<80 in 162/169 patients), while Group 2 had poorer outcomes (PROWL>120 in 48/81). Corneal HOAs and inflammatory biomarkers were markedly elevated in Group 2 ($p<0.05$). AI identified epithelial irregularity as a key predictor of both reduced visual quality and lower QoL.

Conclusions: Corneal epithelial mapping and tear biomarkers serve as effective surrogate markers for predicting both visual outcomes and postoperative quality of life following cataract surgery. Preoperative epithelial mapping helps predict and optimize visual quality after cataract surgery.

CatCapt: A Novel Artificial Intelligence-Based Application to Enhance Cataract Screening Efficiency and Accessibility in Indonesia

First Author: Putry Adenia BAHAR

Co-Author(s): Sri ANDARINI, Hera Dwi NOVITA

Purpose: To evaluate the implementation of the CatCapt application: the novel artificial intelligence-based cataract screening in rural Indonesia using smartphone camera, focusing on its perceived efficiency and accessibility, as assessed through user acceptance variables of Perceived Usefulness (PU) and Perceived Ease of Use (PEU) from the modified Technology Acceptance Model (TAM).

Methods: A quasi-experimental study was conducted among rural health cadres assigned to three groups: roleplay, module-based learning, and video instruction. After training, cadres were instructed to apply CatCapt to the community, screening 448 eyes, and then completed a validated TAM-based questionnaire (Cronbach's alpha >0.6). Efficiency and acceptability were categorized into five levels (very low, low, moderate, high, and very high). Associations with demographic characteristics were analyzed using chi-square tests, and the correlation between PU and PEU was assessed with Spearman's test.

Results: Overall, 95.2% rated PU as very high, while 78.6% rated PEU as very high. No significant association between demographic characteristics and PEU. A strong positive correlation was observed between PU and PEU, indicating that greater perceived usefulness enhanced ease of use.

Conclusions: CatCapt was well accepted by health cadres and perceived as both efficient and accessible for community-based cataract screening to improve early detection and expand access to eye health services in underserved areas of Indonesia.

ChatMyopia: An AI Agent for Myopia-Related Consultation in Primary Eye Care Settings

First Author: Yue WU

Co-Author(s): Xiaolan CHEN, Mingguang HE, Danli SHI

Purpose: While Large language models have been used to provide tailored health information, they still face challenges in multi-task integration and interpretability, particularly for specialized areas such as myopia. Hence, we developed ChatMyopia, a patient-centered AI agent to handle both text-based and image-based myopic inquiries.

Methods: The tool module integrated two components: the image-classifying transformer model trained on 2769 myopic fundus photos, and an RAG-based knowledge base from a diversity of literature. Mistral: 123B was used as the brain to combine tools. We evaluated its performance in the myopic maculopathy classification task, single-choice question (SCQ) exams, and myopia-related question-answering. A randomized controlled study (n=70) was conducted to assess ChatMyopia's effectiveness in enhancing patient education and satisfaction in primary eye care clinics.

Results: ChatMyopia achieved high accuracy in myopic maculopathy grading (AUROC: 0.967, F1 score=0.828), performed comparably to specialists and better than general ECPs in SCQ assessments. In myopic question-answering, ChatMyopia showed equivalent performance to the ECP in terms of utility, relevance, safety, and harmfulness. Both ChatMyopia and the ECP outperformed GPT-4 in these four domains. In the randomized controlled trial, patients who interacted with ChatMyopia demonstrated higher satisfaction with the entire medical service than those who received traditional leaflets. ChatMyopia enhanced patient education and information quality in terms of accuracy, empathy, disease self-consciousness, and patient-ECP communication.

Conclusions: The AI agent can provide high-quality answers to myopia-related questions with improved scalability and interpretability, and serve as a valuable

supplement for patient-centered health information seeking in primary eye care settings.

Choroidal Vascular Fingerprints From Indocyanine Green Angiography Unveil Chorioretinal Disease State

First Author: Ruoyu CHEN

Co-Author(s): Mingguang HE, Xianwen SHANG, Danli SHI, Mayinuer YUSUFU, Ziwei ZHAO

Purpose: To develop an annotation-efficient deep learning algorithm for extracting multi-dimensional features of choroidal vasculature on indocyanine green angiography (ICGA) images via a human-in-the-loop (HITL) strategy and explore their relationship with multiple chorioretinal diseases.

Methods: The segmentation model was trained on a multi-source dataset that included both 55° ICGA and 200° ultra-widefield ICGA (UWF-ICGA) images, utilizing a HITL strategy. Choroidal vascular fingerprints were generated from the segmentation maps, quantifying diameter, density, complexity, tortuosity, and branching angle. Reliability was assessed using intraclass correlation coefficients (ICC), and normal ranges for each measurement were estimated. The study retrospectively included 243 eyes diagnosed with central serous chorioretinopathy (CSC), polypoidal choroidal vasculopathy (PCV), or pathological myopia (PM), as well as 151 normal control eyes, to investigate their association with choroidal vascular fingerprints. Multivariable logistic regression models were used for the analysis.

Results: The model achieved high segmentation accuracy, with the area under the receiver operating characteristic curve (AUC) being 0.975 (95% CI: 0.967–0.983) for 55° view ICGA images and 0.937 (95% CI: 0.914–0.960) for UWF-ICGA images. Twenty-six, twenty-eight, and twenty-nine multi-dimensional measurements were significantly associated with CSC, PCV, and PM, respectively (p value<0.05). The ICC values for 74 choroidal vascular measurements ranged from 0.71 (95% CI: 0.51-0.84) to 0.97 (95% CI: 0.95-0.99).

Conclusions: This study pioneeringly revealed choroidal vascular fingerprints and validated their associations with various chorioretinal diseases. These findings pave the way for future exploration of the pathological mechanisms underlying these conditions.

Abstract No.: 203054**Panel No.: ADV-0056**

Clinical Validation of Artificial Intelligence in Fundus Image Analysis: Real-World Application in Retinal Disease Screening and Diagnosis

*First Author: Ravi Naini KOSTI**Co-Author(s): Narasimha Rao VENKATA*

Purpose: To clinically validate the performance of AI-based fundus image analysis in screening and diagnosing common retinal diseases, and to assess its applicability in real-world ophthalmic practice.

Methods: This prospective clinical study included 100 patients undergoing routine retinal screening. Fundus photographs were analyzed using a deep learning-based AI platform trained to detect diabetic retinopathy (DR), age-related macular degeneration (AMD), and glaucomatous optic neuropathy. AI outputs were compared with diagnoses made by experienced retina specialists, which served as the reference standard. Diagnostic accuracy, sensitivity, specificity, and inter-observer agreement (Cohen's kappa) were evaluated.

Results: The AI system demonstrated an overall diagnostic accuracy of 91.6%, with a sensitivity of 97.0% and specificity of 91.4% for DR detection. For AMD and glaucoma, sensitivity and specificity ranged from 90.2% to 98.5%. The agreement between AI and human experts was substantial ($\kappa = 0.86$). The AI tool reduced evaluation time by 60% without compromising diagnostic reliability.

Conclusions: AI-based fundus image analysis shows high diagnostic accuracy and strong agreement with specialist evaluations in detecting major retinal diseases. Its integration into clinical workflows may enhance early detection, streamline patient triage, and improve access to retinal care, particularly in resource-limited settings.

Abstract No.: 205494**Panel No.: ADV-0069**

Clinical Validation of an Artificial Intelligence-Based Screening Tool for Diabetic Retinopathy at a General Hospital

*First Author: Linh Dieu PHAM**Co-Author(s): Ha Thi Thu HOANG, Anh Thi Lan NGUYEN*

Purpose: To evaluate the clinical effectiveness and feasibility of an artificial intelligence (AI)-based tool for diabetic retinopathy (DR) screening among patients with diabetes at a general hospital.

Methods: A cross-sectional descriptive study was conducted on 383 eyes of patients with diabetes who were examined at a general hospital between July 2022 and February 2024. Fundus photographs were obtained, uploaded, and analyzed using an AI-based

tool. Diagnostic performance was evaluated in terms of sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), accuracy, area under the curve (AUC), and kappa (κ) agreement with ophthalmologists' clinical examinations.

Results: Among 383 eyes, the prevalence of DR, referable DR, and vision-threatening DR was 39.7%, 25.9%, and 14.9%, respectively. For DR detection, the AI tool achieved a sensitivity of 80.3% and a specificity of 96.1% (AUC = 0.882, $\kappa = 0.782$). For referable DR, sensitivity and specificity were 76.8% and 98.2% (AUC = 0.875, $\kappa = 0.797$), and for vision-threatening DR, 71.9% and 98.8% (AUC = 0.854, $\kappa = 0.774$). Overall diagnostic accuracy was high, with kappa values indicating good agreement with ophthalmologists ($\kappa = 0.627$).

Conclusions: AI demonstrated high diagnostic performance for diabetic retinopathy screening, particularly with excellent specificity. However, its limited sensitivity in severe stages requires further improvement and validation.

Abstract No.: 202637**Panel No.: ADV-0053**

Cost-Effectiveness of an AI-Based 3D OCT Image Analysis for Diabetic Macular Edema Identification to Support Triaging

*First Author: Shuyi ZHANG**Co-Author(s): Carmen CHAN, Carol CHEUNG, Anran RAN, Ka Ho SZETO, Jiaying ZHOU*

Purpose: Diabetic macular edema (DME) triaging based on 2D fundus photographs (FPs) has a high false-positive referral rate. We aim to evaluate the cost-effectiveness of employing an AI infrastructure (i.e., AI-OCT system) for DME triaging based on 3D optical coherence tomography (OCT) as an "add-on" to reduce false-positive referrals to tertiary care.

Methods: A decision-analytic Markov model was constructed to compare the costs and effects of the standard practice (status quo) and employing an "add-on" AI-OCT system to the standard practice for DME triaging. It was based on a hypothetical cohort of 100,000 individuals with suspected DME from age 50 years through 30 1-year Markov cycles from the societal perspective. Relevant parameters were from existing literature. Costs were from the Hospital Authority in Hong Kong (HK) and converted to US dollars (USD) at 7.81 HK dollars per USD and with a 3.5% discount rate per year. The study outcomes included incremental cost-effectiveness ratio (ICER), incremental cost, incremental effectiveness, and quality-adjusted life year (QALY) gained. The analysis used a willingness-to-pay threshold of three times the local per capita gross domestic product (GDP).

Results: Over the next 30 years, mean per-person costs and QALYs were \$18,768 and 11.38 for the "add-on" AI system, compared to \$19,515 and 11.35 for the

standard practice, which could save \$74,700,000 and gain 3,000 QALYs, generating an ICER of -24, 900.

Conclusions: Add-on AI-OCT system to standard practice for DME triaging is cost-effective compared to standard practice, providing data on evidence-based healthcare implementation to move AI from “concept” to “real-world”.

Panel No.: ADV-0082

Deep Learning Assisted Retinal Microvasculature Assessment and Cerebral Small Vessel Disease in Fabry Disease

First Author: Xuecong ZHOU

Co-Author(s): Chenying BAO, Yingsi LI, Yuan WU

Purpose: The aim of this study was to assess retinal microvascular parameters (RMPs) in Fabry disease (FD) using deep learning and to analyze the correlation with brain lesions related to cerebral small vessel disease (CSVD).

Methods: In this retrospective case-control study, fundus images from 27 FD patients and 27 age- and sex-matched healthy subjects were collected. RMPs, encompassing diameter, density, symmetry, bifurcation, and tortuosity, were quantified. Laboratory examination results, Mainz severity score index (MSSI) scores, and a brain magnetic resonance imaging scan for CSVD scores were extracted, and their relationships with RMPs were analyzed.

Results: Utilizing artificial intelligence-assisted analysis, compared with controls, FD patients exhibited reduced diameter, density, fractal dimension, and heightened arteriolar and venular asymmetry ratios, venular curvature tortuosity, and simple tortuosity in retinal microvascular networks. Gender-based differences in RMPs were observed among FD patients. Furthermore, RMPs were significantly associated with disease markers such as plasma globotriaosylsphingosine and α -galactosidase A activity, as well as MSSI scores. Notably, there was a significant negative correlation between the arteriolar asymmetry ratio and CSVD-related scores.

Conclusions: Fabry disease patients demonstrated increased vascular tortuosity and asymmetry, reduced density and diameter, and a simpler fractal dimension in retinal microvasculature. These microvascular characteristics may serve as preliminary indicators for assessing brain lesions and could represent potential novel biomarkers for CSVD, aiding in the monitoring of FD severity and progression.

Deep Learning Automated Diagnosis and Grading of Cataracts Using Colour Fundus Images: Internal and External Validation

First Author: Hao Qi MAK

Purpose: The Fundus Cataract-AI project aims to automate cataract diagnosis and grading using deep learning techniques applied to standard macula-centric fundus photos.

Methods: A dataset comprising 11,544 fundus images from Chinese patients, aged 50 and above, from a cross-sectional random population-based study was utilised. Subjects were assessed with visual acuity, best-corrected visual acuity (BCVA), automatic and subjective refraction, IOP, slit-lamp examination of the anterior segment, funduscopy examination of the posterior segment, and Fundus photography. The images were categorized into ‘normal’, ‘early cataract’, and ‘visually significant cataract’ by the ophthalmologist and BCVA. A ResNet152 convolutional neural network, pretrained via transfer learning, was employed. The main outcome was the area under the curve (AUC) with accuracy, sensitivity, and specificity. External validation was performed using a prospective database of 1,200 consecutive subjects, aged >50 with chronic visual impairment.

Results: Excluding images of patients who underwent cataract surgery and those with poor quality, 6,961 images were used. The distribution of ‘normal’, ‘early cataract’, and ‘visually significant cataract’ was 31.7%, 45.9% and 13.0% respectively. Internal validation demonstrated an AUC of 0.95 for normal vs rest, 0.93 for early cataract vs rest, and 0.92 for visually significant cataract vs rest. External validation demonstrated an AUC of 0.88, 0.84, and 0.96, respectively. Review of hot spots showed the optic disc and macula as areas of interest. 36.3% of subjects given a routine appointment at triage already had significant cataracts requiring surgery.

Conclusions: Machine learning can accurately assist in the diagnosis and grading of cataracts using fundus photos alone.

Abstract No.: 205025

Panel No.: ADV-0063

Deep Learning for Automated Diagnosis of Polypoidal Choroidal Vasculopathy Using Indocyanine Green Angiography

First Author: Hiu Ping LAI

Co-Author(s): Rose CHAN, Anthony LAI, Robert LAM, Noel WAT, Eva WONG

Purpose: Polypoidal choroidal vasculopathy (PCV) is an important subtype of neovascular age-related macular degeneration (nAMD). Indocyanine green angiography (ICGA) is considered the diagnostic gold standard but

requires expertise and significant resources. This study evaluated the performance of a deep learning model for automated PCV classification using ICGA.

Methods: We retrospectively collected 1,974 angiography sets (ICGA and fluorescein angiography, FA) from 1,460 eyes of 1,290 patients with nAMD at Caritas Medical Centre between 2010 and 2020. Diagnoses of PCV and choroidal neovascularization (AMD-CNV) were confirmed by three retina specialists using multimodal imaging and EVEREST criteria. A total of 19,740 ICGA images (830 PCV, 1,144 AMD-CNV sets) were de-identified, preprocessed, augmented, and used to train a convolutional neural network with patient-level randomization to avoid inter-eye overlap.

Results: The ICGA-based deep learning model achieved an overall accuracy of 84.6% (95% CI: 83.5–85.7). Sensitivity for PCV detection was 0.873 (95% CI: 0.863–0.883) and specificity was 0.813 (95% CI: 0.801–0.825). The precision (positive predictive value) was 0.848 (95% CI: 0.827–0.859), and the negative predictive value was 0.873 (95% CI: 0.863–0.883). The F1 score was 0.860 (95% CI: 0.850–0.871).

Conclusions: Deep learning applied to ICGA produced diagnostic metrics consistent with clinical applicability. This approach may support clinical decision-making, training, and telemedicine in the management of nAMD.

Deep Learning for Vision Screening in Resource-Limited Settings: Development of a Multi-Branch CNN for Refractive Error Detection Based on Smartphone Image

First Author: Muhammad SYAUQIE

Purpose: This study aimed to develop an automated deep learning-based prediction system to assess refractive error using photorefractive images of Indonesian people taken with a smartphone.

Methods: A multi-branch convolutional neural network (CNN) was developed and trained on a dataset of 2,139 corneal images from Indonesian people. The workflow for the Multi-branch CNN model begins with the acquisition of pupillary red reflex images using a smartphone. These images were preprocessed to ensure uniformity and standardized for optimal training performance. The model is designed as a multi-branch CNN with three branches. The architecture consists of convolutional layers (Conv2D) followed by ReLU activations and MaxPooling layers. The preprocessed images are fed into the selected CNN architecture—1-branch, 2-branch, or 3-branch—for feature extraction and classification. The classification output predicts one of the following four classes: “Not Applicable to Classified,” “Significant Hypermetropia,” “Insignificant Refractive Error,” and “Significant Myopia.” The

workflow culminates in model evaluation, where metrics such as accuracy, precision, recall, and F1-score are computed.

Results: The validation accuracy and loss of the one-branch, two-branch, and three-branch models are 0.9760 and 0.0800, 0.9688 and 0.1137, and 0.9866 and 0.0762, respectively. The 3-branch CNN architecture demonstrated superior performance, achieving an overall test accuracy of 91%, precision of 96%, recall of 98%, and F1-score of 91%, with an area under the curve (AUC) score of 0.9896.

Conclusions: The integration of CNN models with smartphone-based image acquisition systems offers a scalable and cost-effective refractive error screening solution.

Deep Learning-Based Prediction of Secondary Glaucoma Following Retinal Surgery: Toward Personalized Risk Stratification

First Author: Young In SHIN

Co-Author(s): Jin Wook JEOUNG

Purpose: To develop and evaluate deep learning models for predicting glaucoma occurrence after pars plana vitrectomy (PPV), using both laboratory and ophthalmic clinical data.

Methods: This retrospective cohort study analyzed patients who underwent PPV between 2018 and 2025, identified from a clinical data warehouse (CDW). Laboratory data (hematologic and biochemical parameters) and ophthalmic clinical data (preoperative intraocular pressure [IOP], lens status, central corneal thickness, anterior chamber depth, axial length, preoperative spherical equivalent, prior ocular surgery, combined cataract surgery, intravitreal injection counts, and postoperative IOP spikes) were collected. Patients were classified into glaucoma (n=110) and non-glaucoma (n=79) groups. Logistic regression (LR), support vector machine (SVM), random forest (RF), and extreme gradient boosting (XGB) models were trained with two input sets: (1) demographic + laboratory data and (2) demographic + laboratory + ophthalmic clinical data. Model performance was assessed by five-fold cross-validation using accuracy, sensitivity, specificity, F1 score, and area under the curve (AUC).

Results: Models trained on laboratory data alone demonstrated modest performance (AUC ~0.55–0.61). Inclusion of ophthalmic clinical variables markedly improved discrimination. Across folds, SVM and RF achieved the highest performance, with AUC up to 0.82 and F1 scores up to 0.80. Logistic regression models incorporating ophthalmic variables also yielded stable results (AUC 0.73–0.81). Key predictors included baseline IOP, use of antiglaucoma drops, and intraoperative tamponade use.

Conclusions: These findings support the feasibility of AI-assisted risk stratification in postoperative glaucoma surveillance and highlight the importance of combining systemic and ocular parameters for improved predictive accuracy.

Development and Evaluation of the Retrieval-Augmented Large Language Model for Lifestyle Guidance in Dry Eye Patients

First Author: Jiaxin YANG

Co-Author(s): Hongbo YIN

Purpose: We developed an implementation of large language models (LLMs) focused on dry eye disease (DED) lifestyle management based on GPT-O1 and DeepSeek, respectively. Furthermore, how these two LLMs can be used to generate personalized lifestyle guidance for dry eye patients and how their answers compared with those of GPT-O1, DeepSeek, and an ophthalmologist in the dry eye group were evaluated.

Methods: The development process consisted of three key stages: (1) construction of a curated knowledge base, (2) integration of Retrieval-Augmented Generation (RAG), and (3) enhancement through In-Context Learning (ICL) and Role-based Instruction Prompting. The LLM assessment provides both physician and user dimensions. Physicians assessed response quality in the following domains: incorrect or inappropriate content, omissions, and the likelihood and extent of possible harm. User evaluation focused on the fulfillment of user intent and the helpfulness of the content.

Results: A total of 500 responses were evaluated. The trained models, DED-GPT and DED-DeepSeek, showed significantly superior performance in completeness and helpfulness ($P < 0.05$). DED-GPT improved correctness and appropriateness from 70% of the baseline model to 85% ($P < 0.05$), while DED-DeepSeek increased from 64% to 78%. DED-GPT and DED-DeepSeek completely eliminated severe harm events. All response sources performed well in addressing the lay users' intent.

Conclusions: The study has proposed an at-home dry eye consultant with lifestyle guidance for DED patients, aiming to expand personalized education pathways for patients with DED.

Development of a Smartphone Application With Artificial Intelligence for Diagnostic Support of Anterior Segment Diseases

First Author: Yoshikazu ITO

Co-Author(s): Hiroki MAEHARA, Masahiro ODA, Tetsuro OSHIKA, Yuta UENO

Purpose: We developed an artificial intelligence (AI) model to support the diagnosis of anterior segment diseases using slit-lamp images (5,270 images). Based on the existing AI model, we also developed a smartphone application version, specifically designed to process anterior segment images captured by smartphones.

Methods: Smartphone images of the anterior segment (2,530 images) were obtained from a clinical study between September 2020 and September 2024. These images consisted of nine categories (normal condition, infectious keratitis, immunological keratitis, corneal scar, corneal deposit, bullous keratopathy, ocular surface tumor, cataract/intraocular lens opacity, and acute glaucoma attack). Transfer learning was applied to the existing AI model to create a version specifically adapted for smartphone images. Among these images, 860 images were analyzed with the AI model before and after transfer learning, and the classification accuracy of both the existing AI model and the smartphone-adapted AI model was compared on smartphone images to validate the precision of the smartphone version.

Results: The diagnostic accuracy for smartphone images was 67.0% for the existing AI model and 93.5% for the smartphone-adapted AI model. The smartphone-adapted AI model demonstrated significantly improved accuracy ($P = 0.0033$).

Conclusions: For the development of an application, the smartphone-adapted AI model improved diagnostic support accuracy through additional training.

Diagnosis of Forme Fruste Keratoconus Using Corvis ST Sequences With Digital Image Correlation and Machine Learning

First Author: Lanting YANG

Co-Author(s): Wang JUNJIE, Chen SHIHAO

Purpose: This study aimed to employ the incremental digital image correlation (DIC) method to obtain displacement and strain field data of the cornea from Corvis ST (CVS) sequences and assess the performance of embedding these biomechanical data with machine learning models to distinguish forme fruste keratoconus (FFKC) from normal corneas.

Methods: One hundred subjects were categorized into normal (N = 50) and FFKC (N = 50) groups. Image sequences depicting the horizontal cross-section of the human cornea under an air puff were captured using the Corvis ST tonometer. The high-speed evolution of full-field corneal displacement, strain, velocity, and strain rate was reconstructed utilizing the incremental DIC approach. These evolution data were input into two machine learning (ML) models, specifically Naïve Bayes (NB) and Random Forest (RF) models. The performance of the models in diagnosing FFKC from normal corneas was compared to existing CVS parameters.

Results: The results demonstrated that the proposed voting ensemble model yielded the highest performance with an AUC of 1.00, followed by the RF model with an AUC of 0.99. Radius and A2 Time emerged as the best-performing CVS parameters with AUC values of 0.948 and 0.938, respectively. Nonetheless, no existing Corvis ST parameters outperformed the ML models.

Conclusions: This study represents the first instance where displacement and strain data following incremental DIC analysis of Corvis ST images were integrated with machine learning models to effectively differentiate FFKC corneas from normal ones, achieving superior accuracy compared to existing CVS parameters.

Diagnostic Accuracy of Ret-InnoQ: A Portable, Smartphone-Based Fundus Camera for Detection of Vision-Threatening Diabetic Retinopathy

First Author: Anggraeni PUSPITA

Co-Author(s): Moh Eko PRAYOGO, M Bayu SASONGKO, Idhayu Anggit WIDHASARI, Felicia WIDYAPUTRI

Purpose: Standard tabletop fundus cameras, while effective, are costly and cumbersome, limiting their use in primary care and community settings. Ret-InnoQ, a portable smartphone-based fundus camera, offers a potential low-cost, mobile alternative. This study aimed to evaluate Ret-InnoQ's diagnostic performance against a standard tabletop fundus camera in detecting vision-threatening diabetic retinopathy (VTDR).

Methods: This cross-sectional diagnostic study recruited patients with type 2 diabetes in Yogyakarta. Following pupil dilation, macula-centered images of both eyes were captured using the Ret-InnoQ and the Topcon TRC-50DX, which served as the reference standard. Two independent graders classified each eye as referable (VTDR, defined as having severe non-proliferative DR, proliferative DR, or diabetic macular edema) or non-referable. Images with poor quality or those with other ocular pathologies were excluded from analysis.

Results: Of 1,024 retinal images, 110 were excluded due to other eye diseases and 112 for poor image quality, leaving 802 gradable images from 512 patients (mean age 58.5 years; 65.0% females). Exact agreement between Ret-InnoQ and the reference standard was observed in 721 images (89.9%), with substantial intermethod agreement ($\kappa = 0.79$). Ret-InnoQ achieved a sensitivity of 90.6% (95%CI: 86.7-93.7%), specificity of 89.5% (95%CI: 86.4-92.0%), and an area under the ROC curve (AUC) of 0.900 in detecting VTDR.

Conclusions: Ret-InnoQ demonstrated high diagnostic accuracy for detecting VTDR and identifying patients requiring referral. Its portability, affordability, and reliability support its potential as a scalable screening tool, particularly in primary care and low-resource settings.

Diagnostic Performance of Artificial Intelligence in Primary Angle Closure Disease Based on Anterior Segment Optical Coherence Tomography: A Systematic Review and Meta-Analysis

First Author: Kristen WONG

Co-Author(s): Sally CHAN, Carol CHEUNG, Annie LING, Ruyue SHEN, Clement THAM

Purpose: Anterior chamber angle closure can lead to primary angle closure glaucoma, a major cause of visual impairment. Deep learning is promising for disease detection from medical images. This review aims to summarize the performance of deep learning algorithms as an alternative in primary angle closure disease detection from anterior segment optical coherence tomography (AS-OCT) images.

Methods: A literature search was performed on PubMed, Embase, and Web of Science from database inception to August 1, 2024. We selected studies that developed deep learning models detecting angle closure, and extracted study characteristics. R software was used to generate forest plots using a random-effects model and summary receiver operating characteristic curves. Assessments of paper quality were conducted using QUADAS-2 tool and CLAIM checklist. This study was registered in PROSPERO (CRD42024569234).

Results: Our search yielded 19 and 12 studies eligible for qualitative and quantitative analysis, respectively. A pooled AUC of 0.98 (95% CI, 0.95-1.01) was obtained, with the lowest score from our sensitivity analysis achieving 0.92 (95% CI, 0.89-0.95). Though heterogeneity was low (Q-value = 20.80, I² value = 8.66%), the high corresponding P-value prompted an exploratory subgroup analysis into the potential impact of paper quality, publication year, and sample size on diagnostic accuracy.

Conclusions: The high pooled AUCs indicated the feasibility of AS-OCT as an alternative to angle closure detection. However, the predominantly Asian patient population and insufficient datasets constrained the impact of novel techniques. Suggestions for standardization and future technical directions are offered to improve future studies.

Effects of Hypnotic Use on Pupillary Light Reflex and Eye Tracking: A Systematic Review

First Author: Ming Chi CHOY

Co-Author(s): Kam Lung Kelvin CHONG, Ka Hei Kenneth LAI, Chi Pui Calvin PANG, Chee Yung Clement THAM, Yiu Man Hanson WONG

Purpose: This review aims to analyse the effects of hypnotic use on Pupillary Light Reflex (PLR) and Eye Tracking (ET) properties. While PLR and ET parameters provide insight into the conscious level, reliance, and cognitive state, they also offer understanding of the Autonomic Nervous System under hypnotic influence.

Methods: This systematic review was conducted in accordance with the PRISMA guidelines. A systematic search was performed using online databases including Scopus, Medline, PubMed, and Cochrane. Data extraction was conducted by two independent researchers using predefined structural tables.

Results: After screening 112 abstracts, 9 studies were selected. Hypnotic and sedative drugs cause miosis, particularly diphenhydramine. Miosis (decreased baseline pupil diameter) was evident even without a change in the amplitude of PLR, implying disturbance in sympathetic activity. Conventional hypnotic diazepam, however, was found not to significantly alter pupil diameter or PLR. In general, hypnotics blunted the PLR in proportion to the degree of sedation or depth of the hypnotic state. Concerning ET, hypnotics cause decreased blinking, a smaller degree, and shorter saccadic eye movements. Saccades were found to be reduced in both magnitude and frequency across hypnotizable individuals. Two articles suggested that these findings could be related to impaired cognitive control and attention.

Conclusions: Hypnotic has consistently been shown to cause miosis and blunted PLR. Mechanisms of a decelerated saccadic eye movement require further investigation. Future research should be conducted to investigate whether specific changes in pupil diameter, PLR, and ET parameters may be used to detect potential hypnotic misuse and guide rehabilitative treatment.

Panel No.: ADV-0047

Embodied Artificial Intelligence in Ophthalmology

First Author: Xinyuan WU

Co-Author(s): Xiaolan CHEN, Mingguang HE, Danli SHI

Purpose: Embodied artificial intelligence (EAI) integrates perception, reasoning, memory, and action through physical interaction with the environment. In ophthalmology, where precision, multimodal imaging, and adaptive decision-making are essential, EAI offers new opportunities for screening, surgery, education, and research. This work aims to summarize the state of EAI in ophthalmology, highlight its unique advantages, and identify challenges for clinical integration.

Methods: We reviewed current developments in EAI, including multimodal sensing, memory-enabled continuous learning, large language model-based reasoning, and robotic control. Case studies and representative systems were analyzed across ophthalmic screening, surgical assistance, assistive navigation, education, and biomedical research. Challenges about data availability, algorithmic generalization, evaluation protocols, ethics, and regulation were also assessed.

Results: EAI systems demonstrate potential to enhance ophthalmic practice by enabling autonomous screening, intraoperative decision support, visually impaired navigation aids, immersive medical education, and automated research pipelines. Early studies show feasibility in robotic subretinal injection, AI-guided cataract surgery, and at-home retinal monitoring, achieving high accuracy and improved efficiency. However, real-world deployment remains limited due to technical constraints, insufficient evaluation standards, and unresolved ethical and legal concerns.

Conclusions: EAI has the potential to transform ophthalmology by providing real-time, adaptive, and personalized solutions. While still in early development, its integration across clinical care, education, and research could reduce clinician workload and expand access to high-quality eye care. Future work should focus on developing robust evaluation frameworks, addressing ethical and regulatory issues, and conducting multi-center validation to ensure safe and responsible adoption in practice.

Abstract No.: 206439**Panel No.: ADV-0081**

Evaluation of Artificial Intelligence Implementation in Primary Care: A Scoping Review

*First Author: Zehua JIANG**Co-Author(s): Chenyang PEI, Bin SHENG, Tien Yin WONG, Dian ZENG, Zihao ZOU*

Purpose: To systematically synthesize and map the existing evidence on the evaluation of artificial intelligence implementation in primary care, thereby informing future research, clinical practice, and policy development to advance its effective, safe, and sustainable integration.

Methods: PubMed, Web of Science, and the Cochrane Library were searched up to July 31, 2025, for studies on the evaluation of the AI implementation in primary care. Eligible English-language studies developed, implemented, or evaluated AI and reported performance or evaluation data. Screening and full-text review were done independently by multiple reviewers, with discrepancies resolved by consensus. Data were extracted using a standardized form and synthesized in tabular and narrative formats to map study characteristics, AI applications, evaluation methods, outcome measures, and reported findings.

Results: Of 4,184 abstracts, 732 underwent full-text review, and 154 studies were included. Most were conducted in the US (21.4%), UK (14.9%), China (14.3%), and the Netherlands (7.1%), with publications increasing after 2021. Machine learning (59.7%) and deep learning (27.3%) were the main approaches, primarily for prediction (40.3%) and diagnosis (21.4%). Key application areas were preventive care (37.7%), triage/initial diagnosis (35.7%), and chronic disease management (14.9%), targeting cardiovascular (12.3%), cancer (9.7%), metabolic (9.7%), and ophthalmologic (9.7%) conditions. Evaluations focused on technical performance (accuracy 69.5%, discrimination 40.9%), while operational, patient-centered, and system-level outcomes were rare, with most studies being observational (77.3%) and retrospective (51.9%), highlighting a strong focus on model performance over real-world impact.

Conclusions: AI evaluation in primary care mainly focuses on technical performance, highlighting the need for standardized frameworks capturing comprehensive outcomes.

Abstract No.: 201842**Panel No.: ADV-0045**

Evidence-Based Screening Criteria of ROP and Outcomes of ROP Treatment in Mongolia

First Author: Tsengelmaa CHULUUNBAT

Purpose: To investigate the outcomes of ROP screening, intravitreal VEGF and laser surgery in the treatment

of ROP and describe an evidence-based and specific process for identifying BW and GA screening guidelines in Mongolia utilizing telemedicine.

Methods: This was a retrospective of prematurity infants screened for ROP from 2012 September to January 2025 and a prospective cohort study of premature infants with treatment-requiring ROP who received intravitreal injections, laser surgery, and combined therapy from 2015 December 01 to January 31, 2017. Demographic factors, diagnosis, and clinical course were recorded in a de-identified manner using REDCap, a secure, web-based platform to collect image and demographic data. The IRB approved the study protocol, not requiring parental consent, due to the de-identified nature of the data, which was used for program monitoring purposes.

Results: A total of 19,161 premature infants with BW ≤ 2500 g and/or GA ≤ 36 weeks were screened for ROP during the study period. Among them, 691 (3.6%) required treatment. The 193 infants who received ROP screening had a mean GA of 30.09 ± 1.7 weeks and a mean BW of 1500.3 ± 125.42 g. The BW of infants in this study ranged from 750g to 2000g, and the GA at birth ranged from 25 to 35 weeks. The BW of infants in this study ranged from 750g to 2000g, and the GA at birth ranged from 25 to 35 weeks.

Conclusions: After treatment, resolution of ROP was noted in approximately 96 % of the patients who had treatment-requiring ROP.

Abstract No.: 206924**Panel No.: ADV-0088**

Eyes on the Patient: Evaluating Generative Artificial Intelligence for Clinic Letter Writing in Oculoplastic Surgery

*First Author: Victoria NGAI**Co-Author(s): Claire DANIEL, Piers DANIEL, Mohsan MALIK, Basil SURESH, Antonia VIEIRA VENDER*

Purpose: Clinic letters are essential for continuity of care and patient communication. They fail their purpose if they are not understandable to patients. Increasing clinical demands, however, limit the time clinicians can devote to writing clear, comprehensive letters. Medically trained secretaries offer an alternative by transcribing dictated records, albeit with costs and potential transcription errors. Large language models (LLMs) present a novel option, using prompt engineering to automate the transcription of medical records. Our aim was to evaluate the readability of oculoplastic clinic letters written by clinicians, secretaries, and an LLM tool.

Methods: Retrospective analysis of outpatient letters from a tertiary oculoplastic clinic from January to July 2025 (n=483). Letters were evaluated using validated readability tools: Flesch Reading Ease Score (FRES) and Flesch-Kincaid Grade Level (FKGL), and stratified by

authorship: clinician, secretary, or LLM consultation summary tool. Descriptive statistics and one-way ANOVA were used to compare groups.

Results: FRES did not differ between clinician (47.3) and LLM-generated letters (47.4), but both were less readable than secretary-authored letters (57.9, $p < 0.05$). All averages were below 70, the threshold for optimal readability. FKGL differed significantly across groups ($p < 0.05$), with clinicians averaging 11.3 (least readable), LLMs 10.5, and secretaries 9.4 (most readable)—equivalent to adolescents aged 14–16, which remains higher than the average reading level of 9–11-year-olds in the United Kingdom.

Conclusions: LLM-generated letters mirror clinician writing and may offer efficiency and cost advantages. However, letters still remain at too high a reading level for most patients. Further work in prompt engineering may contribute to improved accessibility of clinic letters.

From Detection to Prognosis: Real-World Experience With Machine Learning Models for Identification, Classification, and Progression of Corneal Infections

First Author: Poornima TANDRA
Co-Author(s): Tanmay GOKHALE, Jayang GURUNG, Vineet JOSHI, Naresh NELATURI, Satyam TRIPATHI

Purpose: To measure the impact of deploying Artificial Intelligence (AI)-driven models for the auto-annotation and classification of corneal conditions from slit-lamp images, specifically to (1) distinguish infection from corneal scar and oedema, (2) differentiate fungal and bacterial keratitis, and (3) assess disease progression across follow-up visits in a rural Indian setting.

Methods: Three deep learning models were trained on slit-lamp images of microbial keratitis and related lesions. Images underwent preprocessing, including segmentation and extraction of sharpness, texture, and colour features. Model 1 classified lesions as Infection, Scar, or Edema. Model 2 differentiated microbial infections into fungal, bacterial, or other causes. Model 3 was designed to assess disease progression across sequential follow-up visits. The models were tested on 10,000 prospectively collected real-world images, including smartphone-captured images from rural outreach clinics, to evaluate generalizability. Validation of Model 3 is ongoing.

Results: Model 1 achieved sensitivities of 85.5% for Infection, 85% for Edema, and 82% for Scar. Model 2 showed 87.1% accuracy, AUC of 0.947, and F1 score of 0.876 in classifying infection types. Performance on smartphone-captured images was comparable to internal validation.

Conclusions: AI models trained on slit-lamp images can effectively detect and classify corneal infections. Real-world validation, including smartphone-captured images, demonstrates robustness and highlights the potential to support clinical decision-making in resource-limited rural settings.

Generative AI-Based Chatbot to Triage Ophthalmic Emergencies in Tele-Ophthalmology

First Author: How Sheng Rubin YONG
Co-Author(s): Ziyu David CHEN, Naimah Binte ISMAIL, Dayna YONG

Purpose: To assess the accuracy and patient acceptance of a novel Generative AI-based (GenAI) chatbot for self-triage of acute ophthalmic symptoms.

Methods: A prospective study was conducted at a tertiary institute's ophthalmology clinic from October 2024 to July 2025. Patients presenting with acute ophthalmic symptoms were assessed by two ophthalmologists independently and stratified into high-risk (emergency), medium-risk (urgent), or low-risk (minor) categories based on the Community Minor & Urgent Eye Care Service (CUES) guidelines. Patients also engaged with the chatbot to generate triage recommendations. Agreement between the chatbot and ophthalmologists' gradings was analysed. Patients' acceptance of the chatbot was evaluated using a modified Website User Survey.

Results: A total of 132 eligible responses were analysed - 6 (4.55%) classified as emergency, 106 (80.30%) urgent, and 20 (15.15%) minor. 75.00% were accurately triaged, with the highest accuracy for urgent cases (81.13%), but only 50.00% for emergency and minor cases. Agreement between the clinician's gradings and chatbot recommendations was fair (Cohen's Kappa = 0.373, 95% confidence interval: 0.219-0.528). 19 (14.39%) patients were over-triaged by 1 class, 3 (2.27%) by 2 classes; 9 (6.82%) were under-triaged by 1 class, 2 (1.52%) by 2 classes. Patient feedback was positive, with 127 (96.21%) agreeing the chatbot is user-friendly, and 101 (76.52%) were willing to use it again before seeking in-person care by an ophthalmologist.

Conclusions: Using the chatbot, medium-risk cases had better triaging accuracy. While refinement is required to improve accuracy, positive patient feedback underscores the potential role of GenAI chatbots in enhancing the accessibility and scalability of tele-ophthalmology services.

Implementation of Fast and Precise Quality of Life (QoL) Computerized Adaptive Tests (CATs) in Retinal Eye Clinics at Three Healthcare Clusters in Singapore

First Author: Ryan E.k. **MAN**Co-Author(s): Amudha **ARAVINDHAN**, Beau J. **FENNER**, Eva K. **FENWICK**, Ecosse L. **LAMOUREUX**, Anna C.s. **TAN**

Purpose: This study evaluated the implementation of the RetCAT, a computerized adaptive patient-reported outcome measure assessing the impact of diabetic eye disease on five quality-of-life (QoL) domains in tertiary retinal eye clinics in Singapore.

Methods: This cross-sectional study commenced in Aug 2024 and is currently ongoing in retinal clinics at Singapore National Eye Centre (SNEC), Tan Tock Seng Hospital (TTSH), and National University Hospital (NUH). At SNEC, RetCAT was integrated into electronic medical records (EMR), allowing remote completion via WhatsApp or in-clinic on tablets prior to treatment/consultation. At TTSH and NUH, RetCAT could only be completed in-clinic as EMR integration was not feasible. Implementation outcomes included feasibility (response rates), and user acceptability and satisfaction assessed with validated questionnaires (score range: 0-5; higher is better). Semi-structured interviews explored patient barriers/facilitators to uptake, with transcripts analyzed thematically.

Results: To date, of the 422, 198, and 128 patients who were sent the RetCAT links at SNEC, NUH, and TTSH, respectively, response rates were 85.8% (39% remote, 62% in-clinic), 83.2%, and 90.2%. Patient acceptability (mean $\pm$ SD: 3.75 $\pm$ 0.44) and satisfaction (mean $\pm$ SD: 3.81 $\pm$ 0.56) scores were high. Key barriers included scam concerns, poor visual ability, and having limited RetCATTM information. Facilitators included staff assistance, having adequate time, and the perceived value of CAT data in treatment planning.

Conclusions: Our initial results suggest that implementation of RetCATTM is feasible and acceptable to patients in tertiary retinal clinics in Singapore. Efforts are underway to collect post-treatment QoL data, support doctor-patient result reviews, and gather stakeholders' feedback to optimize processes.

Abstract No.: 201718

Panel No.: ADV-0046

Innovation in Corneal Ulcer Diagnosis-Evaluating Multimodal ChatGPT-4 With Anterior Segment Images

First Author: Bharat **GURNANI**Co-Author(s): Prashant **GIREESH**, Tapesh **NAG**

Purpose: This study aimed to evaluate the diagnostic accuracy of ChatGPT-4, a large language model (LLM),

in identifying corneal ulcers using anterior segment images (ASIs) without prior training or fine-tuning.

Methods: The Anterior Segment Ocular Disease (ASOD) dataset was employed, comprising 300 testing images. ChatGPT-4 was tasked with classifying each image as either "Likely Corneal Ulcer" or "Likely Non-Corneal Ulcer." A confusion matrix was generated to visualize prediction outcomes, with emphasis on binary classification metrics including accuracy, sensitivity, specificity, precision, and F1 score.

Results: ChatGPT-4 achieved an overall diagnostic accuracy of 85% (95% CI: 81%–89%). Sensitivity was 60% (95% CI: 50%–70%), while specificity reached 90% (95% CI: 85%–95%). Precision was 55% (95% CI: 45%–65%), and the F1 score was 0.57. The model demonstrated consistently high performance in correctly excluding non-ulcer cases, thereby reducing false positives, while moderate sensitivity highlighted the challenge of detecting subtle or atypical ulcer presentations. Notably, the balanced trade-off between precision and specificity suggests clinical applicability in triage and screening workflows, particularly when rapid decision-making is critical.

Conclusions: ChatGPT-4 demonstrated promising diagnostic performance in classifying corneal ulcers from ASIs despite the absence of dedicated image-based training. This suggests that advanced LLMs may leverage intrinsic multimodal reasoning to achieve clinically useful results with minimal data preparation.

Machine-Learning Classification of Infrared Pupillometry in Cocaine and Methamphetamine Users

First Author: Andy Lm **AU**Co-Author(s): Kelvin Mh **CHEANG**, Kelvin Kl **CHONG**, Alice Mc **CHOY**, Marco Sy **MAN**, Hanson Ym **WONG**

Purpose: To investigate the characteristics of pupil light reflex (PLR) during infrared pupillometry in cocaine and methamphetamine users, compared to age- and sex-matched controls, and to assess the performance of machine learning algorithms in differentiating drug users and control subjects using PLR.

Methods: Eighteen drug users and 18 healthy controls were recruited. PLR parameters were collected via a commercially available hand-held pupillometer (NeuroLight, IDMed Corp, San Antonio, TX) and a 3-stage infrared pupillometry delivered by a virtual reality-head mount display (VIP) as we recently described. The primary PLR features were extracted by two trained observers masked to subjects' classification, including resting pupil diameters, relative constriction amplitude, and constriction time. Statistical analysis and 7 supervised machine learning classifiers were employed to analyse the extracted

features. The performance of each model was examined through cross-validation and was reported in terms of sensitivity, specificity, and area under the receiver operating characteristic curve (AUC).

Results: Cocaine and methamphetamine users have significantly smaller baseline pupil diameter, minimum pupil diameter, and more pupillary escape ($P < 0.05$). The best-performing machine learning model achieved an accuracy of 0.76 (sensitivity: 0.72, specificity: 0.83, AUC: 0.8025).

Conclusions: PLR parameters differ significantly between stimulant drug users and controls, with the paradoxically smaller pupil size possibly mediated by neuroadaptive changes or autonomic dysfunction in long-standing drug use. A larger sample size is necessary to minimize inter-subject variability. The limited sensitivity, despite good specificity, correlates with variability in drug history and measurement noise associated with VIP. Employing a machine learning approach suggests potential benefits for non-invasive PLR screening in clinical settings.

Panel No.: ADV-0064

Multimodal, Multi-Disease Medical Imaging Foundation Model (MerMED-FM)

First Author: Chrystie QUEK

Co-Author(s): Rick Siow Mong GOH, Yong LIU, Daniel Shu Wei TING, Jun ZHOU, Yang ZHOU

Purpose: Current artificial intelligence models for medical imaging are predominantly single modality and disease. Attempts to create multimodal, multi-disease models have resulted in inconsistent accuracy and require large, labour-intensive, well-labelled datasets. To address these limitations, we developed MerMED-FM, a state-of-the-art multimodal, multi-specialty foundation model designed for robust cross-specialty diagnostic performance.

Methods: MerMED-FM was trained on 3.3 million images spanning ten specialties and seven modalities, including computed tomography (CT), chest X-rays (CXR), ultrasound (US), pathology, colour fundus photography (CFP), optical coherence tomography (OCT) and dermatology images. Training used a self-supervised learning framework and a dynamic memory module with First-In, First-Out mechanism.

Results: MerMED-FM was evaluated on 15 datasets (9 public, 6 private) for ocular disease diagnosis using OCT and CFP. It achieved AUROCs of 0.988 (OCT) and 0.894 (CFP). On OCT, MerMED-FM outperformed a leading ophthalmic model in detecting various retinal conditions, with higher AUROCs on OCTDL (0.991 vs 0.986, $p < 0.01$) and OCTID (0.998 vs 0.960, $p < 0.01$). On CFP, it achieved an AUROC of 0.957 for diagnosing glaucoma, exceeding the comparator (0.937, $p < 0.01$). Performance for diabetic retinopathy was more

variable. Beyond ophthalmology, MerMED-FM also showed strong, data-efficient performance on lung and systemic diseases using CT and CXR.

Conclusions: MerMED-FM is an unsupervised, multimodal, multi-disease foundation model with cross-specialty potential. By bridging siloed imaging domains, it offers a scalable approach to improving diagnostic accuracy, streamlining workflows, and enabling integrated, patient-centred care.

MyopiaGPT: A Specialized Retrieval-Augmented Generation System for Reliable Medical Information in Myopia

First Author: Yawen GUO

Co-Author(s): Edison FUNG, Tsz Tat HUNG, Christopher LEUNG, Ryan WONG, Xu YAN, Xiujuan ZHANG

Purpose: Current commercial language models pose significant clinical risks due to unreliable medical information generation stemming from training on unverified internet data rather than validated clinical sources. Additionally, these models struggle with domain-specific knowledge and raise privacy concerns in clinical settings. We developed MyopiaGPT, a specialized retrieval-augmented generation system addressing these limitations through innovative architecture incorporating peer-reviewed literature and advanced question-answer transformation.

Methods: MyopiaGPT was constructed using peer-reviewed publications (impact factor ≥ 2.5) from PubMed Central, generating 33,070 question-answer pairs with preserved metadata. Our system employs knowledge distillation of long-form text and leverages a score-based module for enhanced retrieval. The system implements impact factor-weighted retrieval during inference. We conducted a systematic evaluation against ChatGPT-4o, Gemini 1.5, ErnieBot 3.5, and conventional LLaMA RAG using 67 free-response clinical questions across six domains and 29 multiple-choice questions, assessing accuracy, comprehensiveness, citation reliability, and response consistency.

Results: MyopiaGPT achieved 100% accuracy in free-response questions, significantly outperforming ChatGPT-4o (94%), Gemini 1.5 (94%), ErnieBot 3.5 (85%), and LLaMA RAG (69%) (all $P < 0.05$). Citation accuracy reached 97.7% versus 0-55.9% for competitors, with zero fake citations compared to 27-82% for other models. In standardized multiple-choice assessments, MyopiaGPT demonstrated 86.2% accuracy versus 31.0-69.0% for other models. Comprehensiveness scores were significantly higher than conventional approaches. Performance remained remarkably consistent across different parameter scales (8B-405B), challenging traditional assumptions that larger models become less reliable.

Conclusions: MyopiaGPT establishes new benchmarks for medical AI applications through specialized RAG architecture, demonstrating superior accuracy, citation reliability, and consistency. The system eliminates manual knowledge base construction requirements while ensuring evidence-based responses. These findings contribute to developing reliable AI-assisted medical information systems and suggest promising approaches for specialized clinical AI that prioritize accuracy over general capabilities.

Noninvasive Early Prediction of Preeclampsia in Pregnancy Using Retinal Vascular Features

First Author: Yuxuan **WU**

Co-Author(s): Haotian **LIN**, Zhenjun **TU**, Xiaohang **WU**, Lanqin **ZHAO**

Purpose: Preeclampsia (PE), a severe hypertensive disorder during pregnancy, significantly contributes to maternal and neonatal mortality. Current prediction biomarkers are often invasive and expensive, hindering widespread application. This study introduces PROMPT (Preeclampsia Risk factor + Ophthalmic data + Mean arterial pressure Prediction Test), an AI-based model using retinal fundus photography as a non-invasive and low-cost screening approach.

Methods: A total of 1,812 pregnancies before 14 gestational weeks were analyzed, and their retinal parameters were extracted using a deep learning-based vessel segmentation and quantification system. Machine learning models were constructed using retinal parameters and metadata for PE and preterm PE prediction. The detection rates of adverse pregnancy outcomes were analyzed by different prediction models. Economic analyses were conducted to evaluate the cost-effectiveness of the PROMPT model compared with routine methods.

Results: The PROMPT achieved an AUC of 0.87 (0.83-0.90) for PE prediction and 0.91 (0.85-0.97) for preterm PE prediction via machine learning, significantly outperforming the baseline model ($p < 0.001$). It improved the detection of severe adverse pregnancy outcomes from 35% to 41%. Economically, PROMPT was estimated to avert 1,809 PE cases and saved over \$50 million per 100,000 screenings.

Conclusions: The study presents PROMPT as a non-invasive, convenient, and cost-effective tool for prenatal care in low- and middle-income countries.

Novel AI-Based Prediction of Ocular Dominance Using Only Standard Biometric Parameters

First Author: Naren **SHETTY**

Co-Author(s): Amulya **PUNATI**, Abhijit Sinha **ROY**, Tejal **SJ**

Purpose: To develop an AI-based model for determining ocular dominance using biometry parameters, eliminating the need for traditional dominance tests, with potential applications in monovision planning.

Methods: Motor dominance was assessed in 240 patients aged 20–40 years using the diamond test for dominance. Patients were categorized into Group 1 (right-eye dominant) and Group 2 (left-eye dominant). All subjects underwent biometry with the IOLMaster 700 (Carl Zeiss Meditech, Inc). Biometric parameters were compared between groups and used to train an AI model to predict ocular dominance.

Results: Among 240 patients, the neural network achieved the best performance (AUC 0.629, accuracy 62.5%), correctly classifying 61.7% of left-eye dominant and 63.3% of right-eye dominant cases. Key predictive parameters included white to white (WTW), Delta K, K2 (RE & LE), and Axial length, enabling ocular dominance prediction from biometry alone.

Conclusions: AI-driven analysis of biometric parameters offers a reliable, non-invasive alternative to conventional dominance tests, facilitating efficient and objective planning for monovision strategies in refractive and cataract surgery.

Optic Disc Laterality as a Novel Biomarker for Glaucoma Using Fundus Image-Based Deep Learning

First Author: Yuta **NARIYA**

Co-Author(s): Makoto **AIHARA**, Shuichiro **AOKI**

Purpose: To evaluate whether optic disc laterality asymmetry can serve as a novel biomarker for glaucoma detection and progression.

Methods: A total of 32,196 fundus images from 5,571 participants were analyzed. Optic discs were extracted, and the left eyes were horizontally flipped to standardize orientation. Laterality (right vs. left) was classified using a deep learning model with 5-fold cross-validation. "Laterality confidence" was defined as the predicted probability of the true label. Glaucoma was defined as self-reported or indicated by a clinical fundus interpretation suggesting suspicion or definite glaucoma. Longitudinal changes in laterality confidence were assessed using generalized estimating equations (GEE).

Results: Laterality classification achieved high accuracy overall, but performance was significantly reduced in glaucomatous eyes compared with non-glaucomatous eyes ($p < 0.001$, chi-square test). In the primary model, GEE analysis showed that laterality confidence declined significantly with age ($\beta = -0.0049$ per year, $p < 0.001$) and exhibited an additional reduction in glaucomatous eyes (interaction $\beta = -0.0031$, $p = 0.042$). Supplementary analyses, including sex, confirmed no significant sex-related differences in baseline values or longitudinal trajectories. Permutation testing further demonstrated that within-eye longitudinal changes were significantly smaller than expected by chance ($p < 0.001$), supporting the robustness of the metric.

Conclusions: Laterality confidence declined with aging and showed accelerated deterioration in glaucomatous eyes. These findings were consistent across sexes. This image-derived, label-independent metric may represent a novel biomarker for glaucoma detection and monitoring, enabling earlier identification of glaucomatous changes in population-based screening.

Optimal Protocol for Visual-Audio Stimulation: A Systematic Review

First Author: Ming Chi CHOY

Co-Author(s): Lok Man AU, Kam Lung Kelvin CHONG, Ka Hei Kenneth LAI, Chi Pui Calvin PANG, Chee Yung Clement THAM, Yiu Man Hanson WONG

Purpose: The purpose of this review is to collect and synthesize findings from published studies to identify an optimal protocol for visual-audio stimulation, based on the treatment protocol, effectiveness, safety, and the potential for personalized treatment for various neurodegenerative disorders.

Methods: This systematic review was performed in accordance with the PRISMA guideline. A search of the English literature was conducted independently by two researchers using the online databases, including Scopus, Medline, PubMed, and Cochrane, as well as citation searching. Findings from eligible articles were narratively synthesised and tabulated.

Results: Of the 3,210 articles screened, 29 studies were eligible for data extraction. 4 studies show that stimulation at 32-40 Hz amplifies the strongest and broadest gamma wave entrainment in the gamma band of the EEG. Among 14 studies, 12 showed a significant reduction in atrophy and preservation of myelin content among subjects in the intervention group. 7 studies yield significant results in improved performance on cognitive and memory tests. 10 studies examined the safety aspect, with 7 of them reporting no adverse events. 2 studies identified significant inter- and intra-individual variability. Analysis of the duration of stimulation reveals that single, short-duration

stimulation shows no significant difference in primary outcomes.

Conclusions: Visual-audio stimulation demonstrates promising benefits for brain stimulation at 40Hz. High inter-subject variability highlights the importance of developing subject-specific or tailored frequencies and wavelengths, and the potential for personalization. Further research is required to develop and validate reliable clinical measures and identify cost-effective interventions.

Outcomes of Artificial Intelligence (AI)-Enabled Melbourne Rapid Fields (MRF) Online Perimeter in Home Monitoring for Glaucoma

First Author: Yu Xiang George KONG

Co-Author(s): Phillip BEDGGOOD, Mo DIRANI, Selwyn PREA, Joyce TIANG, Algis VINGRYS

Purpose: To examine whether glaucoma patients can perform VF testing using their own computers with an AI-enabled web-browser version of MRF Online Perimeter.

Methods: Fifty-one glaucoma patients (98 eyes) were tasked with performing VF testing at home using MRF Online. Written and verbal instructions were provided to participants. The results were compared to previous outcomes on Humphrey Field Analyzer (HFA) SITA-Faster performed in the clinic. AI-Enabled Web-cam technology is used to ensure optimal testing conditions (viewing distance, background lighting) and gaze stability monitoring.

Results: Patient age ranged from 34 to 87 (average 64.61, SD 12.74). High concordance with HFA was found for Mean Deviation (MD) and Pattern Deviation (PD) with intraclass correlation coefficients (ICC) of 0.88 and 0.78, respectively. Bland-Altman analysis returned a bias of -0.69 dB for MD and 95% Limits of Agreement (LoA) of -7.51 dB to 6.12 dB. The PD found a bias of -0.40 dB and a 95% LoA of -5.27 dB to 4.48 dB. Test-retest found high concordance between repeated MRF tests, with ICC ranging from 0.88 to 0.95 for MD. Individual MRF Online results were less reliable outcomes than HFA (FP% rate, 10.18% vs 7.59%, $p = 0.05$), FL% rate (21.01% vs 15.65%, $p < 0.016$), and had longer testing time (4.19min vs 3.41 min, $p < 0.001$).

Conclusions: The AI-enabled MRF Online perimetry software enables patients to conduct reliable, longitudinal visual field testing from home using their personal computers, delivering outcomes comparable to standard Humphrey Field Analyzer (HFA) testing conducted in a clinic.

Abstract No.: 206460**Panel No.: ADV-0077**

Patient User Experience Using a Self-Administered Multi-Purpose Modular Booth for Cataract Monitoring

*First Author: Pamela LEONG**Co-Author(s): David CHEN, Rubin YONG*

Purpose: To evaluate the patient user experience of self-administering a multi-purpose modular booth ("Eye-Pod") for cataract monitoring.

Methods: A single visit prospective study enrolled 150 stable cataract patients. The Eye-Pod housed a portable slit-lamp, an internal visual acuity (VA) test, fundus camera, and portable tonometer. Participants self-administered all tests with minimal supervision. Usability was evaluated on two levels: 1) system-level usability of Eye-Pod using the 10-item questionnaire System Usability Scale (SUS, range 0–100; higher scores = better usability); and 2) individual device-level usability using the 3-item questionnaire After-Scenario Questionnaire (ASQ; range 1–7; 1 = best, 7 = worst).

Results: The mean age of participants was 67.0 ± 6.8 years. The SUS score for the Eye-Pod was 64.2 ± 17.2 , corresponding to an "OK" usability rating. Device-specific ASQ scores were: VA = 1.82 ± 1.08 , tonometer = 3.99 ± 1.71 , slit-lamp = 2.04 ± 1.08 , and fundus camera = 1.58 ± 0.94 . These results indicate excellent usability for the VA test and fundus camera, good usability for the slit-lamp, and fair to poor usability for the tonometer.

Conclusions: The Eye-Pod demonstrated acceptable usability, though design refinements could improve patient experience. The individual device results indicate that the slit-lamp device, the booth VA test, and the fundus camera were highly usable, while the tonometry device demonstrated room for improvement. These findings suggest that a modular self-administered booth is feasible for cataract follow-up.

Abstract No.: 200558**Panel No.: ADV-0036**

Prediction of Spherical Equivalent and Axial Length from Smartphone Anterior Segment Images Using Machine Learning Models

*First Author: Yuichi OKUMURA**Co-Author(s): Masakazu HIROTA, Akie INOMATA, Takenori INOMATA, Ken NAGINO, Shintaro NAKAO*

Purpose: This study aimed to evaluate the accuracy of machine learning models in predicting spherical equivalent (SE) and axial length (AL) using anterior segment images captured with a smartphone external camera.

Methods: A total of 1,226 eyes from 704 participants (mean age: 33.8 years, 73.0% female) were included.

Anterior segment images were captured using a single smartphone. SE and AL were measured using an autorefractor-keratometer and optical biometry, respectively. A convolutional neural network (CNN) model and a stacking ensemble model were developed. Model performance was evaluated using Pearson correlation, mean absolute error (MAE), and Bland–Altman analysis.

Results: The mean SE was -3.19 ± 3.59 D, and the mean AL was 24.76 ± 1.43 mm. The final model achieved a correlation coefficient of $r = 0.69$ with an MAE of 1.75 D for SE prediction. For AL prediction, the correlation coefficient was $r = 0.53$ with an MAE of 1.24 mm. Bland–Altman analysis for SE showed a bias of -0.18 D (Limits of agreement [LoA]: -4.52 to 4.17 D). For AL, the analysis showed a bias of 0.07 mm (LoA: -2.17 to 2.31 mm).

Conclusions: A stacking ensemble model enabled prediction of SE and AL using only smartphone-acquired anterior segment images. These findings suggesting a potential utility in remote eye care and telemedicine applications.

Abstract No.: 206768**Panel No.: ADV-0086**

ROP-Care: A System From Laser Scar Identification to Myopia Prediction for Children With Laser-Treated Retinopathy of Prematurity

*First Author: Duo YUAN**Co-Author(s): Zhenquan WU, Guoming ZHANG, Xinyu ZHAO*

Purpose: To develop ROPCare, an automated Artificial Intelligence (AI) system for identifying and quantifying laser scars in Scanning Laser Ophthalmoscopy (SLO) images of Retinopathy of Prematurity (ROP) patients, and to evaluate its predictive value for myopia risk.

Methods: This study included 532 ROP patients treated with laser photocoagulation (LP). Retinal images were captured by SLO. The system consisted of two AI models: one for the identification of images with laser scars, while another for the segmentation of laser scar areas. The AI-derived laser scar areas index (LAI) was calculated based on the segmented laser scar areas within the region of interest (ROI).

Results: The classification model achieved high accuracy in identifying images with laser scars (AUC=0.9958), while the segmentation model yielded excellent results (DSC=0.8633). The AI-derived LAI showed a significant correlation with spherical equivalent (SE), supporting its potential as a predictor for myopia.

Conclusions: ROP-Care exhibited excellent performance in automatically classifying and segmenting laser scar areas in ROP patients. The AI-derived LAI, a reliable indicator of the extent of laser scarring within the ROI,

reveals the risk and trajectory of developing myopia in school-age children, providing a valuable tool for early intervention in clinical follow-up.

Abstract No.: 207116

Real-World Deep Learning-Based OCT Analysis of Chronic Central Serous Chorioretinopathy: A Swiss RetinAI Consortium Study

First Author: Tahm SPITZNAGEL

Co-Author(s): Chiara EANDI, Justus GARWEG, Gabriela GRIMALDI, Gabor Mark SOMFAI, Sandrine ZWEIFEL

Purpose: To assess structural changes in chronic central serous chorioretinopathy (cCSCR) using deep learning-based OCT segmentation and explore their association with visual acuity (VA).

Methods: This multicenter, retrospective study from six Swiss eye clinics employed the RetinAI Discovery® platform (Ikerian AG, Bern, Switzerland) to assess macular structure on OCT. The central 1mm (C1) and central 6-mm (C6) data were extracted. "Dry" was defined as intraretinal fluid (IRF) < 1 nL and subretinal fluid (SRF) < 1 nL; otherwise, as "not dry." Primary outcomes were dryness rates, change in SRF and VA (logMAR) from baseline (T0) to 1-year follow-up (T2). The secondary outcome was treatment patterns by dryness status at T2. Non-parametric tests were applied.

Results: At T0, 30% of eyes were dry in C1 (38/127) and 10% in C6 (13/126). At T2, dryness rates increased to 69% (67/97, C1) and 51% (49/96, C6), with 30 missing datasets in each analysis. Among «not dry» eyes at T2, SRF decreased significantly in C1 from 76.25 to 34.44 nL ($p < 0.001$) and in C6 from 267.93 to 86.63 nL ($p < 0.001$). VA remained stable in dry eyes for both C1 and C6 (median logMAR 0.00 at T0 and T2). In "not dry" eyes, VA improved from 0.2 (T0) to 0.1 (T2) in C1 ($p = 0.074$), while remaining 0.10 in C6. 22.9% of eyes that were dry in C6 at T2 had received photodynamic therapy (PDT) and 4.2% subthreshold micropulse lasertherapy (SML), whereas among not-dry eyes, 13.3% had undergone PDT and 17.0% SML.

Conclusions: This real-world multicenter study shows that deep learning-based OCT analysis captures disease dynamics in cCSCR, with higher dryness rates, significant SRF reduction, and stable or slightly improved VA. Notably, not-dry eyes at T2 received more often SML than dry eyes, that underwent more often PDT. These findings support AI-derived OCT metrics as practical endpoints for real-world monitoring.

Real-World Performance of a New Online Eye Symptom Triage Tool (Eye+dot) in an Emergency Eye Clinic

First Author: Fengyi LIU

Co-Author(s): Nimesha ALEX, Louise ALLEN, Jen O LIM

Purpose: Hospital emergency eyecare services are under pressure, with a high proportion of attenders suitable for community care. Eye+dot is an online branching-logic MCQ that collates ophthalmic history and suggests triage dispositions to support inexperienced triagers. This study evaluated its effectiveness in real-world emergency eye clinic (EEC) practice and assessed its usability and patients' acceptance.

Methods: This prospective, real-world study compared eye+dot and nurse triage, using ophthalmologist dispositions and clinical findings as the standard. Patients aged ≥ 13 with scheduled EEC appointments were invited by SMS to complete eye+dot. Age, test duration, and acceptability were recorded. The accuracy of urgency assignment and the identification of patients suitable for community optometry were analysed.

Results: A total of 282 patients (mean age 53.14, range 13-92) were included. Mean test duration was 5.6 +/- 2.4 mins; 80.4% of patients rated eye+dot good/excellent. For high-acuity symptomatology, sensitivity was 85.5% and 76.3% ($p = 0.19$), and specificity was 22.8% and 64.1% ($p < 0.001$) for nurse and eye+dot triage, respectively. Of 224 urgent nursing dispositions, 203 (90.6%) were down-rated (considered suitable for non-urgent assessment) by ophthalmologists and 93 (41.5%) by eye+dot. 256 (90.7%) of the 282 patients were considered suitable for community optometry by eye+dot. 145 (56.6%) of these 256 patients subsequently received only advice at their EEC visit, suggesting suitability for community eyecare.

Conclusions: Eye+dot automated triage has similar sensitivity but superior specificity to nursing triage for identifying high acuity symptomatology. This study suggests the potential to improve EEC scheduling and utilisation of community services.

Abstract No.: 200388

Refractive Error Detection Using Smartphone-Based Photorefractive Imaging

First Author: Muhammad SYAUQIE

Purpose: To investigate the inherent properties of pupillary red reflexes captured by smartphone cameras for refractive error detection in the community.

Methods: All patients underwent complete ophthalmic examinations, including subjective and objective

refraction, before eye image capture. The red reflex images were captured in a dark room using an iPhone 6s without cycloplegia. Six hundred fifty-one images were acquired from 350 patients. Images were analyzed considering the pupillary red reflex diameter and pattern. The correlation between the spherical equivalent dioptric power and the red reflex pattern was also analyzed.

Results: High myopia (88.2%) predominantly appeared on the right side of the pupil, whereas low and high hyperopia (91.8% and 92.9%, respectively) predominantly appeared on the left side of the pupil. In low myopia and emmetropia, the red reflex fills the entire pupil (75.4% and 84.5% images, respectively). The left red reflex has a significant positive power (+1.361+1.925 Diopter), whereas the total and right red reflexes have a negative one (-1.174+1.325 and -5.977+3.655 Diopter, respectively). A significantly wider total red reflex diameter ratio was found to be 0.617+0.081 mm compared to the right and left individual red reflexes, which are 0.246+0.066 mm and 0.299+0.087 mm, respectively. Spearman's correlation analysis revealed a moderate correlation between crescent size and dioptric power, with a correlation coefficient of 0.615 and an R2 value of 0.314 ($p < 0.001$).

Conclusions: Red reflex pattern recognition using smartphones can help detect refractive errors in communities because each type of refractive error has distinctive red reflex features.

Retinal Image Generation With Diffusion Models: Realism and Prompt Adherence Evaluation

First Author: Jocelyn Hui Lin **GOH**

Co-Author(s): Ching-yu **CHENG**, Thaddaeus Wai Soon **LO**, Sahana **SRINIVASAN**, Yih Chung **THAM**

Purpose: To evaluate the realism of synthetic retinal images from three fine-tuned Stable Diffusion (SD) models.

Methods: A total of 2,883 retinal images from the Singapore Epidemiology of Eye Disease (SEED) study were used to fine-tune SD models v1.5, v2.0 and XL using Low-Rank Adaptation (LoRA). During inference, 1,117 synthetic images were generated from each model with text prompts derived from the SEED metadata (i.e. age, sex, ethnicity, diabetic retinopathy [DR] severity). Fréchet Inception Distance (FID) between synthetic and real images was calculated with latent features extracted by the RETFound model, where lower FID values indicate that the synthetic images are more closely aligned in feature distribution to the real images. Perceptual realism was evaluated through a visual Turing test, where 100 random synthetic images were assessed by three ophthalmologists within a 30-minute limit.

The ophthalmologists further graded another 100 images from SD XL model for prompt adherence (i.e. consistency between DR severity in the text prompts and DR features manifested on synthetic images), based on a 3-point Likert scale (poor, borderline, good).

Results: The FID score of synthetic images from the SD v2.0 model was 129.8 (95% Confidence Interval [CI]: 127.8 - 131.86), and 130.7 for the SD XL model (95% CI: 128.6 - 132.5). Both were significantly lower than the SD v1.5 model (FID: 158.5, 95% CI: 156.1 - 160.9, $p < 0.001$), suggesting that the images from SD v2.0 and XL exhibited a feature distribution closer to real images. In the visual Turing test, ophthalmologists perceived 35% to 54% of the images as real when they were in fact synthetic. Additionally, 63% of images from the SD XL model exhibited 'good' prompt adherence, indicating that a large proportion of synthetic images generally aligned well with the given conditional prompts.

Conclusions: Diffusion models can generate synthetic retinal images that may be indiscernible from real images to ophthalmologists. Further refinement is needed to improve prompt adherence and ensure overall reliability of these generative models.

Retinal Images as a Window to Myopia: A Deep Learning Pipeline for Myopia Diagnosis and Monitoring

First Author: Haohan **ZOU**

Co-Author(s): Yan **WANG**

Purpose: Here, we present a deep learning pipeline that leverages fundus retinal images to enable objective, non-invasive myopia diagnosis, comparison, and progression monitoring.

Methods: In this study, we developed a 3D spatial model (RIRMD) capable of explaining the elongation of the eye axis and the changes in the curvature of the fundus, addressing the issue of comparing time-series images. Furthermore, based on the images aligned using RIRMD, Myopic-Net was employed to determine the occurrence and progression of myopia by detecting retinal structure features. Using a hybrid regression-classification architecture, the spherical power (SE), cylindrical power, and axis position were predicted from a single fundus image, achieving a level consistent with cycloplegic refraction.

Results: RIRMD reliably compared longitudinal images with excellent registration accuracy (7.82 pixel error, AUC = 0.710). Myopic-Net achieved 87.3% identification accuracy and 86.2% precision in detecting myopia onset and progression on an independent test set. The hybrid model accurately predicted spherical power (MAE = 0.50 D), cylindrical power (MAE = 0.31

D), and axis (89% accuracy), consistent with cycloplegic refraction levels.

Conclusions: This pipeline transforms fundus images into a comprehensive tool for myopia care, from precise image alignment to automated progression detection and refractive error estimation. By eliminating the need for cycloplegia and subjective input, it enables efficient, child-friendly screening and longitudinal monitoring, with potential to advance myopia control strategies globally.

Review of Virtual Reality and Tablet-Based Portable Automated Perimetry Technology Versus Standard Automated Perimetry in Glaucoma

First Author: Natania Rae Xiangqin TAN

Co-Author(s): Victor KOH, Sze Chuan ONG, Dayna YONG, Rubin YONG

Purpose: To review clinical outcomes and patient preferences of Portable Automated Perimetry (PAP) Technology (Virtual Reality and Tablet-based), compared against Standard Automated Perimetry (SAP) in visual field (VF) testing for glaucoma.

Methods: A literature review was performed using the PRISMA approach to identify relevant randomised controlled trials and cohort studies involving adults with suspected or confirmed glaucoma that compared PAP against SAP using objective and/or subjective outcomes.

Results: In total, 36 studies were included. 28 studies reported good reliability and comparability of results. Fourteen studies reported the intraclass correlation coefficient for mean deviation (MD) with high agreement (median 0.94, range 0.86-0.96). Correlation coefficients for MD were variably reported using Pearson's correlation (median 0.89, range 0.62-0.95) and Spearman's correlation (median 0.871, range 0.80-0.94), in 12 and 10 studies, respectively. These findings demonstrate strong overall agreement. Most patients preferred PAP, enjoying comfort and ease of use. The majority of studies showed that 77.0% of tablet and 64.3% of VR-based PAP were faster to administer than SAP. Drawbacks of PAP included difficulties with blind spot localisation and reduced reliability in very early or late-stage glaucoma. Few patients reported discomfort with PAP, due to headset weight or motion sickness.

Conclusions: PAP is cost-efficient, widely-accessible, and a good complementary test for frequent VF monitoring, or an alternative in resource-limited underserved communities. Currently, PAP is unable to replace SAP, due to higher variability in quantitative results especially in peripheral fields, and lower accuracy in detecting glaucoma severity.

Revolutionizing Ophthalmology: A Comprehensive Analysis of AI-Driven Patents in Eye and Vision Care

First Author: Xinyu LIU

Co-Author(s): Sihan LI, Divine Joe Grace MARCELINO, Alice Rh RONG, Shisong RONG, Jinghan ZHANG

Purpose: This study aims to understand AI's application in this domain, facilitating effective technology translation for inventors and stakeholders. It examines inventions that utilize AI in eye and vision care, overviews their global distribution, identifies major development centers, and explores key patent features.

Methods: We developed a search strategy using patent classification codes and keywords to identify patents and patent applications employing AI in eye and vision care. Major patent databases, including USPTO, WIPO, EPO, CNIPA, DPMA, CIPO, IP Australia, JPO, and KIPO, were searched. Features including publication year, days-to-grant, legal status, invention purpose, processed data type, and targeted ophthalmology subspecialties were extracted from each invention. Data analysis involved descriptive statistics and Dunn's Test for statistical comparisons.

Results: We identified a total of 5,144 relevant patents or applications published between 1993 and 2024 from the databases. The volume of inventions started exceeding 100 per year in 2017 and 1,000 in 2023, although data for 2024 is incomplete. In the global distribution, the USA holds the highest number of granted patents (N=646), followed by China, Korea, Australia, and Canada. Conversely, China has the most patent applications (N=1,855), followed by the USA, Japan, Korea, European countries, Canada, and Australia. Among the active granted patents, the average days-to-grant was 953 ± 534 days. There were no significant differences in the days-to-grant across major jurisdictions, including the USA, China, Korea, Australia, and Japan ($P > 0.2$). Most inventions focus on diagnostics (78%), process image data (72%), and target the retina and vitreous sector in ophthalmology (60%).

Conclusions: The surge in AI-related inventions marks a transformative shift in eye and vision care. Further development of AI will advance research and make eye and vision care more accessible. Stakeholders should leverage these insights to drive innovation, meet global needs.

Small Deep Learning Models Outperform RETFound in Colour Fundus Classification Tasks

First Author: Rui SANTOS

Co-Author(s): David ISZTL, Gabor SOMFAI

Purpose: Often, large deep learning models are used for image classification tasks. Our research aims to demonstrate that smaller deep learning models may outperform larger ones for the classification of colour fundus images.

Methods: We evaluated the deep learning models ConvNextv2 (27M), Swin/Swin V2 (27M), DINOv2/ DINOv2 with registers (23M), ViT-base (86M), using both pretrained and de novo variants and compared with the RETfound-MAE model (ViT-large, 300M). The datasets used were: EyePacs, APTOS, Messidor for DR, Messidor-2 for DME, and Papila for glaucoma detection.

Results: For DR, SwinV2 was the best performer (pretrained: AUC = 0.9228, recall = 0.7048; no pretrain: AUC = 0.8402, recall = 0.5969), outperforming RETFound-MAE (AUC = 0.8887, recall = 0.6435). For glaucoma detection, SwinV2 was also the best performer overall (pretrained: AUC = 0.9786, recall = 0.9081; no pretrain: AUC = 0.8888, recall = 0.7629) and slightly better than RETFound (AUC = 0.9637, recall = 0.953). For DME, DINOv2, SwinV2, ConvNextV2 and RETfound all achieve the same levels of AUC and recall above 0.98. We have also documented that models such SwinV2 and ConvNextV2 take between 30-50% less time to train than their ViT counterparts.

Conclusions: Smaller deep learning models like SwinV2 and ConvNextV2 can match or outperform the larger RETFound model in classifying DR, DME, and glaucoma from colour fundus images. Further, pre-training on large datasets such as imagenet-1k significantly improves accuracy and recall, while smaller models also reduce training time. Thus, careful consideration is needed to choose a deep learning model for colour fundus image classification.

Smartphone Applications for Glaucoma Patients and the Visually Impaired

First Author: Megha G

Purpose: There is limited information in the literature about the scope and usability of Smartphone Applications (Apps) for glaucoma patients and those that help the visually impaired. Our responsibility as doctors should not stop at providing treatment for the disease, but also ensuring good compliance with medications and providing accessibility support.

Methods: Our study summarizes the various Smartphone apps that can help glaucoma patients and the visually impaired or blind users. The App Store (for iOS) and Google Play Store (for Android phones) were searched. The available apps can be broadly divided as 1) Eye drop reminders 2) Patient education 3) Testing apps 4) Apps for the visually disabled. Various apps that can be used by eye care professionals, but are not particular to glaucoma or visually impaired patients, were excluded.

Results: Among the total of 108 apps which met the inclusion criteria, there were 6 (5%) apps exclusively for eye drop reminder, 47 (44%) other pill reminder apps in which eye drops and doctor appointments can be entered. 4 (4%) apps for glaucoma education to patients and to help them bond with other glaucoma patients. Among the testing apps, most were for visual acuity screening (41; 38%) and 1 app (1%) for visual fields. 9 apps (8.3%) for the visually impaired.

Conclusions: Apps help patients manage their disease better as reminders, to manage appointments, also to have better knowledge of glaucoma and help blind in daily life. Knowledge about these accessibility features and apps can help us educate our patients better.

Smartphone-Based Offline AI for Multi-Disease Retinal Screening: Real-World Accuracy

First Author: Muskan MANGAL

Co-Author(s): Harsh JAIN, Aditya KELKAR, Jai KELKAR, Sabyasachi SENGUPTA

Purpose: To evaluate the diagnostic accuracy of a multi-disease offline artificial intelligence system (Medios-AI, MAI), integrated into a smartphone-based fundus camera, for simultaneous screening of diabetic retinopathy (DR), glaucoma, and age-related macular degeneration (AMD) in a real-world setting.

Methods: In this prospective cross-sectional study, 193 adults (371 eyes) aged ≥ 18 years with DR, glaucoma, AMD, or normal fundus were enrolled between May and December 2024. Dilated fundus imaging was performed using the Remidio Fundus on Phone (FoP) and Zeiss Clarus 500 cameras. The offline MAI algorithm generated disease-specific reports, which were compared to masked grading of Clarus images by two fellowship-trained ophthalmologists.

Results: MAI achieved a sensitivity of 99.3% (95% CI: 96–100), a specificity of 95.7% (95% CI: 92–98), and an AUROC of 0.99 for detecting any retinal disease. For glaucoma (n=109), sensitivity was 98.2% (95% CI: 94–100), specificity 99.0% (95% CI: 97–100), AUROC 0.99. For AMD (n=56), sensitivity was 88.9% (95% CI: 77–96), specificity 97.5% (95% CI: 95–99), AUROC 0.93. For DR (n=78), sensitivity was 84.6% (95% CI: 75–92),

specificity 99.0% (95% CI: 97–100), AUROC 0.92. Agreement on vertical cup-to-disc ratio between AI and graders ranged from –0.1 to +0.1, with intergrader ICC of 0.97 ($P < 0.001$ for all comparisons).

Conclusions: MAI demonstrated diagnostic accuracy for DR, glaucoma, and AMD using offline, smartphone-based platform, supporting point-of-care retinal screening in resource-limited settings.

The Use of Artificial Intelligence for Diagnosing Retinopathy of Prematurity – a Systematic Review

First Author: Adinda Mulya PERTIWI

Co-Author(s): Yeni Dwi LESTARI, Dian Estu YULIA

Purpose: Retinopathy of prematurity (ROP) is a major but preventable cause of childhood blindness. Screening in developing countries is challenging due to skilled staff shortages. Recent advances in artificial intelligence (AI) offer promising results. This study evaluates the diagnostic performance of AI models for ROP screening.

Methods: This systematic review followed PRISMA guidelines and included studies from Cochrane, MEDLINE, and ScienceDirect. Eligible studies were cross-sectional or cohort designs that compared AI diagnostic accuracy for ROP against a gold standard and reported relevant metrics. Studies were graded using the Oxford CEBM levels of evidence.

Results: Of 608 studies, 12 were included. i-ROP DL showed high sensitivity and specificity (AUC ~0.99), with ResNet-152 and EfficientNet-B0 also performing well. Despite variations in specificity and PPV, AI shows promise for ROP screening. i-ROP DL and ResNet-152 may need demographic adaptation. Though cost-effectiveness data are lacking, AI could reduce workload and improve diagnostic consistency.

Conclusions: AI shows high sensitivity, but variable specificity highlights the need for refinement. The review also underscores the importance of validation across diverse populations to ensure generalizability. AI integration in clinical practice can enhance early detection, standardize diagnoses, and alleviate the burden on healthcare professionals, particularly in low-resource settings.

The Use of Teleconsultation to Assess Paediatric Patients Seeking Urgent Ophthalmic Accident and Emergency (A&E) Assessment and Care

First Author: Karen WONG

Co-Author(s): Clare ROBERTS, Maria THEODOROU

Purpose: To determine and analyse the demographic and outcome of paediatric patients attending teleconsultation with acute concerns in an ophthalmic accident and emergency setting.

Methods: Electronic medical record (OpenEye) data for all paediatric patients (under 18 years of age) accessing the accident and emergency ophthalmic department at Moorfields Eye Hospital (London, UK) using a video consultation platform between July and August 2025 were analysed retrospectively. Patient's demographic, outcome, management, and any subsequent unplanned attendance were analysed.

Results: A total of 140 video consultations had taken place over a 2-month period. Patient age ranged between 1 month to 17 years (average 7.9 years); 20% of consultations had taken place during a public holiday; 30% had taken place out of hours during the working week, and 50% in hours. 65% were deemed not to require hospital A&E review and were managed with advice, including appropriate over-the-counter medication. Reattendance rate among patients who received advice only during initial assessment was 4%. 21% of patients required further ophthalmic assessment face-to-face and were invited to attend A&E; 2% were referred to a paediatrician for urgent review of a non-ophthalmic condition; 6% were directed to a general practitioner/allied professionals for non-urgent assessment/referral/treatment; 4% were directly referred to a subspecialty clinic, and 2% to a local eye unit. Average home-hospital distance ranged between 0.9-188 miles. (average 12.8 miles)

Conclusions: Teleconsultation and triage with paediatric patients in the A&E effectively reduced unnecessary face-to-face attendance, improved patients' and parents' experience by delivering prompt referral and/or advice. It also saves patients' travel time, cost, and potentially reduces carbon emissions.

Use of Artificial Intelligence to Estimate Blink Interval and a Possible Screening for Dry Eye Disease Screening From Portable Slit-Lamp Images

First Author: Eisuke SHIMIZU

Co-Author(s): Kazuki ASAI, Shunpei FUJIOKA, Takanobu INOUE, Shintaro NAKAYAMA, Hiroki NISHIMURA

Purpose: Diagnosis of dry eye disease (DED) requires symptoms together with objective signs, such as a reduced tear film breakup time (TFBUT). However, TFBUT measurement requires a slit-lamp microscope and trained ophthalmologists, limiting its utility for screening outside specialist settings. With the growing interest in ophthalmic artificial intelligence (AI), we focused on the blink interval (BI) obtainable from anterior-segment video. We developed an algorithm to estimate BI from anterior-segment videos and, drawing on the "Blink Test" concept described in the TFOS DEWS reports, evaluated whether AI-estimated BI can predict shortened TFBUT.

Methods: In this prospective observational study, we used blue-light-illuminated anterior segment videos acquired with the Smart Eye Camera at Yokohama Keiai Eye Clinic. The training dataset comprised 676 eyes from 338 participants. Frames were annotated for eyelid state (open/closed), and a machine-learning model was trained to classify eyelid state and derive BI. External validation was performed on an independent set of 101 eyes not used for training. Agreement between AI-estimated BI and BI, and associations with TFBUT, were assessed.

Results: The eyelid state classifier achieved an accuracy of 94.24%. AI-estimated BI showed very strong agreement with BI ($r=0.947$; 95%CI, 0.921–0.964; ICC=0.953; 95%CI, 0.931–0.968). AI-estimated BI was also correlated with TFBUT ($r=0.770$; 95%CI, 0.674–0.841). Using a prespecified Blink Test threshold of BI < 10s, AI-estimated BI closely reproduced BI ($r=0.855$; 95%CI, 0.789–0.901; $\kappa=0.854$; 95%CI, 0.751–0.958) and achieved high diagnostic performance against the BI (sensitivity 0.923 [95%CI, 0.869–0.977]; specificity 0.935 [95%CI, 0.874–0.997]; AUC 0.929 [95%CI, 0.879–0.979]). Relative to TFBUT as the reference, AI-estimated BI also demonstrated robust discrimination (sensitivity 0.804 [95%CI, 0.722–0.887]; specificity 0.945 [95%CI, 0.885–1.000]; AUC 0.875 [95%CI, 0.810–0.939]).

Conclusions: We developed and validated an AI system that infers eyelid state from anterior-segment video and estimates BI with high accuracy. AI-estimated BI closely matches conventional BI, suggesting utility for DED screening where slit-lamp assessment is impractical.

Using Deep Learning to Screen for Hypertension in OCTA Images to Reduce the Risk of Serious Complications

First Author: Yiheng DING

Co-Author(s): Hong ZHANG

Purpose: To discuss the feasibility of combining the deep learning method and optical coherence tomography angiography (OCTA) image findings for investigating the changes in ocular microvessels in hypertension.

Methods: Deep learning architecture Xception and Multi-Swin Transformer were used to screen hypertension with 422 OCTA images (252 from 136 hypertension subjects, 170 from 85 healthy subjects). Besides, the separability of OCTA images from high-dimensional feature angles was analyzed to better understand how deep learning models distinguish OCTA images with Class Activation Mapping.

Results: Under CNN Xception, the overall average accuracy of 5-fold cross-validation is 76.05%, and the sensitivity is 85.52%. As a contrast to Swin Transformer, the average accuracy of Single-model (macular), Single-model (optic disk), and Multi-model in the prediction of hypertension is 82.25%, 74.936% and 85.06%, respectively. Besides, the average sensitivity of the Multi-model is 88%. The high-dimensional features of OCTA images in the test set were displayed using an interpretable Class Activation Mapping method, which illustrates the differences in classification indicators and analyzes the possibility of related characteristics of hypertension classification.

Conclusions: The changes of hypertension on fundus vessels can be more accurately and efficiently observed by recognizing OCTA image features through deep learning. The results would contribute to screening for hypertension and reducing the risk of severe complications of hypertension.

Validating an Artificial Intelligence Prototype Portal for Glaucoma Detection From 3D Optical Coherence Tomography Scans in Real-World

First Author: Anran RAN

Co-Author(s): Carol Y. CHEUNG, Anni LING, Clement C. THAM, Bowen XU

Purpose: To prospectively validate an artificial intelligence (AI) prototype portal to detect glaucomatous optic neuropathy (GON) from 3D OCT volumetric scans in the real world.

Methods: We built an AI portal by integrating our established 3D AI model, an information management

system, a user interface, and a commercially available OCT device together. The AI portal is able to extract raw OCT volumetric images, then analyze image quality, detect GON, and generate AI reports in real-time. We recruited subjects at the Triage Unit of Hong Kong Eye Hospital prospectively. The inclusion criteria were: 1) subjects above 18 years old, and 2) referred by primary care settings due to glaucoma-related suspicious findings, or 3) referred by primary care settings for regular eye check-ups. All the eligible subjects underwent OCT imaging, and the AI portal analyzed their 3D OCT scans. Glaucoma specialists provided the reference standard for all the subjects.

Results: A total of 919 subjects were recruited and 167 of them were confirmed to have glaucoma. The AI infrastructure achieved an AUROC of 0.934, a sensitivity of 86.6%, a specificity of 88.3%, and an accuracy of 88.1% for GON assessment and an AUROC of 0.819, a sensitivity of 83.7%, a specificity of 78.3%, and an accuracy of 83.6% for image quality assessment. In addition, the AI portal only took an average of 1-2 minutes to analyze the 3D OCT scan and generate an AI report for both eyes.

Conclusions: The AI portal achieved stable performance prospectively, which provided real-world evidence for potential implementation.

Panel No.: ADV-0087

Validation of an Augmented Reality-Based Farnsworth-Munsell 100 Hue Test Against the Manual Version in Normal and Color Vision Deficient Participants

First Author: Mingpu XU

Co-Author(s): Shaoying TAN, Fangyu XU

Purpose: The Farnsworth-Munsell 100 Hue Test (FM100) is widely recognized as the gold standard for assessing color discrimination, but it has practical limitations, including high cost, lengthy administration, and strict environmental requirements. Augmented Reality (AR) offers opportunities for portable and digitalized alternatives.

Methods: A Unity-based AR-FM100 was developed and compared with the manual FM100 under standardized conditions in age- and refraction-matched participants (n=52, 40 normal vs. 12 CVD). Based on the total error scores (TES) from both methods, agreement was assessed with correlation and Bland-Altman analyses, and diagnostic accuracy with ROC curves.

Results: The AR-FM100 yielded higher TES than the manual version ($z=-4.22$, $p < 0.001$), though the two methods showed moderate correlation (Spearman's $r = 0.68$, $p < 0.001$). Bland-Altman analysis confirmed a systematic bias with wide limits of agreement (Mean difference=26.72; 95% CI: -65.32, 118.77), reflecting substantial individual variability. Both tests

differentiated normal from CVD participants, but diagnostic accuracy was higher for the manual FM100 (AUC = 0.98 vs. 0.92).

Conclusions: The AR-FM100 showed strong correlation with the traditional FM100 but tends to overestimate TES and exhibits lower diagnostic accuracy. Although it is not yet a substitute for the manual FM100 as a gold-standard diagnostic tool, the AR-FM100 demonstrated potential as a portable, and automated screening method for color vision assessment. Further improvements in calibration and display rendering are required to minimize systematic bias and enhance its clinical applicability.

Vision Transformer-Based Oculomics: Predicting Biomarkers From Fundus Photographs

First Author: Laura GUTIERREZ

Co-Author(s): Kabilan ELANGO VAN, Daniel TING

Purpose: Oculomics leverages advanced retinal imaging and artificial intelligence to extract systemic information from the eye, offering a non-invasive approach for disease detection and risk prediction. This study aimed to use fundus photographs to predict continuous systemic biomarkers.

Methods: The dataset included 552 patients, each with four fundus views: left and right macula-centered, and left and right optic disc-centered. Target biomarkers were age, BMI, HDL, LDL, HbA1c, Hb, and Cr. A pure Vision Transformer architecture was implemented without a CNN backbone. Images were divided into 16×16 patches, embedded into 256-dimensional vectors with positional encoding and a class token. The model consisted of eight transformer blocks, followed by a regression head with batch normalization and dropout. Training was performed from scratch for 30 epochs. Data were split at the patient level (70% training, 10% validation, 20% testing), yielding 28 models across biomarker-view combinations.

Results: The right optic disc (R_OD) view emerged as the most informative, providing the best results in 12 of 21 evaluations (57%). R_OD achieved low prediction errors across several biomarkers, including BMI (MAE 3.05, MSE 14.57), HDL (MAE 0.24, MSE 0.095), LDL (MAE 0.671, MSE 0.803), and creatinine (MAE 30.44, MSE 15665.93). Age and HbA1c were moderately predicted (Age MAE 6.64, MSE 65.95; HbA1c MAE 0.787, MSE 1.14), while Hb showed the strongest performance with MAE 1.09 and MSE 2.09.

Conclusions: Our findings demonstrate the feasibility of predicting systemic biomarkers from fundus photographs using pure ViT models. The optic disc view suggests that prioritizing this imaging perspective may enhance oculomics prediction.

scAAVEVO Drives Precise Cross-Species AAV Capsid Evolution at Single-Cell Resolution

First Author: Zhong **LIU**Co-Author(s): Yingfeng **ZHENG**, Shurui **KE**

Purpose: To address the challenge of cell-type-specific targeting in ocular gene therapy, this study developed scAAVEVO, a generative model for designing recombinant AAV (rAAV) capsids with high specificity and efficiency at single-cell resolution.

Methods: The scAAVEVO model integrates single-cell transcriptomics and capsid protein sequences. Using a reinforcement learning framework guided by a Chain-of-Thought process, it iteratively generates and scores capsid variants. The model was pre-trained and fine-tuned with non-human primate and human single-cell data to enable cross-species prediction. The top-generated capsid, gRPEAAV, was experimentally validated for its targeting ability, safety, and therapeutic efficacy in rescuing blindness in an Rd12 mouse model.

Results: scAAVEVO successfully generated capsid sequences with enhanced predicted tropism. Experimentally, gRPEAAV demonstrated high efficiency in targeting retinal pigment epithelial (RPE) cells across species, coupled with lower dose-dependent toxicity and inflammation. As a therapeutic vector, it effectively delivered a base-editor (saKHHH-ABE8e) to correct a disease-causing point mutation and rescue vision in Rd12 mice. Crucially, its transduction was dependent on the RPE-specific receptor ITGB8, confirming a key model-derived insight.

Conclusions: The scAAVEVO platform represents a novel and powerful approach for accelerating the development of precise gene therapy vectors. It successfully generates functional, safe, and cross-species AAV capsids by leveraging single-cell data and AI-driven design, opening a new paradigm for targeted ocular gene delivery.

Agreement Between Retina Specialists, Optometrists, and Mid-Level Ophthalmic Personnel (MLOP) for Interpreting Macular OCT

First Author: Chitaranjan **MISHRA**Co-Author(s): Anup Kumar **SAH**, Jitendra Kumar **SAHOO**

Purpose: To find the agreement between retina specialists, optometrists, and MLOP in the interpretation of OCT images of common macular diseases.

Methods: Five Optometrists and five MLOPs underwent a structured OCT training module for 12 weeks, followed by an assessment examination on MCQs and open-ended questions. The accuracy of the candidates' responses was noted. The questions were asked on comprehensive OCT macula findings and different sub-headings of macular pathologies like macular holes, choroidal neo-vascular membranes (CNVM), diabetic macular edema (DME), cystoid macular edema (CME), polypoidal choroidal vasculopathy (PCV), vitreo-macular interface disorders (VMID), and OCT biomarkers. The responses (scores) of the optometrists (A) and MLOPs (B) were compared with those of the retina specialist (gold standard) (C), and the agreement was noted.

Results: The agreement was highest for comprehensive OCT macula findings; A+B Vrs C, A Vrs C, and B Vrs C were 94.66%, 96%, and 93% respectively. The agreement was lowest for CNVM findings; A+B Vrs C, A Vrs C, and B Vrs C were 60.50%, 64%, and 57% respectively. For the rest of the pathologies, the score was between. Overall diagnosis of all disease entities A+B Vrs C, A Vrs C, and B Vrs C were 94%, 94.66%, and 93.33%.

Conclusions: With a structured OCT training module, optometrists and MLOPs can help in the diagnosis and triage of macular diseases, which can be helpful for vitreo-retinal services in resource-limited settings. However, caution should be exercised in the interpretation of diseases like CNVM and PCV.

Application of Mixed Reality for Ophthalmic Clinical Skills

First Author: Dayna YONG

Co-Author(s): Victor KOH, Ray MANOTOSH, Jaslyn OH, Clement TAN, Marcus TAN, Yih Chung THAM, Rubin YONG, Yew Sen YUEN

Purpose: We postulate that a hybrid ophthalmology curriculum incorporating EyelearnMR is non-inferior to traditional education alone. EyelearnMR is a Mixed reality (MR) simulation application designed to teach ocular examination using a wearable headset. We compared learning outcomes and obtained user feedback.

Methods: Single-blind cluster-randomised prospective study. Fourth-year medical students were randomly assigned to two groups: EyelearnMR and control arms. The former had an additional 2 hours of practice sessions with the EyelearnMR devices. A video assessment (on technique, examination, and pathology) was conducted for both groups - EyelearnMR during mid-posting and control at the end of posting. The control was allowed to experience the EyelearnMR modules at the end of the posting. Both groups completed the User Experience Questionnaire (UEQ).

Results: Fifty-four medical students were recruited from July 2023 to January 2024, 24 in the control arm and 30 in the EyelearnMR arm. The EyelearnMR group performed significantly better than the control (median score was 16 and 15, respectively, $P=0.032$, Mann-Whitney U test). The EyelearnMR group had 100% of the students scoring full marks for the technique portion, compared to 80.8% of the control students ($P=0.002$). There was no statistically significant difference between the groups for the examination and pathology portions. UEQ showed positive evaluation for attractiveness, efficiency, dependability, stimulation, and novelty.

Conclusions: Students exposed to EyelearnMR had significantly higher scores despite reduced clinical exposure time. EyelearnMR facilitates deliberate practice and experiential learning. It is an effective supplementary teaching tool in ophthalmic education and may confer additional learning benefits to a traditional clinical posting.

Barriers to Learning Phacoemulsification Among Ophthalmology Residents in Peshawar, Pakistan: A Cross-Sectional Study

First Author: Shafiq TANVEER

Purpose: To assess the barriers to phacoemulsification training faced by ophthalmology residents in Khyber

Pakhtunkhwa, Pakistan, and identify the factors influencing their surgical performance and confidence in performing phacoemulsification.

Methods: A descriptive cross-sectional survey was conducted among 47 residents enrolled in the Fellowship of the College of Physicians and Surgeons (FCPS) ophthalmology program. Data were collected using a structured questionnaire covering demographics, surgical exposure, confidence levels, and perceived barriers, including mentorship, institutional support, access to simulation training, and anxiety levels. Statistical analysis was performed using SPSS version 25.

Results: A substantial proportion of residents had limited surgical exposure, with 47.8% assisting in and performing fewer than 20 phacoemulsification procedures. Confidence in performing surgical steps was low, particularly among second- and third-year residents. Key barriers identified included inadequate mentorship, lack of simulation-based training, and insufficient institutional support. Residents with greater surgical experience reported higher confidence and greater satisfaction with their training. Moderate anxiety levels were observed, with a higher prevalence among residents in private institutions.

Conclusions: This study highlights critical gaps in phacoemulsification training for ophthalmology residents in Khyber Pakhtunkhwa, Pakistan. Structured training programs, stronger mentorship, and integration of simulation-based training are essential to enhance residents' confidence, improve skill acquisition, and reduce anxiety. Addressing these barriers will strengthen surgical competency and improve patient care outcomes.

Bibliometric Analysis and Systematic Review of the 100 Most Often Cited Articles in Ophthalmology of the Past 10 Years

First Author: Alicia Hoi Ying LIU

Co-Author(s): Li Jia CHEN, Jason C. YAM, Jun YU, Yu Zhou ZHANG

Purpose: To evaluate the trends and influence of the 100 most often cited articles in ophthalmology ("Ophthalmology-100") in the past decade.

Methods: We conducted a bibliometric analysis and systematic review (PROSPERO: 565231) of all scientific publications in ophthalmology published between 2013 and 2023 listed in the Web of Science Core Collection database. To assess the academic influence of the Ophthalmology-100 articles, we formed a control group composed of the first 100 ophthalmic articles ("Control-100") to calculate and compare the area under the curve (AUC) of the first- and second-layer citations. Applying a fragmented article title analysis,

we determined the major topics addressed by the articles.

Results: Ophthalmology-100 articles were published more often in non-ophthalmic journals (55%) versus ophthalmic journals (45%), with the journal “Ophthalmology” having published the most of the articles (17%), followed by “Progress in Retinal and Eye Research” (11%) and “Lancet” (9%). The most commonly addressed topics were diabetic retinopathy/DME (n=18), AMD (n=13), dry eye disease (n=6), glaucoma (n=6), genetic eye diseases (n=6), and myopia (n=3). Article types were systematic review and meta-analysis (AUC=185,056.5), systemic chronic disease and aging population (diabetic retinopathy/DME: AUC=395,262; AMD: AUC=247,777.5), use of AI (AUC=277,953.5), and the translational value of basic science research in ophthalmology (anti-VEGF: AUC=202,941.5; OCT-A: AUC=159,557).

Conclusions: This review captured the development of ophthalmic research in the past decade, quantified the academic influence of the top 100 articles, and identified major trends in ophthalmic research. It may serve as a guide to suggest future research directions and facilitate funding and policy decision-making.

Panel No.: ART-0001

Bibliometric Analysis of Health Economics in Ophthalmology

First Author: Pasuta **THANMIKSAKUL**

Co-Author(s): Sunee **CHANSANGPETCH**, Mantapond **ITTARAT**

Purpose: To analyze global research trends and key topics in ophthalmic health economics.

Methods: A bibliometric analysis was performed on articles extracted from Scopus on June 20, 2024, using health economics and ophthalmology-related keywords. Data were analyzed using the R Bibliometrix library, with visualizations generated by VOSviewer.

Results: A total of 823 articles from 1962 to 2024 were identified, with a steady increase since the 1990s, surging post-2010s and peaking at nearly 70 articles in 2023. Network analyses revealed a predominant focus on cost evaluations of major eye diseases, with clustering by country, keyword usage, citation patterns, and authorship. The United States led in publication volume (153 articles), followed by the United Kingdom and India. “Cost-effectiveness” emerged as the most frequently associated term, with “glaucoma” and “diabetic retinopathy” as leading topics. Emerging themes included “telemedicine” and “artificial intelligence.” The most studied conditions were diabetic retinopathy and macular degeneration (52 articles), as well as glaucoma and intraocular pressure (48 articles), emphasizing strong economic evaluations in these areas.

Conclusions: The rise in publications reflects a growing recognition of the importance of health economics in ophthalmology. However, research remains concentrated on specific conditions and countries, highlighting a need for broader diversity and globally interconnected representative studies.

Abstract No.: 207458

Panel No.: ART-0026

Bilingual Evaluation of Advanced Large Language Models for Patient Education in Corneal Refractive Surgery

First Author: Tsung-hsien **TSAI**

Purpose: To evaluate the ability of six advanced large language models (LLMs) in providing accurate, comprehensive, and readable patient education on corneal refractive surgeries (LASIK, KLEx, and PRK) in both English and Chinese.

Methods: Twenty-six questions were compiled from authoritative ophthalmologic sources, covering four domains: (1) Procedure Basics and Eligibility; (2) Safety, Risks, and Long-Term Stability; (3) Recovery and Postoperative Experience; and (4) Practical Concerns. These questions were administered in both English and Chinese through fresh chat sessions with each LLM: ChatGPT-4o, Gemini Advanced 1.5 Pro, Claude 3.5 Sonnet, Tongyi Qwen 2.5, OpenAI o1, and DeepSeek-R1. Five performance metrics—accuracy, comprehensiveness, word count, readability, and reproducibility—were evaluated.

Results: OpenAI o1 and DeepSeek-R1 consistently achieved the highest scores for accuracy and comprehensiveness, significantly outperforming ChatGPT-4o, Gemini Advanced, Claude Sonnet, and Tongyi Qwen (Friedman $p < 0.001$). While overall accuracy and comprehensiveness were comparable between English and Chinese, responses in Chinese were significantly longer. Readability varied by model; Claude Sonnet produced the most readable English responses. Reproducibility analysis revealed only moderate consistency, indicating variability in outputs even for identical prompts.

Conclusions: Reasoning-augmented LLMs, particularly OpenAI o1 and DeepSeek-R1, demonstrate superior performance in delivering bilingual patient education for corneal refractive surgery, with high accuracy and comprehensiveness. However, variations in response length, readability, and reproducibility indicate that further refinement is necessary before these tools can be reliably integrated into clinical practice.

Abstract No.: 206180

Breaking Financial Barriers to Eye Health in Nepal: Evidence and Policy Pathways for Equitable Access

First Author: Namrata KARN

Co-Author(s): Anil GORKHALI, Sailesh MISHRA

Purpose: To analyze the barriers to access to eye care in Nepal related to finances and suggest evidence-based policy recommendations to enhance equity and decrease patient costs.

Methods: A survey of the health financing of Nepal, with key national breakdowns, assessed population coverage, service coverage, and out-of-pocket (OOP) expenditure to determine gaps in financial protection of eye care, in terms of insurance coverage, basic service provision financing, financing of assistive products, and household expenditure.

Results: In Nepal, overall health expenditure is less than 2% of the gross domestic product, and out-of-pocket (OOP) payments take nearly 54% of total health expenditure. The National Health Insurance Program insures only a projected 21% of the population, and most citizens are required to cover their own expenses. Over 40% of citizens do not have access to simple eye care, and expensive interventions like cataract surgery and long-term management of chronic eye conditions are normally borne by families. Such high costs leave a huge burden on the low-income earners. There is a fragmented financing system where there is little pooling of resources and inconsistent support of the essential assistive products that reinforces access inequity.

Conclusions: The system of financing eye health in Nepal leaves a high burden on the patients with out-of-pocket costs and service gaps. The inclusion of comprehensive eye care in the national insurance package, promoting risk pooling, and offering special subsidies to the most expensive interventions are crucial because they will guarantee equal and sustainable access and will help households to avoid economic strain.

Combined Proteomics and Metabolomics Analyses Revealed Molecular Signatures Associated With Proliferative Diabetic Retinopathy

First Author: Yixin CUI

Co-Author(s): Qirui LI, Lingna RAO, Lu SHEN, Ling YUAN

Purpose: Diabetic retinopathy (DR) is a microvascular complication of diabetes, and its exact underlying mechanisms have not been fully elucidated. This study aimed to investigate the effects of key proteins and metabolites on the development of DR.

Methods: Undiluted vitreous fluid samples were collected from eight patients with proliferative diabetic retinopathy (PDR) and six non-diabetic idiopathic macular hole (iMH) controls. Integration of TMT-tagged quantitative proteomics and untargeted metabolomics analyses was combined with bioinformatics approaches (PCA, differential expression, PPI network, OPLS-DA, pathway enrichment). Key results were validated by ELISA and immunohistochemistry.

Results: Seven key proteins with six key metabolites were identified to be significantly dysregulated in the PDR. In the vitreous body and retinal nerve fiber layer of the DR group, CD5L expression was upregulated, while CLU was downregulated with SERPINF1 (PEDF). These molecules were co-enriched in pathways such as the "complement and coagulation cascade" and "prion disease," suggesting a common mechanism of abnormal vascular permeability, inflammatory response, and microthrombosis. Disturbances in creatine metabolism suggested AMPK-related energy dysregulation, and the interaction between CD5L and microglia emphasized its neuroinflammatory regulatory function.

Conclusions: This study reveals biomarkers and therapeutic targets, which provide new ideas for diagnosis and precise intervention.

Comparing HelpMeSee and Eyesi Virtual Reality Simulators for Phacoemulsification Training: A Randomized Controlled Trial

First Author: Yuke PAN

Co-Author(s): Haowen LIN, Lixia LUO, Xuhua TAN

Purpose: To compare two virtual reality (VR) simulators for phacoemulsification training and to explore the impact of tactile feedback on training effectiveness.

Methods: Residents without any prior cataract surgery training or operative experience were enrolled in the randomized controlled trial. Participants were randomly assigned to train on two VR simulators with (TF group) or without tactile feedback (Control group), with the TF group receiving HelpMeSee simulator-based training and the Control group receiving Eyesi simulator-based training. The primary outcome was the total score of the modified ophthalmology surgical competency assessment rubric (OSCAR) for phacoemulsification in porcine eyes.

Results: A total of 36 participants were randomized into the TF group (18 [50%]) or the control group (18 [50%]). The participants in the TF group obtained higher scores on the modified OSCAR scale compared to the participants in the control group (23.26 points vs 19.78 points; $P = 0.007$). In subgroup analysis, the TF group showed superior performance in incision creation ($P = 0.04$) and nucleus manipulation ($P =$

0.003). No difference was observed between the two groups with respect to capsulorhexis. Furthermore, a higher level of training satisfaction was exhibited by the TF group.

Conclusions: The employment of a VR simulator with tactile feedback enhanced the effectiveness of phacoemulsification training and improved satisfaction with the learning process. These findings support the use of a VR simulator with tactile feedback for phacoemulsification training.

Cost-Effectiveness Analysis of the Eyesi Cataract Surgery Simulator in Phacoemulsification Surgery by Ophthalmology Residents

First Author: Somporn **CHANTRA**

Co-Author(s): Usa **CHAIKLEDKAEW**, Parinee **KEMCHOKNATEE**, Pophum **LAWTONGKUM**, Pawin **PAKAYMASKUL**, Panida **YOOPETCH**

Purpose: To evaluate the cost-effectiveness of the Eyesi virtual reality cataract surgery simulator in residency training.

Methods: We compared third-year residents trained traditionally (2020–2022) versus those trained with Eyesi plus traditional methods (2023–2025). Forty-two residents (21 per group) contributed their first 41 independent phacoemulsification cases (1,722 eyes). Clinical outcomes included complication rates, surgical times, and postoperative visual acuity. The simulator's capital cost (8,000,000 THB $\approx$ 248,000 USD) was allocated across residents using a 10-year amortization model. Incremental cost-effectiveness ratios (ICERs) were calculated from a healthcare system perspective, and break-even analysis was performed.

Results: Simulator-trained residents had shorter surgical times (40:35 vs. 44:11 min, $p < 0.001$) and phacoemulsification times (3:27 vs. 3:55 min, $p < 0.001$). Posterior capsule rupture was reduced (5.92% vs. 8.94%, $p = 0.0216$). Early visual acuity was superior at Day 1 (0.81 vs. 0.97 logMAR, $p = 0.001$) and 1 month (0.36 vs. 0.48, $p = 0.001$), with no difference at 3 months. Mean direct medical cost per case, including complication-related expenses, was lower in the Eyesi group (414.40 THB $\approx$ 12.85 USD vs. 485.25 THB $\approx$ 15.05 USD, $p = 0.357$) under 10-year amortization. The ICER was 255,596 THB ($\approx$ 7,930 USD) per complication avoided. Subgroup analysis showed the greatest benefits in surgical efficiency and visual recovery during the first 20 cases, with outcomes converging thereafter. Breakeven analysis indicated ~ 70 years with internal residents alone.

Conclusions: The Eyesi simulator improved efficiency, reduced posterior capsule rupture, and enhanced early visual outcomes, particularly in early training. Although

high capital cost limits feasibility, fewer complications and extending the use of Eyesi across successive cohorts enhance cost-effectiveness, supporting its integration into residency programs.

Developing a Smartphone-Based, Interactive, and Experiential-Learning Oriented Direct Ophthalmoscopy Training Module for Medical Students That Consists of Demonstration Videos, Simulation Practice, Self-Evaluating Instruments, and Innovative Assessment

First Author: Julian **CHAN**

Co-Author(s): Poemen **CHAN**, Yan Yu Julia **CHAN**

Purpose: Direct ophthalmoscopy (DO) is a valuable skill that is currently underutilised by medical practitioners, especially non-eye specialists. We aim to develop a DO module consisting of innovative demonstration videos, an application of a portable smartphone ophthalmoscope (PSO) and a smartphone hand-held ophthalmoscopy simulator (SOS) for self-evaluation and self-learning, including an interactive end-of-module assessment scheme.

Methods: Medical students underwent a DO workshop, taught either by the original DO (ODO group, consisting of a 1-hour lecture and hands-on DO practice session) or the new DO module (NDO group, which consists of 3 innovative teaching videos, hands-on DO practice, use of PSO and SOS). At the end of the module, 45 students had their fundus photo taken and were assessed for their DO skill by examining each other with one pupil dilated. The outcomes of objective assessments (based on the tutors' scores) and subjective assessments (via an anonymous Likert scale questionnaire) were compared between the 2 groups.

Results: Students taught using the new DO module achieved significantly higher mean scores (32.38 $\pm$ 4 vs 30 $\pm$ 2.68, $p = 0.03$) when compared to those taught using the old module. From the questionnaire, they felt more confident in their DO skills ($p < 0.01$) and more comfortable utilising the instrument in future practice ($p = 0.03$). Students from the new module also gave higher ratings for the course organisation, instructional methods, assignments and outcomes ($p < 0.01$).

Conclusions: A smartphone-based, interactive, and experiential learning-oriented DO training can potentially increase familiarity with the instrument and provide a better learning experience for medical students, and its implementation in the current curriculum should be considered.

Effectiveness of "Finger-and-Fist" Model in Teaching Functional Anatomy of Extraocular Muscle: A Non-Randomized Controlled Trial

First Author: Liping LV

Co-Author(s): Hongxi WANG

Purpose: To evaluate the effectiveness of the «finger-and-fist» teaching model in teaching functional anatomy of extraocular muscles (EOMs), compared with traditional video-based instruction.

Methods: Non-randomized controlled trial. A total of 244 Year-1 medical students from Shantou University Medical College were allocated to two groups based on the class schedules of functional anatomy of EOMs. Participants in Group A (n=125) received conventional video instruction, which provided a 3-dimensional and dynamic demonstration of EOMs and ocular movement. While students in Group B (n=119) were taught using the «finger-and-fist» model, which allowed students to use their extended finger and clenched fist to represent the EOMs and eyeball, so that functional anatomy could be analyzed through demonstrating the vector orthogonal decomposition of muscular action. Knowledge acquisition was assessed through a multiple-choice quiz, while subjective perceptions of the teaching methodology were investigated via Questionnaire Star.

Results: Group B got significantly higher marks in knowledge acquisition than Group A (4.66 ± 1.86 vs. 4.18 ± 1.82 , $p = 0.045$). Subjective feedback showed that students in Group B reported greater confidence in their ability to retain knowledge long-term and were more satisfied with the teaching method.

Conclusions: The «Finger-and-fist» teaching method improved the comprehension and retention of complex oculomotor anatomy compared to passive video instruction. This method could be a valuable pedagogical tool in medical education.

Enhancing Ophthalmology Education Through A Mobile Flipped Classroom: A New Teaching Method

First Author: Nader NASSIRI

Co-Author(s): Sara KAVOUSNEZHAD, Kourosh SHEIBANI, Maryam YADGARI

Purpose: Glaucoma is a major cause of irreversible blindness globally. Optical coherence tomography (OCT) aids early glaucoma diagnosis. Interpreting OCT scans requires familiarity with the technology and image analysis. This study aimed to evaluate the effects of a mobile flipped classroom model on learning outcomes and satisfaction for teaching optical coherence tomography (OCT) interpretation skills in glaucoma.

Methods: In this quasi-experimental pre/post-test study, ophthalmology residents participated in a 4-session mobile flipped classroom educational intervention (90 min/session) and were assessed on OCT interpretation. Learning was measured via pre-/post-tests designed by a panel. Satisfaction was assessed using a validated questionnaire.

Results: Twenty-two ophthalmology residents entered the present study. Mean participant age was $29.42 (\pm 2.09)$ years. Compared to pre-intervention, post-test scores showed significant improvement after the mobile flipped classroom ($p < 0.001$). Mean satisfaction score was 74.05 ± 16.09 , denoting high satisfaction among participants.

Conclusions: Implementing a mobile flipped classroom significantly improved OCT interpretation skills and was associated with high satisfaction ratings among ophthalmology residents. This model shows promise for enhancing clinical knowledge in graduate medical education.

Panel No.: ART-0002

Evaluation of a Short Training Program to Improve Detection and Management of Retinoblastoma in Nepalese Children

First Author: Purnima RAJKARNIKAR STHAPIT

Co-Author(s): Suzanne CHAMBERS, Manish PAUDEL

Purpose: To evaluate the impact of a retinoblastoma screening training programme on primary health care workers' knowledge, confidence, and practice in Kathmandu, Nepal.

Methods: A half-day training program was conducted by trained ophthalmologists for primary health care workers on education on the importance of early identification of retinoblastoma, screening methods, and its management. Pre- and post-tests were done using the Knowledge and Attitudes to Retinoblastoma Scale (KARS). All participants were provided with the 'Arclight' device that detects the white eye reflex in the pupil, an early sign of retinoblastoma.

Results: The majority of 96 participants were female (90%) with a mean age of 36.7 years (± 10.5). Before the training programme, participants' knowledge about retinoblastoma averaged 85% and reached 100% post-training. Knowledge of the Arclight device and retinoblastoma treatment increased from an average of 58.7% to 68.9% post-training, with overall knowledge increasing from 70% to 84%. Confidence in detecting retinoblastoma increased from 65% before training to 95% post-training.

Conclusions: Primary health care workers are the first line of contact with children. Hence, improving their knowledge and confidence in retinoblastoma screening using a readily accessible device like Arclight has the potential to increase the rate of early detection of

retinoblastoma and reduce the burden of this cancer in low and middle-income countries.

Gender Disparities in Vitreoretinal Subspecialty Training and Career Advancement: A Systematic Review

First Author: Sarah Kamiela JUFFRY

Co-Author(s): Kharisma Zatalini GIYANI, Dewi Alya WINARTO

Purpose: Some studies have reported on low female representation among the vitreoretinal (VR) subspecialty. Despite rising female trainees, significant inequities in academic advancement and leadership roles persisted. This review compared female VR trainees and specialists with their male counterparts.

Methods: A systematic search of PubMed, Scopus, ProQuest, Cochrane Library, and Google Scholar was conducted. Outcomes assessed were representation, career milestones, surgical case volume, and remuneration. Studies were appraised using the Joanna Briggs Institute (JBI) Critical Appraisal tool, and data were synthesized qualitatively.

Results: A total of 381 studies were initially obtained, with 10 articles meeting the inclusion criteria for qualitative assessment. Women are underrepresented among practicing VR specialists. While female fellow representation is increasing (32.8% in surgical retina), career advancement remains unequal. Women hold significantly fewer full professor ranks (18.3%-24%) and VR society presidencies (4.3% in ASRS). Female directors constitute only 16%-18.9% of surgical retina fellowship directorships. Women VR specialists receive lower surgical case volume and obtain significantly lower Medicare reimbursement (65% of males). Female academics also demonstrate lower scholarly productivity (publications, h-index). Inadequate mentorship is a recurrent barrier.

Conclusions: Substantial gender disparities persist in VR subspecialty training and careers despite rising female representation. Women continue to face barriers to equitable career advancement. Systemic inequities necessitate targeted interventions, including fostering mentorship, mitigating implicit bias, and ensuring equal surgical training opportunities, to achieve gender parity and strengthen VR workforce.

Panel No.: ART-0013

Generation and Characterization of iPSC Lines (SPPHi005-A, SPPHi006-A, SPPHi007-a) From a CRB1-Mutation Associated Retinitis Pigmentosa Family

First Author: Xiao JIALING

Co-Author(s): Gong BO, Li HUAN, Wang LIANG, Guo XIAOXIN

Purpose: To generate and characterize human-induced pluripotent stem cell (hiPSC) lines carrying CRB1 mutations associated with autosomal recessive retinitis pigmentosa (RP), as well as a control line, for use in disease modeling and therapeutic research.

Methods: hiPSC lines SPPHi006-A and SPPHi007-A were derived from a consanguineous family affected by RP and carrying a homozygous or heterozygous CRB1 variant (c.1997T>A; p.V666D). An additional control line, SPPHi005-A, was generated from an unaffected family member without the CRB1 mutation. All hiPSC lines were examined for karyotype stability, morphology, expression of pluripotency markers, and differentiation potential into three germ layers.

Results: The CRB1-mutant and control hiPSC lines exhibited normal karyotypes, typical hiPSC morphology, robust expression of pluripotency markers, and successful differentiation into ectoderm, mesoderm, and endoderm lineages.

Conclusions: The established hiPSC lines provide a reliable in vitro platform to investigate CRB1-associated RP mechanisms and to develop and test potential therapeutic strategies.

Improving Referral Letter Writing Skills Among Junior Ophthalmology Colleagues and Residents-in-Training Through Structured Teaching and Feedback

First Author: Channdarith KITH

Co-Author(s): Sreyla CHORK, Kossama CHUKMOL, Piseth KONG, Amarin MAR

Purpose: We aim to assess the referral-writing abilities of junior colleagues and trainee residents through a systematic educational method.

Methods: A two-session teaching module was created and delivered to junior colleagues. Each session featured a pre-test, an interactive lecture, and a post-test. The pre-test consists of 10 multiple-choice questions that assess foundational knowledge. The lecture combined concepts from Good Medical Practice coursework and UK Referral Guidelines, followed by a discussion. Participants had 15 minutes to write a letter of referral based on a specific clinical case in ophthalmology. Small group discussions encouraged

peer collaboration, while letter writing remained an individual task. Feedback was provided during a follow-up session based on “direct observation” and written submissions.

Results: Participants showed improved knowledge of referral structure, clinical terminology, and referral timing. Post-test results indicated a moderate improvement in knowledge acquisition. Referral letters exhibited enhanced clarity and relevance; yet, prevalent concerns encompassed linguistic inconsistencies and minor spelling errors. Students reacted favourably to peer and self-assessment elements, recognising them as essential for skill development.

Conclusions: Effective communication is critical for integrated, patient-centred eyecare (IPEC). Clinical communication has been hampered by inconsistent referral letter writing, which is exacerbated by a lack of a standardised national template for interprofessional collaboration and difficulties with multilingual documentation. In conclusion, “structured teaching” combined with immediate, constructive feedback greatly improved junior colleagues’ referral writing abilities. Incorporating peer and self-reflection encourages deeper learning and accountability. Future efforts should focus on developing a standardised national referral form to improve interprofessional communication and quality of patient care.

Interaction Site Mapping Between Rhodopsin and TMEM138 and Its Role in Retinal Degeneration

First Author: Lijing XIE

Co-Author(s): Yingjie CAO, Jinming GUO

Purpose: Degeneration of the photoreceptor outer segment (OS) is a major cause of irreversible blindness. Proper rhodopsin (RHO) trafficking through the connecting cilium is essential for OS disc morphogenesis and renewal. TMEM138, a ciliary membrane protein, participates in RHO transport and localization. This study aimed to identify and validate the molecular interaction sites between RHO and TMEM138 to elucidate their roles in retinal degeneration.

Methods: Protein–protein docking was performed using HDock, integrating results with structural and clinical mutation databases. Plasmids encoding wild-type and mutant RHO and TMEM138 were constructed, and their interactions were examined by tandem affinity purification and structural visualization using PyMOL.

Results: HDock analysis identified 19 potential amino acid interaction pairs. Among 119 sporadic retinitis pigmentosa (RP) patients from the Chaoshan region, eight RHO and three TMEM138 mutation sites were

detected, with three overlapping HDock predictions in each protein. Integrating structural and mutational data, 12 candidate interaction pairs were prioritized.

Conclusions: Combining computational modeling, structural visualization, and genetic analysis effectively mapped the putative interaction sites between RHO and TMEM138. These findings provide novel insights into ciliary transport mechanisms and potential molecular targets for retinal degenerative disease therapy.

Abstract No.: 206363

Neutrophil-Mediated Antibiotic-Free Antifungal System for Fungal Corneal Blindness: Targeted and Synergistic Intervention to Pathogenic Fungi and Corneal Stromal Fibrosis

First Author: Jingguo LI

Co-Author(s): Zhanrong LI, Lei ZHU

Purpose: Fungal keratitis (FK) is a highly blinding ocular infection disease, accompanying invasive fungal infections and subsequent corneal stromal fibrosis (CFS). However, due to the ocular barriers and antibiotic resistance, the clinically available effective ophthalmic formulation is limited, exhibiting low utilization and lacks of multifunctionality, synchronization and controllability.

Methods: Here, we show a neutrophil (NE)-mediated antifungal drug delivery system that provided synergistic killing of pathogenic fungi and synchronously alleviated CFS for effective FK management.

Results: We also show that the NEs-based drug delivery system could bypass the corneal barrier and target the infection focus in mouse models. Wonderfully and exhilaratingly, the recruitment behavior could be observed 15 minutes after injection via the tail vein. Most notably, the NEs-based antibiotics-free antifungal system showed superior biocompatibility and great biosafety.

Conclusions: This proof-of-concept demonstration may be applicable more broadly to the design of drug delivery systems for the intervention of FK and other deep fungal diseases.

Optimizing Trabeculectomy Wet-Lab Training: Factors Affecting Surgical Skill Acquisition

First Author: Canying LIU

Co-Author(s): Yiqing Li LI

Purpose: Given the growing need for ophthalmic surgical training and the challenges of fragmented training opportunities, this study developed and evaluated a structured wet-lab course for

trabeculectomy to help residents acquire and refine essential surgical skills.

Methods: Residents from Zhongshan Ophthalmic Center (ZOC) participated in this study. The training commenced with one pre-training online session, which was followed by a three-week self-directed practice phase and six one-hour offline classes. Residents recorded their surgical procedures after 3, 6, 9, 12, and 15 hours of cumulative practice which were then evaluated by glaucoma specialists. The final assessment was carried out after a minimum of 15 hours of practice.

Results: Training scores increased steadily with cumulative practice hours. After 3 hours of practice, the average score stood at 64.35 ± 9.00 . It climbed significantly to 78.58 ± 9.24 after 15 hours of practice ($P < 0.001$), and scores for most surgical steps improved remarkably. Bachelor's degree-holding residents achieved an average final score of 79.17 ± 8.90 , much lower than those with a master's (89.5 ± 4.24) or a doctorate (89.85 ± 3.87) ($P < 0.001$). Residents with more centralized practice schedules, as indicated by higher variance or wider range in daily and weekly practice times, achieved lower final scores ($P = 0.025$ for daily practice time; $P = 0.007$ for weekly practice time).

Conclusions: The three-week training program significantly improved residents' proficiency in trabeculectomy. The data emphasize that a practice duration of 12 - 15 hours is crucial for residents to develop competence in this surgical procedure, with further refinement needed in clinical settings. For surgical skill development, evenly distributed practice time is more effective than centralized sessions. Standardizing residents' practice frequency can be a key strategy to optimize future training results. This research validates the efficacy of the training model and provides actionable insights for standardizing ophthalmic surgical education. The teaching and evaluation methods employed in this study can be integrated into an online learning environment, facilitating the improvement of surgical capabilities in institutions equipped with wet-lab facilities.

Abstract No.: 208756

Panel No.: ART-0028

Protective Effects of TUDCA on Light-Damaged Cone Cells in Mice and the Underlying Mechanisms

First Author: Ling LI

Co-Author(s): Yingjie TONG, Ting WANG, Tongdan ZOU

Purpose: TUDCA is formed from ursodeoxycholic acid (UDCA), and many studies have shown that TUDCA can protect the retina, but the underlying mechanism remains undefined. Thus, this study aimed to explore the protective effect and underlying mechanism of TUDCA against light-induced retinal damage, providing

a new therapeutic target and basis for the prevention and treatment of light-induced retinal damage.

Methods: Light-sensitive 1-month-old Balb/c mice were irradiated for 12 h in a self-made 2000 Lux light chamber to establish a retinal light damage model. ERG was used to evaluate the therapeutic effect of TUDCA on visual function in light-damaged mice. Hematoxylin-eosin staining was used to assess the impact of TUDCA on the morphological structure of the retina. Western blot and immunohistochemical staining were used to explore the effect of TUDCA on the expression and localization of photoreceptor marker proteins in the retina, respectively.

Results: TUDCA can partially mitigate the visual function impairment induced by light damage. TUDCA might effectively protect photosensitive cells from light damage in mice through anti-apoptotic properties.

Conclusions: These results reveal that TUDCA's protective effect on the visual function of light-damaged retina is realized through its anti-apoptotic properties, and it mainly protects cone cells among photoreceptor cells.

Seeing Beyond Colour: Addressing Colour Vision Deficiency in Medical Education

First Author: Maverick Wenhao WONG

Purpose: Colour vision deficiency (CVD) affects a significant proportion of medical students, yet its impact on clinical education remains largely unaddressed. In ophthalmology, where colour plays an essential role in interpreting imaging, recognising pathology, and navigating visual-rich assessments, students with CVD may be disproportionately disadvantaged. This abstract explores how medical education can be more inclusive to those with CVD, drawing on personal narrative, literature review, and design theory.

Methods: A reflective narrative approach was used to identify common challenges faced by students with CVD in ophthalmology training. These insights were supported by a targeted review of literature on accessibility in medical education. Recommendations were guided by the Universal Design for Learning (UDL) framework to ensure that proposed interventions benefit all learners, not only those with CVD.

Results: Students with CVD often rely on informal workarounds such as memorisation, peer confirmation, or associating structures with context. However, these adaptations are seldom acknowledged or supported institutionally. Common educational barriers include reliance on colour-dependent visuals in fundus photographs, OCT scans, and EMR interfaces, with limited alternative cues available. By integrating inclusive design strategies such as using text labels,

varied patterns, or adjustable filters; these barriers can be significantly reduced.

Conclusions: CVD should not be a silent disadvantage in ophthalmology and medical education. Thoughtful redesign of learning materials and assessments can improve clarity, fairness, and accessibility. This shift towards inclusivity can empower not only students with CVD, but also enhance educational experiences across the spectrum of learners.

Targeting EPA-Rich Lipid Droplets Alleviates Bietti's Crystalline Dystrophy and Reveals Dietary Risks in Retinal Degeneration

First Author: Jiaqiu HUANG

Co-Author(s): Chen ZHAO

Purpose: Excessive lipid droplet (LD) accumulation in the retinal pigment epithelium (RPE) is implicated in blinding retinal degenerations like age-related macular degeneration (AMD) and Bietti's crystalline dystrophy (BCD). We investigated whether clearing LDs is a viable treatment strategy and explored pathogenic lipid species.

Methods: Using a Cyp4v3 knockout mouse model of BCD, we administered an LD-clearing compound (LD-ATTEC, C3) and evaluated its efficacy compared to gene therapy. Multi-omics analysis identified key pathogenic lipids. We also tested the impact of dietary fish oil (rich in EPA/DHA) in BCD and early AMD mouse models and correlated findings with human AMD risk.

Results: C3 treatment effectively rescued structural and functional visual deficits in BCD mice, achieving near wild-type levels and outperforming gene therapy. Multi-omics identified esters of eicosapentaenoic acid (EPA) as a core pathogenic driver. Dietary fish oil supplementation accelerated disease progression in both BCD and AMD mice and correlated with increased AMD risk in humans. C3 was also effective in patient-derived organoids and showed a favorable safety profile in non-human primates.

Conclusions: Our findings establish LD clearance as a novel therapeutic strategy for BCD and reveal unanticipated risks associated with EPA-containing supplements in retinal degenerative diseases and at-risk individuals.

Panel No.: ART-0022

Targeting GPER Activates YAP Signaling to Ameliorate Epithelial Injury in Nasolacrimal Duct Obstruction

First Author: Xinyue YU

Co-Author(s): Xianming JIANG, Xuanwei LIANG

Purpose: Nasolacrimal duct obstruction (NLDO) is a prevalent cause of debilitating epiphora and ocular surface inflammation, with a striking female predominance suggestive of hormonal involvement. This study aims to investigate the role of the G protein-coupled estrogen receptor (GPER) in NLDO pathogenesis and its potential as a therapeutic target.

Methods: We analyzed serum hormones and tear inflammatory cytokines in NLDO patients. GPER expression was assessed in patient nasolacrimal duct tissues via immunofluorescence and Western blot. The functional role of GPER was investigated in vitro using patient-derived primary nasolacrimal duct epithelial cells and advanced air-liquid interface (ALI) organoid models subjected to MIF-induced injury, GPER overexpression/activation, and YAP1 inhibition. An injury-induced NLDO mouse model was used for in vivo validation.

Results: NLDO patients exhibited significantly reduced serum estrogen levels, decreased GPER expression in the nasolacrimal duct, and elevated tear levels of MIF, IL-6, and IL-8. In vitro, GPER activation protected epithelial cells from MIF-induced damage, promoting proliferation, reducing apoptosis and senescence, and restoring ciliogenesis in organoids. Mechanistically, GPER mediated these effects by promoting YAP1 nuclear translocation. Critically, intraperitoneal administration of the GPER agonist G-1 in mice with NLDO effectively promoted epithelial repair, reduced fibrosis and inflammatory cell infiltration, and improved functional outcomes.

Conclusions: Our study establishes impaired GPER signaling as a key driver of NLDO. By demonstrating that GPER agonism activates YAP1 to promote epithelial repair and suppress inflammation, we position it as a compelling non-surgical therapeutic strategy.

Abstract No.: 207463

Panel No.: ART-0027

Targeting Phospholipase D to Prevent High Glucose-Induced Oxidative Damage in ABC Retinal Pigment Epithelium Cells

First Author: Vicente BERMÚDEZ

Co-Author(s): Nicolas Guillermo BAZAN, Jorgelina CALANDRIA, María Sol ECHEVARRÍA, Melina Valeria MATEOS, Paula Estefanía TENCONI

Purpose: The retinal pigment epithelium (RPE) plays a critical role in maintaining neural retina and photoreceptor viability. Classical phospholipases

D (PLD1/2) hydrolyze phosphatidylcholine (PC) to generate phosphatidic acid (PA) and choline; PA is then dephosphorylated to diacylglycerol (DAG), both serving as key lipid messengers. Previously, we demonstrated that classical PLDs mediate the inflammatory response in RPE cells exposed to high glucose (HG) in ARPE-19 cells. In this study, we investigate whether PLD signaling modulates HG-induced oxidative stress (OS) in a novel RPE cell line, ABC cells. These cells exhibit a phenotype that more accurately reflects native human RPE cells compared to ARPE-19

Methods: ABC cells were maintained under high glucose (HG, 33 mM) or normal glucose (NG, 5.5 mM) conditions. Selective inhibitors targeting PLD1 (VU0359595), PLD2 (VU0285655-1), or NADPH oxidase (DPI) were applied. ROS levels, nuclear enlargement, and caspase-3/7 activation were subsequently assessed. Additionally, NADPH oxidase (NOX) gene expression was examined by RNA-seq in ABC and ARPE-19 cells.

Results: High glucose (HG) markedly elevated ROS, nuclear enlargement, and caspase-3/7 activation in ABC cells compared to normal glucose (NG); these effects were blocked by PLD and NOX inhibition. RNA-seq revealed increased NOX1/2/4 expression in ABC cells, whereas NOX5 and DUOX1/2 were predominant in ARPE-19.

Conclusions: Our findings show that PLD inhibition prevents oxidative stress (OS) induced by high glucose (HG) in RPE cells, likely through downregulation of NOX activity. Therefore, PLDs represent promising therapeutic targets to alleviate both OS and inflammation in degenerative retinal disorders.

Targeting SLC7A11-Mediated Disulfidptosis to Induce Neovascular Regression in Proliferative Diabetic Retinopathy

First Author: Bowei YUAN

Co-Author(s): Jiayan LIU, Yamei LU, Zhihui XIAO, Tingting YANG

Purpose: Current treatments for proliferative diabetic retinopathy (PDR) do not address its core metabolic dysregulation. We hypothesized that the cystine transporter SLC7A11, which is upregulated in PDR neovasculation, creates a therapeutic vulnerability. This study aimed to exploit this dependency to selectively trigger disulfidptosis, a form of regulated cell death, in aberrant retinal vessels and induce disease regression.

Methods: The role of SLC7A11 was investigated using bioinformatics, patient-derived tissues, and functional assays in human retinal microvascular endothelial cells (HRMECs). Loss- and gain-of-function studies were performed using siRNA and lentiviral overexpression. A diabetic mouse model was used to assess the in vivo

therapeutic effect of localized glucose restriction via vitreous irrigation.

Results: SLC7A11 was significantly upregulated in the retinal endothelium of PDR patients and was essential for pro-angiogenic activities in vitro. Critically, SLC7A11 overexpression rendered HRMECs susceptible to disulfidptosis upon glucose deprivation. In a diabetic mouse model, vitreous irrigation with a glucose-free solution successfully induced the regression of neovascular membranes.

Conclusions: SLC7A11 promotes angiogenesis in PDR under hyperglycemia but creates a fatal susceptibility to disulfidptosis under glucose restriction. Exploiting this metabolic vulnerability presents a novel therapeutic paradigm for selectively eliminating pathological neovasculation in PDR.

The Analysis of Adipogenesis and Inflammatory Response in Orbital Fibroblast From Adult and Pediatric Graves' Ophthalmopathy

First Author: Junghyo AHN

Purpose: This study is to elucidate the differences in clinical characteristics between pediatric and adult patients with Graves' ophthalmopathy based on cellular and molecular level differences by examining the inflammatory response and adipogenic differentiation in orbital fibroblasts harvested from pediatric and adult patients with Graves' ophthalmopathy in response to the proinflammatory cytokine (IL-1 β).

Methods: Orbital fat tissue was harvested from, healthy adults, healthy pediatric individuals, and adult patients with Graves' ophthalmopathy, and orbital fibroblasts were cultured from these samples. IL-1 β was administered at the early stage of adipogenic differentiation in orbital fibroblasts, followed by the exchange of adipogenic differentiation medium for 14 days. The expression levels of PGE2, COX-2, PPAR- γ , C/EBP- α , and C/EBP- β were measured on days 1, 3, 5, 10, and 14 during differentiation to assess the inflammatory response and adipogenic differentiation with Western Blotting and RT-PCR. Adipogenic differentiation was additionally confirmed with Oil-red O staining.

Results: Expression of PGE2, COX-2 was higher in healthy child and adult patients than in healthy adult, respectively. Expression of PGE2, COX-2 after IL-1 β was more enhanced in all groups.

Conclusions: Compared to adults, orbital fibroblasts in pediatric patients may exhibit a more active inflammatory response and adipogenic differentiation, and they may be more sensitive to inflammatory conditions, potentially leading to enhanced differentiation into adipocytes. When managing and

developing treatment strategies for pediatric and adult patients with Graves' ophthalmopathy, it will be necessary to adopt a personalized approach that takes into account the biological characteristics of each group.

The Role and Mechanism of Sympathetic Nerve in Regulating the Function of Corneal Limbal Stem Cells in Diabetes

First Author: Zhang ZHENZHEN

Purpose: To investigate the role and mechanism of sympathetic overactivation in regulating the function of corneal limbal stem cells (LSCs).

Methods: Streptozotocin-induced type I diabetic mouse model was used in this study. The intervention of sympathetic nerves was investigated to study its effect on diabetic LSCs. In addition, we detected the predominantly expressed adrenergic receptors in LSCs by single-cell sequencing, magnetic bead sorting, and RT-PCR. Adb2-KO mice, Adb2-specific antagonists, and Shh inhibitors were used to study the downstream signaling pathways of NE-Adb2 regulation in diabetic LSCs. The molecular mechanism of the sympathetic nerve on diabetic corneal epithelial repair was investigated in vitro.

Results: A streptozotocin-induced type I diabetic mouse model was used in this study. The intervention of sympathetic nerves was investigated to study its effect on diabetic LSCs. In addition, we detected the predominantly expressed adrenergic receptors in LSCs by single-cell sequencing, magnetic bead sorting, and RT-PCR. Adb2-KO mice, Adb2-specific antagonists, and Shh inhibitors were used to study the downstream signaling pathways of NE-Adb2 regulation in diabetic LSCs. The molecular mechanism of sympathetic nerve on diabetic corneal epithelial repair was investigated in vitro.

Conclusions: Sympathetic overactivation caused the impairment of diabetic LSCs function and corneal epithelial regeneration through the NE-Adb2-Shh signaling pathway.

Through Their Eyes: Experiencing Glaucomatous Visual Field With VR Headset, Apps & Glaucoma Goggles

First Author: John Davis AKKARA

Purpose: A novel approach to understanding glaucoma's impact by directly simulating its vision loss through various methods - Glaucoma Goggles, Simulator Apps & Virtual Reality Headset. This is useful to teach attendees & relatives of glaucoma patients.

Methods: Participants experience simulated visual field loss using: Glaucoma Goggles: Specially designed glasses mimic blurred peripheral vision loss of glaucoma. Interactive Apps: Utilized to create engaging simulations. Users navigate virtual & real environments while experiencing blind spots and tunnel vision, replicating progressive vision loss. Virtual Reality: Transports viewers into a world affected by glaucoma. Experience disorientation & difficulty navigating environments, emphasizing impact on daily life. Website: VisionMatters Website simulates what browsing the internet looks like for patients with glaucoma, ARMD, cataract, and more.

Results: Visual field loss was demonstrated to patients and attendees on the smartphone app, Glaucoma Goggles, and the Virtual Reality simulator. The app was the easiest to use to demonstrate and most convenient. Since everyone had a smartphone, the attendees could also install the free app to spread the knowledge to others in the family, potentially spreading widespread awareness. Glaucoma Goggles were low-tech and easy to understand, as they personally simulate visual field loss to the wearer Virtual Reality headset was a bit more cumbersome to use but provided the most immersive experience

Conclusions: Increases awareness of glaucoma symptoms, builds empathy & teaches the importance of early detection. By directly experiencing vision loss, individuals gain a deeper understanding of glaucoma, fostering early detection and promoting eye health advocacy. Field loss is difficult to understand, so a visual demonstration helps increase awareness and understanding of glaucoma and the importance of screening.

Transcriptomic Profiling of Conjunctival Tissue in Allergic Conjunctivitis Reveals Immune Dysregulation and Metabolic Remodeling

First Author: Liang WANG

Co-Author(s): Renjie CHAI, Bo GONG, Huan LI, Jialing XIAO, Man YU

Purpose: Allergic conjunctivitis (AC) is a common ocular surface inflammatory disease, yet its molecular mechanisms remain incompletely understood. Identifying key genes and pathways involved in AC may provide new insights into potential diagnostic biomarkers and therapeutic targets.

Methods: We performed transcriptome sequencing of conjunctival tissues from three AC mice and three healthy controls. Differentially expressed genes (DEGs) were identified based on thresholds of $p < 0.05$ and $|\log_2 FC| > 1$. Functional enrichment analysis was conducted using Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG)

databases. Selected DEGs were further validated by quantitative real-time PCR (qPCR).

Results: A total of 428 DEGs were detected, including 286 upregulated and 142 downregulated genes in AC compared with controls. Volcano plot analysis revealed significant expression changes, with multiple immune- and metabolism-related genes prominently dysregulated. GO and KEGG enrichment analyses indicated that downregulated genes were mainly involved in cytokine–cytokine receptor interaction, NF- κ B signaling, and IL-17 signaling pathways, while upregulated genes were enriched in lipid metabolism, fatty acid biosynthesis, and immune response processes. qPCR validation confirmed that Aqp8 and IL20 were significantly upregulated in AC conjunctiva, suggesting their potential as novel biomarkers.

Conclusions: Our study provides a comprehensive transcriptomic landscape of conjunctival tissues in allergic conjunctivitis. The identified DEGs and enriched pathways highlight immune-inflammatory dysregulation and metabolic remodeling in AC. In particular, Aqp8 and IL20 may serve as candidate biomarkers and therapeutic targets for allergic conjunctivitis.

Tubulin Hyperglutamylation Causes Retinal Degeneration by Impairing the Structural Integrity of Cilia and Protein Mistrafficking

First Author: Tongdan ZOU

Co-Author(s): Yingjie TONG, Haolin WANG, Ting WANG, Houbin ZHANG

Purpose: Tubulin polyglutamylation is dynamically regulated by glutamylation and deglutamylation. AGBL5 is a deglutamylase that specifically removes glutamate at the branching point. Mutations in AGBL5 in humans are associated with retinitis pigmentosa, but the underlying mechanism remains undefined. In this study, we generated Agbl5 knockout mice to further explore the role and potential mechanism of tubulin glutamylation homeostasis regulated by AGBL5 in the survival of retinal photoreceptors

Methods: Agbl5 mice were created using the CRISPR/CAS9 technique. The retinal function was tested by ERG. Retinal degeneration was measured by H&E and TUNEL assay. RNA-seq was used to analyze the gene expression in KO and control retinas. Transmission electron microscopy (TEM) was employed to clearly observe the internal scaffold structure of the connecting cilium (CC) in retinal photoreceptors and the disk membrane structure in the outer segment of photoreceptors.

Results: The Agbl5 mutant mouse displayed impaired rod and cone function and developed progressive retinal degeneration. Tubulin hyperglutamylation

altered the structure of the axoneme by destabilizing the Y-links in the connecting cilium, which affected the function of cilia by the attenuated recruitment of IFT particles and defective transport of opsins in cones and rhodopsin in rods.

Conclusions: These results reveal that tubulin glutamylation level, regulated by AGBL5, is critical for the structural integrity of the axoneme and intraflagellar transport of proteins in photoreceptors.

A Case of Rotation of a Toric Multifocal Intraocular Lens After Phacoemulsification and Implantation in a Patient With Prior Laser In Situ Keratomileusis and Presbyopia Correction

First Author: Li CAIYUN

Co-Author(s): Zhang CHAOJUN, Liu MEIQING

Purpose: To report a case of rotation of a toric multifocal intraocular lens (IOL) after phacoemulsification and IOL implantation in a patient with a history of laser-assisted in situ keratomileusis (LASIK) and presbyopia correction.

Methods: A 55-year-old female patient presented with a complaint of «difficulty reading for the past six months.» She had undergone right-eye LASIK and right-eye presbyopia correction. •Right eye: (UDVA) 0.8; (CDVA) -0.75DC $\times$ 180 $\rightarrow$ 0.9; (UNVA) 0.3. Left eye: UDVA 1.0; UNVA 0.4. Diagnosis: Bilateral presbyopia with right-eye refractive error. The patient underwent right-eye phacoemulsification and IOL implantation (TFNT40 +23.0D with -0.05 residual). Postoperatively, on day 1, with 23° IOL rotation. IOL repositioning was performed. At 1 week post-repositioning, with 48° IOL rotation. Right-eye IOL exchange with (CTR) implantation (939MP SE +23D, +21.5D/+3.00 with -0.05 residual) was then performed.

Results: 1 week post-IOL exchange: UDVA/intermediate/near visual acuity 0.8/0.8/0.8; 1 month post-IOL exchange: UDVA 0.6, intermediate 1.0, near 1.0; CDVA -1.25DS $\rightarrow$ 1.0; 3 months post-IOL exchange: UDVA 0.8-, intermediate 1.0, near 1.0; CDVA -1.25DS $\rightarrow$ 1.0.

Conclusions: For patients with enlarged capsular bags, capsular tension rings (CTRs) enhance capsular stability, ensuring reliable fixation of toric multifocal IOLs and achieving optimal distance/intermediate/near visual outcomes. Post-keratorefractive changes in ocular and corneal morphology may increase IOL power calculation errors, and high expectations for visual quality pose challenges in cataract surgery.

Accurate IOL power calculation remains critical. The implantation of toric multifocal IOLs after myopia/presbyopia correction surgeries is rarely reported. Further clinical studies are needed to refine optimal IOL power calculation methods.

A Retrospective Real-World Evidence Study of the Performance of an Enhanced Non-Toric Monofocal Intraocular Lens in Patients Undergoing Cataract Surgery

First Author: Cathleen MCCABE

Purpose: To explore the real-world clinical performance and outcomes of the enVista ASPIRE (EA) and/or EA toric (ETA) enhanced monofocal IOLs, including surgeon satisfaction. This sub-analysis focuses on outcomes with the EA IOL.

Methods: This multicenter, retrospective, real-world study included 6 US cataract surgeons who had conducted cataract surgery using monofocal and/or toric IOLs for ≥ 3 years, including ≥ 5 cases with EA/ETA. In this sub-analysis, participants completed a retrospective user-experience survey and provided a convenience sample of ≥ 5 patient cases of EA implantation following cataract extraction using a standardized case report form. Outcome measures included monocular corrected and uncorrected distance, and uncorrected intermediate visual acuity (CDVA, UDVA, UIVA), refractive outcomes, and surgeon satisfaction.

Results: This sub-analysis included 88 eyes (54 patients). Mean $\pm$ SD spherical equivalent (SEQ) target was -0.08 ± 0.16 (n=88). Follow-up data up to 3 months were reported: 97% of eyes achieved a monocular CDVA of $20/\leq 25$ (n=72); 71% achieved a monocular UDVA of $20/\leq 25$ (n=87); 77% achieved a monocular UIVA of $20/\leq 32$ (n=77). Mean $\pm$ SD SEQ outcome was -0.06 ± 0.30 (n=79). No serious safety events were noted. The mean surgeon satisfaction score for overall lens performance was 9.2 (10=very satisfied; N=6).

Conclusions: In this real-world retrospective case review, EA delivered good distance and functional intermediate vision for most patients following cataract surgery, with minimal occurrences of visual changes or AEs. Surgeons reported high levels of satisfaction with the lens.

Panel No.: CAT-0147

AI-Assisted Smartphone Slit-Lamp for Cataract Detection: A Validation Study Against Clinical Standards

First Author: Naimah BINTE ISMAIL

Co-Author(s): Muhammad Azri BIN RAZALI, Ziyou David CHEN, Quoc Dat DO, Pamela LEONG MEI EN

Purpose: To evaluate the performance of an AI-assisted portable slit-lamp device in predicting nuclear sclerotic cataracts through undilated eyes.

Methods: Two hundred patients on cataract follow-up underwent undilated anterior segment imaging using a portable slit-lamp attached to an iPhone 13 (Apple Inc., Cupertino, CA, USA) and a Samsung S22 Ultra (Samsung Electronics Co., Ltd., Suwon, South Korea). Nuclear colour (NC) of images was graded using the Lens Opacities Classification System III (LOCS III) scale by a clinician and an AI system. Graded images were assessed using Pearson's correlation and Bland-Altman analysis.

Results: The mean age of participants was 68.8 ± 6.8 years. 759 images were analysed across NC Grades 2–6. Mean grading scores were: Clinician = 3.40 ± 0.82 ; and AI = 3.41 ± 0.78 . Pearson's correlation was: [$r = 0.915$, 95%, CI 0.839–0.894, $p < 0.001$]. Bland-Altman analysis highlighted a mean difference of 0.014 (95% limits of agreement: -0.64–0.67), indicating 95% of AI gradings were within 1 LOCS III unit of the clinician's assessment. Mean difference in NC values between AI and clinicians' for the respective gradings were: Grade 2 = 0.11 ± 0.02 , Grade 3 = 0.03 ± 0.25 , Grade 4 = 0.01 ± 0.27 , Grade 5 = 0.24 ± 0.25 , and Grade 6 = 0.55 ± 0.24 . These results indicated a good correlation between the clinician and AI's grading.

Conclusions: AI grading paired with MIDAS demonstrated high accuracy of cataract grading, supporting its use for community-based cataract screening without pupillary dilation.

Accuracy of Refractive Target Prediction Following Cataract Surgery in Vitrectomized Eyes at a Tertiary Eye Hospital

First Author: Lydia Permata HILMAN

Co-Author(s): Andrew M.h KNOCH, Emmy Dwi SUGIARTI, Ludwig Melino TJOKROVONCO, Budiman

Purpose: To determine the accuracy of biometry in predicting target refraction using Barret Universal II who underwent phacoemulsification and primary intraocular lens (IOL) implantation in eyes that have undergone vitrectomy procedure through evaluating the prediction error (PE) and mean error (ME).

Methods: A retrospective descriptive study was conducted from medical records of patients presented to Tertiary Eye Hospital for three months between June and August 2023 who underwent phacoemulsification with IOL that was calculated with Barret Universal II formula after vitrectomy. The characteristics data included age, gender, vitrectomy indications, endotamponade, type of cataract, time between vitrectomy and phacoemulsification, and time between silicone oil removed and phacoemulsification. Refractive results, subject characteristics, and the determining variables affecting the biometry were assessed.

Results: A total of 22 patients were included in this study with the most common type of cataract was nuclear cataract. In this study, the mean interval between PPV and phacoemulsification was more than one year (55%) and the mean interval between silicon oil removal and phacoemulsification was more than six months (83.3%). At one months after surgery, the Postoperative PE within ± 0.50 D was found in 16 eyes (72.7%). The ME in this study was 0.28 ± 1.17 D.

Conclusions: The accuracy of biometry in predicting target refraction using Barret Universal II may achieve good refractive outcome in vitrectomized eye.

Advanced Artificial-Intelligence-Based Jiang Formula for Intraocular Lens Power in Congenital Ectopia Lentis

First Author: Yan **LIU**

Co-Author(s): Tianhui **CHEN**, Yongxiang **JIANG**

Purpose: The purpose of this study was to develop an artificial intelligence (AI)-based intraocular lens (IOLs) power calculation formula for improving the accuracy of IOLs power calculations in patients with congenital ectopia lentis (CEL).

Methods: A total of 651 eyes with CEL that underwent IOL implantation surgery were included in this study. An AI-based ensemble formula, the Jiang Formula, was developed using a training dataset of 520 eyes and evaluated on a testing dataset of 131 eyes. A five-fold cross-validation and a two-layer ensemble learning model were constructed. The formula was then tested in a test set and compared against five current classic formulas.

Results: The cohort included young patients (mean age = 14.38 ± 13.35 years). The Jiang Formula showed the lowest prediction error (PE; = 0.08 ± 1.01 diopters [D]), absolute error (AE; = 0.77 ± 0.65 D), median absolute error (MedAE; = 0.66 D), and root mean square error (RMSE; = 1.02 D) among six formulas ($P < 0.001$). Moreover, 68.00% of the eyes in the test set had AE within 1.0 D in the Jiang Formula.

Conclusions: An AI-integrated two-layer ensemble learning model demonstrates promising applications in IOLs power calculations for patients with CEL, not only providing higher predictive accuracy than current classic formulas but also accommodating extreme values and variations in surgical techniques.

Alcohol Consumption and Risk of Cataract: A Meta-Analysis

First Author: Kwan Lam Kelvin **CHAN**

Co-Author(s): Kelvin Kl **CHONG**, Kenneth Kh **LAI**, Calvin Cp **PANG**, Clement Cy **THAM**

Purpose: Studies have concluded conflicting results for the association between alcohol consumption and risk of cataract. Therefore, this study provides an overview and possible explanation.

Methods: A literature search was conducted in PubMed, ScienceDirect and Embase databases from inception until September 2025. Case-control, cross-sectional and cohort studies that investigated alcohol consumption and risk of cataract were identified. Random Effect Model was used to provide the pooled Risk Ratio (RR) and 95% Confidence Intervals (CI). Description and explanation of conflicting results were provided.

Results: Eight studies assuming 662,567 subjects were entailed. The pooled results demonstrated no significant relationship between alcohol consumption and the risk of cataract (RR 1.08, 95% CI: 0.93-1.25). Several studies conclude that light to moderate alcohol consumption has a protective effect against the risk of cataract. On the contrary, some studies indicate that even light alcohol consumption can increase the risk of cataract. The high heterogeneity between studies might have caused such a result ($\text{Tau}^2 = 0.0309$; $\text{Chi}^2 = 94.82$, $\text{df} = 7$ ($P < 0.0001$); $I^2 = 92.6\%$). Several studies have identified a U-shaped association. Potential mechanisms were discussed, pinpointing the antioxidative function in moderate alcohol consumption, while increased expression of the enzyme CYP2E1 among heavy drinkers causes clustering of lens protein.

Conclusions: No determinative relationship between alcohol consumption and risk of cataract could be established. However, a U-shaped relationship was frequently reported, with plausible biological explanations. Future research with standardized confounder adjustment is needed to delineate such an association.

Alzheimer's Disease Risk Reduction Post-Cataract Surgery: A Systematic Review and Meta-Analysis With Individual-Patient Data

First Author: Yonglin WU

Co-Author(s): Ya Yuan Rachel LEUNG, Natalie Nga Man TAM

Purpose: Visual impairment is a risk factor for cognitive decline. Cataract surgery, as a commonly performed visual impairment corrective intervention, may be a modifiable risk factor to reduce the risk of incident dementia. We conducted a systematic review and meta-analysis with individual patient data on the cumulative risk of incident Alzheimer's disease in patients with cataract.

Methods: We did a systematic review and meta-analysis of studies (from January 1, 1980 through June 1, 2025) reporting the risk of incident Alzheimer's disease in patients with uncorrected cataract and those who received cataract surgery. Individual patient datasets and aggregated data from 3 prospective cohorts enabled longitudinal analysis.

Results: Of 4 studies (36,927 patients, follow-up range: 5-16 years) reporting incident AD, 2 studies were from the UK, 1 study from Taiwan, and 1 study from the US. The cumulative risk of incident Alzheimer's disease was 2.05% (95% CI: 1.90% - 2.21%) in unoperated cataract patients (637 Alzheimer's disease cases out of 31129 patients) and 0.936% (95% CI: 0.83% - 1.06%) in post-cataract surgery patients (241 Alzheimer's disease out of 25752 patients; $p < 0.01$). Cataract surgery was associated with a 54.3% reduction in the cumulative risk of incident Alzheimer's disease (RR 0.45; 95% CI: 0.39 - 0.52) in patients with cataract.

Conclusions: While treatment options for Alzheimer's disease remained limited, cataract surgery may be associated with a reduction in the cumulative risk of incident dementia in the long term. Physicians should be aware of the cognitive sequelae of cataract, and the possible benefits of cataract surgery on cognitive decline risks.

Panel No.: CAT-0137

Astigmatism Tamed: Scleral Fixation of Toric IOLs Without Capsular Bag Support

First Author: Nagesha Chokkahalli KRISHNAPPA

Co-Author(s): Naren SHETTY, Rohitha NAYAK

Purpose: This study aims to analyse visual outcomes following scleral fixation of toric intraocular lenses (IOLs). To observe the amount of astigmatism reduction, tilt and decentration of IOL and complications post intervention.

Methods: Consecutive patients with significant corneal astigmatism (>0.75 DC) without capsular bag support underwent scleral fixation of toric IOLs. Visual outcomes, including residual refraction, were measured at 6 weeks post-surgery. The frequency of immediate and late complications was analyzed.

Results: A total of 9 eyes underwent scleral fixation using a modified abexterno 4-point fixation technique using 9-0 polypropylene/Gore-Tex sutures. 3 eyes had closed-globe internal refixation of dislocated toric IOLs, and 6 eyes had aphakic correction. Four eyes received Alcon AcrySof toric IOLs, and 5 eyes received Envista toric IOLs. The mean preoperative corneal astigmatism was 2.12 DC (range: 0.9-3.7 DC), and the mean subjective refraction was 2.96 DC (range: 0.75-5 DC). Post-surgery, the residual subjective astigmatism was 0.52 DC. The mean postoperative uncorrected visual acuity (UCVA) was 0.2 logMAR units, further improved to 0.12 logMAR units with correction. The mean tilt was less than 5 degrees, and the mean decentration was less than 500 microns. No major immediate or late postoperative complications were noted, except for one eye with a transient vitreous hemorrhage.

Conclusions: Scleral fixation of toric IOLs emerges as a valuable technique for addressing astigmatism in eyes without capsular support, yielding encouraging results in terms of IOL stability, astigmatism reduction, and visual improvement.

Abstract No.: 201996

Panel No.: CAT-0113

Binocular Depth Perception in Blended Vision Using EDOF and +3 Add IOL

First Author: Neha DHOLAKIA

Purpose: The aim of this analysis was to evaluate the preservation of binocular depth perception after bilateral implantation of an asymmetric refractive segmental EDOF intraocular lens (IOL) in one eye, and a +3.0 add asymmetric refractive segmental multifocal IOL in the fellow eye.

Methods: Ten patients (20 eyes) were included. The dominant eye received a FEMTIS IOL with +1.5D add, and the non-dominant eye received a FEMTIS IOL with +3.0D add. Postoperatively, patients were assessed for halos, glare, and uncorrected visual acuity (UCVA) both monocularly and binocularly.

Results: Patient satisfaction was 100%. No halos or glare were reported. There were no complaints of waxy vision. Patients achieved good distance and near binocular vision.

Conclusions: Blended vision with an EDOF IOL in combination with a refractive trifocal IOL is an excellent option for patients who wish to avoid halo and glare while driving, yet still desire spectacle independence.

Abstract No.: 207264**Panel No.: CAT-0157**

Breaking the Mold: Multifocal Intraocular Lenses Through Manual Small Incision Cataract Surgery—Expanding the Boundaries of Cataract Surgery

*First Author: Ankeeta **THALI****Co-Author(s): Ravindra M.S., Deepthi **MEDA**, Tulasi **MEDA***

Purpose: To assess the feasibility and visual outcomes of multifocal intraocular lens (MFIOL) implantation using a modified manual small incision cataract surgery (MSICS) technique.

Methods: A retrospective analysis was performed on 2,600 eyes that underwent modified MSICS with MFIOL implantation between September 2020 and July 2025 by a single surgeon. A reduced and optimized incision size was utilized to minimize surgically induced astigmatism (SIA), aiming to achieve outcomes comparable to phacoemulsification. Preoperative and postoperative uncorrected distance visual acuity (UDVA), best-corrected visual acuity (BCVA), and refraction were evaluated.

Results: At one month postoperatively, 85% of eyes achieved a UDVA of 6/9 or better. The majority of patients reported spectacle independence for both distance and near vision.

Conclusions: With appropriate surgical modifications, MFIOLs can be successfully implanted via MSICS, offering excellent visual outcomes. To our knowledge, this represents the largest reported series demonstrating MSICS as a viable, precise, and resource-efficient technique for premium intraocular lens delivery.

Abstract No.: 203790

Capsular Phimosis in Retinitis Pigmentosa: Role of Capsular Tension Ring, Polishing, and Biomarker Analysis

*First Author: Vaibhav **VISHAL****Co-Author(s): Poornachandra B, Swaminathan **SETHU**, Naren **SHETTY***

Purpose: Retinitis pigmentosa is associated with increased subclinical inflammation, which accelerates the development of capsular phimosis after cataract surgery. This study aimed to evaluate the role of Capsular Tension Ring (CTR) implantation combined with anterior capsular polishing in preventing capsular phimosis. Intraocular biomarkers of inflammation were also analyzed.

Methods: This prospective interventional study included 20 patients (40 eyes) with retinitis pigmentosa who underwent cataract surgery in both eyes. In each patient, one eye underwent CTR implantation with anterior capsular polishing, while the fellow eye served

as control. Patients were evaluated preoperatively and up to six months postoperatively for the incidence of capsular phimosis. Tear fluid and aqueous humor samples were collected and analyzed for inflammatory biomarkers using a novel detection kit.

Results: Eyes receiving CTR implantation with anterior capsular polishing demonstrated significantly lower rates of capsular phimosis, improved visual outcomes, and reduced intraocular lens decentration and tilt compared with controls. Biomarker analysis revealed elevated levels of inflammatory mediators in both groups, with interleukin-1 (IL-1) and matrix metalloproteinase-9 (MMP-9) showing the greatest increase.

Conclusions: CTR implantation with anterior capsular polishing is a simple and effective technique to reduce capsular phimosis in retinitis pigmentosa, resulting in better postoperative outcomes. Biomarker findings suggest that prolonged corticosteroid therapy or safer targeted anti-inflammatory treatments may be warranted to improve long-term surgical success.

Abstract No.: 201931**Panel No.: CAT-0110**

Case-Based Management of Symptomatic IOL Glistening With the Double Sinskey Technique

*First Author: Givenchy Angela **WINARJO****Co-Author(s): Fajri **IJRIAN**, Cindy Prajna **METTA**, Bobby Ramses Erguna **SITEPU**, Kristo Hadi Audric **SUGIAMAN***

Purpose: Intraocular lens (IOL) glistening can significantly degrade visual function, leading to glare and reduced contrast sensitivity. This case report aims to describe the successful surgical management of a patient with severe vision loss secondary to clinically significant IOL glistening, highlighting the utility of the Double Sinskey Technique for IOL explantation.

Methods: A 62-year-old male presented two years after cataract surgery with persistent glare and visual acuity reduced to 3/60 due to an opaque, glistening hydrophobic acrylic IOL. An IOL exchange was performed. The initial plan involved using the Double Sinskey Technique, where two Sinskey hooks engage both haptics simultaneously to lift the IOL from the capsular bag while minimizing zonular stress. Due to the unavailability of an IOL cutter, the approach was modified by enlarging the corneal incision to facilitate the extraction of the intact IOL. A new polymethyl methacrylate (PMMA) lens was subsequently implanted into the capsular bag.

Results: The surgical procedure was completed successfully without intraoperative complications. One week postoperatively, the patient's uncorrected visual acuity showed substantial improvement from 3/60 to 6/18. The patient also reported a complete resolution of the debilitating glare and visual disturbances.

Conclusions: IOL exchange is the definitive and effective treatment for visually significant IOL glistening. This case demonstrates that the procedure can lead to excellent visual rehabilitation. The Double Sinsky Technique is a valuable and simple method for safely explanting an IOL from the capsular bag, as it helps distribute forces evenly and reduces the risk of iatrogenic zonulysis.

Panel No.: CAT-0135

Clinical Outcomes of a Non-Diffractive EDOF IOL with Emmetropia vs. Mini-Monovision in a Taiwanese Population

First Author: Chen-cheng **CHAO**

Co-Author(s): Chao-kai **CHANG**, Tzu-te **HU**, I-hung **LIN**, Yu-lun **LO**

Purpose: To compare visual outcomes, spectacle independence, and dysphotopsia after bilateral implantation of a non-diffractive extended depth of focus (EDOF) intraocular lens (IOL) with either emmetropia or mini-monovision targets.

Methods: This prospective, multi-center study included 168 eyes of 84 patients bilaterally implanted with the AcrySof IQ Vivity IOL. Patients were targeted for either emmetropia (n=42) or mini-monovision (max offset $\leq 0.50D$, n=42). At 3 months post-surgery, outcomes included binocular visual acuity (VA), spectacle independence (IOLSAT questionnaire), visual disturbances (QUVID questionnaire), and reading speed (IREST).

Results: The mini-monovision group achieved slightly better mean binocular uncorrected visual acuity at all distances compared to the emmetropia group. At 3 months, uncorrected near VA was 0.24 ± 0.17 logMAR for mini-monovision and 0.26 ± 0.17 logMAR for emmetropia. Spectacle independence was high in both groups, with the mini-monovision group showing a slight advantage (e.g., for near vision in bright light, 85.7% vs. 82.4% rarely or never needed glasses). The incidence of bothersome photic phenomena was low, with the majority of patients unaffected by starbursts (82.4%), halos (85.3%), or glare (86.8%). Mean intermediate reading speed significantly improved from 172 ± 67 wpm preoperatively to 201 ± 58 wpm postoperatively ($p < 0.05$).

Conclusions: Bilateral implantation of this non-diffractive EDOF IOL provides good distance and intermediate vision with functional near vision and minimal dysphotopsia. A mini-monovision strategy offers a slight enhancement in uncorrected near vision and spectacle independence compared to targeting emmetropia.

Collodion Kid With White in the Eyes

First Author: Nayan **GUPTA**

Purpose: The following case report highlights the difficulties in a cataract surgery in a child with trichothiodystrophy.

Methods: A 7-year-old child, a known case of trichothiodystrophy, was accompanied by parents for the diminution of vision in both eyes. The child was diagnosed with bilateral developmental cataract and taken up for surgery. The child was approached by a multi-disciplinary team involving a dermatologist, pediatrician, and ophthalmologist for systemic stabilisation before surgery.

Results: Child had good visual gain post cataract surgery and was kept on close follow up to prevent any infections.

Conclusions: Children with trichothiodystrophy rarely survive beyond the neonatal period. The ophthalmic complications for such children do not end in the neonatal period but are also carried into school-going age groups. Regular follow-ups and appropriate treatment can help them to live a better life.

Abstract No.: 201440
Panel No.: CAT-0109

Comparative Evaluation of 6 Toric Intraocular Lens Formulas Using Predicted and Measured Posterior Corneal Astigmatism

First Author: Jooye **PARK**

Co-Author(s): So-hyang **CHUNG**, Youngseo **JEON**, Ga-gyeong **KIM**, Soonwon **YANG**

Purpose: This study aimed to evaluate and compare the accuracy, trueness, and precision of six toric intraocular lens (IOL) calculation methods that utilize either predicted or measured posterior corneal astigmatism (PCA), using vector analysis of refractive astigmatism prediction error (RA-PE).

Methods: A total of 146 eyes implanted with enhanced monofocal toric IOLs were retrospectively analyzed. The six formulas compared included Barrett and EVO toric calculators using predicted PCA (PPCA), measured PCA obtained from IOLMaster (MPCA IOLM), and measured PCA from Pentacam (MPCA Pentacam). RA-PE was evaluated using the Eyetemis platform, which applies robust t-tests and Hotelling T^2 tests to assess absolute RA-PE (accuracy), centroid error (trueness), and spread of error (precision).

Results: The centroid error of EVO MPCA IOLM, EVO MPCA Pentacam, and Barrett MPCA IOLM did not show a statistically significant difference from zero ($p = 0.44$, $p = 0.48$, and $p = 0.35$, respectively). The mean absolute RA-PE of EVO PPCA and EVO MPCA Pentacam was significantly lower than that of Barrett MPCA

Pentacam ($p < 0.01$ and $p = 0.04$, respectively). The spread of RA-PE compared to the centroid error was significantly smaller with EVO PPCA than with Barrett MPCA IOLM ($p = 0.02$).

Conclusions: Formulas using predicted PCA showed favorable results in terms of accuracy and precision, while those incorporating measured PCA tended to perform better in trueness.

Comparing Daily Task Performance Using Virtual Reality Following Bilateral Multifocal versus Monovision IOL Implantation

First Author: Ho Yin TANG

Co-Author(s): Yawen GUO, Ka Ngai Alexander LAM, Kai Shun LEUNG

Purpose: To compare visual outcomes and performance using virtual reality (VR) simulations in cataract patients receiving bilateral multifocal versus monofocal intraocular lens (IOL) implantation with monovision.

Methods: Forty-six bilateral cataract patients were randomized to receive either bilateral multifocal IOLs ($n=24$) or bilateral monofocal IOLs with monovision ($n=22$). Preoperatively and three months postoperatively, patients underwent comprehensive clinical assessments and three VR simulations: supermarket shopping, daytime city navigation, and nighttime city navigation. Overall VR performance scores were calculated with age adjustment. Visual outcomes and performance were compared using t-tests and regression analyses.

Results: While the multifocal IOL group demonstrated trends toward better uncorrected near, intermediate, and distance visual acuity compared to the monofocal group, these differences did not reach statistical significance. However, the multifocal group showed significantly superior defocus curves with better visual acuity at $-1.0D$, $-2.0D$, $-3.0D$, and $-4.0D$ ($p \leq 0.005$). Both groups showed improved overall VR performance scores following surgery, with the multifocal group demonstrating greater improvements from baseline.

Conclusions: The multifocal IOL group demonstrated superior defocus curves, indicating better tolerance to refractive error and potentially reduced spectacle dependence. VR simulation offers a novel, objective method for assessing functional visual performance beyond traditional clinical measures, providing valuable insights into real-world visual function following different IOL strategies.

Abstract No.: 200672

Comparison of Anti-Inflammatory Effects of Prednisolone Versus Nepafenac 0.3% After Phacoemulsification and Intraocular Lens Implantation

First Author: Adnan ABDUL MAJEED

Purpose: To compare the anti-inflammatory effects and safety profiles of prednisolone acetate 1% and nepafenac 0.3% in patients undergoing phacoemulsification with intraocular lens implantation (IOL).

Methods: This is a cross-sectional study. The study included patients who underwent uneventful phacoemulsification with IOL implantation. Post-operative outcomes were assessed at a single follow-up conducted at 4 weeks. The primary efficacy endpoint was improvement in best-corrected visual acuity, measured as the reduction in Logarithmic Minimum angle of resolution (logMAR) values from baseline to follow-up. Clinically significant improvement was defined as a reduction of ≥ 0.2 logMAR units. Secondary outcomes included anterior chamber inflammation, graded using Standardization of Uveitis Nomenclature criteria, and incidence of adverse events.

Results: Of the total 324 patients, the mean age was 64.77 ± 9.27 years. Mean logMAR change from baseline to follow-up was 0.28 ± 0.11 units in the Prednisolone group and 0.30 ± 0.11 units in the Nepafenac group, with a statistically significant difference (p -value 0.050). The findings of clinical improvement showed that 121 (48.8%) patients achieved clinical improvement in the Prednisolone group and 127 (51.2%) in the Nepafenac group. The distribution of inflammation grades (0, 1+, 2+, 3+), was similar between the Prednisolone and Nepafenac groups. A total of 76 (23.4%) adverse events were reported, with 40 (52.6%) occurring in the Prednisolone group and 36 (47.4%) in the Nepafenac group.

Conclusions: Both prednisolone acetate and nepafenac are effective and safe in managing post-operative inflammation and improving visual outcomes following phacoemulsification.

Comparison of Visual Outcomes Between Extended Depth-of-Focus and Advanced Monofocal Intraocular Lenses and Exploring the Role of Micromonovision

First Author: Disha CHETANI

Co-Author(s): Amit GUPTA, Chintan MALHOTRA, Sonam YANGZES

Purpose: To make a comparative analysis between Extended Depth of Focus (EDOF) and advanced Mono focal intraocular lenses post cataract surgery.

Methods: In a prospective interventional study, 56 eyes were implanted either with EDOF or advanced Mono-focal IOLs. Uncorrected visual acuity, contrast sensitivity, defocus curve, spectacle dependence and patient satisfaction using a validated questionnaire were assessed at 2 months

Results: EDOF IOLs showed significantly better uncorrected distance, intermediate and near vision with higher spectacle independence (88% vs 65%). The defocus curve of EDOF IOLs demonstrated a significantly broader range of functional vision. They comparatively had higher contrast sensitivity at low-to-medium frequencies but lower at higher ones. EDOF showed higher internal spherical aberrations. Patient satisfaction was significantly better in EDOF group

Conclusions: EDOF IOLs provide a broader range of functional vision and reduce spectacle dependence. EDOF IOLs offer better intermediate and near vision and thus greater spectacle independence, without compromising distance vision. Advanced mono focal IOLs provide superior contrast at high frequencies. IOL choice should be individualized based on lifestyle and visual needs.

Panel No.: CAT-0106

Comparison of the Efficacy of Symmetric pFSAK in Cataract Patients With Different Magnitudes of Corneal Astigmatism

First Author: Zunxia HU

Co-Author(s): Li LI, Jing SIMA

Purpose: To compare the efficacy of symmetric pFSAK in cataract patients with preoperative corneal astigmatism ≥ 1.5 diopters (D) versus < 1.5 D.

Methods: Arcuate incisions were made with an 8-mm diameter and 85% depth using the DONO algorithm. The correction index (CI) was calculated using the Alpins method. Patients were stratified into Group A (< 1.5 D, 90 eyes) and Group B (≥ 1.5 D, 74 eyes), with outcomes evaluated at 6 months postoperatively.

Results: The TIA and SIA in Group A (1.07 ± 0.19 , 0.66 ± 0.37) were both lower than those in Group B (1.84 ± 0.44 , 1.15 ± 0.68), with statistically significant

differences (both $P = 0.000$). The correction index (CI) for Group A and Group B was 0.62 ± 0.33 and 0.63 ± 0.32 , respectively, showing no statistically significant difference between the two groups ($P = 0.974$). The DV in Group B (0.95 ± 0.60) was greater than that in Group A (0.71 ± 0.36), with a statistically significant difference ($P = 0.028$). The regression equation between SIA and TIA was calculated as: $SIA = 0.59 \times TIA + 0.03$. This formula can be used to preliminarily estimate the SIA and residual astigmatism for each patient based on preoperative TIA.

Conclusions: Symmetric pFSAK achieves comparable correction efficacy across varying degrees of corneal astigmatism. To maintain postoperative residual astigmatism < 0.75 D, the TIA should be kept below 1.9 D.

Corneal Parameter Variations After One-Handed Phacoemulsification

First Author: Irum RAZA

Purpose: To assess the corneal parameters variations after one-handed phacoemulsification.

Methods: One hundred cases of age-related cataract were selected for surgery after approval of the study from the institutional ethical review board. Inclusion criteria were cataracts with normal corneal parameters and no prior intraocular surgery. While the exclusion criteria was mature/ hypermature cataracts, more than the grade 3 NS (Nuclear Sclerosis) and only eyed patients. Pre-op study related SOAP (Specific Ocular Assessment Parameters) included VA (Visual Acuity), astigmatism, CCT (Central Corneal Thickness) and endothelial cell count besides routine examination. A single limbal incision without any side port was created at 12 o' clock. All the surgical steps, including hydrodissection, phacoemulsification with high vacuum and adequate power, and intraocular lens implantation, were done through this single port. SOAP was repeated on the 1st postoperative day, 1st postoperative week, 1st and 3rd postoperative months, and compared to calculate results.

Results: Out of 100, 45 were cortical cataracts, 32 were NS grade 2, and the remaining were of NS grade 3. VA was 6/6 to 6/9 in 83% cases and 6/12 to 6/18 in the rest of the cases. Astigmatism turned out to be < -1.00 diopter in 72% cases and > -1.00 diopter in the rest of the patients. Increased CCT was noted in 11 corneas on the first postoperative day, which regressed with time, and remained increased in only 4 corneas on the last visit, which was non-significant (p -value=0.06). Percentile decrease for endothelial cell count (19%) was also non-significant (p -value=0.5).

Conclusions: One-handed phacoemulsification induces minimal trauma to the cornea and little astigmatism, leading to excellent visual outcomes.

Correlation Between Catalase Level and DNA Damage in Lens Extract Epithelial Cells of Senile Cataract Patients

First Author: Harshal SAHARE

Purpose: Cataracts, a leading cause of blindness worldwide, are primarily associated with oxidative stress-induced damage to the lens, with catalase playing a pivotal role in defending against oxidative damage by decomposing hydrogen peroxide (H_2O_2). This study investigates the correlation between catalase activity and DNA damage in lens epithelial cells (LECs) derived from cataract patients, aiming to understand the contribution of oxidative stress to cataractogenesis.

Methods: Fifty individuals diagnosed with senile cataracts (ages 45–60) were included in the study. Lens epithelial cells were isolated from the anterior lens capsule during cataract surgery. Catalase activity was measured using Beer's method, and DNA damage was assessed via the Comet assay, which quantifies DNA fragmentation at the single-cell level. Correlation analysis was performed using Pearson's coefficient.

Results: A weak negative correlation was observed between catalase activity and DNA damage ($r = -0.298$, $p = 0.03754$), with a small explanatory power ($r^2 = 0.08882$), indicating that only about 9% of the variance in catalase activity could be attributed to DNA damage. Although the correlation was statistically significant, the effect size was small, suggesting that other factors contribute to catalase activity and oxidative DNA damage in cataract development. Additionally, the data showed a slight inverse trend between age and Tail (% DNA), with a weak negative correlation ($r = -0.18$) that was not statistically significant ($p = 0.209$).

Conclusions: A weak association between reduced catalase activity and increased oxidative DNA damage lens epithelial cells of cataract patients. However, the modest correlation and low explanatory power highlight the complexity of cataractogenesis.

Customized Toric Intraocular Lens for Correcting Corneal Astigmatism: A Case Series

First Author: Nikita DAS

Co-Author(s): Shilpa TARINI

Purpose: To evaluate the refractive and visual outcomes of customized Smart Toric intraocular lenses (IOLs) in eyes with corneal astigmatism.

Methods: This retrospective case series included 10 eyes of 8 patients who underwent phacoemulsification with implantation of customized Smart Toric IOLs (ultima smart toric hydrophilic IOL- Care group). Indications were high myopia s/p ICL explantation (5 eyes), high myopia without ICL (2 eyes), pellucid marginal corneal degeneration (PMCD, 2 eyes), and post-DALK (1 eye). Preoperative assessment included refraction, keratometry, and biometry. Postoperative outcomes included uncorrected (UCVA) and best-corrected visual acuity (BCVA), spherical equivalent, manifest cylinder, and patient-reported symptoms. Statistical analysis was performed using Jamovi software.

Results: Median preoperative UCVA was 1.25 logMAR (20/360), improving to 0.20 logMAR (20/32) postoperatively ($p < 0.001$). Median BCVA improved from 0.32 logMAR (20/42) to 0.00 logMAR (20/20) ($p = 0.006$). Median SE improved from -4.50 D (IQR -7.25 to -3.25) to $+0.06$ D (IQR 0.00 to $+0.25$) ($p = 0.009$). Median refractive cylinder reduced from -2.17 D (IQR -2.48 to -1.92) to -0.95 D (IQR -1.08 to -0.76) ($p < 0.001$). Visual outcomes were favorable across all subgroups, including PMD and post-DALK eyes. Complications included posterior capsular opacification (20%) and glare (20%).

Conclusions: Customized toric IOLs are effective for correcting corneal astigmatism across diverse indications, including ectasia and post-keratoplasty. They enable precise refractive correction in eyes with low spherical and high cylindrical requirements, overcoming limitations of conventional IOL ranges.

Dual Challenge: Phacoemulsification in the Presence of a Traumatic Iris Cyst

First Author: Prika Maulina AGARISTI

Co-Author(s): Syska WIDYAWATI, Cecillia Apriliana WULANDARI

Purpose: Iris cysts are rare ocular anomalies characterized by fluid-filled lesions within the iris, often posing diagnostic and therapeutic challenges. Accurate differentiation is crucial to exclude malignant intraocular tumors. There are various approaches in managing iris cysts, and performing phacoemulsification can be particularly complex. This article presents a case of managing a challenging, complicated cataract extraction in the presence of an iris cyst.

Methods: A 44-year-old male presented with progressive blurred vision in the right eye for one year, with a remote trauma history. Initially, the visual acuity of the right eye was 0.5/60, with an iris cyst at the inferotemporal, anterior synechiae, a flat anterior chamber (AC), and a hazy lens. While minimally invasive techniques are golden rules in iris cyst

management, surgery was unavoidable due to visual axis obstruction and a flat AC, which could potentially compromise corneal endothelial integrity. Iris cyst aspiration, anterior chamber reformation, along with phacoemulsification and intraocular lens implantation, were performed uneventfully. A small pupil was another intraoperative challenge, which was managed successfully with an iris retractor.

Results: Postoperatively, the patient showed remarkable recovery, achieving 6/6 visual acuity at one week. The anterior chamber was deep and well-formed, and corneal edema resolved completely. Despite a small recurrent inferotemporal iris cyst, the visual acuity remained stable, and the cornea remained clear. Corneal endothelial cell density was later measured at 811 cells/mm², indicating sufficient endothelial function.

Conclusions: A tailored approach to iris cysts with coexisting cataracts is essential. Preoperative and intraoperative planning are crucial to overcome potential complications and ensure optimal visual outcomes.

Effect of Steep-Axis Clear Corneal Incision on Postoperative Residual Astigmatism in Cataract Surgery

First Author: Yingshi ZOU

Co-Author(s): Yali GAO, Yingyue XIONG, Ming-ming YANG, Jianan XU

Purpose: To examine the relationship between surgically induced astigmatism (SIA) and corneal astigmatic axis, establish a predictive model for residual astigmatism, and evaluate the effect of steep-axis clear corneal incisions on postoperative residual astigmatism.

Methods: This observational study included 170 subjects (305 eyes). Measurements were taken using the IOLMaster 700, and the Barrett Universal II formula was applied to simulate postoperative residual astigmatism under varying SIA values following steep-axis clear corneal incisions. Patterns of astigmatism and axis changes were analyzed to develop the predictive model.

Results: The mean age of the cohort was 67.47 ± 10.88 years (range: 31–94), with 104 eyes from males and 201 from females. With-the-rule (WTR) astigmatism showed a non-linear relationship between postoperative residual astigmatism and SIA, while against-the-rule (ATR) and oblique (OBL) astigmatism exhibited linear relationships. For a fixed SIA, WTR allowed the largest correction threshold, followed by OBL, and then ATR.

Conclusions: Based on the derived model, surgeons can assess—according to their typical SIA and the

patient's preoperative astigmatism magnitude and axis—whether to perform a steep-axis clear corneal incision or implant a toric IOL, thus optimizing surgical outcomes.

Panel No.: CAT-0165

Efficacy and Safety Analysis of LenSX and Catalys Femtosecond Laser Systems in Short Axial Length Patients

First Author: Bin LIN

Co-Author(s): Dongkan LI

Purpose: This study compared cumulative dissipated energy (CDE), effective phacoemulsification time (EPT), fluid perfusion volume, corneal endothelial quantity changes, and capsular shrinkage incidence in short-axial cataract patients with LenSX and Catalys femtosecond laser systems.

Methods: A single-center, prospective, randomized controlled trial included 100 eyes of short axial length patients. They were randomly grouped for different femtosecond laser pretreatment before cataract phacoemulsification and IOL implantation. Data like age, LOCS III grade, and corneal endothelial counts were collected. Capsule tissue was stained, and its cell-free area was calculated to analyze capsular shrinkage.

Results: The two groups had similar preoperative features. Except for femtosecond laser time, there were no statistically significant differences in CDE, EPT, fluid perfusion, and corneal endothelial counts. Complications showed no significant difference either. LenSX had more capsule edge problems, while Catalys might affect surgeons. Pupil miosis and capsular shrinkage incidences were similar.

Conclusions: Catalys is better for soft cataracts or uncooperative patients with short axial lengths. LenSX is more suitable for cloudy and hard cataracts. Selecting the right system based on cataracts and patient conditions can improve surgical outcomes.

Enhancing Vision in Cataract With Congenital Aniridia: A Case Report of Yamane Technique for Scleral Fixation

First Author: Saraya AMAJIDA

Co-Author(s): Budiman, Andrew Maximilian KNOCH, Emmy Dwi SUGIARTI, Ludwig TJOKROVONCO

Purpose: To report the outcomes of sutureless scleral-fixated IOL implantation using the Yamane technique in a patient with bilateral congenital aniridia and cataracts.

Methods: A 30-year-old male fisherman presented with progressive bilateral blurred vision. Clinical evaluation revealed congenital aniridia with subluxated

cataracts in both eyes. Ultrasound confirmed posterior vitreous detachment and vitreous opacities. He underwent cataract extraction, anterior vitrectomy, and scleral-fixated IOL implantation in both eyes using the sutureless Yamane technique.

Results: Postoperatively, visual acuity improved from close-face finger counting to 0.16 in the right eye and 0.2 in the left eye. At the 7-day follow-up, both eyes demonstrated stable IOL centration, clear corneas, and well-controlled intraocular pressure without complications.

Conclusions: The Yamane technique provides a safe and effective method for visual rehabilitation in congenital aniridia with cataracts and absent capsular support. Proper surgical technique and postoperative management are crucial to minimize complications and optimize visual outcomes.

Panel No.: CAT-0155

Evaluation of Kane, Barrett, EVO, and DGS Formulas for Refractive Outcomes in Trifocal IOL Implantation

First Author: Yingjie LIN

Co-Author(s): Xianjun LIANG

Purpose: To evaluate the predictive accuracy of four intraocular lens (IOL) power calculation formulas—Kane, Barrett Universal II (Barrett), Emmetropia Verifying Optical (EVO), and Double-Gaussian Spline (DGS)—in cataract patients implanted with trifocal IOLs (PanOptix, Alcon).

Methods: Prediction errors for each formula were analyzed and compared. Key outcome measures included median arithmetic error (ME), mean absolute error (MAE), and the percentage of predictions within tolerance ranges of ± 0.25 D, ± 0.50 D, ± 0.75 D, and ± 1.00 D. Statistical analysis was conducted to assess differences in formula performance.

Results: The EVO formula yielded the lowest ME (-0.37 D) and MAE (0.48 D), with the highest percentages of predictions within ± 0.25 D (30%) and ± 0.75 D (78%). The Barrett formula showed the largest ME (-0.50 D) and MAE (0.60 D), with the lowest percentages within ± 0.25 D (24%) and ± 0.75 D (68%). The Kane and DGS formulas demonstrated intermediate performance, with Kane outperforming DGS in predictions within ± 0.50 D (56% vs. 52%).

Conclusions: The EVO formula exhibited superior accuracy compared to the Kane, DGS, and Barrett formulas for trifocal IOL power calculations. These results suggest that EVO may offer the most reliable option for achieving precise refractive outcomes in patients receiving trifocal IOLs, potentially enhancing postoperative visual performance in clinical practice.

Panel No.: CAT-0132

Factors Influencing the Ocular Surface Microbiota During the Perioperative Period of Phacoemulsification

First Author: Xiaochen ZHANG

Co-Author(s): Zhaohui LI, Zi YE

Purpose: To evaluate the dynamics of conjunctival sac and eyelid margin flora in cataract patients across key perioperative stages, including the impact of preoperative levofloxacin application, disinfection, and intraoperative eyelid speculum exposure.

Methods: This prospective, single-center study was conducted by extracting DNA from perioperative swab samples and sequencing the V3-V4 region of the 16S rRNA gene to assess the impact of various factors on the conjunctival sac and eyelid margin microbiome in phacoemulsification patients. Statistical analysis was done by SPSS Statistics Version 27.

Results: A total of 48 patients undergoing phacoemulsification were enrolled. Conjunctival sac swabs were collected at admission and after levofloxacin application, while eyelid margin swabs were obtained at admission, post-disinfection, and post-surgery. *Acinetobacter* was the most frequently isolated microorganism (32.50% of isolates), followed by *Corynebacterium* (19.26%), *Agrobacterium* (5.34%), and *Sphingomonas* (5.21%). After using of levofloxacin, the conjunctival microbial distribution shifted: *Acinetobacter* decreased to 30.36%, *Corynebacterium* to 12.37%, and *Agrobacterium* to 1.20%, while *Sphingomonas* increased to 7.95% and norank-f-*Neisseriaceae* increased from 2.48% to 6.73%. In the baseline eyelid margin flora, *Corynebacterium* (30.06%) was the most abundant genus. Following a series of procedures including ocular irrigation and disinfection, the abundance of *Corynebacterium* decreased to 2.64%. In contrast, the proportion of norank-f-*Neisseriaceae* showed little change before and after disinfection; however, it increased significantly to 11.83% post-surgery.

Conclusions: Despite limited susceptibility of the ocular surface microbiota to ofloxacin, levofloxacin application led to compositional changes in the conjunctival sac. Moreover, the pressure from the eyelid speculum partially counteracted the effect of disinfection on the eyelid margin flora.

First Case of Intravitreal Bevacizumab Injection for Persistent Serous Retinal Detachment Associated With Vogt-Koyanagi-Harada Disease in Timor-Leste

First Author: Frenky Ramiro DE JESUS

Purpose: To introduce the first case of Vogt-Koyanagi-Harada (VKH) disease associated with Serous retinal detachment (SRD) in Timor-Leste, which resolved with intravitreal injection of bevacizumab.

Methods: Interventional case report to show the effect of bevacizumab for the serous retinal detachment in VKH patient.

Results: A 43-year-old woman from a rural area with a sudden loss of vision for 2 weeks. The best-corrected visual acuity (BCVA) in both eyes was FC 1 m. The patient was diagnosed with VKH disease. OCT was performed, and SRD was confirmed. On OCT, the height of SRD in the right eye was 1029 μ m and 1084 μ m in the left eye. Even after 5 weeks of steroid treatment, the SRD was not totally resolved. At the time, the height of SRD in the right was 254 μ m and 203 μ m on the left. The BCVA was 6/15 on the right and 6/12 on the left. Despite a long-term dose course of systemic steroid therapy, an intravitreal injection of 3mg/0.12ml of bevacizumab was administered for the right eye, following informed consent. 2 weeks later, reabsorption of SRD was observed during the OCT examination. The retinal thickness was 191 μ m on the right and 199 μ m on the left. The BCVA was improved to 6/6 on the right and 6/9 on the left.

Conclusions: An intravitreal injection of bevacizumab combined with systemic steroids in VKH is expected to solve the persistent presence of SRD and to prevent permanent visual impairment.

Abstract No.: 202958

Panel No.: CAT-0119

From Relative Afferent Pupillary Defect Positive to Orbital Apex Tumor

First Author: Lingxi ZHANG

Co-Author(s): Zeyi LI, Cangeng XU

Purpose: This study presents an investigation into the etiology of unimproved visual acuity following cataract phacoemulsification with intraocular lens implantation surgery in a single case.

Methods: A 66-year-old woman underwent uncomplicated right-eye phacoemulsification with IOL implantation. However, preoperative BCVA of 0.3 (OD) persisted two weeks postoperatively. Subsequent examination revealed a RAPD, an inferior arcuate visual field defect, prolonged VEP latency, and reduced P100 amplitude. Consequently, MRI was performed and demonstrated a well-defined 16x10mm

extraconal orbital apex mass, which was isointense on T1, hyperintense on T2, and showed homogeneous enhancement.

Results: Based on these findings, the patient was diagnosed with a right orbital apex mass causing compressive optic neuropathy. She therefore underwent endoscopic endonasal tumor excision and optic nerve decompression using navigation. Subsequent pathology confirmed cavernous hemangioma. Postoperatively, intravenous methylprednisolone (500mg/day for 3 days) was administered. As a result, the RAPD was no longer detectable. At the 3-week follow-up, BCVA had improved to 0.7, the visual field defect had completely resolved, and VEP parameters had normalized.

Conclusions: Despite uncomplicated surgery, some patients exhibit no visual improvement even in the absence of fundus abnormalities, often leading to overlooked underlying causes. This case highlights one such patient in whom a postoperative RAPD crucially led to the diagnosis of an orbital apex tumor. Thus, we emphasize the importance of including RAPD testing in preoperative assessments, particularly for cases with unexplained vision loss. Ultimately, prompt tumor excision and nerve decompression achieved significant visual recovery.

Abstract No.: 204135

Gradual Hydrodissection Technique to Enhance Safety of Phacoemulsification in Posterior Polar Cataract

First Author: Fajri IJRIAN

Co-Author(s): Cindy Prajna METTA, Gede PARDIANTO, Diyah PURWORINI

Purpose: To evaluate the safety of gradual hydrodissection during phacoemulsification in patients with posterior polar cataract.

Methods: This quasi-experimental pre-post study included 50 eyes of 50 patients with posterior polar cataract who underwent phacoemulsification. All procedures were performed by a single experienced surgeon using the phaco chop technique combined with gradual hydrodissection. This technique involved injecting small amount, sequential aliquots of balanced salt solution through the capsulorhexis to gently separate corticocapsular adhesions. Preoperative and 1-month postoperative data were collected, including best-corrected visual acuity (BCVA) and intraocular pressure (IOP). Intraoperative complications, posterior capsule rupture, vitreous prolapse, and nucleus drop, were meticulously documented. Data were analyzed using paired Student's t-test, with $P < 0.05$ considered statistically significant.

Results: The mean age of participants was 64.8 ± 16.5 years, 16 (32%) male and 34 (68%) female.

Postoperative BCVA improved significantly from a mean of 0.21 ± 0.13 to 0.93 ± 0.14 ($P < 0.001$). Similarly, mean IOP decreased significantly from 17.9 ± 2.7 mmHg to 13.2 ± 2.2 mmHg ($P < 0.001$). Notably, no cases of posterior capsule rupture, vitreous prolapse, or nucleus drop occurred during surgery. All procedures were completed successfully without complications.

Conclusions: Gradual hydrodissection may appear to be a safe technique during phacoemulsification for posterior polar cataract.

Grx Resists Diabetes Cataract by Activating AMPK/BNIP3/BNIP3L-Mediated Mitophagy in Lens Epithelial Cells

First Author: Jessica

Co-Author(s): Chenjun, Mia

Purpose: Glutaredoxin (Grx) plays an important antioxidant role in cataract pathogenesis. While its knockout accelerates age-related cataract, its regulatory mechanism in diabetic cataract (DC) remains unclear.

Methods: AMPK activity and Grx expression were assessed in lens capsules from DC patients and high-glucose (HG)-treated HLEC-B3 cells. We overexpressed Grx to examine its effects on HG-induced oxidative stress, apoptosis, and mitophagy. Mechanisms were probed using AMPK-siRNA, compound C (an AMPK inhibitor), and BNIP3L-siRNA.

Results: AMPK activity was decreased in DC and HG-HLEC-B3 models, with compensatory upregulation of Grx. Grx overexpression protected against HG-induced damage and induced mitophagy via the BNIP3/BNIP3L pathway. Inhibition of AMPK or knockdown of BNIP3L reversed the protective effects of Grx on mitophagy, oxidative stress, and apoptosis. In vivo experiments confirmed that Grx overexpression alleviated DC.

Conclusions: Our findings demonstrate that Grx protects against DC by activating AMPK/BNIP3/BNIP3L-mediated mitophagy, highlighting its potential as a novel therapeutic target.

High Glucose Induces Lens Epithelial Cells Senescence via H3K18la-CDK5RAP3 Axis in Diabetic Cataract

First Author: Lifang BAI

Co-Author(s): Jin YANG

Purpose: This study aims to elucidate the role and underlying molecular mechanisms between histone lactylation and senescence of lens epithelial cells (LECs) under high-glucose(HG) environment, providing a new target for the diagnosis and treatment of diabetic cataract (DC).

Methods: The senescence model was established by culturing human LECs under HG conditions. Transcriptomics and metabolomics analysis identified key mediators. The functional role of Cyclin-dependent kinase 5 regulatory subunit-associated protein 3 (CDK5RAP3) was investigated using siRNA knockdown and overexpression plasmids. Senescence was evaluated by SA- β -gal staining, cell cycle analysis, and p16/p21 expression. Oxidative stress, epithelial-mesenchymal transition (EMT) markers, and histone lactylation were analyzed via RT-qPCR, western blot, or immunofluorescence. Clinical validation used lens capsules and aqueous humor from patients with transparent lens, age-related cataracts (ARC), and DC.

Results: HG treatment induced cell cycle arrest, LECs senescence and oxidative stress. Multi-omics profiling revealed CDK5RAP3 upregulation and significant lactate accumulation under HG. CDK5RAP3 knockdown alleviated HG-induced senescence, ROS production, and EMT, while its overexpression exacerbated these effects. Mechanistically, HG-enhanced lactate accumulation promoted histone lactylation, predominantly at the H3K18 site. Crucially, clinical samples from DC patients confirmed elevated lactate levels, increased H3K18 lactylation, and higher expression of CDK5RAP3 and senescence markers compared to ARC.

Conclusions: This study uncovers a novel pathogenic axis for DC: HG-induced lactate accumulation drives H3K18 lactylation, which upregulates CDK5RAP3 expression, culminating in LECs senescence, which promotes EMT to accelerate the progression of DC. This H3K18la-CDK5RAP3 pathway links metabolic imbalance to epigenetic regulation and cellular senescence, identifying this axis as a potential therapeutic target for DC.

Impact of Phaco Tip Exposure on Corneal Endothelium and Central Corneal Thickness in Hard Cataract

First Author: Shreya SARAOGI

Co-Author(s): Tejal SJ, Naren SHETTY, Abhijit SINHA ROY

Purpose: To evaluate role of phacoemulsification probe tip exposure on corneal endothelial cell loss and central corneal thickness (CCT) in hard cataracts, comparing between more & less tip exposure.

Methods: A prospective study was conducted on 57 eyes in each group undergoing phacoemulsification for hard cataracts using a more tip exposure or a less tip exposure on the phaco probe. Tip exposure was measured from the phaco tip to the silicone sleeve, with less tip exposure set at 0.5 mm, and more tip exposure at 1.25 mm. Corneal endothelial cell density (ECD) and CCT were measured preoperatively,

on postoperative days 1 (POD1) and 30 (POD 30). Intraoperative cumulative dissipated energy (CDE) was also recorded. Median [IQR] values were calculated, and intergroup comparisons were performed.

Results: The less tip exposure group had lower CDE (9.31 [7.43 to 14.65]) than the more tip exposure group (12.00 [8.67 to 17.72]); this difference was statistically significant ($p = 0.05$). Cell count and CCT were lowest before surgery, peaked on day 1, improved by day 15 & day 30 in less tip exposure group. Compared to more tip exposure group, the short tip group showed better recovery with lower endothelial cell counts loss (2571 to 2277 cells/mm² vs. 2482 to 2233 cells/mm²) and less corneal oedema, demonstrated by a smaller increase in CCT (535 to 527 μ m vs. 517 to 528 μ m) at day 15, day 30. These differences were statistically significant, and the less tip-exposed group stabilised faster by postoperative day 15.

Conclusions: The less-tip exposure group showed reduced endothelial cell loss & less central corneal thickness post-cataract surgery.

Panel No.: CAT-0122

Initial Clinical Outcomes of a Partial Range of Field Monofocal Intraocular Lens Following Cataract Surgery

First Author: Yau KIN

Purpose: The purpose of this study is to assess the preliminary visual outcomes at different distances, and to assess the functional benefits of an enhanced monofocal intraocular lens (IOL) in patients who underwent cataract surgery.

Methods: Retrospective single-surgeon case series of an enhanced monofocal (Aspire, EA, Bausch & Lomb) IOL in patients following cataract surgery. Patients with previous ocular surgery were excluded. All procedures were conducted by a single surgeon and in the same clinic. The clinical outcomes collected were corrected and uncorrected visual acuity at distance (CDVA and UDVA) and intermediate (DCIVA and UIVA), manifest refraction spherical equivalent (MRSE), and safety outcomes at up to 1 month follow-up.

Results: 9 eyes implanted with EA IOLs following cataract surgery were included. Mean $\pm$ SD SEQ target was -0.58 ± 0.60 D. Mean monocular CDVA was 0.08 ± 0.06 logMAR, with 78% of eyes achieving 0.1 logMAR or better. Mean monocular UIVA was 0.25 ± 0.11 logMAR. Mean postoperative MRSE was -0.42 ± 0.74 D. No serious adverse events were reported, and no photic phenomena were noted.

Conclusions: In the cases provided with this enhanced IOL, most patients achieved good visual acuity at distance with functional intermediate visual acuity and no AEs were reported.

Investigation Into the Influence of Secondary Suction Within FLACS on the Postoperative Ocular Surface and Associated Mechanisms

First Author: Bin LIN

Co-Author(s): Dongkan LI

Purpose: To explore secondary suction's impact on postoperative ocular surface, tear factors, and dry eye risk factors in femtosecond laser-assisted cataract surgery (FLACS).

Methods: Age-related cataract patients undergoing FLACS (Dec 2023–May 2024) were included (inclusion: FLACS consent, no prior eye surgery/trauma, pupil dilation >7 mm; exclusion: ≥ 3 suction attempts, lens dislocation, pregnancy, psychiatric issues, poor compliance). Preoperative parameters (corneal diameter, corneal K value) and intraoperative eye movement were recorded. Ocular Surface Disease Index (OSDI), Tear Meniscus Height (TMH), and tear cytokines were assessed preoperatively and at 1 day, 1 week, and 1 month post-surgery.

Results: 41 patients (21 secondary suction, 20 conventional) were analyzed. The secondary suction group had higher 1-week OSDI (6.43 ± 7.96 vs 1.90 ± 5.85 ; $P=0.045$), higher 1-week TMH (0.04 ± 0.09 vs 0.01 ± 0.07 mm; $P=0.020$) and 1-month TMH (0.07 ± 0.17 vs 0.03 ± 0.07 mm; $P=0.023$), and greater tear Interleukin-6 (IL-6) log increases at 1 day (0.44 ± 0.68 vs -0.04 ± 0.78 ; $P=0.042$) and 1 week (0.01 ± 0.64 vs -0.49 ± 0.89 ; $P=0.045$). Risk factors: smaller corneal diameter ($P=0.025$) and obvious eye movement ($P<0.001$).

Conclusions: Secondary suction in FLACS may worsen early-stage postoperative dry eye, but it recovers in 1 month. Key risk factors for secondary suction include smaller corneal diameter and significant ocular movement, which inform targeted prevention strategies to reduce secondary suction incidence.

Panel No.: CAT-0125

Inward Haptic Collapse: A Rare and Severe Manifestation of Capsular Contraction Syndrome

First Author: Vinit TANWAR

Purpose: To report a case of unusually rapid and aggressive capsular contraction syndrome (CCS) leading to severe inward deformation of intraocular lens (IOL) haptics in a patient with a history of healed choroiditis, and to highlight the successful management with Nd:YAG laser.

Methods: A case report. A patient with healed choroiditis and a posterior subcapsular cataract underwent uneventful phacoemulsification with an adequate capsulorhexis and in-the-bag IOL

implantation. The patient received a standard postoperative regimen along with oral steroids for one week. The postoperative course was documented with serial slit-lamp photography. Management of the complication involved Nd:YAG laser.

Results: One month after surgery, the patient presented with decreased vision. Examination revealed severe anterior capsular phimosis and posterior capsular opacification. The constrictive force of the fibrotic capsule caused a dramatic inward «crumbling» and deformation of the IOL haptics. An Nd:YAG laser was used to perform both an anterior and posterior capsulotomy. This intervention successfully opened the visual axis and released the compressive forces, resulting in immediate visual improvement.

Conclusions: Eyes with a history of Uveitis are at high risk for an exaggerated postoperative fibrotic response. This can manifest as a rapid and severe CCS capable of physically deforming IOL haptics. This case underscores that standard anti-inflammatory prophylaxis may be insufficient in high-risk patients and demonstrates that timely YAG laser capsulotomy is an effective management strategy.

Loneliness and Social Isolation Are Associated With Increased Risk of Cataract: Evidence From the UK Biobank and Metabolomic Profiling

First Author: Xintian ZHU

Co-Author(s): Li Jia CHEN, Jason C. YAM, Yuzhou ZHANG

Purpose: To examine the associations between loneliness and social isolation with incident cataract risk, and to investigate the potential role of plasma metabolites as underlying biomarkers.

Methods: We included 172,971 participants from the UK Biobank without cataract at baseline. Loneliness and social isolation were assessed using questionnaire data. Incident cataract was identified via hospital records. Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for cataract incidence, adjusting for demographic, socioeconomic, lifestyle, and clinical covariates. LASSO logistic regression was applied to identify plasma metabolites associated with loneliness and isolation. Cox models were used to assess associations between these metabolite signatures and cataract risk. Restricted cubic spline (RCS) models were used to visualize dose-response relationships.

Results: Loneliness (HR: 1.10, 95% CI: 1.06–1.14), isolation (HR: 1.08, 95% CI: 1.04–1.12), and both (HR: 1.17, 95% CI: 1.11–1.22) were significantly associated with higher cataract incidence. LASSO identified 21 metabolites associated with isolation and 5 with loneliness. The metabolite signature for isolation was

independently associated with cataract (HR per SD increase: 1.57, 95% CI: 1.44–1.71). For loneliness, HR per SD increase was 1.60 (95% CI: 1.40–1.83).

Conclusions: Loneliness and social isolation are significant risk factors for incident cataract. Metabolomic profiling reveals biological signatures that may link psychosocial adversity to ocular aging. These findings underscore the importance of social determinants in ophthalmic disease and suggest potential roles for metabolite-based risk stratification.

Long-Term Outcomes of Primary Piggyback IOL Implantation in Nanophthalmic Eyes: A Retrospective Study

First Author: Vijayavarshcini DHANASEKARAN

Co-Author(s): Jebinth BRAYAN, Narayan RAJPAL

Purpose: To evaluate the outcomes of primary piggyback intraocular lens (IOL) implantation in nanophthalmic eyes.

Methods: A retrospective analysis of 18 eyes with nanophthalmos that underwent piggyback IOL implantation between 2019 and 2023 was conducted. All cases underwent phacoemulsification with in-the-bag placement of a single-piece IOL and sulcus placement of a three-piece IOL.

Results: The mean axial length was 17.85 ± 2.17 mm, and the mean follow-up duration was 8.3 months. At final follow-up, the mean best-corrected visual acuity (BCVA) was 0.3 logMAR, with 73% of eyes achieving BCVA better than 6/12. Intraoperative complications included a posterior capsular rent in one eye. Transient postoperative intraocular pressure (IOP) rise was observed in three eyes. No cases of IOL decentration, pigment dispersion, or interlenticular opacification were noted.

Conclusions: Primary piggyback IOL implantation is a safe and effective technique for visual rehabilitation in nanophthalmic eyes, providing good visual outcomes with minimal complications.

Abstract No.: 206082

Long-Term Visual Performance of the Increased Range of Focus RayOne EMV® Premium IOL in Filipino Eyes

First Author: Maria Isabela DE GUIA

Co-Author(s): Victor Jose CAPARAS, Keshia Lourdes DUYONGCO-LENON

Purpose: To evaluate visual outcomes after bilateral implantation of the Increased Range of Focus RayOne EMV® intraocular lens (Rayner, Worthing, UK).

Methods: Sixteen patients (32 eyes) underwent phacoemulsification with bilateral RayOne EMV® implantation, targeting emmetropia. Post-op visits were at 2-8 days (V1), 30-45 days (V2), and 90-105 days (V3). Monocular/binocular and uncorrected/corrected visual acuity (VA) at 4 m, intermediate VA at 80cm and 63 cm, and near VA at 40 cm were measured. Defocus curve, contrast sensitivity (CS), photic phenomena (Halo and Glare Simulator, ViSU-L GmbH), and quality of vision (McAlinden QOV questionnaire) were also assessed.

Results: At V3, mean spherical refraction was -0.10 (std dev ± 0.31) D. Mean binocular uncorrected distance, intermediate (80cm and 63cm) and near VA were -0.11 (± 0.12), 0.40 (± 0.07), 0.36 (± 0.11), and 0.33 (± 0.11) logMAR; while binocular corrected distance, intermediate (80cm and 63cm), and near VA were -0.14 (± 0.07), 0.41 (± 0.09), 0.39 (± 0.13), and 0.35 (± 0.13). Defocus curve showed corrected distance VA ≤ 0.60 logMAR from +2.0D to -4.0D. Mean halo size/intensity were 10/100 and 9/100; glare size/intensity 11/100 and 12/100. Far (1 m) and near (40 cm) binocular CS were 1.57 (± 0.13) and 1.58 (± 0.13) logCS. Mean QOV was 87.8/100. Light and spectacle independence were high.

Conclusions: Implantation with the increased range of focus RayOne EMV provided an excellent postoperative VA for far, and a very good vision for intermediate and near distance. These features, along with outstanding contrast sensitivity and very low level of haloes and glare phenomena yielded a high degree of patient satisfaction after surgery.

Panel No.: CAT-0124

Macular Morphology After Cataract Surgery With and Without Primary Posterior Continuous Curvilinear Capsulorhexis: A Randomized Intraindividual Comparative Clinical Trial

First Author: Wenjie WU

Co-Author(s): Yulong HUANG, Chishan KANG

Purpose: To evaluate changes in macular morphology after cataract surgery with and without primary posterior continuous curvilinear capsulorhexis (PPCCC).

Methods: One hundred and thirty eyes of 65 age-related cataract patients with normal macular morphology and function waiting for bilateral cataract surgery and intraocular lens (IOL) implantation were enrolled. Cataract surgery combined with PPCCC was performed in one eye, and routine cataract surgery in the fellow eye (NPCCC group). Optical coherence tomography (OCT) measurements were performed in all patients preoperatively and postoperatively on 1 day, 1 week, 1 month, and 3 months. Corrected distance visual acuity (CDVA) was also measured at each visit.

Results: One hundred and twenty eyes of 60 patients were able to complete scheduled follow-ups and were analyzed in the study. There was no statistically significant difference between the PPCCC group and NPCCC group in terms of subfoveal central retinal thickness (CRT), central 1-mm subfield (CSF), average retinal thickness of 1-3mm middle and 3-6mm outer rings at all timepoints postoperatively ($P > 0.05$). Three eyes developed cystoid macular edema (CME) 1 month post-surgery. One eye in the PPCCC group recovered in two weeks after topical treatment, while two in the NPCCC group took eight weeks to recover. In the NPCCC group, PVD progressed in two eyes. No PVD progression in the PPCCC group. The CDVA of all patients was logMAR 0.1 or better at 3 months.

Conclusions: Cataract surgery with combined manual PPCCC does not increase the risk of CME and PVD in patients. PPCCC is a safe cataract surgery technique.

Abstract No.: 203131

Panel No.: CAT-0121

Mechanism of a Novel Traditional Chinese Medicine Formula in Treating Senile Cataract Identified by Network Pharmacology and Experimental Validation

First Author: Jing DING

Co-Author(s): Xuemin LI

Purpose: To systematically investigate the active components and mechanism of a novel 8-herb Traditional Chinese Medicine (TCM) formula for senile cataract using network pharmacology and in vitro validation.

Methods: Bioactive components and their targets, as well as senile cataract-related targets, were screened from databases. Common targets were identified using the STRING database to construct a protein-protein interaction (PPI) network. A drug-component-target-disease network was visualized with Cytoscape. Kyoto Encyclopedia of Genes and Genomes (KEGG) and Gene Ontology (GO) pathway enrichment analyses for core targets were performed using Metascape. Molecular docking was used to verify interactions. The formula's effect on human lens epithelial cells (LECs) was assessed with a CCK-8 assay.

Results: Network pharmacology identified 110 bioactive compounds interacting with 1,024 targets, including 178 specific to senile cataract. Pathway analysis indicated a primary role in regulating phosphotransferase activity. Molecular docking confirmed strong binding affinities between the formula's components and key targets, with the lowest binding energy observed between naringenin and protein tyrosine phosphatase (PTP). In vitro, the formula significantly inhibited the proliferation of human LECs.

Conclusions: This study suggests that the novel TCM formula may delay senile cataract progression by modulating phosphotransferase activity. The findings provide a theoretical basis for further development of this formula as a potential cataract treatment.

Outcomes of Combined Vitreoretinal Surgery and Trifocal Intraocular Lens Implantation: A Case Series

First Author: Yuanfei **ZHU**

Co-Author(s): Wenxing **SHI**, Tieying **ZHAO**, Weihong **ZHAO**

Purpose: Multifocal intraocular lenses (IOLs) are typically avoided in eyes with vitreoretinal pathology due to concerns about reduced visual quality. This study aims to evaluate the feasibility and visual outcomes of combining vitreoretinal surgery with implantation of a diffractive trifocal IOL in patients with coexisting cataract.

Methods: This retrospective case series included 5 eyes of 4 patients (age range 34-57 years). Surgical indications included: silicone oil removal with traumatic cataract (1 eye), and epiretinal membrane (ERM) removal (4 eyes). Specific diagnoses were high myopia with macular schisis and lamellar hole (1 eye), secondary ERM after retinal tear and vitreous hemorrhage (1 eye), and idiopathic ERM (2 eyes). All procedures comprised standard vitrectomy (27G for ERM or 23G for silicone oil removal) with femtosecond laser-assisted phacoemulsification and implantation of a trifocal IOL (AT LISA tri 839MP or AcrySof IQ PanOptix) in the capsular bag. Patients were followed for 1 year.

Results: All surgeries were completed successfully without complications. Postoperative visual outcomes were excellent: mean monocular uncorrected distance visual acuity (UDVA) was 0.00 logMAR, mean uncorrected intermediate visual acuity (UIVA) was 0.00 logMAR, and mean uncorrected near visual acuity (UNVA) was 0.04 logMAR. Mean spherical equivalent was -0.38 D. All patients achieved spectacle independence and reported high satisfaction with their visual outcomes.

Conclusions: Combined vitreoretinal surgery and trifocal IOL implantation effectively restores full-range vision and addresses both cataract and macular pathology, ensuring high patient satisfaction and spectacle independence.

Abstract No.: 207357

Outcomes of Primary Retropupillary Fixated Iris Claw IOLs: A Retrospective Analysis Report of 227 Eyes

First Author: Narayan **RAJPAL**

Co-Author(s): Jebinth **BRAYAN**, Vijayavarshcini **DHANASEKARAN**

Purpose: To evaluate the outcomes of primary retropupillary fixated iris claw intraocular lens (IOL) implantation for the management of aphakia in various clinical scenarios.

Methods: A retrospective analysis of 227 eyes that underwent iris claw IOL implantation between 2016 and 2023 at a tertiary eye care center was conducted. Data collected included demographics, visual outcomes, and postoperative complications.

Results: The study included 124 males and 103 females with a mean age of 60.2 years (range: 45-93 years). The mean follow-up duration was 9.2 months (range: 7-60 months). The mean postoperative best-corrected visual acuity (BCVA) at the final follow-up was 0.52 LogMAR, with 75% of eyes achieving BCVA better than 6/12. The most common complication was cystoid macular edema (CME), occurring in 15% (34 eyes), followed by raised intraocular pressure in 11% (25 eyes). Re-enclavation for disencavation was required in 4% (9 eyes).

Conclusions: Retropupillary fixated iris claw IOL implantation is an effective and safe option for visual rehabilitation in aphakic patients, offering favorable visual outcomes and a manageable complication profile.

Panel No.: CAT-0133

Protective Effect of Metformin on Accommodation Amplitude in Type 2 Diabetes

First Author: Ruofan **LI**

Co-Author(s): Xuemin **LI**, Ziyuan **LIU**

Purpose: To determine whether metformin use is associated with better accommodative amplitude (AMP) in patients with type 2 diabetes mellitus (T2DM).

Methods: This cross-sectional study recruited patients with T2DM and age-matched controls (1:1) from Peking University Third Hospital. The T2DM patients were divided into two groups by metformin use. Binocular AMP was measured using the push-up method. A general linear model was applied to evaluate the association between metformin use and AMP with adjustments for age, disease duration, and blood glucose levels.

Results: Of 168 participants, there were 84 patients with T2DM, including 42 metformin users (Met) and

42 non-users (Non-Met). Overall, patients with T2DM had a significantly lower AMP than healthy controls (3.6 D vs 4.6 D, $P < 0.001$). Among the diabetic patients, a general linear model evaluating the combined effect of metformin use, age, disease duration, and blood glucose level on AMP was statistically significant ($R^2 = 0.324$). However, only metformin use ($F = 6.186$, $P = 0.016$) and age ($F = 20.855$, $P < 0.001$) were identified as significant independent predictors within the model. Cumulative metformin exposure (g-year) was not correlated with AMP ($P = 0.647$).

Conclusions: Metformin use is associated with preserved ocular accommodative function in patients with T2DM, suggesting a potential therapeutic strategy for presbyopia.

Radial Iris Depigmentation in a Child With 13q Deletion Syndrome Accompanied by Hematuria

First Author: Ting QIU

Purpose: 13q deletion syndrome is a rare chromosomal disorder in which part of the long (q) arm of chromosome 13 is missing. This syndrome causes great variability in clinical phenotypes and can involve multiple organs. It may cause hypoplasia of pigment-containing tissues in the eyeball.

Methods: An 11-year-old Chinese male child visited the hospital due to intermittent hematuria for 5 years. Imaging of the urinary system revealed no obvious abnormalities. General examination revealed intellectual delay, growth retardation, pectus excavatum, and double orifice mitral valve. Ophthalmic examination revealed that the most prominent feature was bilateral radial depigmentation of the iris, which causes a heterochromatic appearance of the iris. It is also accompanied by mottled depigmentation in the fundus and punctate opacities in the peripheral part of the lens. Chromosome G-banding analysis showed a partial deletion of chromosome 13 (q22-q32). Genetic sequencing revealed a 17.85 Mb deletion in the q21.33-q31.2 region of chromosome 13.

Results: Chromosome G-banding analysis revealed a partial deletion of chromosome 13 (q22-q32), along with a benign polymorphic variation of chromosome 9 (9qh+). Whole Exome Sequencing revealed a 17.85 Mb deletion in the q21.33-q31.2 region of chromosome 13, and this deleted region contains about 10 OMIM genes.

Conclusions: Radial iris depigmentation is extremely rare and highly characteristic. It might be the first report of radial iris depigmentation in a patient with 13q deletion syndrome accompanied by hematuria.

Abstract No.: 207215

Panel No.: CAT-0156

Randomised Controlled Trial to Compare Bromfenac and Difluprednate in Preventing Macular and Choroidal Changes in Cataract Surgery

First Author: Aanvi ALAKSHYA

Co-Author(s): Vishal KATIYAR, Sanjiv KUMAR GUPTA, Arun SHARMA

Purpose: Cataract surgery is known to induce postoperative macular and choroidal changes due to inflammation. This randomized controlled trial compared the efficacy of bromfenac and difluprednate in preventing such changes following uneventful phacoemulsification.

Methods: A total of 120 patients undergoing cataract surgery were randomized into two groups: bromfenac 0.09% (twice daily) and difluprednate 0.05% (QID, tapered). Baseline and postoperative best-corrected visual acuity (BCVA), intraocular pressure (IOP), and macular/choroidal thickness using OCT were recorded at 1 and 4 weeks. Data were analyzed with ANOVA, t-tests, and regression ($p < 0.05$ considered significant).

Results: Bromfenac showed superior control of macular thickening with minimal postoperative changes, while difluprednate was associated with significant IOP elevation at 4 weeks. Both drugs improved BCVA, but bromfenac demonstrated earlier and greater visual recovery. Patient satisfaction was higher in the bromfenac group.

Conclusions: Bromfenac was found to be more effective and safer than difluprednate in preventing postoperative macular and choroidal changes, with comparable visual outcomes and fewer side effects. It may be considered to be the preferred monotherapy in routine, non-diabetic cataract surgery.

Recognising the Triangle Sign – a Case of Reabsorbed Cortex of Morgagnian

First Author: Hong Nien LEE

Purpose: To highlight the importance of recognising the triangle sign and its surgical management.

Methods: Case report.

Results: A 52-year-old man presented with poor vision in his right eye for many years. He had a prior history of blunt trauma. On examination, the vision was hand movement. RAPD was positive. The lens had nuclear sclerosis 3+ and appeared subluxated inferiorly. No phacodonesis nor zonular fibrils seen. On close inspection, a triangle sign was noted superiorly. A 3-piece IOL was ordered with a planned phacoemulsification. Intraoperatively, the bag was able to be hydrodissection and reformed with an

ophthalmic viscoelastic device. CCC was performed with phacoemulsification. A 3-piece IOL was implanted.

Conclusions: A reabsorbed-cortex morgagnian cataract differs greatly from a subluxated crystalline lens. The triangle sign is a clue not to be missed. Surgical approach depends on clinical judgement.

Refractive Outcomes of the Four-Flanged Intrasceral Intraocular Lens Fixation Technique in the Philippine National Specialty Center for Eye Care

First Author: James Michael SUAREZ

Co-Author(s): Robert William KING, John Philip LIM

Purpose: To describe the refractive outcomes of eyes that underwent four-flanged intrasceral IOL fixation in the Philippine National Center for Eye Care

Methods: This was a retrospective single-center chart review of eyes that underwent four-flanged intrasceral IOL fixation using the Canabrava technique. Manifest refraction was measured at least 1 month following suture removal. Refractive prediction error (RPE) and absolute RPE (APE) were evaluated using the Barrett Universal II, Hoffer Q, Kane, SRK/T, and Holladay 1 formulas. Correlation analysis between the APE for each formula and axial length, mean keratometry, anterior chamber depth, and white-to-white was done.

Results: In total, 40 eyes from 40 patients were included in the study. Mean postoperative uncorrected and best correct DVA (LogMAR) were 0.35 ± 0.29 and 0.15 ± 0.19 , respectively. Mean postoperative spherical equivalent was 0.20 ± 1.53 D, with 60% of patients having a hyperopic postoperative refraction. Mean and median APEs for all IOL formulas were statistically significant from zero ($p < 0.005$). Mean RPEs for all formulas were positive and were highest for Hoffer Q (0.38 ± 1.47 D) and lowest for SRK/T formulas (0.19 ± 1.42 D). The percentage of eyes within ± 1.00 D of APE was highest for Kane (70%) and SRK/T formulas (70%), and lowest for the Hoffer Q formula (58%). There was no statistically significant difference in the APEs among the several formulas. Linear regression analysis showed no statistically significant relationship between postoperative mean APE with the biometry parameters tested.

Conclusions: Patients had refractive outcomes more hyperopic than predicted across all formulas. The difference in APEs among formulas was not statistically significant. The lack of significant association between APE and biometry values suggests that the outcomes of four-flanged intrasceral IOL fixation are less influenced by axial length and keratometry than other techniques. This suggests that effective lens position, as determined by the position of the sclerotomies and

point of fixation, may be the most important factor in refractive prediction accuracy.

Panel No.: CAT-0116

Retrospective Real-World Evidence Study: Performance of a Full Visual Range, Non-Toric Intraocular Lens in Patients Undergoing Cataract Surgery

First Author: Cathleen MCCABE

Purpose: This multicenter, cross-sectional, retrospective case series aims to document health care providers' (HCPs) real-world experience using the enVista ENVY (EN) intraocular lens (IOL), including satisfaction, IOL utilization patterns, and patient (pt) outcomes. This interim sub-analysis reports pt outcomes.

Methods: This sub-analysis includes case report forms (CRFs) from 13 HCPs from the USA and Canada. HCPs provided on-label EN electronic medical record cases using a standardized CRF to document real-world clinical performance. Outcomes included monocular and binocular vision outcomes (uncorrected distance visual acuity [UDVA], corrected distance visual acuity [CDVA], uncorrected intermediate visual acuity [UIVA], uncorrected near visual acuity [UNVA]), mean refractive spherical equivalent (MRSE), occurrence of glistenings and posterior capsule opacification (PCO), and adverse events (AEs).

Results: This sub-analysis included 94 pts (144 eyes): 44 unilateral. Mean $\pm$ SD spherical equivalent target: 0.05 ± 1.91 (n=135). Monocular outcomes were: CDVA of 20/25 or better was achieved in 98% of eyes (116/118); UDVA of 20/32 or better in 88% of eyes (117/133); UIVA of 20/32 or better in 91% of eyes (53/58); UNVA of J2 or better in 78% of eyes (88/113). Mean $\pm$ SD MRSE was -0.09 ± 0.38 (n=116). No serious AEs or glistening was reported.

Conclusions: This multicentre, cross-sectional, retrospective study provides insights into the real-world vision outcomes and clinical performance of EN. Most patients achieved good distance, intermediate, and near vision. No serious AEs or glistening was reported.

Abstract No.: 202007

Panel No.: CAT-0115

Rotational Asymmetry Combined With Lens Technology and Its Benefits

First Author: Neha DHOLAKIA

Purpose: Multifocal intraocular lenses (IOLs) have transformed cataract surgery and presbyopia correction by improving the range of vision and reducing dependence on spectacles. Among the various designs, asymmetric refractive segmental IOLs have emerged

as a superior option. Their asymmetric design enables more precise focusing at different distances by distributing optical power more effectively.

Methods: By combining an asymmetric refractive segmental optic with advanced IOL design, three longstanding challenges can now be addressed: aligning IOLs with the visual axis, controlling lens tilt and decentration, and ensuring stable anterior-posterior positioning. This approach refines surgical outcomes and minimizes unexpected refractive errors.

Results: When a capsulorhexis is perfectly aligned with the visual axis—optimally achieved using a femtosecond laser—the IOL aligns precisely with the axis of vision. In contrast, IOLs centered within the capsular bag often align with the bag's equator, which may not correspond to the true visual axis.

Conclusions: Clinical studies and patient-reported outcomes confirm the superiority of this new IOL design as a significant advancement in ophthalmology. It provides a more balanced vision profile, enhances patient satisfaction, and reduces postoperative complications.

Sleep, Physical Activity, Sedentary Behavior, and Risk of Cataract: A Cross-Sectional and Prospective Study From UK Biobank

First Author: Yu PENG

Co-Author(s): Li Jia CHEN, Calvin Cp PANG, Jason Cs YAM, Yuzhou ZHANG

Purpose: To examine the independent and combined effects of sleep, physical activity (PA), and sedentary behavior (SB) on cataract risk.

Methods: The cross-sectional analyses included 440,645 participants from the UK Biobank with complete data on sleep, PA, and SB. For the longitudinal analyses, a subset of 426,540 participants without cataract at baseline was included. Logistic regression and Cox proportional hazards models were used to examine the independent and synergistic associations between sleep, PA, SB, and cataract.

Results: In the cross-sectional analyses, 440,645 participants were evaluated, of whom 14,105 (3.2%) had cataract. Significant associations were found between poor sleep (OR, 1.35; 95% CI, 1.23-1.48), low PA (OR, 1.06; 95% CI, 1.01-1.11), and cataract. Longitudinal analyses included 426,540 participants. During a mean follow-up period of 10.8 years, 55,658 incident cataract cases were recorded. Poor sleep (HR, 1.14; 95% CI, 1.08-1.19), low PA (HR, 1.05; 95% CI, 1.02-1.07), and high SB (HR, 1.08; 95% CI, 1.06-1.11) were correlated with increased cataract risk. The combination of poor sleep, low PA, and high SB further elevated the risk, with the highest odds in cross-sectional (OR, 1.73; 95% CI, 1.37-2.15) and prospective

(HR, 1.37; 95% CI, 1.21-1.55) analyses. Replacing 1 h/day of SB time with an equal time spent in total PA and sleep was associated with a 1.7% and 2.7% decreased risk of cataract, respectively.

Conclusions: Poor sleep, low PA, and high SB are independently and jointly associated with an increased risk of cataract. Modifying these behaviors, either individually or in combination, can effectively mitigate the risk of cataract.

Successful Management of Delayed Hyaluronidase Hypersensitivity Post Subtenon Anesthesia: A Rare Case

First Author: Kirandeep KAUR

Co-Author(s): Bharat GURNANI

Purpose: To report a rare case of delayed hypersensitivity reaction to hyaluronidase following subtenon's anesthesia (STA) in a patient undergoing manual small incision cataract surgery (MSICS).

Methods: A 65-year-old female underwent MSICS under subtenon's block in the left eye. On postoperative day 1, she presented with acute proptosis, periorbital edema, conjunctival chemosis, and restriction of extraocular movements. Pupillary reactions were intact, and dilated fundus examination was unremarkable. Clinical history, systemic review, and examination were carefully documented, and differential diagnoses including orbital cellulitis, mucormycosis, and hyaluronidase hypersensitivity (HH) were considered.

Results: The absence of fever, normal pupillary responses, and normal ENT, neurological, and fundus findings reduced the likelihood of orbital cellulitis and mucormycosis. The clinical picture was consistent with a diagnosis of delayed HH following STA. The patient was managed with intravenous dexamethasone (1 cc daily for 3 days) in addition to routine postoperative medications. Clinical signs, including proptosis, edema, and chemosis, resolved completely within a few days, with no residual ocular morbidity. A detailed literature review revealed that delayed HH after STA is extremely rare, with this case likely representing only the second such report.

Conclusions: Delayed hyaluronidase hypersensitivity, although rare, should be considered in the differential diagnosis of acute postoperative orbital swelling following STA. Early recognition and prompt administration of corticosteroids can lead to complete resolution without long-term sequelae. Awareness of this entity is essential for ophthalmic surgeons to avoid misdiagnosis and unnecessary interventions.

Sutureless Scleral Fixation of Intraocular Lens Implantation Using Yamane's Technique in Timor-Leste: Initial Experience

First Author: Frenky Ramiro DE JESUS

Purpose: To report the first successful case of intraocular lens scleral fixation (SFIOL) implantation using Yamane's technique performed at the eye department of Hospital Nacional Guido Valadares, Timor-Leste.

Methods: Interventional case report in one patient with a dislocated IOL following ocular trauma.

Results: We performed SFIOL using Yamane's technique in a 55-year-old woman with a dislocated IOL in OD. The visual acuity (VA) was FC 1/2 m in OD and 6/9 in OS. Her medical history included cataract surgery performed 4 years earlier. A 5 mm scleral tunnel was created superiorly to remove the previous rigid polymethylmethacrylate (PMMA) three-piece IOL, and anterior vitrectomy was performed. A bimanual approach with 27-gauge needles was used, with the needles inserted at the 3 and 9 o'clock positions, 2 mm posterior to the limbus, and a Kelmsom forcep was used to thread the haptics into the needles. Both haptics were then cauterized and externalized onto the conjunctiva. The best-corrected visual acuity (BCVA) on the first day was 6/19, and the intraocular pressure was 11. The IOL is centered, the haptics well covered. The BCVA in the first week was 6/12. No post-operative complications were found.

Conclusions: Yamane scleral fixation IOL implantation technique can be considered as the treatment of choice for patients without adequate capsular support as a viable, and perhaps preferable option for patients requiring secondary IOL placement in Timor-Leste.

Abstract No.: 206041**Panel No.: CAT-0142**

Targeting Mitochondrial Dysfunction and Impaired Endogenous Melatonin Signaling: A Novel Mechanism for Melatonin's Anti-Fibrotic Action in the Lens

*First Author: Rong HUANG**Co-Author(s): Lei DU, Guojing LU, Hang XIE, Ke XU*

Purpose: While melatonin demonstrates anti-fibrotic effects in the lens, its mechanistic basis remains elusive. Given its known mitochondrial protection and high intramitochondrial concentration, this study investigated whether melatonin's benefits involve rescuing impaired endogenous melatonin synthesis and signaling, as well as counteracting mitochondrial dysfunction during TGF- β 2-induced lens epithelial cell (LEC) EMT.

Methods: Human and rat lens explants were treated with TGF- β 2. Expression of melatonin-synthesizing enzymes (AANAT, HIOMT) and receptors (MT1, MT2) was analyzed by qPCR and Western blot. Mitochondrial integrity and membrane potential ($\Delta\Psi$ m) were assessed via TOM20 immunofluorescence and JC-1 staining, respectively.

Results: Key components of the endogenous melatonin system (AANAT, HIOMT, MT1, MT2) were expressed in normal LECs but were significantly downregulated at both mRNA and protein levels after TGF- β 2 exposure. TGF- β 2 concurrently induced severe mitochondrial damage, evidenced by perinuclear clustering, fragmentation, loss of TOM20, and a reduction in JC-1 aggregate/monomer ratio (indicating $\Delta\Psi$ m loss). Treatment with melatonin effectively restored TOM20 expression, preserved mitochondrial morphology, and reversed the TGF- β 2-induced $\Delta\Psi$ m collapse.

Conclusions: Lens fibrosis is associated with a novel pathomechanism: the failure of the endogenous melatonin system and disruption of mitochondrial homeostasis. Melatonin exerts its anti-fibrotic effect, at least partially, by rectifying both these deficits—restoring endogenous signaling and rescuing mitochondrial function. This work unveils a new therapeutic axis for preventing fibrotic cataract.

The 3D Genome Structure of a Blcap-Linked Silencer Loop Regulates Apoptosis-Like Differentiation During Lens Fiber Cell Denucleation

*First Author: Shurui KE**Co-Author(s): Zhong LIU, Lixia LUO, Yingfeng ZHENG*

Purpose: Lens fiber cells (LFCs) exhibit apoptosis-like organelle and nuclear clearance during terminal differentiation but avoid full execution of apoptosis. The underlying anti-apoptotic mechanisms remain poorly understood. This study integrates Hi-C, CUT&Tag, and RNA-seq to characterize chromatin dynamics and epigenetic regulatory networks during the transition of lens epithelial cells (LECs) into LFCs. We focus on a distal silencer region (DSR)-mediated chromatin loop near the Blcap gene and its role in repressing apoptosis during nuclear degradation, thereby contributing to lens transparency.

Methods: Hi-C sequencing mapped chromatin architecture in E16.5 mouse LECs and LFCs, focusing on apoptosis-related loci. CUT&Tag profiling for H3K27me3, CTCF, and SMC3, integrated with RNA-seq, identified a novel silencer element and an LFC-specific chromatin loop linking Blcap to the DSR. To assess function, an Adeno-Associated Virus-delivered saCas9 dual-sgRNA system was used to delete loop anchor regions in vivo. We validated the functional impact

through DNA-FISH, Western blotting, flow cytometry, and phenotypic analyses.

Results: Multi-omics analysis revealed extensive chromatin remodeling during LEC-to-LFC differentiation, including A/B compartment switching, silencer reprogramming, and transcriptional changes in differentiation- and apoptosis-related genes. A specific loop tethering Bicap to the DSR was identified in LFCs. Loop disruption abolished their spatial proximity, derepressed Bicap, reduced anti-apoptotic genes Bcl2 and Bcl2l1, increased apoptosis, and caused lens opacification.

Conclusions: The Bicap-DSR chromatin loop plays a key anti-apoptotic role by repressing Bicap in LFCs. Through silencer-associated looping and epigenetic reprogramming, LFCs evade terminal apoptosis during differentiation, preserving nuclear degradation and lens transparency.

The Effect of Incision Site on Surgically Induced Astigmatism in Manual Small Incision Cataract Surgery: A Systematic Review and Meta-Analysis

First Author: Annamalai ODAYAPPAN

Co-Author(s): Gopal ARCHANA, Senthil PRASAD, Ramalakshmi RAMAN, Rd RAVINDRAN, Madhu SHEKHAR

Purpose: To ascertain the relationship between surgically induced astigmatism (SIA) and manual small incision cataract surgeries (MSICS) performed through superior or temporal incision.

Methods: Literature search was conducted across PubMed, Scopus, Embase, and Web of Science. Studies published from January 1990 to January 2025 that reported surgical outcomes of MSICS with either a temporal or superior incision approach and described SIA were included. Two independent reviewers assessed the titles and abstracts for eligibility based on the predefined inclusion criteria. Risk of bias assessment and study quality reporting were performed using NIH quality assessment tools.

Results: The initial search yielded 2,014 articles; after removing duplicates, 831 were screened, 53 underwent full-text review, and 28 were included in the meta-analysis. The pooled mean SIA for the superior incision and temporal incisions were 1.10D (95%CI: 0.94 to 1.26D) and 0.82D (95%CI: 0.68 to 0.96D), respectively. A higher mean SIA was noted with straight incision compared to frown incision for both superior (1.14D vs 1.06D) and temporal approaches (1.02D vs 0.72D). The risk of bias assessment indicated that most studies had a low risk of bias with substantial heterogeneity ($I^2=98.7\%$ for superior incision and 97.05% for

temporal incision studies), and no publication bias (Egger's test, $p=0.122$).

Conclusions: Around 1D of pre-existing astigmatism can be neutralized by placing an incision along the steep axis. In the absence of any pre-operative astigmatism, a frown incision placed on the temporal aspect should be preferred since it produces the least SIA. The influence of sutures on SIA needs to be evaluated further.

Tips and Tricks for a Crystal-Clear Cornea on Day One: Optimizing Outcomes in Phacoemulsification

First Author: Adnan ABDUL MAJEED

Purpose: To share evidence-based surgical tips and intraoperative techniques that contribute to achieving a clear cornea on the first postoperative day after phacoemulsification.

Methods: A descriptive clinical audit was conducted on 1000 consecutive uncomplicated phacoemulsification cases performed by a single surgeon. Key intraoperative parameters were monitored including: phaco energy settings, fluidics, nucleus disassembly technique, incision architecture, use of dispersive vs cohesive viscoelastics, and intraoperative handling of the endothelium. Postoperative clarity was assessed at 24 hours using slit-lamp grading and correlated with intraoperative techniques.

Results: A clear cornea on day one was observed in 88% of cases. Strong correlations were found with the following surgical strategies: • Use of low effective phaco time (EPT) via divide-and-conquer or pre-chop technique • Minimizing fluid turbulence through stable anterior chamber maintenance • Proper construction of triplanar clear corneal incisions to prevent hydration-related edema • Routine use of dispersive viscoelastics (e.g., Viscoat) for endothelial protection • Gentle nucleus manipulation and complete viscoelastic removal Cases with corneal haze were primarily associated with prolonged phaco time and excessive fluid use.

Conclusions: A combination of thoughtful preoperative planning, energy-efficient nucleus removal, careful fluidic management, and endothelial preservation techniques can significantly enhance the likelihood of a clear cornea on the first postoperative day. These pearls are especially beneficial for young surgeons seeking to optimize early visual outcomes and patient satisfaction.

Toric Intraocular Lens Rotational Stability and Tilt After Cataract Surgery With and Without Primary Posterior Continuous Curvilinear Capsulorhexis: A Randomized Comparative Clinical Trial

First Author: Chishan **KANG**Co-Author(s): Yulong **HUANG**, Jianyang **LIM**, Wenjie **WU**, Mengting **YU**

Purpose: To evaluate toric intraocular lens (IOL) rotational stability after cataract surgery with and without primary posterior continuous curvilinear capsulorhexis (PPCCC).

Methods: The prospective randomized controlled trial was conducted at Fuzhou University Affiliated Provincial Hospital in Fujian, China, between September 2024 and December 2024. Thirty-eight eyes of 28 adult patients were included with cataracts undergoing phacoemulsification cataract surgery with toric IOL implantation. Eyes were randomized into two groups: one group received cataract surgery combined with PPCCC (PPCCC group), and the other group received cataract surgery without PPCCC (NPCCC group). Toric IOL axis orientation and residual astigmatism were measured at 1 day, 1 week, 1 month, and 3 months postoperatively using the OPD-Scan III.

Results: No eye exhibited a toric IOL rotation exceeding 10°. There was no statistically significant difference in toric IOL axis misalignment between the PPCCC and NPCCC groups at 1 day, 1 week, 1 month, and 3 months ($1.62^\circ \pm 1.69^\circ$ vs. $1.35^\circ \pm 1.53^\circ$, $2.15^\circ \pm 1.47^\circ$ vs. $1.77^\circ \pm 1.26^\circ$, $2.07^\circ \pm 1.76^\circ$ vs. $2.55^\circ \pm 2.06^\circ$, and $1.80^\circ \pm 1.61^\circ$ vs. $2.44^\circ \pm 1.75^\circ$, respectively, $P > 0.05$). Residual astigmatism was -0.37 ± 0.29 D at 3 months post-surgery. No statistically significant difference in residual astigmatism was found between the two groups at any postoperative time point ($P > 0.05$).

Conclusions: Cataract surgery involving PPCCC demonstrated comparable outcomes with conventional procedures regarding toric IOL rotational stability. PPCCC is a safe and effective option for cataract patients with toric IOL implantation.

Unveiling Modern Cataract Surgery: Comparative Study of Intraoperative Biometry and Its Outcome

First Author: Ritu **SINGH**Co-Author(s): Nishi **SATISH**, Harinder **SINGH SETHI**

Purpose: To compare the Refractive Predictive Error between preoperative A Scan biometry and peroperative aphakic biometry using IOL master 500.

Methods: This prospective interventional study was conducted at a tertiary care centre after obtaining Institutional Ethical Clearance. The study adhered to the tenets of the Declaration of Helsinki. 109 patients, with cataracts of higher grades, wherein the IOL master reading was variable, underwent A scan immersion biometry. Preoperative keratometry values were used along with the new axial length values in the Barrett universal formula II to calculate the final IOL power. All patients were examined on the post-operative days 1, 3, and 7. Visual acuity and slit lamp examination were performed on each visit. Refraction was performed three weeks after the surgery by a single optometrist for all cases.

Results: Paired sample t-tests performed on these variables revealed a significant statistical difference ($p=0.007$) with 95% confidence interval (0.714, 0.113) and a mean difference in axial length of 0.413mm. The IOL powers (in dioptres) with pre-operative versus intra-operative showed a mean of 22.34 ± 2.45 and 22.15 ± 2.68 respectively. Paired statistical samples for refractive predictive outcomes in both preoperative immersion biometry and peroperative aphakic biometry revealed a mean of -1.21 ± 1.68 D, which was significant ($p = 0.0001$). The mean refractive prediction difference (RPE-d) was $1.21 \text{D} \pm 1.67$.

Conclusions: Aphakic intraoperative biometry proved to be a useful tool for IOL power calculation.

Utility of the Three-Dimensional (3D) Heads-Up Visualization System for Phacoemulsification and goniotomy(GT) in Patients With Cataract and Glaucoma

First Author: Ye **XIANGYU**

Purpose: The purpose is to evaluate the clinical outcomes of a three-dimensional (3D) heads-up visualization system in cataract surgery combined with glaucoma procedures.

Methods: A single-center case series study. to evaluate the efficacy of the procedure and the subjective satisfaction of the surgeon. The clinical outcome of the procedure was evaluated by observing IOP control and best corrected visual acuity at 3 months postoperative follow-up. A questionnaire of the surgeon was used to evaluate the comfort of the operation, the quality of the images, the visibility of the structures in the anterior chamber angle, and the cooperation with the surgical procedure on a numerical scale from 0 to 10.

Results: Preoperatively, 8 eyes (16.7%) had a BCVA < 0.1 . At 3-month follow-up, 5 eyes (10.4%) showed a slight decrease in BCVA, 13 eyes (27.1%) showed no change in BCVA, and 30 eyes (62.5%) showed an increase in BCVA compared with the preoperative period. Preoperative IOP decreased from $29.08 \pm$

12.03 mmHg to 16.22 ± 2.58 mmHg at three months postoperatively. The questionnaire showed that surgeons were very satisfied with the simplicity of the procedure. The three-dimensional (3D) heads-up visualization system helped to enhance intraoperative recognition of anterior segment structures.

Conclusions: The three-dimensional (3D) heads-up visualization system applied to phacoemulsification+GT was easy to operate, convenient, and effective in patients with cataract and glaucoma.

Visual Outcomes and Cost-Utility Analyses of Toric Intraocular Lens Implantation in Cataract Patients Over 80 With Corneal Astigmatism: A Retrospective Cohort Study

First Author: Jiaqi SUN

Purpose: This study aimed to assess visual and refractive outcomes and cost utility of toric intraocular lens (IOLs) implantation in cataract patients over 80 with corneal astigmatism.

Methods: Patients ≥ 80 years with corneal astigmatism ≥ 1.50 diopters (D) who underwent cataract surgery with toric or monofocal IOLs were enrolled. Uncorrected distance visual acuity (UDVA) and residual refractive astigmatism at the 3-month postoperative follow-up were compared between the toric and non-toric groups. Cost data were gathered, long-term quality-adjusted life years (QALYs) were calculated, and the incremental cost-effectiveness ratio (ICER) was determined.

Results: The study included 50 eyes from 50 patients, with 25 eyes receiving toric IOLs and the remaining 25 receiving non-toric IOLs. Three months after surgery, both the mean UDVA ($P < 0.0001$) and the mean residual refractive astigmatism ($P < 0.0001$) in the toric group significantly outperformed those in the non-toric group. An average of 4.04 ± 0.25 QALYs were obtained in the toric group through cataract surgery, while 3.78 ± 0.26 QALYs were obtained in the non-toric group. The median ICER stood at 11,222 CNY (1,753 USD) per QALY [95% CI: 5,840 ~ 25,295 CNY (913 ~ 3,952 USD) per QALY], which is lower than the threshold of cost-effectiveness in China (80,976 CNY (12,653 USD) per QALY).

Conclusions: In cataract patients aged over 80 with corneal astigmatism and no complicating vision-threatening conditions, toric IOL implantation not only improved UDVA and reduced residual astigmatism but also emerged as a cost-effective intervention compared with non-toric IOL implantation.

Abstract No.: 206906

Panel No.: CAT-0151

Visual Outcomes of Aurovue vs Alcon AcrySof IQ Toric IOLs: A Retrospective Single-Surgeon Study

First Author: Narayan RAJPAL

Co-Author(s): Jebinth BRAYAN, Vijayavarshcini DHANASEKARAN

Purpose: To compare the visual outcomes and performance of Alcon AcrySof IQ Toric and Aurovue Toric intraocular lenses (IOLs) implanted during phacoemulsification, and to assess the viability of the cost-effective, indigenous Aurovue Toric IOL.

Methods: This retrospective study included 136 eyes operated on by a single surgeon between 2023 and 2024. Of these, 61 eyes received Alcon AcrySof IQ Toric IOLs, while 75 received Aurovue Toric IOLs. Patients were evaluated at 1 year for best-corrected visual acuity (BCVA), uncorrected visual acuity (UCVA), residual astigmatism, rotational stability, and subjective visual quality.

Results: At 1 year, both groups achieved comparable visual outcomes. Mean postoperative BCVA was 0.04 ± 0.07 logMAR for the Alcon group and 0.05 ± 0.08 for the Aurovue group. Residual astigmatism and UCVA were similar across both groups. Alcon IOLs showed better rotational stability, though the difference was not statistically significant ($P < 0.05$). Patients implanted with Aurovue IOLs reported better subjective contrast and color perception, likely due to its untinted optic.

Conclusions: Aurovue Toric IOLs delivered visual and refractive outcomes comparable to Alcon AcrySof IQ Toric lenses. Though Alcon showed slightly better rotational stability, Aurovue offered improved subjective visual quality. As a cost-effective, indigenous alternative, Aurovue Toric IOLs are well-suited for high-volume and resource-limited settings.

Abstract No.: 206811

Panel No.: CAT-0149

Visual Performance Comparison of Enhanced Monofocal and Non-Diffractive Extended Depth-of-Focus Intraocular Lenses in Cataract Surgery: A Systematic Review and Meta-Analysis

First Author: Ametysa MIRANDA

Co-Author(s): Angelina Patricia CHANDRA, Siti Rayhani FADHILA, Rio RHENDY, Angelina Riadi Alim SUPRAPTO

Purpose: To compare the visual performance and patient-reported outcomes of enhanced monofocal and non-diffractive extended depth-of-focus (EDOF) intraocular lenses (IOLs) in patients undergoing cataract surgery.

Methods: A systematic search of PubMed, ScienceDirect, Cochrane Library, ProQuest, Wiley, and

Scopus was conducted. Eligible studies were RCTs or observational studies published between 2015 and 2025, including adults undergoing cataract surgery with enhanced monofocal or non-diffractive EDOF IOLs, reporting ≥ 1 visual outcome at 3–6 months. Risk of bias was assessed (RoB 2.0, NIH tools), and random-effects meta-analysis was conducted in RevMan 5.4.

Results: From 3,598 records, 4 studies (376 eyes; 2 RCTs, 1 cohort, 1 case-control) were included. EDOF IOLs provided significantly better near vision, with superior UNVA (MD = 0.14, 95% CI: 0.05–0.23, $p = 0.003$) and DCNVA (MD = 0.14, 95% CI: 0.05–0.24, $p = 0.004$). Mean UNVA and DCNVA were 0.27 and 0.34 LogMAR with EDOF IOLs, versus 0.40 and 0.47 LogMAR with enhanced monofocal IOLs. No significant differences were observed in distance and intermediate vision. Photoc phenomena, including halo and glare, were less frequent with enhanced monofocal IOLs, though not statistically significant. Patient satisfaction was comparable, while spectacle independence was higher with EDOF IOLs (OR = 5.19, 95% CI: 2.01–13.39, $p = 0.0007$).

Conclusions: Enhanced monofocal and non-diffractive EDOF IOLs yielded comparable outcomes, with EDOF providing superior near vision and spectacle independence. Enhanced monofocal IOLs, however, may serve as a more affordable alternative. Standardized, multicenter trials are needed to confirm these findings.

Abstract No.: 200456

Panel No.: CAT-0102

Visual and Patient-Reported Outcomes After Hybrid Implantation of Trifocal and EDOF Intraocular Lenses in Cataract Surgery Patients

*First Author: Vong Virak **OU***

*Co-Author(s): Piseth **KONG**, Amarin **MAR**, Thorn **POK**, Vanlyda **YIN***

Purpose: To evaluate the visual performance, refractive outcomes, and patient satisfaction following hybrid bilateral implantation of premium intraocular lenses (IOLs), using a trifocal IOL in one eye and an extended depth-of-focus (EDOF) IOL in the fellow eye. This study aims to assess whether such a combination provides satisfactory spectacle independence and visual quality across different distances.

Methods: This prospective study included 138 patients who underwent bilateral cataract surgery between January and December 2024, receiving a trifocal IOL in the dominant eye and an EDOF IOL in the non-dominant eye. Postoperative evaluations were conducted at 1 and 3 months and included uncorrected distance visual acuity (UDVA), intermediate visual acuity (UIVA), near visual acuity (UNVA), and a standardized questionnaire measuring patient satisfaction, visual disturbances, and spectacle dependence.

Results: At 3 months, patients achieved excellent binocular UDVA (mean logMAR: 0.08 ± 0.05), functional intermediate and near vision, and high overall satisfaction. Spectacle independence was reported in 87% of participants, with minimal complaints of glare or halos. The hybrid approach offered a smooth visual transition across distances and reduced photic phenomena compared to bilateral trifocal implantation.

Conclusions: Hybrid implantation of trifocal and EDOF IOLs is a safe and effective strategy that yields excellent functional vision at all distances while minimizing visual disturbances. This method may be considered a viable option for patients seeking a balance between visual quality and spectacle independence.

Abstract No.: 207394

Panel No.: CAT-0160

Visual and Refractive Outcome After As – Oct-Guided Optimization of Ocular Surface in Cataract Surgery

First Author: Sangeetha T

*Co-Author(s): Inchara N, Harshitha **REDDY**, Rohith **REDDY***

Purpose: To determine the impact of anterior segment optical coherence tomography (AS-OCT) on detection and preoperative optimization of ocular surface abnormalities and its effect on refractive predictability and visual outcomes in cataract surgery.

Methods: This prospective study included 150 eyes undergoing cataract surgery. All patients underwent baseline clinical ocular surface evaluation (tear breakup time, Schirmer's test, corneal staining) and high-resolution AS-OCT imaging (tear meniscus height, epithelial thickness mapping, corneal surface regularity). Based on AS-OCT findings, targeted optimization (lubrication, lid hygiene, punctal plugs, thermal pulsation, epithelial remodeling) was performed. Biometry and keratometry were repeated post-optimization. Outcomes measured: change in keratometric variability, repeatability of IOL power, refractive prediction error, and uncorrected distance visual acuity (UDVA) at 1 month.

Results: AS-OCT revealed occult ocular surface disease in 46% of eyes not clinically apparent. After optimization, mean keratometric variability reduced ($0.58 \text{ D} \rightarrow 0.19 \text{ D}$; $p < 0.001$) and IOL power repeatability improved ($\pm 0.21 \text{ D} \rightarrow \pm 0.08 \text{ D}$). Mean absolute prediction error decreased ($0.39 \pm 0.27 \text{ D} \rightarrow 0.15 \pm 0.11 \text{ D}$), and 89% achieved UDVA $\geq 6/9$ versus 63% pre-optimization ($p < 0.001$). Epithelial thickness asymmetry strongly correlated with keratometric instability ($r = 0.71$, $p < 0.001$).

Conclusions: AS-OCT enables objective, non-invasive detection of subclinical ocular surface disease, guiding personalized optimization and significantly improving refractive accuracy and visual outcomes. Routine AS-

OCT integration should be considered a new standard in pre-cataract evaluation, particularly in premium IOL planning.

Cornea, Dry Eyes, External Eye Diseases and Eye Banking

Abstract No.: 203458

100 Eyes, 1 Solution: Clinical Outcomes of Corneal Allogenic Intrastromal Ring Segments in Keratoconus

First Author: Shivohn Annalie DA SILVA
Co-Author(s): Jagdeesh Kumar REDDY, Vandhana SUNDARAM K, Prabhu VIJAYARAGHAVAN

Purpose: To evaluate the efficacy and safety of Corneal Allogenic Intrastromal Ring Segment (CAIRS) implantation in keratoconus, focusing on visual, refractive, and topographic outcomes in a large consecutive series.

Methods: In this prospective interventional study at a tertiary eye hospital (February 2024–September 2025), 100 eyes of keratoconus patients underwent femtosecond laser–assisted implantation of donor corneal intrastromal ring segments customised to cone morphology with or without crosslinking. Primary outcomes were changes in uncorrected distance visual acuity (UDVA) and corrected distance visual acuity (CDVA, Snellens), proportion gaining ≥ 2 lines UDVA or ≥ 1 line CDVA, changes in spherical equivalent (SE), and maximum keratometry (Kmax). Secondary outcomes included higher-order aberrations (HOAs) and complication rates. Patients were followed up at 1, 6 and 12 months.

Results: At 12 months, UDVA improved by a mean of 3.9 lines (95% CI, 3.5–4.3) and CDVA by 2.1 lines (95% CI, 1.8–2.4). SE shifted by +2.6 D toward emmetropia. Kmax and Kmean flattened by 4.5 D (95% CI, 4.1–4.9) and 4.7 D (95% CI, 4.4–5.0), respectively. Immune infiltrates occurred in 20 eyes at 1 week but resolved with topical steroids. One patient required segment adjustment, and one developed cross-linking–related haze that persisted but was non–vision-threatening. No cases of infection, extrusion, or corneal melt were observed.

Conclusions: Corneal allogenic intrastromal ring implantation yielded consistent improvements in visual acuity and corneal regularity with minimal complications. CAIRS represents a safe, reproducible, and minimally invasive alternative to synthetic rings in keratoconus, with better outcomes in treatment-naïve than post-cross-linking corneas.

3D Mesenchymal Stem Cell Exosome-Functionalized Hydrogels for Corneal Wound Healing

First Author: Yuehe XU

Purpose: Construction of a 3D exosome (Exos) functionalized gelatin methacrylate (GelMA) hydrogel sustained-release system for multi-dimensional repair of corneal injury.

Methods: 3D-Exos were prepared by culturing mesenchymal stem cells in a GelMA hydrogel 3D system. The Exos were characterized using scanning electron microscopy, dynamic light scattering, nanoparticle tracking analysis, and Western blot. The behavioral effects of 3D-Exos on corneal epithelial cells and stromal cells were assessed through Exos uptake assays, scratch wound healing assays, PCR, and immunofluorescence staining. The anti-inflammatory effects of 3D-Exos in vitro were evaluated using immunofluorescence staining and flow cytometry. The fabricated 3D-Exos functionalized GelMA hydrogel sustained-release system was applied to repair a rabbit corneal stromal injury model (3 mm in diameter) with partial limbal stem cell deficiency. Its in vivo biocompatibility and functionality were examined using slit-lamp microscopy, optical coherence tomography, confocal microscopy, immunofluorescence staining, PCR, and hematoxylin-eosin staining.

Results: Compared to traditional 2D-Exos, 3D-Exos not only exhibit increased yield but also demonstrate superior anti-inflammatory, pro-proliferative, and tissue remodeling properties. The 3D-Exos functionalized GelMA hydrogel effectively restores corneal morphology and function, mitigates inflammation, promotes the repair of corneal epithelium and limbus, and reduces stromal scar formation.

Conclusions: The 3D-Exos functionalized GelMA hydrogel sustained-release system developed in this study represents an effective cell-free therapy strategy for comprehensive repair of damaged corneas.

A Case of Conjunctival Malignant Melanoma With BRAF T599dup Mutation

First Author: Ryan LEE
Co-Author(s): Ka Wai KAM, Alvin Lerrmann YOUNG

Purpose: Conjunctival melanoma is a rare yet highly lethal ocular malignancy. It can clinically resemble conjunctival nevus or primary acquired melanosis.

Methods: This case report of conjunctival malignant melanoma highlights the challenges in managing this condition.

Results: A 60-year-old male presented with right temporal ocular surface mass since late 2022. Examination revealed a large melanotic mass measuring 18 x 15 mm on the right temporal conjunctiva, obscuring the temporal cornea. The patient underwent excisional biopsy with 100% alcohol application and double freeze-thaw cryotherapy performed on the conjunctival edge. Histopathological report confirmed conjunctival malignant melanoma with maximal thickness of 4.1 mm and involvement of deep margins. Genetic analysis revealed a positive BRAF mutation at NP_004324.2:p.T599dup. Post-operative MRI showed linear enhancement at surgical site, with no evidence of residual disease. PET-CT and ultrasound of the liver showed no distant metastasis. The patient completed four cycles of adjuvant topical mitomycin C 0.04% within 3 months after the surgery. In view of positive margin, adjuvant radiotherapy was suggested by oncologist and patient attended Beijing Tongren hospital for assessment, however adjuvant therapy was not recommended as no visible tumor was detected.

Conclusions: This case demonstrates the challenges in the management of conjunctival melanoma and highlights the importance of careful follow-up to monitor for potential recurrence or metastasis. A multidisciplinary approach is crucial for effective management.

A Case of *Trichomonascus ciferrii* Keratitis in an Immunocompetent Adult

First Author: George Michael SOSUAN

Co-Author(s): Pierre Aldwin ARCEO, Ruben LIM BON SIONG, Richard Raymund NEPOMUCENO, Patricia Kaye SY

Purpose: Fungal keratitis is a serious ocular infection that can result in permanent vision loss if not promptly diagnosed and treated. It is commonly caused by filamentous fungi following trauma in tropical countries and *Candida* species among the immunocompromised in temperate countries. *Trichomonascus ciferrii* is a rare etiologic agent of fungal keratitis following trauma in a young, healthy woman living in a tropical country.

Methods: Case report and review of related literature.

Results: A 20-year-old healthy woman developed keratitis nearly two weeks after an ocular trauma with an organic material, a cardboard paper, on her left eye. Ocular examination revealed a mid-stromal corneal infiltrate with brush-like borders and hypopyon. The Giemsa stain of the corneal scraping demonstrated branching septated hyphae, and fungal culture grew *T. ciferrii* resistant to amphotericin B. She was successfully treated with topical natamycin 5% drops for 2 weeks, leading to complete eradication of the corneal infection with a residual stromal scar.

Conclusions: This case documented *T. ciferrii*, a rare fungal etiology in post-traumatic keratitis in a tropical country, successfully treated with natamycin 5%. Despite the virulence of *T. ciferrii*, the infection was promptly treated, resulting in good functional vision.

A Case of a Missing Eyeball: Sequelae of Congenital Glaucoma Surgery

First Author: Tsabita ANNISA

Co-Author(s): Hisar DANIEL, Rina La Distia NORA, Fitri ROKIM, Erica WIDODO

Purpose: Corneal ulcers in eyes with absolute glaucoma can result in severe complications, including corneal perforation, infection, and eventual structural loss of the globe. We report a rare presentation of complete globe destruction in a patient with a history of absolute glaucoma and corneal ulceration.

Methods: Observational case report.

Results: A 46-year-old woman with a history of congenital glaucoma surgery in the left eye (LE) during childhood presented with pain, redness, and persistent mucopurulent discharge. Examination revealed absolute glaucoma, advanced scleromalacia, and corneal thinning in the right eye (RE), which served as her only functional eye. Ocular ultrasonography confirmed total globe loss of the LE, with absent scleral wall. Microbiological analysis revealed gram-positive cocci, and topical antibiotics were commenced. Due to the fragile residual tissue and risk of infection, surgical exploration was performed using a technically demanding evisceration combined with dermis-fat grafting to restore orbital volume. Histopathology revealed fibrotic tissue with acute inflammation and abscess formation. The patient's right eye, her only functional eye, was placed under close surveillance.

Conclusions: This case demonstrates not only the rare progression of absolute glaucoma to complete globe destruction, but also the surgical challenges of managing such sequelae. Complex reconstructive procedures, such as dermis-fat grafting in the absence of scleral support, may be required to preserve cosmesis and socket integrity. Early recognition of corneal complications and rigorous fellow-eye monitoring remain crucial to prevent irreversible blindness and maintain quality of life.

A Cost-Calculator Analysis of Diquafosol (DQS/DQS-S) Compared With Standard of Care in Dry Eye Disease

First Author: David CHAMPION

Co-Author(s): Jieyi LI, Yi Shi, Qi Qing NG, Jureeporn RATTAMANEE, Kun SHI-VAN WIELINK

Purpose: Dry eye disease (DED) is a chronic, multifactorial condition associated with substantial symptom burden and healthcare utilization. While standard of care is widely used, newer agents such as diquafosol ophthalmic solution and its preservative-free formulation (DQS/DQS-S) may offer additional benefits. This study quantifies the total costs and potential savings of DQS/DQS-S versus current treatments for DED in the Asia Pacific.

Methods: A cost-calculator model was developed for six countries (Thailand, Philippines, Indonesia, Malaysia, Vietnam, and Taiwan) to compare DQS/DQS-S with the most frequently used artificial tear or ointment/gel in each country. Analyses were conducted from a patient perspective. Annual costs included direct medical, indirect, and intangible components. Incremental costs between DQS/DQS-S and the respective comparators were calculated as total cost differences.

Results: DQS/DQS-S demonstrated per-patient cost differences compared with the standard of care in each country. For DQS-S, incremental costs were negative, indicating cost savings: -IDR 5.17 million in Indonesia (vs. Cenfresh), -MYR 2,604 in Malaysia (vs. Systane), -PHP 23,086 in the Philippines (vs. Systane), and -THB 7,965 in Thailand (vs. Systane). For DQS, the incremental cost was -TWD 18,191 in Taiwan (vs. Systane), reflecting country-specific cost-savings.

Conclusions: DQS/DQS-S demonstrated per-patient cost-savings in the majority of comparisons with the most frequently used alternative treatments across countries. These findings highlight the economic value of DQS/DQS-S, offering potential savings for patients and healthcare systems across diverse healthcare settings.

A Novel Drug Delivery Device – 3D-Printed Modified Morgen Lens for the Treatment of Fungal Keratitis

First Author: Jiannan LIU

Co-Author(s): Jianzhang YE

Purpose: To evaluate the efficacy and safety of a novel drug delivery device in the treatment of fungal keratitis.

Methods: The conventional Morgen lens, which has a single corneal drug delivery port, was modified

to incorporate a 360-degree corneal drug delivery channel. The ocular surface contact base was redesigned with a reduced diameter suitable for the palpebral fissure size of Chinese patients, and three different vault heights were created according to corneal curvature, using 3D printing technology. This device can be directly connected to an infusion set for alternating administration of two drugs, with controllable drop rate. Twenty-seven patients were randomized to a device group (13 eyes) or topical group (14 eyes). The device delivered alternating 1% voriconazole/2.5% amphotericin B for 4 h daily, up to two 3-day cycles, plus standard care between infusions. The topical group received alternating drops every 15 min; tropicamide was added for anterior-chamber inflammation. Daily assessments guided discharge or surgery. Primary outcome: 3-month cure rate; secondary outcomes: day-6 efficacy, infiltrate area, central corneal thickness, epithelial defect area, and symptom/sign scores after irrigation.

Results: Baseline characteristics were similar. At 3 months, the device group showed higher cure rate (71.4% vs 31.5%, $P = 0.045$) and faster reduction in infiltrate area, epithelial defect, infiltration depth, and hyphal density versus the topical group.

Conclusions: The novel ocular surface drug delivery device is an effective, safe, convenient, and non-invasive method for treating fungal keratitis, and it accelerates corneal lesion recovery.

A Single-Cell RNA Sequencing Atlas Revealed Immune Activation and Functional Keratinocyte Loss in the Conjunctiva of Sjögren's Syndrome-Related Dry Eye

First Author: Bowen WANG

Purpose: The role of conjunctiva in the pathophysiology of Sjögren's syndrome (SS) related dry eye disease (DED) remains obscure, especially in view of functional conjunctival epithelia. In order to illustrate the effects of the conjunctiva in SS, we investigate interactions between parenchymal cells and immune cells in the conjunctiva with the single-cell RNA sequencing technique.

Methods: Freshly collected conjunctiva from a canonical SS model was prepared for 10xGenomics single-cell RNA sequencing and TCR sequencing. Conjunctiva was collected for Western blot, immunofluorescence, multiplex immunohistochemical (mIHC), and flow cytometry. Phenol red thread test, lissamine staining, and qRT-PCR were applied to evaluate signs of DED.

Results: The DED phenotype was validated in the SS model. Loss of water-secreting keratinocyte was projected in scRNA-seq data and proved by mIHC test

in SS mice. The proportion of Lgr4+ basal epithelial cells with poor ability to differentiate into mature keratinocytes increased, and Wnt/ β -catenin signaling was upregulated in them under the regulation of TGF- β derived from macrophages. Such macrophages promoted angiogenesis through the secretion of VEGFA to activate endothelial cells. Immuno-fibroblasts had an increased population, which was implicated in specifically activated T cell chemotaxis.

Conclusions: In the SS conjunctiva, a TGF- β -Wnt/ β -catenin axis downregulated the formation of functional keratinocytes, accompanied by infiltration of pro-angiogenic and pro-fibrotic macrophages and pro-inflammatory T cells.

A Systematic Review and Meta-Analysis of the Long-Term Outcomes of Toric Intraocular Lens on Astigmatism

First Author: Chi-ying christine LAM

Co-Author(s): Ka Wai KAM, Alvin TSANG, Alvin YOUNG

Purpose: Toric intraocular lenses (IOLs) are widely used to correct corneal astigmatism during cataract surgery; however, most studies reported early post-operative outcomes. This study aimed to assess the effectiveness of toric IOL on reducing refractive astigmatism at one year or beyond, as well as long-term rotational stability, and reoperation rates.

Methods: We conducted a systematic review with a meta-analysis on the long-term outcomes following toric IOL implantation. We searched Ovid Embase and PubMed using the terms '(toric IOL)' OR '(toric intraocular lens)' AND '(long term)' OR '(outcome)' up to 11 April 2025. Studies reporting outcomes of at least 1 year after implantation were included. Residual refractive astigmatism, rotational stability, and reoperation rates were outcomes of interest.

Results: Twenty studies with 1221 participants were identified, and 1584 eyes with a mean pre-operative refractive astigmatism of -2.14 ± 1.05 D were analysed. The mean follow-up period was 21 ± 22.5 (range 12-96) months. The mean residual cylinder were -0.68 ± 0.38 D at one year and -0.64 ± 0.02 D at two years respectively. The mean rotation was 3.39 ± 1.20 degrees at one year. All IOL rotations reported were within 10 degrees except for one eye which rotated by 40 degrees and required surgical repositioning.

Conclusions: Toric IOL implantation maintains good astigmatism reduction for up to two years. The majority of toric IOLs exhibited excellent rotational stability and did not require surgical reoperation.

A Transcriptome Atlas of the Spleen Identifies B Lymphocytes As Critical Effectors Against Ocular HSV-1 Infection

First Author: Dingwen CAO

Co-Author(s): Jiayu MENG, Yu SUN, Chao WEI

Purpose: Herpes simplex virus-1 (HSV-1) is a major pathogen causing viral keratitis. The spleen plays a vital role in modulating both local and systemic innate and adaptive immunity. However, its connection to ocular HSV-1 infection remains unclear. This study seeks to underscore the functional relevance between ocular regional immunity and the spleen, supporting the spleen as a potential target for treating ocular HSV-1 infection.

Methods: Using a well-established murine herpes simplex keratitis (HSK) model, histopathology and transcriptional profiling of spleens post-infection were assessed via hematoxylin-eosin staining and RNA sequencing (RNA-seq). Splenectomy, EdU incorporation assays, pharmacological interventions, and other analyses were conducted to explore the relationship between the spleen and ocular infection and to evaluate the role of B cells in ocular HSV-1 infection.

Results: Compared to uninfected mice, HSV-1-infected mice exhibited splenomegaly, characterized by an increased splenic index and enlarged white pulp. Splenectomized mice showed more severe HSK symptoms than sham-operated controls. RNA-seq and EdU incorporation experiments revealed that the enlarged spleens had increased enrichment of proliferation-associated signaling pathways and greater accumulation of T and B lymphocytes. Blocking splenic proliferation with PCNA-I1 exacerbated HSK progression and significantly reduced T and B lymphocyte percentages in both spleens and corneal tissues. Notably, topical depletion of B cells in infected mice alleviated clinical symptoms but increased viral titers.

Conclusions: These findings demonstrate a functional connection between the spleen and ocular infection, highlighting the spleen-eye axis in controlling ocular HSV-1 infection. This suggests that targeting the spleen may be a potential therapeutic strategy for treating ocular HSV-1 infections.

ACE Inhibitors or ARBs Reduce Myofibroblast Activation in an Ex Vivo Porcine Model of Corneal Fibrosis

First Author: Yue CHANG

Co-Author(s): Jennifer CRAIG, Sanjay MARASINI, Jay MEYER, Jie ZHANG

Purpose: Corneal injuries frequently result in fibrosis, yet effective pharmacological interventions remain limited. Given the emerging role of the renin-angiotensin system (RAS) in fibrotic processes, this study aimed to evaluate the anti-fibrotic potential of angiotensin-converting enzyme inhibitors (ACEIs) and angiotensin II receptor blockers (ARBs) in an ex vivo corneal scarring model.

Methods: An ex vivo porcine corneal injury model was established by applying 1 M NaOH for 30 seconds to induce stromal fibrosis. After injury, corneas were treated daily with topical ACEI pro-drugs and active forms (0.1% Enalapril, Enalaprilat, Perindopril, Perindoprilat, Ramipril, Ramiprilat) and ARBs (0.1% Losartan, Olmesartan, Valsartan) for 7 days. Untreated injured corneas and uninjured corneas served as controls. Corneal opacity was quantified from images using ImageJ. Tissues were fixed, cryosectioned, and subjected to immunofluorescence for α -smooth muscle actin (α -SMA) and vimentin, markers of myofibroblasts.

Results: Topical application of active ACEIs or ARBs resulted in a visible reduction in corneal opacity by day 7. Prodrug formulations showed a similar trend, though to a lesser extent and without statistically significant differences. Preliminary data also suggest reduced α -SMA and vimentin expression in some of the treatment groups, indicating potential suppression of myofibroblast differentiation.

Conclusions: Topical application of ACEIs or ARBs may attenuate corneal fibrosis by modulating keratocyte and fibroblast activation, thereby limiting myofibroblast differentiation and excessive extracellular matrix deposition. These findings highlight the therapeutic potential of repurposing ACEIs and ARBs for managing corneal scarring and strongly warrant further validation in relevant in vivo models.

Accelerometer-Derived "Weekend Warrior" and Regularly Active Physical Activity and Risk of Dry Eye Disease

First Author: Aixia JIN

Co-Author(s): Ning FAN, Rong ZHANG

Purpose: To explore the associations between accelerometer-derived moderate-to-vigorous physical activity (MVPA) patterns and the risk of dry eye disease (DED).

Methods: Methods: Retrospective analysis of UK Biobank cohort study participants who provided a full week of accelerometer-derived MVPA data between June 8, 2013, and December 30, 2015. Three MVPA patterns were compared: inactive (< 150 minutes), active weekend warrior (active WW, $\geq$ 150 minutes with 50% of weekly MVPA accumulated within 1 - 2 days), active regular ($\geq$ 150 minutes and not meeting active WW status). Association between MVPA patterns and DED's risk was assessed using multifactorial Cox models and restricted cubic spline models.

Results: Results: A total of 93,895 participants (mean [SD] age, 56.05 [7.85] years; 44.38% women) without DED at baseline were included. In multivariable-adjusted models, higher weekly MVPA was significantly associated with a lower risk of incident dry eye ($P = 0.0002$). The association was non-linear ($P = 0.0001$), with the steepest decline in risk observed between 0 and approximately 150 min/week, beyond which the risk plateaued. Active WW was associated with a similarly lower risk of DED as the active regular pattern (WW: hazard ratio [HR], 0.82 [95% CI, 0.70-0.96]; active regular: 0.77 [95% CI, 0.63-0.93; inactive: HR, 1.00 [the reference group]). Importantly, this trend persisted across multiple definitions of WW pattern in the sensitivity analyses.

Conclusions: Active MVPA was associated with lower risk of DED. Notably, the WW and regular exercise patterns conferred similar protective effects against DED.

Acupuncture Versus Sham Acupuncture for Dry Eye Disease: A Systematic Review and Meta-Analysis

First Author: Elva Lau Yung WONG

Co-Author(s): Nicole Ka Ying CHENG, Kelvin Kam Lung CHONG, Zhichao HU

Purpose: This study aims to evaluate the efficacy of Acupuncture (AC) used as a dry eye disease (DED) intervention by comparing AC and sham acupuncture (SA) groups.

Methods: A systematic search was conducted from 1 January 2005 to 21 July 2025 by importing data from Embase, PubMed, and Web of Science. Back-to-back data screening and extraction were applied by 2 researchers to intervene in patients with DED who were analysed. Ocular surface disease index (OSDI), tear break-up time (TBUT), and ocular surface grading (OSG) were the main outcomes. (PROSPERO ID: CRD420251148655)

Results: Four masked, randomized controlled trials met the inclusion criteria and 207 DED patients were involved. The analysis results of OSDI [Standard mean difference (SMD)=-0.18, 95% confidence interval (CI)

(-0.48, 0.11), $P=0.22$] and OSG [SMD=-0.12, 95% CI (-0.45, 0.22), $P=0.49$] showed that AC has a slightly better effect than SA, although the difference was not statistically significant. TBUT [SMD=0.13, 95% CI (-0.21, 0.46), $P=0.45$], in contrast, displayed improvement in the SA group with no statistically significant difference. No statistically significant difference is suggested between the two groups regarding all outcomes analysed.

Conclusions: No significant evidence showed that acupuncture was superior to sham acupuncture for treating DED. Future large-scale, rigorously designed clinical trials are needed to provide a more definitive conclusion.

Abstract No.: 205172

Panel No.: CDE-0261

Agreement Between a Swept-Source Optical Coherence Tomography and Dual Scheimpflug Placido Analyser in Healthy, Keratoconus Suspect and Keratoconus Eyes

*First Author: Mohd Asyraf **ABDUL KADIR***

Purpose: Accurate corneal assessment is essential for diagnosing and monitoring keratoconus (KC) and its early forms. This study evaluated the agreement between a swept-source optical coherence tomography device (ANTERION) and a dual scheimpflug-placido analyser (GALILEI) in measuring anterior and posterior corneal parameters in healthy, keratoconus suspect (KS), and keratoconus eyes.

Methods: A cross-sectional study was conducted at the IIUM Eye Specialist Clinic from July 2023 to February 2025. Participants underwent same-session imaging with ANTERION and GALILEI. Parameters analysed included anterior and posterior keratometry (K1, K2, Kmax, Best-Fit Sphere (BFS)), central corneal thickness (CCT), and minimal corneal thickness (MCT). Agreement was assessed using Bland-Altman analysis and intraclass correlation coefficients (ICC).

Results: A total of 221 eyes were analysed (normal = 129, KS = 40, KC = 52). In normal eyes, anterior parameters showed excellent agreement (ICC >0.94), posterior parameters showed good-excellent agreement (ICC 0.86–0.96), and pachymetry showed strong agreement (ICC >0.94). However, some statistically significant differences in anterior and posterior curvatures and pachymetry values. KS and KC groups demonstrated excellent agreement (ICC ≥0.90) across most parameters, except for anterior BFS in KC group. Variability increased in advanced KC, particularly for posterior measurements and pachymetry.

Conclusions: ANTERION and GALILEI provide reliable, clinically acceptable corneal measurements across normal, KS, and KC eyes. While devices may be used interchangeably for most parameters, caution is advised when interpreting posterior curvature and

pachymetric values in advanced KC, especially for longitudinal follow-up.

Abstract No.: 210164

Panel No.: CDE-0307

Air Pollutants Disrupt Ocular Surface Immunity and EGFR-Mediated Repair in Dry Eye Disease: An Integrated Network Toxicology and Single-Cell RNA Sequencing

*First Author: Yuan **ZHONG***

*Co-Author(s): Qinghua **PENG***

Purpose: To elucidate how air pollutants drive dry eye disease (DED) at the molecular level by integrating network toxicology, immune infiltration, single-cell RNA sequencing (scRNA-seq), and molecular docking.

Methods: Targets of air pollutants were predicted from ChEMBL and SwissTargetPrediction. PM2.5-responsive genes were obtained with limma. DED-associated genes were collected from OMIM and GeneCards. Functional enrichment (GO/KEGG/GSEA/GSEA) was conducted on the intersecting genes. Hub genes were screened using a PPI network and visualized in Cytoscape. Immune infiltration analysis was assessed using the CIBERSORT algorithm. GEO scRNA-seq data were used to profile expression of hub targets in the cornea. Finally, molecular docking examined the binding between air pollutants and hub targets.

Results: Five hub targets (EGFR, IL-1 β , IL-6, MYC, and JUN) were identified, demonstrating significant involvement in inflammatory responses, immune microenvironment imbalance, and corneal epithelial repair mechanisms. Immune infiltration analysis revealed increased activated dendritic cells in the DED. IL-6 expression showed a positive correlation with activated dendritic cells, while IL-1 β and JUN both positively correlated with M1 macrophage-specific signaling. ScRNA-seq confirmed expression of EGFR, IL-1 β , MYC, and JUN in corneal tissue, providing cellular-level evidence for the toxic mechanisms of air pollutants. Molecular docking showed high binding affinity between air pollutants and the hub targets.

Conclusions: Air pollutants may promote DED by disrupting the immune homeostasis of the ocular surface, amplifying inflammatory responses, and impairing epithelial repair. These findings enhance our understanding of air pollutant-induced DED and provide a theoretical basis for potential treatment strategies.

Panel No.: CDE-0286

Altered Sphingolipids in Tear Are Potential Biomarkers of the Disease Severity of Vernal Keratoconjunctivitis

First Author: Shobhit GUPTA

Co-Author(s): Shweta AGARWAL, Nabanita HALDER, Angayarkanni NARAYANASAMY, Madhu NATH, Thirumurthy VELPANDIAN

Purpose: Vernal keratoconjunctivitis (VKC) is an allergic conjunctival inflammation, predominantly affecting boys during early childhood and typically subsiding by puberty. The mechanisms underlying this age-related resolution and male predominance remain unclear. The study aims to analyze the changes in the sphingolipid, chiefly the ceramides, in VKC cases less than 16 years, classified based on disease status.

Methods: Tear samples were collected using Schirmer's strips from VKC patients aged <16 years (n=105) classified as active and quiet based on disease status, and from age-matched (<16 years) healthy controls (n=39) at a tertiary eye care centre in South India. Sphingolipids were quantified in the pooled tears (n=3), VKC (n=35 sets), and healthy control (n=13 sets) after lipid extraction followed by LC-MS/MS analysis, as per US-FDA guidelines for bioanalytical method validation.

Results: Analysis revealed significantly higher levels of C2 C1P (d18:1/2:0) ($p < 0.004$) and S1P(d20:1) ($p < 0.05$) in VKC compared to the controls. Further, when VKC was further classified, C18(d18:1/18:0) ($p < 0.004$), C24(d18:1/24:0) ($p < 0.005$), and C2C1P (d18:1/2:0) ($p < 0.003$) were significantly increased in the active state of the disease compared to the quiet.

Conclusions: Altered sphingolipid metabolism in the ocular surface results in low tear ceramide levels in quiet VKC compared with the active cases. These novel findings support the use of sphingolipids as potential biomarkers for disease monitoring and for exploring targeted therapy.

An On-Table Diagnosis of Brittle Cornea Syndrome During Surgery

First Author: Ronak SOLANKI

Purpose: To describe a rare case of Brittle Cornea Syndrome (BCS), which was diagnosed while operating on the patient in the operating theatre, thereby confirming the spectrum of preoperative suspicious clinical findings.

Methods: A 36-year-old male born to parents with a non-consanguineous marriage presented with a painful, sudden onset of Loss of vision OD after an alleged minor finger nail trauma. Ocular Examination revealed OD visual acuity of Perception of Light (PL)

positive, projection of rays(PR) accurate, full-thickness linear corneal tear inferiorly, and a flat chamber. Documented blue sclera OD on one of his previous visits. OS no light perception, previous childhood trauma, and Pthysis Bulbi. General Examination revealed mental retardation, Short stubby nose, use of a Hearing Aid, mild contractures of fingers (5th finger), clinodactyly, Small joint hypermobility, and apparent Dentinogenesis imperfecta-like features.

Results: A corneal tear repair under local peribulbar anesthesia was undertaken. An additional side port entry was planned and made, which spontaneously extended into a larger linear tear than the expected size. Subsequent cheese wiring of sutures and difficulty in sealing the wound under air and viscoelastic agents helped us make an on-table diagnosis of Brittle Cornea Syndrome while operating on the patient.

Conclusions: In BCS with corneal rupture, primary repair is required. Surgical repair of spontaneous corneal ruptures in brittle cornea syndrome is difficult. Corneal sealing is achieved by a combination of cheese-wiring sutures with bandage contact lenses, pressure patches, and systemic CAIs. Gas(C3F8)/air tamponade, tissue adhesives in a dry operative field, viscoelastic agents, and onlay epikeratoplasty can be used.

Abstract No.: 201705

Panel No.: CDE-0199

Antiseptic Efficacy and Toxicity of Three 1% Povidone-Iodine Drops Versus a Single 5% Povidone-Iodine Drop on Patients Undergoing Elective Ocular Surgery.

First Author: Raphael GUMAFELIX

Co-Author(s): Ruben LIM BON SIONG, Reginal Robert TAN

Purpose: This prospective, randomized, single-blinded study compared the antiseptic efficacy and ocular surface toxicity of repeated 1% versus single-dose 5% povidone-iodine (PI) application in patients undergoing elective ocular surgery.

Methods: Seventy generally healthy adult participants (aged 18 to 80 years) without significant systemic comorbidities were randomly assigned to receive either three drops of 1% PI or one drop of 5% PI. Conjunctival swabs were collected before and after PI application for microbial culture on blood and chocolate agar. Corneal epithelial toxicity was assessed via fluorescein staining and graded using the National Eye Institute (NEI) scale.

Results: Both PI concentrations significantly reduced conjunctival bacterial counts ($p < 0.001$). The 5% PI group showed a significantly greater mean reduction in colony counts on blood agar (59.9% vs. 50.4%; $p = 0.007$). No significant difference was observed on chocolate agar ($p = 0.817$). However, corneal toxicity was significantly higher in the 5% PI group (Mean NEI

score: 9.5) compared to the 1% PI group (Mean NEI score: 4.3; $p < 0.001$).

Conclusions: While single-dose 5% PI showed slightly superior efficacy on blood agar, repeated application of 1% PI achieved comparable antiseptic effectiveness with significantly less epithelial toxicity. Repeated 1% PI may serve as a safer alternative for preoperative ocular disinfection.

Assessing Presentation of the Uniformly Thin, Non-Ectatic, Cornea: Brittle Cornea Syndrome Compared With Anterior Megalophthalmos

First Author: Dian ZHUANG

Co-Author(s): Charles MCGHEE

Purpose: To report anterior segment features in patients presenting with thin corneae, highlighted in Brittle Cornea Syndrome associated with Ehlers-Danlos Syndrome, and anterior megalophthalmos.

Methods: Two unique cases with thin corneae were evaluated by: slit lamp anterior segment assessment, anterior segment OCT, corneal tomography, central corneal thickness (CCT), and endothelial cell count. Associated ocular and systemic features were documented and analysed.

Results: A young female diagnosed with Ehlers-Danlos Syndrome, initially presented with marked, uniformly thin corneas (CCT: 331 μm OU). From 2021 to 2024, corneal thickness remained stable, with a significant increase to 408 μm (right eye) and 409 μm (left eye). Other anterior segment features remained unremarkable. A 29-year-old male, with a family history of anterior megalophthalmos, presented with megalocornea and pigment dispersion syndrome. He had large, uniformly thin corneas (CCT: right 452 μm , left 437 μm) and significant iris transillumination. Endothelial cell counts were 2247 cells/ mm^2 (right) and 2150 cells/ mm^2 (left). Annual follow-up showed stable corneal thickness and endothelial cell counts with marked arcus lipoides/shagreen.

Conclusions: Non-ectatic thin cornea, though uncommon, may indicate underlying ocular or systemic conditions such as Brittle Cornea Syndrome or megalophthalmos. These two cases highlight the importance of comprehensive anterior segment evaluation, in the context of thin corneas. Long-term monitoring is essential to detect potential progression or complications, guide appropriate management, and ensure timely referral when systemic involvement is suspected. Given the hereditary involvement, genetic considerations should also be part of the clinical evaluation to support diagnosis, counselling, and family screening when indicated.

Astaxanthin Mitigates Benzalkonium Chloride-Induced Dry Eye Disease by Inhibiting Inflammation and Oxidative Stress Through the Keap1-Nrf2/HO-1 Pathway

First Author: Mengzhen XIE

Co-Author(s): Ying JIE, Ziyu LIU

Purpose: This study aims to explore whether astaxanthin (AST) alleviates dry eye disease (DED) induced by benzalkonium chloride (BAC) and to elucidate the role of the Keap1-Nrf2/HO-1 pathway in its protective mechanism.

Methods: Potential targets of AST and DED were identified using network pharmacology. Binding interactions between AST and core targets were assessed by molecular docking and dynamics simulations. A DED mouse model was established with 0.1% BAC, followed by oral AST administration (100 mg/kg/day) for 7 days. Human corneal epithelial cells (hCECs) were exposed to hyperosmotic stress with and without AST. Ocular surface evaluation, RTqPCR, Western blot, and immunofluorescence were performed to assess therapeutic effects and mechanisms.

Results: Network analysis suggested AST mitigates DED through anti-oxidative pathways. In vivo, AST restored ocular surface health, downregulated Keap1, and enhanced Nrf2 and HO-1 expression. In vitro, AST increased cell viability and reduced ROS generation under hyperosmotic conditions.

Conclusions: AST effectively protects against DED by activating the Keap1-Nrf2/HO-1 signaling axis, reducing oxidative stress and inflammation. These results support the potential of AST as a novel therapeutic agent for dry eye disease.

Axenfeld-Rieger Syndrome Family Analysis: Clinical Characteristics Report of Two Cases in Mother and Daughter

First Author: Ying WU

Co-Author(s): Lijun ZHANG

Purpose: To analyze clinical manifestations of Axenfeld-Rieger syndrome in a mother-daughter pair and explore diagnostic features of this rare hereditary ocular disease.

Methods: Systematic ophthalmologic examinations were performed on two confirmed cases of Axenfeld-Rieger syndrome (mother and daughter), including best-corrected visual acuity, intraocular pressure measurement, slit-lamp biomicroscopy, gonioscopy, visual field testing, optical coherence tomography (OCT) anterior chamber angle imaging, and corneal

endothelial microscopy. A detailed family history was collected to analyze the correlation between genetic patterns and clinical phenotypes.

Results: The proband was a 39-year-old female presenting with right eye pain and blurred vision for 5 days. Ophthalmologic examination revealed typical manifestations of bilateral anterior segment dysgenesis: posterior embryotoxon, shallow anterior chamber, and angle dysgenesis. Intraocular pressure measurements showed 26mmHg in the right eye and 19mmHg in the left eye. Gonioscopy demonstrated peripheral anterior chamber angle adhesions with iris-like tissue bands extending from the peripheral iris to Schwalbe's line. OCT examination confirmed angle closure with adhesions in the right eye and a slit-like angle configuration in the left eye. Corneal endothelial cell counts were 1993cells/mm² in the right eye and 2870cells/mm² in the left eye. Family history analysis showed a maternal inheritance pattern consistent with autosomal dominant inheritance with high penetrance.

Conclusions: Axenfeld-Rieger syndrome is a rare autosomal dominant hereditary ocular disease characterized by anterior segment dysgenesis and associated glaucoma. The condition originates from neural crest cell developmental abnormalities during embryogenesis. Early recognition and timely intervention are crucial for preventing glaucoma and preserving visual function.

Berberine Ameliorate Inflammation and Apoptosis via Modulating PI3K/AKT/NFκB and MAPK Pathway on Dry Eye

First Author: Jiani LI

Purpose: To detect the effects and explore the potential mechanisms of BBR on DED.

Methods: Human corneal epithelial viability was assayed across BBR doses. Desiccating stress-induced murine dry eye received topical CSA, BBR, or vehicle for 7 days; tear secretion (phenol-red thread), Oregon-Green-dextran leakage, and PAS staining quantified ocular surface damage. Inflammation and apoptosis were assessed by qPCR/Western blot. Putative BBR targets were mined from public databases; PPI networks and GO/KEGG enrichment (STRING, Metascape, Cytoscape) identified hub genes and pathways. Molecular docking (Schrödinger) and visualization (PyMOL) supported binding predictions. PI3K/AKT/NF-κB and MAPK pathway activation was determined.

Results: The data revealed BBR could rescue impaired HCE under hyperosmotic conditions. In addition, BBR eye drops could ameliorate dry eye. And BBR eye drops suppressed the inflammatory factors and CD4+T cells infiltration in conjunctiva. Besides, BBR eye

drops protected ocular surface by avoiding the severe apoptosis and decreasing the level of MMP-3 and MMP-9. 148 common targets intersection between BBR and dry eye were found via network pharmacology analysis. Core proteins and core pathways were identified through PPI and GO&KEGG enrichment analysis. Molecular docking displayed excellent binding between BBR and those core targets. Finally, in vivo study verified that BBR eye drops had a therapeutic effect in dry eye by inhibiting PI3K/AKT/NFκB and MAPK pathways.

Conclusions: The research provided convincing evidence that BBR could be a candidate drug for dry eye.

Beyond Systemic Toxicity: A Rare Ocular Complication of Antibody-Drug Conjugate Therapy

First Author: Keli MAO

Co-Author(s): Man YU

Purpose: To establish an accurate diagnosis for an elderly female patient presenting with acute bilateral hypopyon.

Methods: Comprehensive medical history documentation was obtained. A detailed slit-lamp biomicroscopy examination was performed. In vivo confocal microscopy (IVCM) were used to characterize pathological features.

Results: A 63-year-old female presented with a 3-day history of bilateral foreign body sensation, redness, and blurred vision. The patient had undergone a resection for urothelial carcinoma six months prior to presentation, after which she began Antibody-Drug Conjugate (ADC) therapy 20 days before the onset of ocular symptoms. Slit-lamp examination showed conjunctival hyperemia and edema without discharge. Both corneas exhibited edema with well-demarcated central ulcers (right eye: 6×5 mm; left eye: 8×4 mm) and 1 mm hypopyon. Best-corrected visual acuity was 0.5. IVCM revealed increased Langerhans cells without fungal hyphae. A diagnosis of ADC-induced ocular surface complication was established. Following treatment with topical corticosteroids, deproteinized calf blood extract gel, and growth factor eye drops, the ulcers showed significant regression, and the hypopyon resolved completely.

Conclusions: ADC-related ocular complications primarily involve the corneal surface, with manifestations including conjunctivitis, reversible epithelial lesions, and ulceration. To our knowledge, this is the first reported case of ADC-associated severe ocular surface disease accompanied by hypopyon. Multidisciplinary coordination and standardized

management are essential for effective symptom control.

Bilateral Peripheral Ulcerative Keratitis With Positive Syphilis Serology: Four-Year Follow-Up After Combined Medical and Surgical Management

*First Author: Brigitta Marcia **BUDIARDJA***

*Co-Author(s): Yulia **AZIZA**, Lukman **EDWAR**, Rina La Distia **NORA**, Ratna **SITOMPUL**, Made **SUSIYANTI***

Purpose: Peripheral ulcerative keratitis (PUK) is an acute, sight-threatening corneal condition with diverse systemic associations. Syphilis is rarely implicated, and the relationship remains uncertain. This report presents a rare case of bilateral PUK in a patient with positive syphilis serology and long-term follow-up demonstrating favorable visual and structural outcomes after combined systemic and ocular treatment.

Methods: Single-patient observational case report with four-year follow-up.

Results: A 70-year-old man presented with five months of progressive bilateral redness, pain, and visual loss (visual acuity 0.5/60 in the right eye, hand movement in the left eye). Slit-lamp revealed peripheral thinning with edema, and the right eye developed iris prolapse within one week despite initial therapy. Systemic work-up was negative except for positive treponemal serology. Although this may represent a coincidental finding, systemic therapy with benzathine penicillin was given together with oral corticosteroids, methotrexate, and azathioprine. Sequential corneal patch grafting and amniotic membrane transplantation were performed in both eyes. At four years, visual acuity improved to 6/15 in the right eye and 6/12 in the left eye, with stable graft-host junctions and no recurrence. Literature remains sparse, and direct evidence of *Treponema pallidum* in corneal tissue has not been established.

Conclusions: Positive syphilis serology in PUK cases may be coincidental but should not be overlooked. Early recognition, comprehensive systemic evaluation, and pathogen-directed therapy combined with timely surgical intervention can help preserve vision and ocular integrity, even in severe cases. This case underscores the importance of considering syphilis in the differential diagnosis of bilateral or rapidly progressive PUK while acknowledging that causality remains unproven.

Bilateral Sequential Microsporidial Stromal Keratitis in an Immunocompetent Patient With Underlying Uveitis: A Case Report

*First Author: Rinrada **KREESANG***

*Co-Author(s): Weerapat **UDOMWONG***

Purpose: To report a case of bilateral sequential microsporidial stromal keratitis in an immunocompetent patient with chronic anterior uveitis and herpes keratouveitis.

Methods: Case report and literature review.

Results: A 66-year-old woman with chronic bilateral anterior uveitis and herpes keratouveitis in the left eye was referred for evaluation. Examination revealed bilateral keratic precipitates and central stromal haze in the left eye. Despite topical corticosteroids and systemic antivirals, the left cornea developed deep central stromal infiltration. Microsporidial stromal keratitis was suspected, and topical polyhexamethylene biguanide, voriconazole, and moxifloxacin were initiated. Due to poor clinical response, penetrating keratoplasty (PK) was performed, and histopathology confirmed microsporidia. The graft subsequently failed, and repeat PK was planned. Eighteen months later, the right eye developed central stromal infiltration. Corneal scraping confirmed microsporidial stromal keratitis. Intensive topical and systemic antifungal therapy was ineffective, necessitating therapeutic PK. Histopathology again demonstrated microsporidia. Post-operative recovery in the right eye was uneventful, and the graft remained clear. Predisposing factors in this patient included possible exposure to contaminated water or soil, long-term corticosteroid use, and chronic ocular inflammation.

Conclusions: Microsporidial stromal keratitis can occur sequentially in both eyes of immunocompetent patients with pre-existing ocular inflammatory disease. It should be considered in cases of chronic stromal keratitis unresponsive to conventional therapy. Early diagnosis and timely surgical intervention are essential for achieving a favorable outcome.

CLARITY Trial: 4-Week Interim Analysis of Chloroquine (0.03%), Lifitegrast (5%), and Cyclosporine (0.05%) in Moderate-Severe Dry Eye Disease

*First Author: Shweta **DHIMAN***

*Co-Author(s): Raj **KENIA**, Madhusmita **BEHERA**, Santosh **MAHAPATRA**, Anjalika **PARHI***

Purpose: To compare the short-term efficacy and safety of chloroquine 0.03%, lifitegrast 5%, and cyclosporine 0.05% eye drops as monotherapy in moderate-severe

dry eye disease (DED), focusing on tear film stability, symptoms, and ocular surface health.

Methods: The CLARITY trial (CTRI/2025/07/091185) is an ongoing, randomized, parallel-group, active-controlled, assessor-masked clinical study conducted at a single tertiary center in Odisha, India. Adults aged 18–70 years with OSDI >13, TBUT <10 s, and Schirmer's ≤10 mm without anesthesia were randomized (1:1:1) to chloroquine (four times daily), lifitegrast (twice daily), or cyclosporine (twice daily) for 12 weeks. Due to different approved dosing schedules, identical dosing could not be maintained; however, outcome assessors were masked to treatment allocation. The primary endpoints are change in TBUT and OSDI from baseline to week 12. This interim analysis includes patients completing the 4-week follow-up, assessing early change in TBUT, OSDI, Schirmer's test, and ocular surface staining.

Results: Of 225 planned participants, 48 have been enrolled; 11 (chloroquine: 3, lifitegrast: 4, cyclosporine: 4) have completed the 4-week follow-up. Baseline mean TBUT ranged 4–6 s across groups; mean OSDI ranged 18–28. At 4 weeks, mean TBUT improved by +2.0 s with chloroquine, +3.5 s with lifitegrast, and +2.5 s with cyclosporine. Mean OSDI decreased by –7 points, –9 points, and –8 points, respectively. All treatments were well tolerated; no serious adverse events occurred.

Conclusions: Early 4-week findings suggest all three agents improve tear stability and symptoms in moderate–severe DED, with lifitegrast showing the largest numerical gains so far. Longer follow-up and full cohort analysis will determine comparative efficacy and cost-effectiveness at 12 weeks.

Calotropis-Induced Ocular Toxicity

First Author: Mariya DOCTOR

Purpose: Outcome of Calotropis-induced ocular trauma.

Methods: Retrospective analysis based on an Electronic medical record search using the keywords Calotropis and ocular toxicity, where patients who presented to our institute with these keywords were included in the data analysis.

Results: Thirty-two patients were included, 17 females and 15 males, with a mean age of 46 years. Average duration of the exposure to calotropis was 3+/-10days. Decrease in vision and pain were the most common symptoms, while corneal edema was the most common sign. Eyewash was given along with topical steroids to most patients. Mean time for total recovery 7+/-2 days, and significant recovery in visual acuity was noted from LogMar 0.607 +/- 0.591 to LogMar 0.166 +/-0.434 at 1 month.

Conclusions: Calotropis is a perennial plant, used for curing various systemic ailments and also worshipping gods in many countries. It can cause corneal edema and toxic keratopathy if exposed to the ocular tissue. This can be easily resolved with topical steroids. Hence, awareness about Calotropis-induced ocular toxicity and differentiating it from viral stromal keratitis is important. Simple health education, like washing hands, avoiding contact, and rubbing of eyes while plucking the Calotropis flower, is important to prevent this kind of injury. Early intervention and prompt management can result in full recovery of corneal edema in a short period of time, and surgical intervention is seldom needed.

Case Report: Ocular Surface Squamous Neoplasia

First Author: Leesha SHRESTHA JOSHI

Purpose: To report clinical features and treatment outcome of five cases of Ocular Surface Squamous Neoplasia.

Methods: This case series presents 5 patients with isolated OSSN. Data collected included presenting signs and symptoms, including vision, anterior segment examination, medical and surgical outcomes, and signs and symptoms at the last post-treatment visit.

Results: Case 1 was a 25-year-old female who presented with an isolated reddish amoeboid corneal lesion, which was excised with alcohol assisted epitheliectomy with cryotherapy, and the mass was sent for biopsy. Case 2 was a 64-year-old male with a corneal lesion, which was completely excised, and cryotherapy was done, followed by topical steroid. However, the pterygium-like lesion recurred after a few months post-treatment. Case 3 was a 52-year-old male patient who presented with a corneal lesion, including conjunctiva, that was excised with cryotherapy. Case 4 was a 65-year-old male with a conjunctival mass, which was excised, followed by cryotherapy. Case 5 was a 55-year-old female with a conjunctival mass, which was also excised, followed by cryotherapy. All the excised mass was sent for biopsy, and the result was mild to moderate dysplasia.

Conclusions: Ocular Surface Squamous Neoplasia is a rare entity with few reported cases in the literature. In this case series, we report the management outcomes of combined surgical and medical therapy.

Abstract No.: 205129**Panel No.: CDE-0260****Characteristics of Ocular Demodicosis in Dry Eye Patients***First Author: Varissaranan AUERAREERAT**Co-Author(s): Raveewan CHOONTANOM, Pichaya CHUEPHANICH***Purpose:** To identify the characteristics of demodex blepharitis in patients with dry eye disease.**Methods:** This prospective, cross-sectional study investigated the characteristics of ocular demodicosis in 92 patients with dry eye disease. Participants completed the OSDI questionnaire and underwent a comprehensive eye examination. Ocular staining score assessment, Schirmer's test, meibography, and meibomian gland dysfunction (MGD) grading were conducted. Cylindrical dandruff was defined as the presence of scales ranging from clear to total coverage around the base of the eyelashes. Eyelash samples were collected and examined under a microscope by a single investigator to ensure consistency.**Results:** Of the total 92 patients, Demodex infestation was detected in 57 (61.96%), and Demodex blepharitis was present in 21 (22.83%). The Demodex blepharitis group had a significantly higher mean age compared to the non-Demodex blepharitis group ($p=0.001$). The presence of collarettes was strongly associated with blepharitis ($p<0.001$), with both total ($p=0.004$) and partial ($p=0.006$) eyelash coverage showing significant associations compared to no collarette. Moreover, collarette location on the upper eyelid was also strongly correlated with Demodex blepharitis ($p<0.001$).**Conclusions:** An increased number of collarettes, particularly on the upper eyelid, is the most frequently observed and significantly associated clinical sign of Demodex blepharitis in dry eye patients. This should be given particular attention in cases where Demodex infestation is suspected. Although there is a clear association between Demodex infestation and blepharitis, no significant association was found between Demodex and the severity of dry eye.**Abstract No.: 204330****Panel No.: CDE-0238****Clinical Course of a Case of Corneal Penetrating Bee Sting Injury***First Author: Benedicto Juan Enrique AGUILAR**Co-Author(s): Stricklyn CAINGLES-PAASA, Margarita ECHAVEZ-QUITOS, Shasta Grace TIRO***Purpose:** To present the clinical course of a patient with a penetrating bee sting injury who underwent emergency wound exploration and removal of the foreign body.**Methods:** Case report.**Results:** The patient was seen two hours post-injury. Visual acuity was counting fingers. Slit lamp examination showed a dark linear foreign body lodged in the patient's midperipheral 3 o'clock cornea with epithelial sloughing, and surrounding corneal inflammation, which precluded full examination of the anterior chamber and depth of the foreign body penetration. Generalized grade 4 corneal edema with microcysts was also noted. Anterior Segment Optical Coherence Tomography showed penetration of the foreign body into the anterior chamber. The patient underwent removal of the foreign body with suture closure of the wound and intracameral antibiotics. Topical nonsteroidal anti-inflammatory and antibiotics were given immediately post-operation, which showed promising resolution of inflammation, thus it was followed by cautious initiation of topical steroid. The patient had a gradual recovery of vision to LogMAR 0.1 at two months post-surgery, with a persistent corneal scar around the point of entry.**Conclusions:** Corneal penetrating bee sting injury can lead to rapid loss of vision. Immediate surgical removal with subsequent aggressive anti-inflammatory treatment can resolve corneal inflammation and restore vision; however, persistent endothelial damage may be a consequence.**Abstract No.: 201793****Panel No.: CDE-0193****Clinical Features and Antiviral Response in Epstein-Barr Virus-Associated Endotheliitis Patients: A 12-Year Retrospective Case Series Study***First Author: Fok Chak IENG**Co-Author(s): Hung-chi CHEN, Yueh-ling CHEN, Ching-hsi HSIAO, Yih-shiou HWANG***Purpose:** To describe the clinical characteristics and outcomes of polymerase chain reaction (PCR)-confirmed Epstein-Barr virus (EBV) corneal endotheliitis and to compare them with Cytomegalovirus (CMV) corneal endotheliitis.**Methods:** We retrospectively reviewed 14 eyes of 14 patients with PCR-confirmed EBV endotheliitis managed at a tertiary referral center. Demographic data, best-corrected visual acuity (BCVA), intraocular pressure (IOP), anterior segment findings, endothelial cell density (ECD), and treatment response were analyzed. Aqueous humor samples from cataract patients served as negative controls.**Results:** The mean age was 60.9 ± 15.7 years; 71% were male. Mean follow-up was 40.9 ± 29.6 months. All patients presented with corneal edema and keratic precipitates, with anterior chamber inflammation ranging from trace to 2+. The mean BCVA at baseline was 1.68 ± 1.25 logMAR and mean IOP 18.0 ± 11.1 mmHg; 29% had prior keratoplasty and 14% prior glaucoma surgery. Antiviral regimens included

famciclovir, acyclovir with intravitreal ganciclovir, topical ganciclovir, or valganciclovir. Despite transient clinical improvement, most patients showed progressive endothelial cell loss. Longitudinal ECD analysis revealed a steady decline, with several eyes ultimately requiring keratoplasty. Control aqueous samples from cataract patients were uniformly negative for EBV DNA.

Conclusions: EBV is an under-recognized cause of corneal endotheliitis, often mimicking CMV infection but demonstrating a more relapsing and refractory course. Even with antiviral and corticosteroid therapy, endothelial deterioration frequently progresses. Routine inclusion of EBV in aqueous PCR testing is warranted in atypical or recurrent cases. Development of EBV-specific antiviral strategies is needed to improve long-term outcomes.

Panel No.: CDE-0302

Clinical Profile and Indications of the First 125 Patients Who Underwent Corneal Transplants at a New Tertiary Care Eye Center in a Metropolitan City in Western India

First Author: Somasheila MURTHY

Co-Author(s): Prajakta DANDEKAR, Supriya SHARMA

Purpose: To analyze the demographic profile and indications of patients who underwent keratoplasties over a period of 18 months at a newly established tertiary eye care centre in Mumbai.

Methods: Retrospective observational study. Details were obtained from the hospital electronic medical records. All patients who underwent partial or full-thickness keratoplasty, including corneal patch grafts, were included, with a minimum period of follow-up of 6 months. Success for grafts for an optical indication was visual improvement of 20/40 or better, and for grafts for a therapeutic indication was infection control. All patients were followed up for at least six months.

Results: A total of 127 eyes of 125 new patients underwent surgery during the study period. Male: female ratio was 1.6, and the majority of the patients (97, 77.6%) hailed from the same city. The majority (92, 72%) were from poorer socio-economic strata. The commonest indication for surgery was: pseudophakic bullous keratopathy (30%), followed by failed graft (18%), corneal scar (11%), and microbial keratitis (10%). Keratoconus and other indications comprised 3%. When combining all indications, visual outcomes were good (<20/60) in 42%, moderate (20/100-20/200) in 24% and poor vision (<20/400 -PL) in 34%.

Conclusions: This is the first study to report the outcomes of corneal transplant in this metropolitan city. Males were almost twice as likely to get surgery, and a large majority of our patients had limited paying ability. Overall, the results for optical indications

showed 90% success at 6 months follow-up. In one year, the hospital was able to provide care for over 100 patients, and this study is an indicator of existing gaps in the management of corneal blindness.

Comparative Correlation Analysis of Dry Eye Screening Methods With Self-Reported Symptoms in Drug Users

First Author: Kin Yip YIN

Co-Author(s): Yan Hei Yannis CHAN, Kelvin Kl CHONG, Kenneth Kh LAI, Calvin Cp PANG, Clement Cy THAM

Purpose: To compare the correlation between measurements of dry eye screening tools and self-reported ocular symptoms.

Methods: Fifty-eight (36 males, 22 females) regular drug users within the past 24 months were recruited under the project supported by the Beat Drug Fund (BDF210067). Dry eye assessments were conducted on the right eye using OCULUS Keratograph 5M, TearScience LipiView II Interferometer, and Tearlab Osmolarity System. Metrics obtained were correlated with the Ocular Surface Disease Index (OSDI) questionnaire.

Results: In Methamphetamine users, Tear osmolarity showed a stronger positive correlation with the composite OSDI score ($r = 0.254$), while NIKBUT had a weaker positive correlation ($r = 0.004$). In polysubstance (Cocaine and Methamphetamine) users, a stronger negative correlation existed between Tear osmolarity and OSDI score ($r = -0.222$) when compared with that between NIKBUT and OSDI score ($r = -0.144$). The stronger correlations shown in both directions potentially hint that tear osmolarity might be a more sensitive measure in screening drug abusers with dry eye symptoms compared to NIKBUT. Interestingly, Lipid Layer Thickness showed a positive correlation with the OSDI score in both groups ($r = 0.298, 0.107$, respectively), implying that a thicker tear film lipid layer might abnormally cause more discomfort in patients.

Conclusions: Though the current statistics support that tear osmolarity might be more sensitive in screening dry eye patients among drug addicts, significant correlations were not found between the metrics and reported symptoms. Hence, post-screening investigations are necessary.

Abstract No.: 204375**Panel No.: CDE-0240**

Comparative Evaluation of CORVIS ST Imaging of Post-Full-Thickness and Lamellar Keratoplasty Corneas

*First Author: Tapashree GHOSH**Co-Author(s): Vanathi MURUGESAN*

Purpose: To compare corneal biomechanics by CORVIS ST in penetrating keratoplasty (PK) & Deep Anterior Lamellar Keratoplasty (DALK) grafts.

Methods: A retrospective cross-sectional observational study of CORVIS ST data was done. Comparative evaluation of 17 CORVIS-ST parameters [b-IOP, AT1, HCT, 2nd AT2, DA, WD, HCR, VELin, VELout, DA ratio, IR, IVR, SSI, SP-A1, ARth, CBI, TBI] between corneas with full-thickness & anterior lamellar grafts was done.

Results: Data of 59 PK (mean age 38.55±16.37 years) & 52 DALK (mean age 23.03±8.99 years) corneas over a mean follow-up of 2.9±3.60 years (3 months-16 years)[PK - 3.53±4.56; DALK 2.38±2.44 years] was analysed. Median CBI of PK & DALK corneas was 0.78 & 0.93 (0.001) respectively. 5 CORVIS ST parameters (median values) were significantly altered [HCR 7.14 & 6.24 (0.009); VELout 0.28 & 0.32(0.043), IR 8.15 & 9.5 (0.001), SSI 0.98 & 0.85 (0.010), ARth 319.75 & 193.95 (0.001).

Conclusions: CORVIS ST parameters were reduced in all keratoplasty corneas; DALK corneas had a significantly lesser biomechanical strength as compared to full thickness grafts.

Abstract No.: 206964**Panel No.: CDE-0290**

Comparison of Culture Positivity of Corneal Scraping With Half Corneal Tissue for Patients Undergoing Therapeutic Keratoplasty

*First Author: Sujata DAS**Co-Author(s): Himansu BEHERA, Nisha RAHUL*

Purpose: To compare the culture positivity of corneal scraping with half-corneal tissue (HCT) for patients undergoing therapeutic penetrating keratoplasty (TPK) and the role of HCT culture after TPK for the management of fungal keratitis.

Methods: This hospital-based retrospective observational study performed at a tertiary eye care centre in eastern India from September 2023 to August 2024 included 73 cases. This is a comparison of microbiology records of culture positivity of fungal ulcer that underwent diagnostic scraping, with culture positivity of half-corneal tissue in patients undergoing therapeutic keratoplasty using an electronic medical record system.

Results: Out of 73 patients, fungus was found on direct smear examination in 64/73 (87.67%) corneal scraping samples. Fungus was recovered in culture from scraping

in 49/73 (67.12%), mixed organisms in 7/73 (9.58%). Half-corneal tissue sent for culture after therapeutic keratoplasty showed fungus in 19/73 (26.02%) and no organism in 54/73 (73.97%) samples. Half-corneal tissue sent for histopathological evaluation revealed fungal filaments in fifty-nine (80.82%) samples.

Conclusions: This study shows less culture positivity of half-corneal tissue post therapeutic keratoplasty in patients compared with culture from cornea scraping.

Abstract No.: 206194**Panel No.: CDE-0277**

Comparison of the NEI-VFQ and OSDI Questionnaires in Drug Users With Dry Eye

*First Author: Sze Wing LEE**Co-Author(s): Kelvin Kl CHONG, Kenneth Kh LAI, Calvin Cp PANG, Clement Cy THAM*

Purpose: Aim to explore the relationship between NEI-VFQ and OSDI questionnaires in drug users with dry eye.

Methods: Twenty-six regular drug users (26 worst eyes) within past two years were recruited under the project supported by Beat Drug Fund (BDF210067), completed objective dry eye assessments including fluorescein tear breakup time (FBUT), Schirmer's test (ST), lipid layer thickness (LLT) by TearScience LipiView II Interferometer, and non-invasive keratography break-up time (NIK BUT) from OCULUS Keratograph 5M. Ocular Surface Disease Index (OSDI) and the 25-item National Eye Institute Vision Functioning Questionnaire (NEI-VFQ) measuring subjective symptoms were also correlated.

Results: The mean age of subjects was 41.7±11.8, and consisted of 15 males and 11 females. Correlation between OSDI score and objective ocular parameters- NIK BUT ($p=-0.328$) was the modest among four parameters and not statistically significant. Moderate correlations were observed between NEI-VFQ score and ocular parameters, with a mild significance for FBUT ($r=-0.397$, $p=0.046$). The strongest association of the two questionnaires were composite score of OSDI with overall NEI-VFQ score ($r=-0.653$, $p<.001$); and OSDI overall score showed significant negative correlations with ocular pain, distance activities, social functioning, mental health, dependency, color vision and peripheral vision ($p=-0.52$, -0.55 , -0.55 , -0.63 , -0.73 , -0.55 , and -0.67 respectively).

Conclusions: Correlations between objective measures of dry eye and its impact were mild. Strong relationship between NEI-VFQ and OSDI have been shown, therefore these two questionnaires have similar ability in measuring the impact of drug usage on dry eye.

Comprehensive Evaluation of Large Language Models for Dry Eye Knowledge Question-Answering Tasks

First Author: Xinyuan DU

Co-Author(s): Wei LI, Zugu LIU, Shaopan WANG, Yuqian WANG

Purpose: To compare the accuracy and completeness of state-of-the-art large language models (LLMs) in answering questions related to dry eye disease (DED).

Methods: Twenty questions encompassing the definition, epidemiology, symptoms and signs, examination methods, diagnosis, treatment, and prevention of DED were selected. Each question was individually input into six LLMs: GPT-4o, GPT-o1, GPT-o3, Deepseek-V3, Deepseek-R1, and Gmini-2.0. The responses generated by these models were de-identified and independently assessed by three expert ocular surface specialists. Each response was evaluated along two dimensions, accuracy and completeness, using 10-point and 6-point Likert scales, respectively. Statistical analyses were conducted using nonparametric methods, including the Kruskal–Wallis and Mann–Whitney U tests.

Results: Deepseek-R1 consistently achieved the highest scores across both dimensions, with significantly better accuracy and completeness than the other five models ($P < 0.001$). GPT-4o demonstrated the lowest performance in accuracy, with considerable variability across raters and question sets. Expert-level differences were also observed: senior ophthalmologists tended to favor medically rigorous and structured responses, while junior physicians were more influenced by fluent and intuitive language.

Conclusions: This study thoroughly and comprehensively evaluated the accuracy and completeness of responses provided by state-of-the-art LLMs in the context of DED knowledge. Despite advancements, inaccuracies persist even among the most advanced LLMs, indicating that specialized, domain-specific LLMs may represent a more appropriate approach for disseminating expert knowledge within specialized medical fields.

Comprehensive Immune Landscape in Allergic Conjunctivitis: Insights From Mendelian Randomization Analysis

First Author: Tianyi ZHOU

Purpose: Current understanding of the immune landscape underlying allergic conjunctivitis (AC) remains rather limited. We investigated the potential association between circulating immunophenotypes

and AC using Mendelian randomization (MR) methodology.

Methods: Based on genome-wide association study (GWAS) summary-level statistics, a 2-sample MR was employed to analyze the bidirectional causal relationships between 731 circulating immunophenotypes and AC risk.

Results: A total of 33 genetically predicted immunophenotypes were significantly associated with AC risk. A protective effect of 18 immunophenotypes against AC was found, such as CD3 on CD39+CD8br (inverse variance weighted [IVW] odds ratio [OR] = 0.936, 95% confidence interval [CI]: 0.925–0.985, $p = 0.003$) and CD25 on CD28+CD4+ (IVW OR = 0.921, 95% CI: 0.863–0.983, $p = 0.013$). Conversely, 15 immunophenotypes were found to be significantly associated with AC risk, such as CD25 on IgD–CD38dim (IVW OR = 1.042, 95% CI: 1.012–1.073, $p = 0.006$). Reverse MR based on these 33 genetically predicted immunophenotypes suggested that AC also had a significant influence on four circulating immune cells, including CD33–HLA DR–AC (IVW OR = 1.187, 95% CI: 1.034–1.362, $p = 0.015$), CD3 on CD39+CD8br (IVW OR = 0.876, 95% CI: 0.779–0.985, $p = 0.027$), HLA DR on CD14+monocyte (IVW OR = 0.831, 95% CI: 0.725–0.953, $p = 0.008$), and CD39 on CD39+secreting Treg (IVW OR = 1.123, 95% CI: 1.002–1.259, $p = 0.046$).

Conclusions: Our study highlights the intricate association between immune cells and AC, providing a valuable basis for future mechanistic and therapeutic studies from an immunological perspective.

Contact...Lens for Help: Game Changer for the Varying Irregular Cornea

First Author: Yash GALA

Co-Author(s): Pavan LOHIYA

Purpose: To demonstrate the critical role of specialized contact lens designs in the visual and functional rehabilitation of patients with complex corneal irregularities stemming from trauma, previous refractive surgeries, and their complications.

Methods: Case 1 - 44/Y old male s/p traumatic corneal tear repair and subsequent lens extraction in LE, CDVA (3/60) with severe photophobia due to a large, irregular pupil. Case 2 - 42/Y old male with a history of RK and LASIK, presenting with acute corneal hydrops in LE, CDVA 1/60, Dense epithelial-deep stromal edema along RK cuts, along with irregular DM noted on ASOCT. Case 3 - 69Y/M one-eyed came with h/o grade 4 pterygium excision with a patch graft with PCIOL, CDVA 2.5M in RE, a dense demarcation scarred line along the visual axis bisecting the cornea was noted.

Results: Case 1 - Piggyback lens system(a soft prosthetic lens with a 4mm pupil paired with a Rose K rigid lens)

successfully improved CDVA to 6/12 with a dramatic reduction of the patient's debilitating photophobia and glare. Case 2 - Acute episode managed by air descemetopexy & topical steroids led to the complete resolution of corneal edema. Subsequent fitting with a scleral lens successfully rehabilitated CDVA to 6/9p, overcoming the irregular astigmatism caused by ectasia. Case 3 - Corneal-scleral lens with appropriate size and fitting parameters improved CDVA to 6/18P.

Conclusions: Specialized CL (including scleral, prosthetic, and piggyback systems) are indispensable tools for visual rehabilitation in eyes with complex corneal surface irregularities. They effectively correct irregular astigmatism and manage associated symptoms like photophobia, often serving as the definitive treatment after surgical correction of acute complications. A tailored, patient-specific approach is essential for optimal functional and quality-of-life outcomes.

Corneal Globular Cells and Their Association With the Ocular Surface in Dry Eye Disease and Diabetes Mellitus

First Author: Haotian LIAO

Co-Author(s): Isabelle Xin Yu LEE, Chang LIU, Yu-chi LIU, Louis TONG, Mingyi YU

Purpose: To characterize corneal globular cells (GC) and dendritic cells (DC) in diabetes mellitus (DM), dry eye disease (DED), and healthy subjects, and investigate the relationship between GCs, DCs, and ocular surface health.

Methods: This retrospective study included 452 eyes from 320 subjects, comprising 231 DM, 52 DED, and 37 healthy subjects. In-vivo confocal microscopy was used to image GCs and DCs. Cell parameters, including cell count, density, area, elongation, and length, were quantified. Ocular surface assessment included corneal sensitivity, tear break-up time (TBUT), Schirmer test, and corneal and ocular surface staining.

Results: The DED group had significantly higher GC count than controls ($p=0.033$). DED patients also had significantly lower DC elongation than DM patients ($p=0.036$), suggesting more mature DC activity. Significant and positive correlations were found between DC count and GC count, area, elongation, and length (all $p<0.05$). Significant inverse correlations were found between DC elongation and GC count, density, and elongation (all $p<0.05$). DC length was negatively correlated with GC density ($p=0.027$). Linear mixed model analysis showed that higher GC count was significantly associated with lower TBUT ($p=0.047$). Multivariable logistic regression demonstrated that GC count was significantly associated with TBUT<10 seconds ($p=0.015$). GC count >15 per IVC frame

were 2.51-times more likely to have TBUT <10 seconds (OR=2.51, 95% CI, 1.12 to 5.26, $p=0.015$).

Conclusions: Corneal GCs were increased in DED and associated with tear film instability. It may serve as an imaging indicator for ocular surface health.

Correlation Between Serum Autoantibodies and Severity of Dry Eye Disease in Sjögren's Syndrome Patients: A Systematic Review and Meta-Analysis

First Author: Siu Ting FU

Co-Author(s): Yan Yu Julia CHAN, Wing Sze Vanissa CHOW

Purpose: To investigate the correlation between serum antibody positivity and dry eye disease severity in patients with Sjögren's syndrome.

Methods: Observational studies published between 2000 and 2025 in PubMed, Embase, and Scopus were systematically reviewed. Eligible studies reported correlations (r) or odds ratios (ORs) between antinuclear antibody (ANA), rheumatoid factor (RF), anti-SS-A/Ro, and anti-SS-B/La and dry eye outcomes, including Ocular Surface Staining (OSS), Schirmer's test, and Tear Break-Up Time (TBUT). ORs were converted into correlation coefficients using the logoddsratio to Cohen's d method and then to r . Fisher's z transformed correlations were pooled using random effects models with restricted maximum likelihood estimation. Heterogeneity was assessed with Q and I^2 statistics.

Results: Nine studies, including 2,870 patients with Sjögren's syndrome, were analysed. Anti-Ro/SSA was modestly correlated with worse OSS ($r = 0.17$, 95% CI 0.12 to 0.21), shorter TBUT ($r = -0.27$, 95% CI -0.40 to -0.12), and lower Schirmer's test scores ($r = -0.15$, 95% CI -0.31 to 0.02). Anti-La/SSB displayed weak and inconsistent correlations across ocular measures. RF was associated with shorter TBUT ($r = -0.18$, 95% CI -0.30 to -0.06), while ANA was negatively correlated with both Schirmer's ($r = -0.15$, 95% CI -0.29 to -0.01) and TBUT ($r = -0.16$, 95% CI -0.30 to -0.02). All correlations were weak in magnitude.

Conclusions: Anti-Ro/SSA, RF, and ANA are weakly but significantly correlated with more severe ocular surface damage and tear film instability in patients with Sjögren's-related dry eye disease, suggesting the possible use of antibody profiling for risk stratification of dry eye severity in Sjögren's syndrome patients.

Panel No.: CDE-0192

Correlation Between Symptom Burden and Productivity in Patients with Hay Fever: A Digital Cross-Sectional Study

*First Author: Weicong **PENG***

*Co-Author(s): Kenta **FUJIO**, Takenori **INOMATA**, Ken **NAGINO**, Shintaro **NAKAO***

Purpose: To examine how specific nasal and non-nasal symptoms and demographic factors relate to work productivity, activity impairment, and quality of life (QoL) in patients with hay fever in Japan.

Methods: In this cross-sectional study, participants with hay fever who used the AllerSearch smartphone application between February 2018 and May 2025 were enrolled. Symptoms were evaluated by nasal (NSS), non-nasal (NNSS), and total symptom scores (TSS); QoL by JACQLQ. Productivity impairment, including absenteeism (work time missed), presenteeism (reduced on-the-job effectiveness), total productivity loss, and activity impairment, was assessed via WPAI:AS. Spearman correlation and multivariable regressions were used to evaluate and visualize the association between symptoms and productivity.

Results: Among 3,351 participants with hay fever (mean age 40.1 ± 11.7 years; 48.7% female), NSS and NNSS were strongly correlated (Spearman coefficient, all $P < 0.001$) with presenteeism (NSS 0.565; NNSS 0.477), total productivity loss (0.560; 0.474), activity impairment (0.572; 0.496), and QoL (0.611; 0.534). Rhinorrhea showed the highest correlation with productivity loss (presenteeism 0.469; productivity loss 0.463; activity impairment 0.471). In multivariable regression analysis (regression coefficient [95% CI]), nasal congestion predicted QoL worsening (2.374 [1.748–2.999], $P < 0.001$) but not productivity loss. Non-nasal symptoms had stronger impacts on both productivity loss and QoL than nasal symptoms. Preventive measures were linked to reduced presenteeism and activity impairment.

Conclusions: Nasal and non-nasal symptoms drive productivity and QoL impairment in the working population with hay fever in Japan. Nasal congestion predominantly worsens QoL, whereas non-nasal symptoms more strongly affect work performance.

Abstract No.: 201732

Panel No.: CDE-0197

Cross-Sectional Study on the Quality of Life of Patients With Recurrent Ocular Herpes Simplex Virus Disease

*First Author: Julia **CHAN***

Purpose: Herpes Simplex Virus (HSV) is the most common eye disease-causing virus. The frequent relapse leads to corneal opacification, causing permanent visual loss. The psychological impact

of recurrent ocular HSV disease has been under-reported in the literature. The study aims to report the psychological impact and the effect on their daily activities and living in patients with the condition.

Methods: Thirty-six Chinese patients with recurrent ocular HSV disease underwent face-to-face interviews for the National Eye Institute Visual Functioning Questionnaire-28R (NEI VFQ-28R) and Ocular Surface Disease Quality of Life (OSD-QoL) questionnaire delivered by a single research assistant between February and August 2025.

Results: Subjects interviewed were 56% male ($n=20$), with a mean age of 67.06 ± 13.3 years (range: 18–89). 19.4% ($n=7$) of patients were at the active phase, while the remaining were in remission. For the VFQ-28R Questionnaire, the mean VFQ28R composite score was 83.01 ± 19.03 , with a general vision score of 53.18 ± 20.15 . Components with worse responses are near activity (71.76 ± 30.23) and mental health (73.79 ± 23.09), while social functioning (91.67 ± 18.18) and colour vision (90.44 ± 20.23) were relatively unaffected. For the OSD-QoL Questionnaire, the mean scores for most of the components were low, especially for “Perception of the Others” ($67.14 \pm 18.21\%$) and “Fear of the future” ($56.24 \pm 29.13\%$), reflecting that uncertainty of disease prognosis had caused a significant burden in the subjects.

Conclusions: Due to the characteristic relapsing nature of the condition, Recurrent Ocular HSV Disease has a significant impact on patients’ quality of life and activities of daily living.

Panel No.: CDE-0251

Development of a Translational Model to Explore the Effect of Surface Topography on Corneal Epithelial Wound Healing

*First Author: Isabel **COWLISHAW***

*Co-Author(s): Richard **CLARKE**, Trevor **SHERWIN***

Purpose: Delayed re-epithelialisation over collagen-based artificial corneal implants has been implicated in the loss of transparency. Interactions of corneal epithelial cells with basement membrane topography may modulate wound healing. In silico modelling offers an inexpensive approach to assess material design iterations. However, predictive accuracy is dependent on the availability of physiologically representative data. A translatable in vitro model was established to evaluate the macro-level trends of void closure and inform in silico model design.

Methods: An in vitro circular exclusion assay was developed with spontaneously immortalised human corneal epithelial cells (HCE-S) cultured outside cylindrical stainless-steel barriers. Polystyrene inserts with 5 μm height and width ridges in a 5 mm diameter radial pattern were fabricated via photolithography.

Hydrophilicity was induced by oxygen plasma treatment and polyvinylpyrrolidone (PVP) coating. Controls included unpatterned inserts and both collagen-coated and untreated tissue culture plastic (TCP). Time-lapse imaging at one-hour intervals on the Nikon BioStation captured void closure over two weeks ($n=3$ for all interventions).

Results: Void area on untreated TCP exhibited a distinct lag-phase for ~24 hours following barrier removal, with closure between days 5-7. Closure on collagen-coated TCP occurred within 4-5 days. PVP-coated inserts did not exhibit a lag phase and closed by day 4 for unpatterned and days 6-7 for patterned inserts. Ridges appeared to direct leading cell migration without accelerating closure.

Conclusions: HCE-S demonstrated comparable hole-closing behaviour on patterned inserts and untreated TCP. The complexity of cell behaviour during wound healing highlights the limitations of simplified computational models in capturing biological variability.

Diagnostic Accuracy of Rapid Immunoassay-Based Point-of-Care Tests for Adenoviral Conjunctivitis: A Systematic Review and Meta-Analysis

First Author: Christina WUNARDI

Co-Author(s): Muhammad ALFATIH, Alfiani Zukhruf Fitri RIFA'I

Purpose: To evaluate the diagnostic accuracy of rapid immunoassay-based point-of-care (POC) tests for adenoviral conjunctivitis compared with polymerase chain reaction (PCR) or adenoviral culture.

Methods: Five electronic databases were searched from inception to September 2025. Eligible studies assessed immunoassay-based POC tests against PCR or culture as the reference standard. A systematic review and bivariate random-effects meta-analysis were conducted. Pooled sensitivity, specificity, likelihood ratios, diagnostic odds ratio (DOR), and the summary receiver operating characteristic (SROC) curve with area under the curve (AUC) were calculated. Risk of bias was assessed with QUADAS-2, and between-study heterogeneity was quantified with I^2 .

Results: Nine studies (910 eyes) were included. Pooled sensitivity was 75.0% (95% CI: 56.1–87.5) and specificity was 92.1% (95% CI: 87.0–95.4). The positive likelihood ratio was 9.7 (95% CI: 5.8–15.4), negative likelihood ratio 0.3 (95% CI: 0.1–0.5), and pooled DOR 38.4 (95% CI: 15.3–80.4). The SROC analysis yielded an AUC of 0.93 (95% CI: 0.86–0.94), confirmed by bootstrap validation. Between-study heterogeneity was low to moderate (I^2 : 8–13%). Most studies were judged at low risk of bias.

Conclusions: Rapid immunoassay-based POC tests demonstrate high specificity and good sensitivity compared with PCR or culture, with excellent diagnostic accuracy. They represent a reliable tool for diagnosing adenoviral conjunctivitis and can support more precise clinical decision-making while reducing unnecessary antibiotic use.

Dome-Shaped Protrusions on Descemet's Membrane in Bullous Keratopathy: Preliminary Histopathological Observations

First Author: Naruki HIGASHISE

Co-Author(s): Takahiko HAYASHI, Noriko KOIZUMI, Sayaka NISHIHATA, Naoki OKUMURA, Satoru YAMAGAMI

Purpose: In advanced bullous keratopathy (BK), structural alterations of Descemet's membrane (DM) are sometimes observed, but their details remain unclear. Intracellular dark endothelial spots (IDESs) are dark lesions detected by specular microscopy and have been regarded as one of the clinical indicators of corneal endothelial dysfunction. However, no histopathological correlate of IDES has yet been established.

Methods: We investigated two patients with severe BK who underwent endothelial keratoplasty (EK): an 88-year-old male with a history of multiple intraocular surgeries, and a 77-year-old male following trabeculectomy. During EK, DM specimens were excised, and corneal endothelial cells were removed by gentle water washing. The isolated DM was then examined using phase-contrast microscopy and scanning electron microscopy (SEM).

Results: Phase-contrast microscopy revealed dome-shaped lesions on the DM surface that differed morphologically from guttae typically seen in Fuchs endothelial corneal dystrophy. It was not possible to determine whether these represented elevations or depressions on phase-contrast images alone. SEM analysis confirmed that these structures were true protrusions extending outward from DM.

Conclusions: This preliminary observation highlights the presence of previously unrecognized dome-shaped protrusions on DM in patients with advanced BK. Although we cannot definitively conclude whether these lesions correspond to IDESs observed on specular microscopy, the morphological similarity raises this intriguing possibility. Further investigation with larger cohorts is warranted to clarify the nature, clinical significance, and potential relationship of these protrusions to IDES.

Donor-Transmitted Infectious Keratitis and Endophthalmitis Following DSAEK: Clinical Features, Management, and Outcomes

First Author: Somasheila MURTHY

Co-Author(s): Vaibhav NAGPAL, Madhu RAI

Purpose: Transmission of infection from donor tissue during corneal transplantation is rare, however, due to the sequestration of infection in a closed space, these cases can be difficult to manage. Medical management alone may be ineffective due to inadequate penetration. Repeat surgery is often indicated in order to avoid unchecked spread of the infection, which can even lead to endophthalmitis. We report the clinical features, management, and outcomes in three patients who developed donor-related ocular infections at our center.

Methods: Retrospective case series.

Results: Three patients presented with post- DSAEK infection. The first two presented on day one and day five with fulminant infection due to multi-drug-resistant gram-negative organisms and the third patient had an indolent course, presenting one month after the surgery with candida infection. All three patients underwent surgical intervention, which included therapeutic keratoplasty and vitrectomy in the first and third cases and primary evisceration in the second case. The third case subsequently underwent evisceration too. A good outcome was obtained only in the first case, which could be correlated with early presentation.

Conclusions: Lamellar procedures carry a higher risk of donor contamination due to loss of the cold chain during tissue processing, such as pre-cut. In our series, acute presentation correlated with bacterial and delayed with fungal etiology, similar to that reported in literature. In addition, multidrug-resistant organisms suggest hospital-based contamination. Delayed identification or presentation carried a very poor prognosis. We recommend immediate surgical intervention as soon as the infection is identified, as medical therapy is unlikely to be effective.

Dry Eye Prevalence and Associated Factors Among School-Age Children in Yingjisha County, Kashgar Prefecture, Xinjiang, China

First Author: Nuan ZHANG

Co-Author(s): Lingyi LIANG

Purpose: To investigate the prevalence and risk factors of dry eye disease (DED) among schoolchildren in Yingjisha County, Kashgar, Xinjiang and to provide an evidence base for prevention and control strategies.

Methods: This cross-sectional study was conducted from May to June 2024 at Yingjisha County No. 3 Middle School and Mangxin Central Primary School. A total of 3,305 schoolchildren completed the questionnaire, and 557 were randomly selected for ocular surface examinations. Tear meniscus height and non-invasive tear break-up time were measured using the Keratograph 5M. DED diagnosis was based on the Dry Eye WorkShop II criteria published by Tear Film & Ocular Surface Society. Multivariate logistic regression was used to assess associated risk factors.

Results: Among the 557 examined children, the prevalence of DED was 16.88% (94/557). No significant difference was found between genders ($p = 0.81$). DED prevalence increased with age, showing a significant linear trend. Children with refractive errors in either eye had a significantly higher prevalence of DED (29.05% vs. 12.47%, $p < 0.001$). Logistic regression identified age ($OR = 1.21$) and refractive error ($OR = 2.72$) as risk factors. No significant associations were found for gender, Body Mass Index, axial length of the right eye, or parental myopia.

Conclusions: The prevalence of DED among school-age children in Yingjisha County is comparable to, or slightly lower than, the national average. Age and refractive error significantly increase the risk of DED. More attention should be paid to refractive status in children to protect ocular surface health and implement early preventive measures.

Abstract No.: 201986

Early Transcriptomic and Pathologic Changes of Col8a2 Mutant Fuchs Endothelial Corneal Dystrophy

First Author: Xintian ZHAO

Purpose: To characterize early transcriptomic and pathologic changes in Fuchs endothelial corneal dystrophy (FECD) using the Col8a2 Q455K/Q455K mutant mouse model.

Methods: Mutant mice were classified into an early stage (≤ 2 months) and a late stage (≥ 8 months) according to corneal endothelial morphology assessed by slit-lamp, OCT, and confocal microscopy. Corneal endothelial cells from early- and late-stage mutants, together with age-matched wild-type controls, were subjected to RNA sequencing, followed by validation with qPCR and immunofluorescence staining.

Results: No apparent corneal abnormalities were observed for 2 months, whereas endothelial alterations and stromal edema emerged after 4 months and progressively worsened with age. Despite the absence of early morphological changes, transcriptomic analysis revealed 221 upregulated and 55 downregulated genes in early-stage mutants compared with controls; these transcriptomic changes became more pronounced

at the late stage. Differentially expressed genes were enriched in extracellular matrix remodeling (Lgals3, Timp1, Mmp3), endoplasmic reticulum stress (Hspa5, Dnajb9, Atf3), and early immune activation (Icam1, Bpifb1, C1q). These molecular alterations were further validated at both the RNA and protein levels.

Conclusions: The Col8a2 Q455K/Q455K mutant model exhibits extracellular matrix remodeling, endoplasmic reticulum stress, and immune activation in the corneal endothelium before overt corneal pathology, suggesting potential early biomarkers and therapeutic targets for FECD.

Panel No.: CDE-0274

Effect of Alcohol Consumption on the Risks of Dry Eye Disease: A Systematic Review

First Author: Hei Ching **CHEUNG**

Co-Author(s): Kam Lung **CHONG**, Kai Hei **LAI**, Chi Pui Calvin **PANG**, Clement Chee Yung **THAM**, Tate **WAI**

Purpose: To identify the association between alcohol consumption and risks of Dry Eye Disease (DED).

Methods: Articles were screened from PubMed, ScienceDirect, and Google Scholar. Twelve studies and three meta-analyses (2000-2025) involving 92,700 subjects globally were included. Studies included acute alcohol administration (3) and habitual alcohol drinkers of different degrees vs non-drinkers (9). Participants either measured breath alcohol concentration values (BrAC) (3) or reported drinking habits through questionnaires (9). Indicators of DED and its severity included self-reported questionnaires (including SPEED), OSDI, tear evaporation and blink rate, tear lipid, TBUT, Schirmer's test, PRT tear test, and visual analogue scale (VAS) evaluation.

Results: The majority of ten articles presented a positive association between alcohol use and risk or prevalence of DED. One of which reported that alcohol consumption caused higher OSDI scores ($\beta = -0.15$, $t = -3.21$, $p = 0.001$). With machine learning prediction, alcohol drinking is suggested to be a heavily weighted predictor which negatively affect meibum quality, SPEED score, and VAS scores. However, two studies found no statistically significant relationship between alcohol drinking and DED. Whereas another study even suggested an inverse correlation ($OR = 0.47$). Moreover, two studies highlighted a gender difference in the impact of alcohol on DED. One discovered alcohol was a risk factor of DED in females ($OR = 1.08$) but showed statistically significant mild protective effects in males ($OR = 0.77$).

Conclusions: The association between alcohol consumption and DED is not conclusive based on current studies. Further investigation is needed to determine whether different levels and types of

alcohol use in different genders may contribute to the development of DED.

Effectiveness of Intense Pulse Light Therapy (IPL) in Treatment of MGD (Meibomian Gland Dysfunction)

First Author: Samhitha H R

Co-Author(s): Namita **ANAGOL**, Sri **GANESH**, Puja **NAYAR**

Purpose: To study the effectiveness of intense pulsed light therapy in treatment of meibomian gland disorders.

Methods: Intense pulsed light therapy was done for a total of 170 eyes and the lipid layer thickness and partial blink detection were evaluated using lipiview 1st sitting, 2nd sitting 3rd sitting and 4th sitting at 2 weeks 1 month, and 2 months respectively. Patient satisfaction was also evaluated after each sitting

Results: The study included 170 eyes (85 participants) aged 20 to 80 years, with the most represented age groups being 20–30 years and 61–70 years (20.5% each). The mean age was 50.19 ± 19.18 years. The sample comprised 45.2% males and 54.8% females. A majority (75.9%) reported symptoms, with 92.8% having undergone prior medical management. Symptom duration varied, with 76% experiencing onset within 1–5 years. Nearly half (49.4%) had no systemic conditions, while common comorbidities included hypertension (19.4%), diabetes mellitus (12.9%), hypothyroidism (12.4%), and autoimmune disorders (4.7%). Most participants (68.1%) had not undergone other interventions, while 28.3% had a post-surgical history. Among 158 eyes (92.9%) who received four IPL sessions, lipid layer thickness improved significantly over time from 55.88 ± 19.638 at baseline to 76.55 ± 17.932 at 2 months ($p < 0.05$). Partial blink frequency also decreased, indicating improved ocular surface stability. Pairwise comparisons confirmed a statistically significant increase in lipid layer thickness, highlighting the effectiveness of IPL therapy.

Conclusions: Our study found that intense pulsed light (IPL) therapy significantly improved meibomian gland function by increasing lipid layer thickness and reducing partial blinking. These physiological changes enhanced tear film stability, with benefits sustained over follow-ups. IPL shows promise as an adjunct or alternative for chronic, treatment-resistant meibomian gland dysfunction (MGD). IPL is a well-tolerated, non-invasive option for MGD.

Panel No.: CDE-0303

Efficacy of Topical Insulin in Refractory Neurotrophic Keratopathy: A Case Series

First Author: Andrea Chor Kiu AU

Co-Author(s): Wing Man HO, Anita Lai Wah LI, Kai Wang Kenneth LI

Purpose: To present the results of topical insulin in refractory neurotrophic keratopathy (NK).

Methods: A retrospective case series of four Chinese patients on topical insulin for refractory NK. Topical insulin was prepared by mixing short-acting insulin in artificial tears with a polyethylene glycol and propylene glycol base at a concentration of 1 unit/mL, prescribed 4-6 times daily for 1-2 months.

Results: Four patients, aged 31-67 years, with stage 1-2 NK were included. Etiologies included herpetic stromal keratitis, trigeminal nerve damage from resection of trigeminal schwannoma, and facial nerve palsy. All patients failed to respond to conventional treatment including topical lubricants, steroid, cyclosporine, bandage contact lens, punctal occlusion, amniotic membrane grafting and temporary tarsorrhaphy. Each patient was started on topical insulin eyedrops. Complete corneal re-epithelialization was achieved in 3 patients within 7-14 days. The fourth patient reported significant symptomatic relief. The patients were maintained on lubricants, apart from one who also used ciclosporin 0.05%. No recurrence was observed up to 6-11 months at the latest follow-up. No local or systemic side effects were reported.

Conclusions: Topical insulin has been reported to be effective and safe for treating refractory NK. It is also an inexpensive and widely available drug with excellent tolerability, making it an easily accessible treatment option. This case series demonstrated encouraging results of topical insulin in refractory NK patients who failed all conventional treatment. Further studies are needed to determine the long-term efficacy and safety of topical insulin, and stability tests with a defined concentration and diluent have to be developed.

Endothelial Cell Loss Following Cataract Surgery in Eyes With Pseudoexfoliation: A 10-Year Comparative Study

First Author: Hari Priya ARAVIND

Co-Author(s): Shivkumar CHANDRASHEKARAN, Kalpana NARENDRAN, Venkatesh RENGARAJ, Alan ROBIN, Madhu SHEKAR

Purpose: During a 10-year period, we compared endothelial cell density (ECD) and best corrected visual acuity (BCVA) in eyes with and without pseudoexfoliation (PEX) undergoing cataract surgery.

Methods: This is a prospective study of 930 cataract patients with and 476 cataract patients without PEX who underwent phacoemulsification.

Results: The ten-year follow-up rate was 82.2% in the PEX and 85.6% in the control group. Mean ECD before surgery was 2144 (349) cells/mm² in the PEX group and 2241 (330) cells/mm² in the control group ($p < 0.001$). After 10 years, ECD was 2026 (376) in the PEX group and 2097 (328) in the control group ($p = 0.009$). There was a significant reduction ($p < 0.001$) in ECD from pre-op to final follow-up. At 10 years, logMAR BCVA was better in control than the PEX group (0.08 versus 0.12; $P = .035$).

Conclusions: In this large-scale, long-term, prospective study, ECD was significantly lower in PEX compared to control eyes, with significant endothelial cell loss in both groups.

Abstract No.: 204867

Panel No.: CDE-0254

Endothelium-In Preloaded versus Surgeon-Loaded DMEK: A Comparative Study in Asian Eyes

First Author: Wen Pei Angeline TOH

Co-Author(s): Marcus ANG, Ezekiel CHEONG, Qiu Ying WONG

Purpose: To prospectively compare complications between imported preloaded grafts and surgeon-loaded grafts in Descemet membrane endothelial keratoplasty (DMEK) amongst Asian eyes.

Methods: Twenty preloaded DMEKs were compared with donor-matched 40 surgeon-loaded DMEKs, all performed by a single surgeon in the Singapore National Eye Centre using endothelium-in pull-through cartridges (CORONET DMEK Endoglide; Network Medical Products, United Kingdom). Imported preloaded grafts were prepared 72 to 96 hours prior to surgery for the indications of Fuchs' endothelial cell dystrophy and pseudophakic bullous keratopathy. The primary outcome was intraoperative complications, with secondary outcomes including endothelial cell loss and postoperative complications within 3 months.

Results: Preloaded DMEKs had significantly shorter intra-operative times compared with surgeon-loaded DMEKs (26.2 min vs 39.5 min; $P < 0.001$), but a higher conversion rate to standard injector-DMEK (15% vs 0%; $P = 0.033$). No significant differences were observed between the groups in overall intraoperative (40% vs 22.5%; $P = 0.156$) or postoperative (40% vs 30%; $P = 0.439$) complications, rebubbling rates (5% vs 5%; $P > 0.999$), visual outcomes, or endothelial cell loss.

Conclusions: In our Asian cohort of pull-through DMEKs, endothelium-in preloaded grafts were significantly faster than surgeon-loaded grafts while demonstrating comparable clinical outcomes. Preloading endothelium-in, rather than endothelium-

out, appears to achieve outcomes similar to surgeon-loaded DMEKs.

Enhanced Staff Referral Program in the Accident and Emergency Department Increases Opportunities for Corneal Donation

First Author: Agnes HO

Co-Author(s): Yan Yu Julia CHAN, Wing See Vanissa CHOW, Amanda LUK, Catherine WONG, Maggie WU

Purpose: Corneal tissue shortage poses a significant challenge in Hong Kong, with almost 600 patients awaiting corneal transplants as of July 2025. Given that 40% of eye donors originate from Accident and Emergency Departments (AEDs), an enhanced staff referral program was implemented in 2017 to boost donation rates. This initiative included providing educational lectures, posters, and pamphlets for healthcare professionals across 16 AEDs and the incorporation of a simplified checklist and referral procedure into the workflow of death certification. A retrospective study is conducted to study the effect of the enhancement in the AED Staff Referral Program.

Methods: This retrospective study analyzed Hospital Authority Eye Bank data from January 2017 to December 2024, comparing referred, solicited, approached, and consented AED cases to those solicited by Eye Donation Coordinators (EDCs) using independent t-tests in SPSS (significance level at $p < 0.05$).

Results: After implementation of the program, AED referrals increased until 2020 (peaked at 190 cases in 2018) but declined below baseline during 2021-2023 amid the pandemic, with a modest recovery to 81 cases in 2024. Consent rates for AED-referred cases averaged 49.8%, significantly higher than 35.3% for EDC-solicited cases ($p = 0.002$).

Conclusions: The Enhanced AED Staff Referral Program had a significant impact on the number of referred cases. Nevertheless, cases identified by AED staff had a significantly higher consent rate over the years. The program's success underscores its potential to boost donation rates and make a meaningful impact on the lives of those awaiting corneal transplants.

Favourable Response to Tacrolimus in a Case of Refractory Peripheral Ulcerative Keratitis in Paediatric ANCA-Associated Vasculitis

First Author: Tsz Him Johnson KWOK

Co-Author(s): Eugenie MOK, Alvin L. YOUNG

Purpose: To report a case of peripheral ulcerative keratitis (PUK) in a girl with ANCA-associated vasculitis

(AAV) which progressed despite conventional B cell depletion therapy and eventually responded to oral tacrolimus.

Methods: A 14-year-old Chinese girl with anti-myeloperoxidase (MPO) positive AAV developed aggressive PUK. Her clinical course, immunosuppressive regimens, and outcomes were reviewed.

Results: The patient with known AAV presented with right eye PUK after an upper respiratory infection. She received cyanoacrylate glue, intravenous methylprednisolone and rituximab. However, after 2 months, there was progression in corneal thinning and anti-MPO antibodies remained positive despite B-cell depletion. She was therefore initiated on oral cyclosporine, but its side effects led to poor compliance. During this time, the disease continued to progress and culminated in corneal perforation, requiring a second application of cyanoacrylate glue. The patient eventually responded to a combination of oral tacrolimus and intravenous immunoglobulin, with stabilisation of corneal thinning and complete resolution of conjunctival injection.

Conclusions: The patient had disease progression despite adequate B cell depletion and only achieved disease control after switching to tacrolimus. Although AAV is considered a primarily B cell driven disease, this case illustrates that T-cell mediated immunity may play a critical role in the pathophysiology as well. When first line B-cell depletion therapy fails, T-cell-directed treatments such as tacrolimus can be an effective salvage option.

Ferroptosis Pathway Dysregulation in Fuchs Endothelial Corneal Dystrophy Revealed by RNA-Seq

First Author: Taichi YUASA

Co-Author(s): Noriko KOIZUMI, Taisuke NUMAO, Naoki OKUMURA, Yasuomi URANO

Purpose: Fuchs endothelial corneal dystrophy (FECD) is a progressive disorder characterized by extracellular matrix accumulation beneath corneal endothelial cells and subsequent corneal edema leading to visual impairment. Although oxidative stress, endoplasmic reticulum stress, and trinucleotide repeat (TNR)-induced splicing abnormalities in the TCF4 gene have been implicated, the full pathogenesis of FECD remains unclear. Recently, ferroptosis, an iron-dependent form of regulated cell death, has emerged as a potential mechanism. This study aimed to investigate the involvement of ferroptosis in the pathogenesis of FECD using RNA-Seq analysis.

Methods: RNA-Seq data from corneal endothelial cells of FECD patients (with and without TCF4 TNR expansion) and healthy controls were analyzed.

Differentially expressed genes (DEGs) were identified, with a focus on ferroptosis-related genes (FRGs) curated from the FerrDb database. Functional enrichment and pathway analyses were performed, and findings were validated using two additional independent RNA-Seq datasets.

Results: A total of 150 FRGs were significantly dysregulated in FECD samples compared with controls. Principal component analysis and heatmap clustering revealed a distinct ferroptosis-related gene expression signature in all FECD patients, regardless of TCF4 TNR expansion status. Pathway enrichment implicated ferroptosis together with oxidative stress response and TNF signaling pathways. Cross-validation across three independent datasets consistently identified 27 dysregulated FRGs.

Conclusions: Our findings confirm the potential involvement of ferroptosis in FECD pathogenesis, independent of the common genetic risk factor of TCF4 TNR expansion. The identified genes provide novel insights into the disease's mechanisms and represent potential targets for future therapeutic strategies.

Abstract No.: 206087

From Drink to Blink: Associations Between Chronic Alcohol Consumption and Dry Eye Disease: A Cross-Sectional Study

First Author: Stephany Wing Lam TAI

Co-Author(s): Kelvin KI CHONG, Kenneth Ka Hei LAI, Calvin Cp PANG, Clement Cy THAM

Purpose: To investigate associations between chronic alcohol consumption and Dry Eye Disease (DED).

Methods: A cross-sectional study was conducted in the community during March-September 2025. We included adults with chronic alcohol consumption who reported continuous drinking for ≥ 1 year. Controls were recruited who had never consumed alcohol during their lifetime. Exclusions: any type of inflammatory disease, recent use of eyedrops, or having had ocular surgeries. Evaluations of ocular surface included lipid layer thickness (LLT) by LipiView® II, tear meniscus height (TMH), and non-invasive keratography break-up time (NIKBUT) by Keratograph® 5M, Schirmer Test (ST), and slit lamp examination conducted by ophthalmologists. Ocular Surface Disease Index (OSDI) was self-reported.

Results: We recruited 61 chronic alcohol users (aged 46.4 ± 15.8 years; 46 current, 15 former; mean consumption 16.6 ± 11.5 years) and 61 age- and sex-matched controls. Alcohol users exhibited lower ST (7.0 vs 9.5 mm, $P=0.003$); lower FBUT (4.8 ± 2.9 vs 6.1 ± 2.4 s, $P=0.012$); lower NIKBUT (8.2 ± 5.1 vs 10.7 ± 6.4 s, $P=0.005$). They also presented more severe MGD signs: lower LLT (58.3 ± 21 vs 66.4 ± 17 nm, $P=0.008$), rounding ($P=0.002$); foaming ($P=0.013$); telangiectasia ($P=0.003$); capping ($P=0.032$); conjunctival injection ($P=0.0001$).

They also showed 4.0 points higher OSDI scores ($P=0.026$). On LLT subgroup analysis, no difference among females between alcohol users and controls: (52.9 ± 23 vs 57.5 ± 18 nm, $P=0.084$), yet remained significant for males (45.2 ± 20 vs 56.8 ± 17 nm, $P=0.021$). On dose-response analysis, median ST differed among controls, former, and current drinkers ($9.5/7.0/5.0$ mm, $P=0.045$).

Conclusions: Alcohol consumption is associated with DED. Our study, for the first time, shows both aqueous deficiency and evaporative dry eye found in chronic alcohol users. We suggest ocular surface evaluation is warrant in patients with chronic alcohol usage.

From Rupture to Rescue: Crescent Deep Anterior Lamellar Keratoplasty for a Paper-Thin Cornea Terrien's Marginal Degeneration

First Author: Kiara NURMATHIAS

Co-Author(s): Rio RHENDY

Purpose: To report successful surgical rescue of a paper-thin cornea in Terrien's Marginal Degeneration (TMD) using Crescent Deep Anterior Lamellar Keratoplasty (DALK).

Methods: A 29-year-old woman suffered right-eye rupture after trauma, managed with corneal-limbal patch graft and pupilloplasty. The fellow left eye displayed classical TMD features: clear central cornea, multiple peripheral dystrophic opacities, superior lipid deposition, and nearly 320° of peripheral thinning without staining. Topography revealed high irregular astigmatism, while AS-OCT confirmed extreme thinning of $150 \mu\text{m}$ compared with $502 \mu\text{m}$ centrally. Preoperative best corrected visual acuity (BCVA) was 3/60. Given the imminent risk of perforation, a crescent DALK was performed.

Results: Intraoperatively, surgery proceeded with a manual layer-by-layer keratoplasty. After stromal dissection, a Descemet membrane rupture was identified. A deep stromal bubble could not be formed. The surgery was then carefully continued, and a donor lamellar graft was successfully implanted, restoring corneal contour and tectonic stability. Serial postoperative AS-OCT confirmed smooth graft-host integration and progressive peripheral thickening. Visual outcome improved significantly, BCVA 6/20 at last follow-up. The graft remained stable, with no recurrence or failure.

Conclusions: In cornea thinner than $200 \mu\text{m}$, Crescent DALK can preserve globe integrity and restore functional vision in TMD. Multimodal imaging with topography and AS-OCT was essential for surgical planning and precise depth assessment, while careful adaptation to intraoperative steps allowed safe manual

completion with stable graft integration and significant visual improvement.

Full-Thickness Corneal Perforation in Femtosecond Laser-Assisted Deep Anterior Lamellar Keratoplasty Due to Unpredictable Micro-Cavitation Bubble Size

First Author: Lauren Ya Wen FONG

Co-Author(s): Julia CHAN, Vanissa CHOW

Purpose: Femtosecond laser (FSL) is widely utilized in keratoplasties. We report a rare case of intraoperative Descemet's membrane (DM) perforation despite a sufficient safety margin in FSL planning.

Methods: Inadvertent full thickness right eye corneal perforation occurred during FSL-assisted lamellar corneal trephination in a 21-year-old Chinese male. He was originally planned for deep anterior lamellar keratoplasty (DALK) due to dense corneal scarring secondary to Acanthamoeba keratitis. FSL-assisted DALK with circular graft and "peeling-off" method was performed with the FEMTO LSV Z8 laser system. Surgical planning was guided by intraoperative anterior segment optical coherence tomography. The intended residual stromal bed was 190um. The laser cutting and energy speed were 8.0 mm/s and 130% respectively, for the stromal cut, and 1.0mm/s and 160% respectively, for the side cut.

Results: Inadvertent full-thickness corneal perforation with a circumferential break from 9 to 12 o'clock at the DM was only made aware to the surgeons during anterior lamella dissection. In view of the status of the DM, the surgery was converted to a penetrating keratoplasty. The patient had an uneventful recovery postoperatively. FSL-assisted keratoplasties aim to reduce the risk of DM perforation. DM perforation despite a safety margin of 1/3 corneal thickness is rare. Subsequent in-vivo porcine eye testing showed large discrepancies between actual and set cutting depth secondary to micro-cavitation bubble variations, where increased cutting power would lead to a larger cavity and downward directional movement.

Conclusions: Micro-cavitation bubble variations should be considered and evaluated to increase the success of FSL-DALK and to reduce intra-operative complications.

Glue to the Rescue!

First Author: Gaurav VERMA

Co-Author(s): Jagadeesh Kumar REDDY, Vandhana SUNDARAM

Purpose: To evaluate the safety and efficacy of use of Fibrin glue as an adjuvant in management of

Descemet's membrane detachment post Deep Anterior Lamellar Keratoplasty.

Methods: This retrospective observational case series consisted of 7 eyes which had Descemet's membrane detachment after DALK due to micro perforations.

Results: The mean age of patients included in the case series was 21 +/- 2.5 years with a mean follow up period of 18 +/- 5 months. The need for re air injection was significantly reduced. By reducing reliance on air tamponade, it removes the need for extended supine positioning. The glue gradually gets absorbed with time, with no interface vascularization or infiltration. There was also reduced risk of pupillary block, postop fixed dilated pupil, cataract and posterior synechia formation.

Conclusions: Fibrin glue can be a valuable adjunct in the management of micro perforation in DALK even post operatively.

Growth Factor Receptor-Bound Protein 2-Mediated Corneal Epithelial Injury Drives Depression-Associated Dry Eye Disease

First Author: Kuangqi CHEN

Purpose: Depression is increasingly recognized as a comorbidity of dry eye disease (DED), yet its underlying mechanisms remain unclear. This study investigates the therapeutic effects of fluoxetine on depression-associated corneal injury and explores the molecular pathways involved.

Methods: Chronic unpredictable mild stress (CUMS) mice received fluoxetine treatment. Behavioral tests, corneal wound healing, tear secretion, and 4D-DIA proteomics were performed. GRB2 expression was validated via immunohistochemistry, qRT-PCR, and western blot. Human corneal epithelial cells (hCECs) under hyperosmotic stress (450 mOsm) were transfected with GRB2 siRNA to assess oxidative stress, inflammation, and migration.

Results: Fluoxetine treatment significantly reduced depressive behaviors, accelerated corneal epithelial wound healing, and restored tear secretion. Proteomic analysis of corneal tissues revealed dysregulation of cytoskeletal and metabolic pathways in depressed mice, which fluoxetine partially reversed. GRB2 emerged as a critical protein, showing elevated expression in depressed mice and hyperosmolar-stressed hCECs. Silencing GRB2 in hCECs attenuated hyperosmolarity-induced oxidative stress, inflammation, and migration inhibition. Immunohistochemical and behavioral analyses confirmed GRB2's role in corneal epithelial thinning and depression-related DED pathology.

Conclusions: These findings highlight GRB2 as a potential therapeutic target and underscore

fluoxetine's dual efficacy in mitigating depressive symptoms and ocular surface damage. This study provides novel insights into the molecular interplay between depression and DED, advocating for integrated therapeutic strategies addressing both psychiatric and ophthalmic dimensions.

Herpes Simplex Keratitis as a Consideration in Interface Fluid Syndrome Following Small Incision Lenticule Extraction

First Author: Cristina Erika ELAZEGUI

Co-Author(s): Irwin CUA

Purpose: To report a case of presumed herpes simplex virus (HSV) keratitis following small-incision lenticule extraction (SMILE), which subsequently led to interface fluid syndrome (IFS).

Methods: We describe the case of a 31-year-old man who underwent uneventful SMILE surgery and later presented with persistent corneal edema, ultimately diagnosed as IFS secondary to HSV keratitis. Anterior segment findings, visual acuity, refraction, intraocular pressure (IOP), pachymetry values, and AS-OCT were documented throughout the clinical course

Results: Two weeks postoperatively, the patient presented with whitish granular material within the SMILE interface in the left eye. A presumptive diagnosis of diffuse lamellar keratitis was made, and topical corticosteroids were started. Although initial improvement was noted, corneal edema recurred within the lenticule interface, accompanied by a decline in visual acuity from 20/25 to 20/100 and an IOP of 40 mmHg. Pressure-induced stromal keratitis (PISK) secondary to steroid use was initially suspected, and IOP-lowering medications were prescribed. At the 6-week follow-up, worsening edema, a 93 μ m increase in pachymetry, fine keratic precipitates, and grade 1 anterior chamber cells were observed. A diagnosis of HSV keratitis with secondary IFS was made. The patient was treated with oral acyclovir, topical corticosteroids, and aggressive IOP control, resulting in marked clinical improvement.

Conclusions: HSV keratitis is a potential but underrecognized complication following SMILE. Postoperative corneal interface anatomy may mask classic signs and predispose to secondary IFS in the setting of elevated IOP. Prompt recognition and antiviral therapy are essential to prevent vision-threatening sequelae.

Impact of Glaucoma on Descemet Membrane Endothelium Keratoplasty Using a Widefield Endothelial Imaging Technique

First Author: Ezekiel CHEONG

Co-Author(s): Marcus ANG, Qiu Ying WONG

Purpose: Glaucoma has been shown to be a risk factor for endothelial graft failure following endothelial keratoplasty. We used a novel widefield endothelial imaging technique to examine the impact of glaucoma on peripheral, paracentral, and central regions of the endothelium following Descemet membrane endothelial keratoplasty (DMEK).

Methods: Prospective study of 50 consecutive DMEKs performed in Asian eyes with Fuchs' endothelial cell dystrophy (FECD) and pseudophakic bullous keratopathy (PBK). All eyes had serial non-contact widefield endothelial imaging specular microscopy (CEM-530, Nidek Co. Ltd, Japan) at 1, 3, and 6 months follow-up. Central, paracentral (1-2mm), and peripheral (7-8mm) regions of the cornea endothelium, which correspond to the approximate dimensions of a DMEK donor, were scanned. The main outcome measure was the effect of glaucoma on cornea endothelial cell loss (ECL) comparing central, paracentral, and peripheral regions of the DMEK graft. Secondary outcome measures the effect of glaucoma on intra-operative and post-operative complications, including graft survival.

Results: Mean age was 69 ± 9 years, 54% female, majority Chinese (88%) with 21/50 (42%) eyes with pre-existing glaucoma. Central ECL alone was not significantly different between glaucoma and non-glaucomatous eyes (32.1% vs 29.7%; $P = 0.770$). Including the paracentral region resulted in significant differences between glaucoma and non-glaucomatous eyes (40.4 vs 27.0%, $P = 0.033$) at 3-month follow-up. Overall, intra-operative complications ($P > 0.05$) and post-operative complications were not significant between groups ($P > 0.05$).

Conclusions: Our pilot prospective study suggests that pre-existing glaucoma may impact ECL at the paracentral region in DMEK, which may not be detected when only the central corneal ECL is examined.

Abstract No.: 205806

In Situ Integrated Spermidine Hydrogel Suppresses Subconjunctival Inflammation and Fibrosis

First Author: Haohao CUI

Co-Author(s): Jingguo LI

Purpose: Subconjunctival fibrosis (SCF) treatment is challenging due to drug side effects and ocular barriers. This study aimed to develop a novel adhesive hydrogel for the sustained delivery of spermidine, an

endogenous substance with anti-inflammatory and anti-fibrotic potential, to effectively treat SCF.

Methods: A dual-crosslinked hydrogel was fabricated via dynamic covalent chemistry. Hyaluronic acid was functionalized with phenylboronic acid and aldehyde groups, then mixed with polyvinyl alcohol and spermidine to form a network stabilized by imine and borate ester bonds. The hydrogel's mechanical properties, self-healing, injectability, adhesiveness, and drug release profile were characterized. Its anti-fibrotic efficacy was evaluated in a subconjunctival injury model.

Results: The resulting hydrogel exhibited excellent self-healing, injectability, and tissue adhesiveness, allowing for minimally invasive in-situ formation and sustained spermidine release. It also demonstrated multiple free radical scavenging abilities. In the animal model, the hydrogel significantly reduced early inflammatory cell infiltration, congestion, and edema. At 8 weeks post-treatment, it markedly suppressed the deposition of collagen I and III, confirming a potent anti-fibrotic effect at the tissue level.

Conclusions: This spermidine-delivering hydrogel platform synergistically modulates the oxidative stress microenvironment and sustainably releases its cargo, effectively intervening in the SCF pathological process. It represents a promising single-administration strategy for treating fibrotic diseases.

Insulin Eye Drops as Novel First-line Treatment for Persistent Epithelial Defect Secondary to Radiation Keratopathy: A Case Report

First Author: Pauline Andrea WONG

Co-Author(s): Richard Dean DELA CRUZ, Raymond Nelson REGALADO, Reginald Robert TAN

Purpose: To describe the use of insulin eye drops in the management of persistent epithelial defect secondary to radiation-induced neurotrophic keratopathy.

Methods: A 21-year-old female with a history of surgical resection of optic nerve schwannoma and sixteen cycles of radiation therapy to the right eye presented with mild conjunctival hyperemia and diffuse punctate epitheliopathy. Initial treatment with unpreserved lubricating eye drops and lubricating gel was given. Two weeks later, after completing twenty-eight cycles of radiotherapy, she developed severe conjunctival hyperemia and a central oval epithelial defect (3 × 4.5 mm) with elevated edges. Insulin eye drops (1 IU/mL) were prescribed in addition to unpreserved lubricating eye drops.

Results: At the 7-day follow-up, a 90% reduction in the size of the epithelial defect (0.6 × 2.6mm) was observed. At the 14-day follow-up, the epithelial defect

remained stable in size. Epithelial debridement was done at this time and insulin eye drops continued. Complete epithelial healing was observed at 28 days after initiating insulin eye drop therapy.

Conclusions: To our knowledge, this is the first reported case of using insulin eye drops as a novel first-line treatment for persistent epithelial defect secondary to radiation-induced neurotrophic keratopathy. Insulin eye drops were well-tolerated without significant adverse effects, supporting its feasibility in clinical use.

Integrated Blink Analysis Technologies for Ocular Surface Diseases: A Scoping Review

First Author: Chee Wui ONG

Co-Author(s): Sanjiv BHATIA, Blanche Xiaohong LIM, Chris Hong Long LIM, Tareq NABHAN, Tjaart VAN DER WALT

Purpose: To describe integrated technologies for blink analysis and their utility in evaluating ocular surface diseases.

Methods: A literature search was conducted using PubMed, Embase and Google Scholar. Search terms included "Eye Blink", "Blink", "Blinking", "Device", "Technology", "Appliance", "Application". Publications from January 1, 2000 to August 15, 2025 were included. Studies describing the use of integrated technologies to capture and analyze blink metrics for the evaluation of dry eye disease and other ocular surface conditions were included. Publications describing technical engineering or technologies without an evaluation of ocular surface diseases were excluded. Findings from relevant studies were extracted and compared.

Results: Of 2,565 identified records, 37 met the final inclusion criteria, evaluating the use of 10 technologies. These comprised desk-bound devices – Intelligent Vision Sensor, LipiView™, and IDRA, wearable devices – Wink Glass, DualBlink, Blink-sensing Glasses, and smartphone or computer applications – HealthyRoad, DryEyeRhythm, Dry eye or not? and EyeScore. LipiView™ and IDRA were most commonly studied. Blink rate and partial blink rate were the most commonly analyzed parameters. DED was the most commonly evaluated ocular surface condition. Consistent with existing literature, some studies demonstrated associations between increased partial blink rates and ocular surface disease. There was heterogeneity in methods of blink analysis and insufficient validation of the accuracy and diagnostic ability of measured blink parameters for ocular surface conditions.

Conclusions: Integrated blink analysis technologies are promising for the assessment of ocular surface diseases. Further studies are needed to evaluate the validity and reliability of these technologies.

Integrated Clinical and Proteomic Evaluation of Dry Eye Symptoms and Signs Following Administration of a Novel Nanoemulsion Artificial Tear Formulation

*First Author: Kenrick Kai-yuen **CHAN***

*Co-Author(s): Jingfang **BIAN**, Biyue **GUO**, Thomas Chuen **LAM**, Xulin **LIAO**, Jimmy Sung-hei **TSE***

Purpose: Dry eye disease (DED) significantly impacts people worldwide. This study investigated changes in dry eye symptoms, clinical signs, and tear proteomic profiles following preservative-free nanoemulsion artificial tear application in mild-moderate DED patients.

Methods: This prospective study recruited 31 Chinese DED adults (aged 20-50 years) with OSDI scores of 13-32 and positive dry eye signs using the TFOS DEWS II diagnostic criteria. Subjects used artificial tears four times daily and attended baseline, 2-week, and 3-month visits. The primary outcome was the OSDI score change at 2 weeks. Secondary outcomes included non-invasive tear break-up time (NITBUT), lipid layer thickness, and tear meniscus height. Tear samples were collected using Schirmer's strips and processed by an in-house S-TRAP protocol. Samples were then analyzed by LC-MS/MS with data-independent acquisition and dual proteomics software at 1 % false discovery rate (FDR). Differentially expressed proteins with $q\text{-val} < 0.05$ and $\text{Log}_2\text{FC} > 0.585$ were profiled.

Results: OSDI scores significantly improved at 2-weeks (18.7 ± 9.2 vs 23.9 ± 5.3 , $p = 0.002$) and 3-months (16.1 ± 11.3 , $p = 0.001$) versus baseline. First and average NITBUT showed a numerical reduction at 2 weeks ($p = 0.007$, $p = 0.027$) but not at 3 months. Proteomic analysis identified >1,800 unique proteins with 3 and 23 differentially regulated at 2 weeks and 3 months, respectively. Compared to baseline, previously proposed DED biomarkers were downregulated at 2 weeks, with broader downregulation of inflammatory and stress-related proteins at 3 months.

Conclusions: The preservative-free nanoemulsion artificial tear demonstrated sustained subjective improvement with corresponding reduction in key DED biomarkers. This represents the first study concurrently showing clinical and molecular improvements in the same cohort. Larger validation is needed to confirm therapeutic mechanisms.

Intraoperative OCT as a Reliable Tool for Predicting Graft Thickness and Microkeratome Selection in DSAEK

*First Author: Manasi **TRIPATHI***

*Co-Author(s): Manpreet **KAUR**, Shraddha **SNEHA***

Purpose: To evaluate the reliability of intraoperative optical coherence tomography (iOCT) in predicting Descemet's Stripping Automated Endothelial Keratoplasty (DSAEK) graft thickness, and its utility in guiding microkeratome head selection.

Methods: In this prospective observational study, donor lenticules were assessed intraoperatively using iOCT before microkeratome-assisted cut. Based on the donor thickness, an appropriate microkeratome head size was selected, aiming the lenticule thickness to be between 100-130 microns. After microkeratome cut, graft thickness was re-evaluated intraoperatively on iOCT and postoperatively on day 1 using anterior segment OCT. Measurements were taken centrally, paracentrally, and peripherally. The primary outcome was the agreement between intraoperative and postoperative thickness measurements.

Results: The mean expected central graft thickness was $127.10 \pm 27.2 \mu\text{m}$ while the measured post-cut thickness was $113.30 \pm 26.7 \mu\text{m}$. There was no statistically significant difference between expected graft thickness and actual post-cut thickness measurements ($p = 0.65$). Additionally, no intraoperative complications such as incomplete cuts or perforations occurred. On POD-1, the mean graft thickness was measured to be $123.20 \pm 24.3 \mu\text{m}$ as measured on ASOCT. The difference between intra-operative and post-operative measurement was not statistically significant ($p = 0.37$). The close agreement between expected (post-cut) and actual (POD-1) graft thickness, along with accurate pre-cut lenticule assessment, allowed for appropriate microkeratome head selection in all cases and matched expected lenticule thickness profiles.

Conclusions: iOCT is a safe and dependable adjunct in DSAEK procedures. It aids accurate prediction of graft thickness and enables informed intraoperative decisions regarding microkeratome head selection.

Panel No.: CDE-0292

Investigating Shared Diagnostic Genes and Mechanisms Between Metabolic Syndrome and Dry Eye Disease via Integrated Bioinformatics Analysis and In Vivo Validation

*First Author: Ziyu **LIU***

Purpose: This study aimed to identify shared diagnostic genes and molecular mechanisms between MetS and DED using integrated bioinformatics analysis and in

vivo validation. The goal was to uncover overlapping pathogenic pathways and provide insights for improved diagnosis and treatment strategies for patients with both conditions.

Methods: This study employed bioinformatics and in vivo validation to investigate the shared diagnostic genes and underlying mechanisms linking MetS and DED. Differential expression analysis using Limma and weighted gene co-expression network analysis (WGCNA) identified 247 shared driver genes from MetS and DED cohorts. Functional enrichment analysis indicated that these genes are associated with immune regulation and inflammatory responses. Key diagnostic genes were identified via PPI network analysis and validated using a ROC curve. The MetS-DED mouse model further demonstrated CXCR4 overexpression in the corneal epithelium and liver.

Results: Bioinformatics: 247 shared genes were identified between MetS and DED. Functional enrichment highlighted immune and inflammatory processes. KEGG analysis revealed significant pathways, including Cytokine-Cytokine Receptor Interaction and Chemokine Signaling. Four hub genes were identified and validated with high diagnostic accuracy (AUC > 0.7). In Vivo Validation: HFD mice exhibited MetS (weight gain, glucose intolerance, liver steatosis) and DED (reduced tear secretion, corneal damage). CXCR4 was significantly upregulated in both liver and corneal tissues of HFD mice, confirming its role as a key gene in MetS-DED comorbidity.

Conclusions: In this study, we have, for the first time, employed a variety of bioinformatics methods to explore and validate the hub gene in MetS-DED in vivo, providing new insights for future clinical treatments.

Iota-Carrageenan Eye Drops: Effective Treatment for Mild to Moderate Dry Eye Disease

First Author: Anaïs CASTEX

Co-Author(s): Marta BLANCO-VÁZQUEZ, Margarita CALONGE, Hanna DELLAGO, Eva PRIESCHL-GRASSAUER, Sabine ROCH-NAKOWITSCH, Markus SAVLI, Nicole UNGER-MANHART

Purpose: This investigation aimed to evaluate the lubricating performance of Iota-Carrageenan (I-C) eye drops in patients with mild to moderate dry eye disease (DED).

Methods: In this prospective, single-arm investigation, 30 patients with mild to moderate DED (OSDI score 13-32) used I-C eye drops three times daily for 28 days. Assessments were conducted in both normal and adverse controlled environments (ACE). The primary endpoint was the change between baseline and Day28 in DED symptoms, measured by a composite symptom

score (CSS). Secondary endpoints included Ocular Surface Disease Index (OSDI), tear film break-up time, and corneal staining.

Results: Data from 28 patients revealed a significant 54% reduction in mean CSS, decreasing by 11.9 points (95% CI: -15.1, -8.7; $p < 0.001$). The mean OSDI also decreased by 7.8 points (95% CI: -10.9, -4.6; $p < 0.001$). Improvements in tear film stability and corneal integrity were noted after ACE exposure ($p < 0.05$ and $p < 0.001$, respectively). A total of 98 mild adverse events were reported by 21 patients (70%), with no serious events. Additionally, 93% of patients rated I-C eye drops as «well» or «very well» tolerated.

Conclusions: I-C eye drops have demonstrated lubricating performance, safety, and excellent tolerability in the management of mild to moderate dry eye disease (DED). They significantly improve symptoms and enhance tear film stability while protecting the ocular surface, presenting a promising therapeutic option for DED management.

Isolated Streptococcus pyogenes Keratitis With Scleritis: A Case Series and Review of Literature of Streptococcus pyogenes Ophthalmic Manifestations

First Author: Vincent YUEN

Co-Author(s): Jacqueline CHAN, Julia CHAN, Vanissa CHOW, Ke LIU, Rachel TSUI

Purpose: To present two cases of isolated Streptococcus pyogenes keratitis and scleritis from a tertiary ophthalmology referral center in Hong Kong, emphasizing their rapidly progressive and intensely inflammatory nature.

Methods: Patient records were reviewed to identify cases of isolated Streptococcus pyogenes keratitis and scleritis between October 2024 and July 2025. Both cases lacked systemic involvement. Diagnoses were made through clinical examinations, microbiological cultures, and B-scan ultrasonography. A literature review of Streptococcus pyogenes ophthalmic manifestations was conducted using PubMed, Medline, and Cochrane Library databases.

Results: Two eyes from two patients were included. Both had histories of prior ocular trauma or surgery. In contrast to previous reports with systemic involvement, these cases only had ophthalmic manifestations. Each exhibited severe inflammation unresponsive to intensive topical antibiotics alone, requiring the use of topical NSAIDs and steroids. One case rapidly progressed to endophthalmitis and required emergency tap-and-inject surgery. Despite bandage contact lenses and amniotic membrane transplantation, persistent epithelial defects led to bullous keratopathy and corneal scarring. The patient

is awaiting corneal transplantation. The second case showed a favorable response to timely topical steroid administration, resulting in the resolution of inflammation and minimal residual scarring, suggesting the potential benefit of early topical steroid even in the presence of an epithelial defect.

Conclusions: Although rare, isolated *Streptococcus pyogenes* keratitis and scleritis without systemic involvement are possible. These cases highlight the need for prompt diagnosis and early intervention, with topical steroids playing a possible role in improving clinical outcomes.

Keratoconic Mirage: Posterior Pseudo-Lenticulus Sign

First Author: Jann Perrie ALIPIO

Co-Author(s): Sharlene NOGUERA

Purpose: We report the first documented case in our country, and only the second worldwide, of keratoconus presenting with posterior pseudo-lenticulus, a novel optical phenomenon mimicking posterior lenticulus and accompanied by an oil droplet-like reflex.

Methods: We present the case of a 24-year-old male with a three-year history of progressive blurring of vision in the left eye. He was initially diagnosed as a case of posterior lenticulus, a rare congenital anomaly classically characterized by posterior conical protrusion of the posterior lens capsule and oil droplet sign on slit-lamp examination. In contrast, keratoconus is a bilateral ectatic corneal disease that may also present with a posterior pseudo-lenticulus and an oil droplet-like reflex (Charleaux sign), leading to diagnostic confusion.

Results: Anterior segment optical coherence tomography (AS-OCT) revealed that the apparent conical protrusion of the posterior lens capsule, initially suggestive of posterior lenticulus, was an optical illusion of keratoconus, termed the posterior pseudo-lenticulus sign. Following scleral contact lens fitting, the left eye improved from uncorrected visual acuity (UCVA) of 5/200 to 20/40 at distance and J1 at near. Resolution of both the posterior pseudo-lenticulus and the oil-drop-like reflex was also noted.

Conclusions: Keratoconus can create a mirage of posterior conical protrusion of the posterior lens capsule. Differentiating true from pseudo-lenticulus is important, as these two unrelated clinical entities differ in etiology, management, and prognosis, and misdiagnosis can lead to incorrect treatment. AS-OCT is a valuable imaging tool in establishing the correct diagnosis.

Longitudinal Evaluation of Central and Peripheral Corneal Endothelium After DMEK Using Widefield Imaging

First Author: Qiu Ying WONG

Co-Author(s): Marcus ANG, Ezekiel CHEONG, Angeline TOH

Purpose: To evaluate longitudinal corneal endothelial changes after Descemet Membrane Endothelial Keratoplasty (DMEK) using widefield specular microscopy (WSM), a novel modality allowing comprehensive assessment across central, paracentral, and peripheral regions.

Methods: Fifty-three eyes from 43 patients with existing DMEK grafts were imaged at baseline and 6 months using widefield specular microscopy (WSM; CEM-530, Nidek, Japan) and Scheimpflug tomography (Pentacam HR, Oculus Optikgeräte GmbH, Germany) at a tertiary eye center in Singapore. Endothelial cell density (ECD) and image quality (IQ) were evaluated across central, paracentral, and peripheral corneal regions.

Results: Mean age at DMEK was 67.4 years; 49.1% were female. 35.8% of eyes were glaucomatous, 71.7% had Fuchs endothelial corneal dystrophy and 22.6% had pseudophakic bullous keratopathy as DMEK indications. Over 6 months, ECD declined significantly across central, paracentral, and peripheral regions ($P = 0.012$, <0.001 , 0.016), whereas image quality decreased only in peripheral regions ($P < 0.001$). Central ECD decline correlated strongly with paracentral ($r = 0.698$) but weakly with peripheral ECD ($r = 0.332$).

Conclusions: This study demonstrates the utility of widefield specular microscopy beyond the central cornea. Peripheral ECD loss, potentially discordant with central changes, may be missed by conventional imaging, highlighting the value of widefield assessment in detecting early regional endothelial compromise.

Lycium barbarum Polysaccharide (LBP): Investigating Its Anti-Fibrotic and Pro-Healing Properties on the Cornea Utilizing an In-Vivo Alkali Injury Model

First Author: Wang Yee CHU

Co-Author(s): Yau Kei CHAN, Kendrick Co SHIH

Purpose: Corneal scarring affects 5.1% of the blind, a heavy socioeconomic burden on healthcare systems. Although topical Mitomycin-C and corticosteroids are used to treat corneal opacity, they lead to increased intraocular pressure and scleral necrosis. Lycium barbarum polysaccharide (LBP) is an extract of goji berries and has demonstrated in vitro anti-fibrotic properties on corneal fibrosis. This study aims to

investigate the efficacy of topical LBP application in reducing corneal opacity and promoting corneal healing utilizing a mice corneal alkali-injury model.

Methods: Right eye of C57Bl/6J wild-type mice (n=6) was injured with 0.5M NaOH for 45 seconds under sedation. Excessive NaOH was rinsed off with filtered water. Two concentrations of LBP were used in the treatment groups: 2 mg/mL and 20 mg/mL, while PBS was used in the control group. LBP treatment was given either for 7 consecutive days before injury (pre-injury), 7 consecutive days after injury (post-injury), or both (pre-post-injury). Corneal opacity was assessed until Day 28 after injury, quantified using Modified Fantes score (0-4). Epithelial defect was estimated using fluorescein staining. Corneal thickness and Fibronectin expression was evaluated using H&E staining and ELISA.

Results: 0.5M NaOH was effective in inducing corneal opacity. Pre-post-injury treatment with 2 and 20 mg/mL LBP significantly reduced corneal opacity, with Modified Fantes score of 2.00 and 1.67 respectively on Day 28, compared to 3.17 in control group ($p < 0.0245$; $p < 0.0051$). 20 mg/mL LBP pre-post-injury treatment reduced total corneal thickness and corneal fibronectin expression. Estimated corneal epithelial defect area was smaller in 2 and 20 mg/mL LBP pre-post-injury treatment groups on Day 1 ($0.06 \pm 0.14 \text{ mm}^2$ and $0.05 \pm 0.11 \text{ mm}^2$ respectively, vs $0.45 \pm 0.15 \text{ mm}^2$ in control group ($p < 0.05$)).

Conclusions: 2 mg/mL and 20 mg/mL LBP reduced corneal opacity and expedited corneal healing when applied topically before and after alkali injury, exemplifying its therapeutic potential against alkali burns.

Abstract No.: 206796

Management Outcomes of Tenon Patch Graft With Cyanoacrylate Glue Overlay for Moderate-Sized Perforated Corneal Ulcers

First Author: Pranita SAHAY

Co-Author(s): Subhash DADEYA, Arushi SAINI, Vaishali TOMAR

Purpose: To evaluate the visual, anatomical, and morphological outcomes of Tenon patch graft (TPG) combined with cyanoacrylate glue overlay for moderate-sized perforated corneal ulcers (CU).

Methods: Twenty-five patients with perforated CU (3-5 mm) who underwent TPG with cyanoacrylate glue overlay and had a minimum follow-up record of 3 months were included. A record review was done to obtain baseline findings, Intra-operative details, and post-operative outcome. Anterior segment optical coherence tomography (ASOCT) records were also reviewed. The primary outcome was complete success, defined by anatomical integrity of the globe and graft integration.

Results: The study involved 25 eyes of 25 patients, with a mean age of 47.4 ± 20.9 years (range 5-77 years) and a male-to-female ratio of 2:3. The etiology for corneal perforation was sterile corneal melt in 52% and infectious in 28%. The perforations were peripheral in 24%, mid-peripheral in 20%, and central in 56%. The mean maximum size of perforations was $4.1 \pm 0.3 \text{ mm}$ (range 3-5 mm). No intra-operative complications were reported. Complete Success was noted in 70.8% cases. Overall complication was 28% (phthisis 8%, staphyloma 20%). Re-intervention was needed in 12%. Multi-logistic regression analysis for complete success did not show any association with etiology, site or size of perforation. However, post-op ACD showed significant association with etiology ($p=0.0001$; PUK>sterile melt>infection>chemical injury). Graft thickness from $328 \mu\text{m}$ on the first post-operative day to $256 \mu\text{m}$ at last follow-up

Conclusions: Tenon patch graft is a good rescue measure for moderate-sized perforated CU. The primary diagnosis, perforation site, and size do not affect the overall success.

Abstract No.: 200252

Panel No.: CDE-0167

Management of Small Corneal Perforation with Recurrent Graft Melting: A Case Report

First Author: Basitali LAKHANI

Purpose: Case Presentation: A patient presented with a small corneal perforation approximately 5mm in size. An initial corneal patch graft was successfully performed under antibiotic coverage. The patient initially demonstrated good recovery, with complete healing observed over the first 1.5 months. However, the graft subsequently melted, raising suspicion of an underlying viral etiology. Consequently, antiviral treatment was initiated. Under antiviral coverage, a second corneal patch graft with tarsorrhaphy was performed. The patient's condition stabilized, and they continue to do well on prophylactic antiviral therapy

Methods: .

Results: .

Conclusions: This case underscores the critical importance of considering viral etiologies in cases of recurrent graft melting. The successful management of this case with antiviral therapy and repeat grafting, along with adjunctive tarsorrhaphy, highlights the need for a comprehensive diagnostic approach. Recognizing and treating the underlying viral infection can lead to favorable outcomes and prevent further complications in recurrent corneal perforations.

Management of Superior Limbic Keratoconjunctivitis in a Patient With Severe Meibomian Gland Dysfunction: Role of Thermal Pulsation Therapy

First Author: Stella Weng Chi SIO

Co-Author(s): Vanessa Wing See CHOW

Purpose: To report the clinical effectiveness of combining LipiFlow thermal pulsation with meibomian gland expression for treating Superior Limbic Keratoconjunctivitis (SLK) associated with Meibomian Gland Dysfunction (MGD).

Methods: A case report of a 28-year-old female with bilateral SLK complicated by severe MGD who failed conventional treatment. The patient presented with intense foreign body sensation, tearing, and sharp pain during horizontal eye movement for 2 weeks. Initial treatment included artificial tears, topical steroids, and cyclosporine 0.1% eye drop, eyelid hygiene, warm compress therapy, therapeutic bandage contact lens (BCL), and punctal occlusion. While the BCL provided symptomatic relief and reduction of SLK, symptoms recurred immediately upon BCL removal. After poor response to these treatments and unsuccessful conjunctival cautery, LipiFlow thermal pulsation, followed by meibomian gland expression, was performed for treatment of the co-existing MGD.

Results: Following LipiFlow and meibomian gland expression, significant reduction in upper eyelid margin thickening and hardening was observed. Unlike previous reports where patients required long-term BCL wear, our patient was successfully weaned off BCL wear and remained asymptomatic. This approach may work by addressing the underlying meibomian gland dysfunction, potentially reducing lid margin thickening, which could lead to decreased friction between the superior tarsal conjunctiva and the cornea.

Conclusions: LipiFlow thermal pulsation combined with meibomian gland expression may be an effective treatment option for SLK associated with MGD. This case suggests that treating MGD can result in remission of SLK symptoms and offering advantages over long-term BCL dependency in select patients where the two conditions coexist.

Matrix Stiffness Regulates Corneal Fibrosis and Energy Metabolism Through the Hippo/ β -Catenin Signaling Pathway: Mechanisms and Therapeutic Implications

First Author: Kexin LI

Co-Author(s): Liang HU

Purpose: To investigate how matrix stiffness acts as an initial mechanical trigger for corneal fibrosis development and to clarify its potential mechanotransduction pathways, focusing on the interaction between the Hippo signaling pathway and β -catenin.

Methods: Human primary corneal fibroblasts were cultured in hydrogel models with varying matrix stiffness to replicate the natural compliance of the corneal stroma and the stiffness of fibrotic corneas. Combined with proteomics analysis, we comprehensively characterized cellular changes induced by stiffness. Key findings were validated through functional assays, including Western blotting and immunofluorescence staining, to assess changes in protein expression and pathway activation after pharmacological inhibition of key nodes in the Hippo and β -catenin pathways.

Results: We demonstrate for the first time that increased matrix stiffness significantly enhances the fibrotic response and reprograms cellular energy metabolism. Proteomics findings suggest this process may be mediated through activation of the Hippo/ β -catenin signaling axis. Functional studies show that inhibiting the Hippo pathway effectively reduces fibrosis, lowers β -catenin levels, and restores normal metabolic functions. However, while β -catenin inhibition lessens fibrosis and decreases TAZ expression, it does not reverse YAP activation or fix abnormal energy metabolism, indicating that the Hippo pathway acts at a more upstream regulatory level in stiffness sensing.

Conclusions: This study first maps a "mechanical signal-biochemical pathway/cellular metabolism" regulatory network in corneal fibrosis. Our findings establish the Hippo/ β -catenin pathway as a key mechanosensitive effector, offering a highly promising new therapeutic target for anti-fibrotic strategies and opening new avenues for treating corneal scarring and other fibrotic diseases.

Abstract No.: 208558

Mechanism Studies of Pathogenic Role of CMTM3 Through the Regulation of Th17 in Dry Eye Disease

First Author: Liang **YEUNG**

Purpose: This research aims to investigate the molecular mechanism of CMTM3 promoting Th17 differentiation and to provide potential diagnostic and therapeutic targets for Th17-mediated dry eye disease.

Methods: Immunofluorescence, Flow Cytometry, RT-qPCR, Western blot, Gene overexpression, and knockout techniques.

Results: The membrane molecule CMTM3 is highly expressed in human Th17 cells and may be involved in Th17-mediated autoimmune diseases. Preliminary experiments demonstrated that CMTM3 expression was elevated in corneal tissues of dry eye mice; CMTM3 exerted pathogenic effects in dry eye, and Cmtm3 knockout mice had reduced dry eye phenotype and decreased Th17 secretion of IL-17A in conjunctiva and draining lymph nodes; in vitro experiments confirmed that CMTM3 significantly promoted Th17 secretion of IL-17A during pathogenic Th17 differentiation.

Conclusions: CMTM3 expression is upregulated during Th17 differentiation after the onset of dry eye, aggravating ocular surface damage, and promoting a vicious cycle of ocular surface inflammation.

Melatonin-Mediated Inhibition of Proinflammatory Response Attenuates Meibomian Gland Dysfunction In Vitro and In Vivo Models

First Author: Jiaxu **HAN**Co-Author(s): Lingyi **LIANG**, Ren **LIU**, Caizhen **QIU**, Jianwen **XUE**

Purpose: Inflammation is a significant risk factor for meibomian gland dysfunction (MGD), yet effective therapies remain unavailable. This study examined the synthesis and release of neurohormone melatonin (MLT) within the meibomian gland (MG) and investigated the therapeutic potential of MLT for MGD.

Methods: Human MG tissues were stained to identify MLT receptors (MT1/MT2) and MLT synthetic enzymes (AANAT/ASMT). To establish an in vitro MGD model, human meibomian gland epithelial cells (HMGECS) were exposed to LPS and then pre-treated with MLT. For the in vivo MGD model, mice were fed with a high-fat diet and intraperitoneally injected with MLT. Cytokine levels, lipid metabolism, apoptosis, and MAPKs/JAKs phosphorylation in two models were analyzed.

Results: MT1/MT2 and AANAT/ASMT were expressed in human MG acini. Pretreatment with MLT attenuated proinflammatory response and lipogenesis in LPS-stimulated HMGECS, manifested as decreased production of cytokines (IL-1 β , IL-6, IL-8, and TNF- α), reduced lipid droplet formation, and downregulated expression of meibum lipogenic proteins. Systemic MLT administration alleviated corneal epithelial erosion, MG orifice obstruction, and glandular dropout in MGD mice. MLT markedly rescued progenitor depletion, cellular apoptosis, lipogenic derangement, and ductal hyperkeratinization by reinstating Ki67/Lrig1 expression, rectifying the PPAR γ -AWAT2/SOAT1/HMGR lipogenic axis, and suppressing inflammatory cells recruitment. MLT protective actions may be mediated through the dephosphorylation of MAPK and JAK inflammatory signaling cascades.

Conclusions: MG is the producer and target organ of MLT, and MLT supplementation effectively suppressed inflammation-mediated MG structural and functional damage in LPS-stimulated HMGECS and MGD mice, indicating MLT represents a promising therapy for MGD.

Mitochondria-Targeted Polymer With ROS-Scavenging Capacity Ameliorates Ocular Surface Inflammation

First Author: Yijia **ZHANG**Co-Author(s): Jian **LI**, Nasha **QIU**, Youqing **SHEN**, Yangla **XIE**, Jiabei **XIONG**

Purpose: Ocular surface inflammation is associated with excessive reactive oxygen species (ROS) accumulation. There are challenges for current treatments, such as limited bioavailability and several side effects. This study investigates the anti-inflammatory effects of OPT10, a novel mitochondria-targeted polymer with potent ROS-scavenging properties.

Methods: The H₂O₂-induced oxidative stress model in human corneal epithelial cells (HCECs) and a benzalkonium chloride (BAC)-induced dry eye mice model were employed. In vitro: HCECs were divided into control, H₂O₂-injured, and OPT10-treated (different concentrations) groups. Assessments included cell viability, intracellular ROS levels, and inflammatory cytokines secretion. In vivo: Mice were allocated into saline, dexamethasone, and OPT10 (different concentrations) treatment groups. Clinical inflammatory scores for ocular surface tissues, corneal ROS detection, ocular surface retention, and histopathological analysis were evaluated.

Results: OPT10 treatment significantly and concentration-dependently reduced intracellular ROS and suppressed the secretion of inflammatory cytokines in HCECs, without inducing cytotoxicity

even at high concentrations. In the BAC-induced dry eye mice model, OPT10 markedly improved clinical manifestations, decreased corneal ROS levels, and inhibited expression of inflammatory cytokines. Its efficacy was comparable to dexamethasone, and no ocular surface irritation was observed. Histopathological analysis revealed preserved corneal epithelial integrity with minimal tissue damage and inflammatory infiltration in OPT10-treated mice.

Conclusions: OPT10 effectively mitigates oxidative stress and ocular surface inflammation, demonstrating efficacy comparable to steroid treatment while exhibiting favorable biosafety and ocular retention. These findings support its potential as a novel therapeutic strategy for oxidative stress-related ocular surface inflammatory diseases.

Multifocal Nodular Conjunctival Ulcers as a Rare Presentation of Ocular Herpes Simplex

First Author: Manasi TRIPATHI

Co-Author(s): Ashish MARKAN

Purpose: To report a rare presentation of herpes simplex virus (HSV-1) infection manifesting as multifocal conjunctival ulcers.

Methods: A 20Y/M presented with persistent conjunctival redness, worsening after steroid use. Examination revealed multiple fluorescein-staining conjunctival epithelial defects & a superotemporal purulent nodule. Corneal sensations were reduced; the cornea remained clear. Investigations included a conjunctival swab for bacterial culture and tear fluid PCR for HSV-1 DNA.

Results: PCR confirmed HSV-1. Bacterial cultures were negative. Initiation of topical and oral acyclovir led to the rapid resolution of nodules and ulcers over 3 weeks, with flattening of the conjunctival lesion.

Conclusions: HSV conjunctivitis may rarely present with multifocal conjunctival ulcers and nodules, mimicking other infectious or immune-mediated etiologies. Prompt recognition and discontinuation of steroids are essential to avoid exacerbation and facilitate recovery.

Neuropathic Corneal Pain and Blepharospasm: A Case Series

First Author: Zhang Zhe THIA

Co-Author(s): Yu-chi LIU, Aya TAKAHASHI, Louis TONG

Purpose: Chronic involuntary muscle contraction in blepharospasm may lead to irritation of trigeminal afferents and corneal neurogenic inflammation, causing neuropathic corneal pain (NCP). We herein present the clinical manifestations, corneal imaging features, and

treatment modalities in 3 patients with NCP associated with blepharospasm.

Methods: Ocular surface evaluation was performed using slit-lamp biomicroscopy and corneal in-vivo confocal microscopy (IVCM). Pain symptoms and quality of life (QoL) were assessed using the Ocular Pain Assessment Survey (OPAS). The median follow-up period is 1 year.

Results: The subjects had a median age of 50 years. Initial findings included minimal ocular surface staining but disproportionate ocular pain, accompanied by burning sensation and photophobia. IVCM scans revealed reduced corneal nerve density, increased nerve tortuosity, and corneal microneuromas. All patients received weekly periorbital quantum molecular resonance electrotherapy for 2 months. 2 of the 3 cases received 4 to 5 injections of botulinum toxin for blepharospasm, while 1 had previously undergone treatment at a private clinic prior to review. Additional treatments included oral Pregabalin or Gabapentin, topical lubricants, Cyclosporine 0.05% (1 case), and autologous serum eye drops (1 case). Improvement in all domains of OPAS evaluation, including QoL, ocular pain, and non-ocular pain scores, was observed among all 3 subjects following a multimodal treatment.

Conclusions: Blepharospasm is a possible predisposing factor of NCP. Concurrent treatment for blepharospasm and NCP can effectively relieve symptoms, and adopting a multimodal approach is recommended.

Abstract No.: 201907

Panel No.: CDE-0200

Neurotrophic Keratopathy With Medicamentosa Keratoconjunctivitis In Trigeminal Trophic Syndrome: A Rare Case Report

First Author: Vinit TANWAR

Purpose: To present a rare case of neurotrophic keratopathy (NK) complicated by keratoconjunctivitis medicamentosa in a patient with Trigeminal Trophic Syndrome (TTS), highlighting the vision-threatening implications and the importance of early recognition.

Methods: A 55-year-old female with a four-year history of TTS presented with a persistent, non-healing corneal epithelial defect in her right eye. Her symptoms had acutely worsened following self-administration of an Ayurvedic eye drop. A comprehensive evaluation included clinical examination, corneal sensation testing, and neuroimaging (MRI). The implicated eye drop underwent pharmacological analysis for pH and osmolality.

Results: Examination revealed a 6x6.5 mm central corneal epithelial defect with significantly reduced corneal sensation. MRI showed enhancement at Meckel's cave, consistent with trigeminal nerve involvement. The Ayurvedic drop was found to

be highly acidic (pH 3) and hyperosmolar (>1500 mOsm/L), confirming its epithelial toxicity. Following a diagnosis of NK exacerbated by medicamentosa keratoconjunctivitis, the patient was treated with preservative-free lubricants, topical antibiotics, and a bandage contact lens. This regimen led to complete corneal re-epithelialization and visual recovery within two weeks.

Conclusions: Trigeminal Trophic Syndrome is a rare but significant cause of corneal hypoesthesia predisposing to NK. This case underscores the severe risk of ocular surface toxicity from unregulated topical agents, which can dangerously complicate the underlying neurotrophic state. Meticulous history-taking, patient education on avoiding irritants, and prompt, appropriate management are crucial to prevent permanent ocular damage and preserve vision.

New Exploration of Epiphora Treatment in Patients With Narrow Tear Point and Dry Eye Syndrome

First Author: Yi ZHANG

Purpose: To explore new treatment methods for epiphora caused by stenosis of the lacrimal puncta with dry eye syndrome and evaluate their effectiveness.

Methods: A total of 56 patients with narrow lacrimal puncta, dry eye syndrome, and epiphora were selected. All patients underwent pre-treatment examinations including Schirmer's test for tear secretion, tear film break-up time, meibomian gland photography, mite detection, anterior segment photography, corneal staining, and lacrimal duct irrigation. Patients with stenosis or obstruction of the lacrimal duct as revealed by lacrimal duct irrigation were excluded. All patients received lid margin deep cleaning therapy (including demodex removal for patients with mites). Dry eye syndrome patients were treated with intense pulsed light combined with medication. Patients whose epiphora symptoms remained unresolved after the above treatments underwent surgical intervention, which included either removal of lacrimal punctal polyps or implantation of a porous non-degradable punctal plug.

Results: All patients showed improvement in their tearing symptoms. After conservative treatment (intense pulsed light combined with medication for eyelid margin cleaning), tearing symptoms significantly improved in 40 patients. In 16 patients where tearing symptoms did not improve with conservative treatment, they underwent punctal surgery (punctoplasty or implantation of a porous non-degradable punctal plug) and their tearing symptoms then significantly improved.

Conclusions: Epiphora caused by narrow lacrimal puncta accompanied by dry eye syndrome require consideration of multiple factors in treatment, and combined therapeutic approaches can be adopted; surgery is not the only solution.

Panel No.: CDE-0198

Nick, Loop and Pull Technique of Corneal Suture Removal

First Author: Vinit TANWAR

Purpose: To devise and report a standardized step-wise approach to corneal suture removal.

Methods: A review of the literature and observed practiced suture removal techniques by ophthalmologists and corneal surgeons was performed. Associated problems were noted, such as epithelial defects, wound dehiscence, and bleeding from the vascularized cornea in deeply buried sutures. A step-wise approach was devised, hitherto described as the Nick, Loop, and Pull technique, providing a systematic step-wise method of corneal suture removal, which was tested clinically for complications.

Results: This technique was performed successfully in 20 eyes with comparatively fewer complications after corneal suture removal compared to routine methods.

Conclusions: This standardized step-wise approach of corneal suture removal is feasible, reproducible, and easy to learn, and causes less deleterious effects on the cornea and its wound integrity.

Nigrospora oryzae Keratitis: A Rare Fungal Etiology

First Author: Huy TRAN NGOC

Co-Author(s): Huong DUONG NGUYEN VIET, Simon FUNG, Vinh LAM MINH, Mai NGUYEN THI TRUC

Purpose: To report a rare case of fungal keratitis caused by *Nigrospora oryzae* in an immunocompetent patient without a history of ocular trauma, and to compare its clinical and microbiological features with a previously published case.

Methods: A 62-year-old female farmer presented in December 2019 with a two-week history of ocular pain, redness, and visual loss in the right eye. Initial treatment by a local provider was unsuccessful. On presentation, slit-lamp examination revealed a raised central corneal infiltrate with feathery margins, associated with corneal neovascularization and hypopyon, but without epithelial defect. Corneal scraping was performed, and the specimen was analyzed by fungal staining, culture, and DNA sequencing.

Results: Staining revealed septate hyphae, suggestive of a filamentous fungus. Culture confirmed *Nigrospora oryzae* with susceptibility to amphotericin B, itraconazole, and fluconazole. The patient was treated with oral itraconazole, topical amphotericin B 0.15%, and fortified povidone-iodine 5%. Complete resolution was achieved without recurrence, but with residual central scarring. No prophylactic antibiotics or corticosteroids were used. A comparative review with the only other reported case revealed differences in ulcer characteristics, treatment protocols, and antifungal susceptibility.

Conclusions: *Nigrospora oryzae* is a rare cause of fungal keratitis that can present in immunocompetent individuals without apparent trauma. In resource-limited settings like Vietnam, delayed diagnosis due to limited microbiological support may obscure the detection of uncommon pathogens. This case underscores the need for enhanced diagnostic capacity and awareness of atypical fungal agents in cases of infectious keratitis.

Novel Eye Drops Based on Iota-Carrageenan for the Treatment of Dry Eye: In Vitro and Ex Vivo Studies

First Author: Anaïs CASTEX

Co-Author(s): Eva PRIESCHL-GRASSAUER, Sabine ROCH-NAKOWITSCH, Antonella RUSSO, Nicole UNGER-MANHART

Purpose: Iota-Carrageenan (I-C) is a natural high molecular weight polysaccharide polymer that has mucoadhesive, lubricating, and moisturizing properties. The aim of this study was to evaluate the protective effect of I-C eye drops against dehydration in vitro and ex vivo, in comparison to other marketed moisturizing products.

Methods: Human cornea epithelial cells were incubated in vitro with eye drops for two hours, and then dehydrated at 33°C for 2 to 40 minutes. Cell survival was determined using an Alamar blue fluorometric assay. In an ex vivo assay, porcine eyes were placed in a laminar flow for 6 hours to induce dehydration. Every 15 minutes, one drop of product was applied to the eyes. Corneal damages were evaluated using a fluorescein staining.

Results: In vitro, I-C treatment induced a fourfold increase in cellular half-life upon dehydration, when compared to the untreated control (15.1 min versus 3.6 min). Its efficacy was also higher than other marketed products, for which cellular half-lives ranged from 5.3 to 10.1 min. In the ex vivo model, I-C significantly reduced the corneal damage in comparison to NaCl treated eyes (reduction by 53.4%). The other marketed products exhibited lower reductions (maximum 34.9%).

Conclusions: I-C demonstrated superior efficacy in dry eye in vitro and ex vivo models when compared to other marketed products, therefore highlighting the potential of I-C as a treatment for dry eye disease.

Observation on Omitting Bandage Contact Lenses in Primary Hospital Pterygium Surgery With Standardized Medication

First Author: Xudong FANG

Co-Author(s): Jian LI

Purpose: To assess short-term postoperative efficacy and complications of omitting bandage contact lenses (BCLs) after pterygium excision plus limbal stem cell transplantation in primary hospitals.

Methods: Retrospective analysis was performed on 50 patients (50 eyes) who underwent the above surgery without BCL. Perioperative medications: 1 day preoperatively, levofloxacin eye drops (1 drop, qid); immediately postoperatively, tobramycin-dexamethasone eye ointment; 1 week postoperatively: ① levofloxacin drops (1 drop, qid), ② tobramycin-dexamethasone drops (1 drop, qid), ③ sodium hyaluronate drops (1 drop, qid), ④ tobramycin-dexamethasone ointment (1 drop, qn). Corneal epithelial healing time, subjective discomfort and complications were recorded.

Results: All 50 patients achieved corneal epithelial healing within 3-5 days; postoperative irritative symptoms were manageable. Complications: 1 case (2%) of conjunctival flap displacement (eye rubbing-induced), 2 cases (4%) of conjunctival granuloma; no scleral melting or corneal infection.

Conclusions: With standardized anti-inflammatory/anti-infective medications (quinolones, corticosteroids, lubricants perioperatively), omitting BCL is feasible in primary hospitals, ensuring 100% corneal healing and avoiding severe complications. Strict patient education (no eye rubbing), vigilance for granulomas (4%), standardized surgery and close follow-up are essential, which reduces healthcare costs.

Panel No.: CDE-0280

Ocular Manifestations in Alport Syndrome: A Retrospective Case Series From a Tertiary Eye Care Center in India

First Author: Swetha BUGGAREDDIGARI

Co-Author(s): Muralidhar RAMAPPA

Purpose: To describe the spectrum of ocular manifestations in Alport syndrome, assess associated systemic involvement, and evaluate the visual outcomes following surgical intervention.

Methods: A retrospective analysis was conducted on 22 patients with Alport syndrome who presented to a tertiary eye care centre between 2013 and 2025. Data on demographics, systemic findings, visual acuity, anterior and posterior segment examination (including Optical Coherence Tomography when available), and surgical outcomes were analysed.

Results: Twenty-two patients (44 eyes) were included. Mean age at presentation was 23.3 years (range: 8–54), with a male predominance of 86%. Bilateral anterior lenticonus was seen in all patients; in some, one eye had undergone cataract surgery prior to presentation. Dot-and-fleck retinopathy, consistent with classical mid-peripheral retinal changes, was observed in 36% of eyes. OCT revealed macular thinning in selected cases. Central corneal thickness ranged from 450–546 µm (available records). Surgical intervention (lens aspiration with IOL implantation) in visually significant lenticonus or cataract resulted in Best Corrected Visual Acuity improvement from as low as 20/600 to 20/20. Systemic involvement included nephropathy and sensorineural hearing loss in 72 % patients. Genetic confirmation with COL4A5 mutation was available in three cases. A family history suggestive of renal disease or early-onset hearing loss was documented in 18% patients.

Conclusions: Ocular signs, particularly bilateral anterior lenticonus and dot-and-fleck retinopathy, are reliable diagnostic markers in Alport syndrome. In resource-limited settings, their presence, along with systemic and family history, can support early syndromic diagnosis. Surgical intervention offers excellent visual rehabilitation.

Abstract No.: 200488

Panel No.: CDE-0173

Ocular Mucous Membrane Pemphigoid on a 59-Year-Old Male: A Case Report

*First Author: Paul Gilbert **APILADO***

Purpose: To present the clinical course, diagnosis, and management of a 59-year-old male, Filipino with ocular mucous membrane pemphigoid presenting as recurrent cicatricial entropion and ocular surface disease.

Methods: A detailed history was performed, presenting a case of recurrent cicatricial entropion for both eyes and a previous history of surgical repair. A conjunctival biopsy was obtained, and direct immunofluorescence (DIF) was performed to confirm the diagnosis.

Results: DIF showed a homogenous linear deposition of immunoglobulin G (IgG), A (IgA), M (IgM), and C3 in the conjunctival basement membrane zone, confirming the diagnosis.

Conclusions: Ocular mucous membrane pemphigoid is an autoimmune disease primarily affecting the conjunctiva that may lead to vision loss. A high index

of suspicion in patients with cicatricial conjunctivitis, forniceal shortening, and symblepharon is vital. Supportive management for ocular surface disease and Methotrexate was given as an immunosuppressant. Surgical intervention with blepharoplasty and anterior lamellar recession was done once the ocular inflammation was stable, providing better ocular surface and visual acuity. Overall, early detection and prompt treatment are essential to halt disease progression for early surgical intervention.

Ocular Tuberculosis Presenting as Nodular Scleritis in an Immunocompetent Host: A Case Report

*First Author: Rishanne Meire **ORTIZ***

*Co-Author(s): Mary Ellaine **DIAZ**, Rey Carlo **NARAVAL***

Purpose: Ocular tuberculosis (OTB) is a rare extrapulmonary presentation of Mycobacterium tuberculosis. Its clinical manifestation varies and can mimic various ocular and systemic conditions that can make its diagnosis and management challenging. The purpose of this study is to report a case of intraocular tuberculosis presenting as nodular scleritis in an immunocompetent individual with no presenting symptoms other than its ocular findings.

Methods: A 45-year-old immunocompetent male presented with eye redness accompanied with pain and blurring of vision in the left eye with iris-angle granuloma, scleral thinning and anterior chamber inflammation on slit lamp examination.

Results: The work-up revealed a positive QuantiFERON-TB test, while other systemic signs and chest radiography were unremarkable. The patient was then managed as a case of presumptive ocular tuberculosis and was started on antitubercular therapy. Within days, the patient developed worsening inflammation and posterior synechiae formation, consistent with a paradoxical immune response. Topical steroids and introduction of systemic corticosteroids led to marked clinical improvement, with gradual resolution of inflammation and improvement of vision.

Conclusions: This case underscores the importance of considering OTB even with atypical presentations such as nodular scleritis and even in immunocompetent patients. Early recognition, appropriate diagnostic testing, and a timely treatment approach are essential to prevent long-term visual sequelae.

One Donor, Three Visions: Clinical Outcomes of Shared Corneal Tissue in Limbal Dermoid Cyst, Corneal Scarring, and Perforation

First Author: Yaumil QORISA

Co-Author(s): Rio RHENDY

Purpose: Donor cornea shortage remains a major limitation in corneal transplantation, especially in developing countries. Innovative tissue-sharing strategies may help overcome this gap.

Methods: We report the utilization of a single donor cornea for three patients. The anterior stromal lamella was transplanted via anterior lamellar keratoplasty in a patient with limbal dermoid cyst. The remaining donor lamella was used for anterior lamellar keratoplasty in a pediatric patient with corneal cicatrix. The excised cicatricial tissue from this second procedure was subsequently repurposed as a patch graft to seal a corneal perforation following foreign body injury. The limbal dermoid cyst and corneal perforation cases achieved favorable outcomes with corneal integrity and stable recovery, whereas the cicatrix case showed a suboptimal outcome due to poor compliance with postoperative medication.

Results: This case series illustrates the potential of combining split donor cornea allocation with host tissue recycling to maximize surgical benefit. Previous studies have reported comparable visual and anatomical outcomes between conventional and split corneal grafting, supporting feasibility of such approaches. Proper case selection, meticulous surgical planning, and careful handling of donor and host tissue are essential for graft adequacy and clinical success. By integrating donor sharing and tissue recycling, corneal surgeons may expand the impact of limited tissue availability, particularly in resource-constrained regions.

Conclusions: The use of one donor cornea for two anterior lamellar keratoplasties, combined with recycling host tissue for a corneal patch graft, represents a practical strategy to optimize scarce resources, though outcomes may be influenced by compliance, especially in pediatric cases.

Optimized Transepithelial Corneal Cross-Linking for Keratoconus: A Mid-Term Clinical Observation

First Author: Liu JUNQI

Purpose: Early diagnosis and timely intervention with corneal cross-linking (CXL) are crucial for halting keratoconus progression. Epi-off CXL penetrates deeper but causes discomfort, while epi-on CXL is more comfortable but less effective. We optimized

the epi-on CXL protocol for early-stage keratoconus, demonstrating effective disease control and patient comfort.

Methods: A clinical study on 15 patients (25 eyes) with keratoconus used an optimized epi-on CXL protocol with 7.2 J/cm² energy at 24 mW/cm² for 5 minutes via continuous UV-A irradiation. Preoperative assessments included corneal biomechanics, anterior segment OCT, and endothelial cell density. Follow-ups were at 1 day, 1 week, and 1, 3, 6, 12, 18, and 24 months postoperatively. Primary outcomes were corneal stiffness, maximum K-value (Kmax), and epithelial integrity.

Results: Follow-up from 1 week to 1 year showed all treated eyes maintained intact epithelia. Mild corneal edema resolved by day 7, with thickness restored by 1 week. Biomechanical enhancement was significant (2.0–2.75-fold stiffness increase). Mean Kmax decreased by 0.5–1.5 D at 1 month and 1.5–2.0 D at 3 months. No significant decrease in comfort was reported throughout the study.

Conclusions: This interim analysis confirms that the optimized epi-on CXL protocol leads to favorable outcomes: increased corneal rigidity, reduced keratometry values, and preserved comfort. Future studies will refine the protocol for individualized keratoconus management.

Osimertinib Induces Oxidative Stress in Corneal Epithelial Cells and Therapeutic Effects of Tacrolimus

First Author: Li LI

Co-Author(s): Xinyi ZHAO

Purpose: Osimertinib, a first-line tyrosine kinase inhibitor for advanced non-small cell lung cancer (NSCLC), has been associated with increased keratitis risk. This study aims to investigate the mechanisms of osimertinib-induced damage to corneal epithelial cells and evaluate the role of tacrolimus.

Methods: Immortalized human corneal epithelial cells (HCEC-T) were cultured on polyacrylamide hydrogels mimicking corneal stiffness. Cells were treated with osimertinib, tacrolimus, osimertinib plus tacrolimus, or blank control. Cell viability was assessed via CCK-8 assay; migration ability via scratch assay; intracellular reactive oxygen species (ROS) production using DCFH-DA fluorescent staining; hydrogen peroxide release and membrane permeability via scanning electrochemical microscopy (SECM); protein expression via Western blot; and mRNA levels via RT-qPCR.

Results: Osimertinib exhibited time- and concentration-dependent cytotoxicity in HCEC-T cells. Compared to control, 2.5μM osimertinib reduced cell viability, slowed migration, increased ROS generation and

hydrogen peroxide release, elevated membrane permeability, and suppressed EGFR/AKT pathway mRNA and protein expression. Coadministration of 1 μ M tacrolimus with osimertinib attenuated these effects. Furthermore, pretreatment with tacrolimus prevented osimertinib-induced damage.

Conclusions: The corneal epithelial toxicity of osimertinib, which is characterized by oxidative stress, increased membrane permeability, and deficits in migration, viability, and survival, coincides with the inhibition of EGFR/AKT signaling. Tacrolimus counteracts these cytotoxic effects by alleviating oxidative stress and maintaining epithelial homeostasis.

Overactivation of Mineralocorticoid Pathway Aggravates UVB-Induced Corneal Damages: Restoration by Spironolactone Eyedrops

First Author: Linxin ZHU

Co-Author(s): Francine BEHAR-COHEN, Min ZHAO

Purpose: Ultraviolet radiation (UVR) is a known trigger of ocular diseases, with the majority of UVB absorbed by the cornea. Chronic exposure can cause irreversible damage, including neovascularization and keratopathy, potentially linked to limbal stem cell dysfunction. The mechanisms of UVB-induced corneal opacity remain unclear, and no specific treatment exists. Mineralocorticoid receptor (MR) antagonism has been reported to improve corneal integrity in models of stem cell deficiency and wound healing. We aimed to investigate the role of MR signalling in UVB-induced corneal damage and assess spironolactone (SPL) therapy.

Methods: Eyes of adult SD rats and hMR-overexpressing transgenic rats ($n = 24$ / group) were exposed to UVB (370 μ W/cm²; 280–315 nm) for 3 mins daily over 3 days. SPL (0.1%) or placebo (PBO) eye drops were applied three times daily for 14 days. Corneal morphology was assessed by OCT, while opacity, smoothness, and epithelial defects were evaluated by slit lamp and fluorescein staining. Corneas were collected for histological analysis.

Results: UVB exposure significantly increased corneal thickness ($p < 0.001$), irregularity, and opacity. hMR-overexpressing rats developed larger epithelial defects and greater edema compared to wild-type rats ($p < 0.05$). Histology confirmed epithelial loss, stromal edema, and inflammatory infiltration, which were more pronounced in transgenic rats. SPL treatment markedly reduced edema and neovascularization, improved epithelial integrity, and limited inflammation.

Conclusions: MR overactivation exacerbates UVB-induced keratopathy by promoting epithelial damage, edema, and inflammation. SPL eye drops significantly alleviated these changes, supporting MR antagonism

as a promising therapeutic strategy for UVB-related corneal injury. Transcriptome will be investigated to further elucidate underlying mechanisms.

Possible Contribution of Early FECD to Bullous Keratopathy Following Argon Laser Iridotomy: A Preliminary Observation in Japanese Patients

First Author: Sayaka NISHIHATA

Co-Author(s): Takahiko HAYASHI, Noriko KOIZUMI, Naoki OKUMURA, Toshiki SHIMIZU, Satoru YAMAGAMI

Purpose: Bullous keratopathy (BK) after argon laser iridotomy (ALI) is more frequent in Japanese patients than in Western populations. However, the underlying mechanisms remain unclear, and the contribution of subclinical Fuchs endothelial corneal dystrophy (FECD) has not been fully explored.

Methods: We retrospectively analyzed 8 patients who underwent endothelial keratoplasty for BK presumed to be secondary to ALI. Descemet's membrane (DM) specimens were excised during surgery and examined by phase-contrast microscopy to evaluate the presence of guttae. Clinical history and slit-lamp findings at the time of ALI were reviewed to exclude cases with overt FECD.

Results: All 8 cases demonstrated histopathological evidence of guttae on DM, consistent with FECD. None of these patients were clinically diagnosed with FECD at the time of ALI, and although referral cases limited full verification, no definite signs of FECD were recorded. Moreover, due to corneal edema associated with BK, guttae could not be reliably confirmed by slit-lamp biomicroscopy before ALI. These findings suggest that ALI may have accelerated endothelial stress in eyes with unrecognized early FECD or guttae alone, leading to BK.

Conclusions: This preliminary observation raises the possibility that the relatively high prevalence of so-called ALI-induced BK in Japanese eyes may, in fact, reflect the presence of underlying FECD, particularly in populations with shallow anterior chambers. Although confirmatory studies are required, clinicians should exercise caution when performing ALI in eyes with even subtle endothelial abnormalities.

Posterior Blepharitis Mimicking Ectasia on Corvis-ST

First Author: Khushbakht PETERS

Co-Author(s): Kanwal RUKHSAR

Purpose: To report a case of posterior blepharitis in which tear film instability mimicked early ectasia by

causing a false-positive elevation of the Tomographic and Biomechanical Index (TBI) on Corvis-ST, despite normal tomography and clinical findings.

Methods: A 24-year-old male presented with a 2-week history of burning sensations in both eyes. Best corrected visual acuity (BCVA), refraction, slit-lamp examination, keratometry, Pentacam tomography, and Corvis-ST analysis were performed.

Results: BCVA was 6/6 in the right eye with $-0.50/-2.00 \times 15$ and 6/7.5 in the left eye with $-0.75/-2.00 \times 165$. Keratometry revealed 42.50/45.25 D in the right eye and 42.25/45.00 D in the left eye. Slit-lamp examination showed bilateral posterior blepharitis, while the rest of the ocular examination was unremarkable. Pentacam tomography was normal in both eyes. Corvis-ST revealed a normal TBI in the right eye but an elevated TBI of 0.52 in the left eye, falsely suggesting ectatic risk. After initiating lubricants and lid hygiene, repeat imaging at 2 weeks showed normalization of TBI values, confirming that the apparent "ectasia" was secondary to tear film instability rather than true biomechanical weakness.

Conclusions: Posterior blepharitis can mimic corneal ectasia by producing false-positive elevations in TBI despite structurally and biomechanically normal corneas. In patients with ocular surface disease, repeat imaging after surface optimization is crucial to avoid misdiagnosis and inappropriate management.

Power of the Air Bubble in Descemet Membrane Detachment

First Author: Vishakha WADIBHASME

Co-Author(s): Yogesh JIBHAKATE

Purpose: To demonstrate the simple and easy technique of air bubble instillation in the management of corneal edema due to Descemet membrane detachment.

Methods: Fifteen patients having corneal edema due to Descemet membrane detachment were included in the study. All the patients were thoroughly examined on the slit lamp and investigated with anterior segment OCT. The patients were managed by a simple procedure of air bubble instillation. The trick is we have to identify the part of the clear cornea, and from that side, we have to inject air towards the edematous. Cornea with 30 gauge needle and 5 ml syringe. As the anterior chamber becomes air-tight, we have to make multiple perpendicular incisions with the tip of MVR. Triangular sponges are used over the slit incisions pressed and consequently gush of water trapped between descemet membrane and corneal stroma is ejected. These steps are repeated till we get a clear cornea at the end of the procedure. Anterior chamber is well formed and patient is made to lie in

supine position for 30 minutes. Pad and patch done. The patients were started on antibiotics steroids and hyperosmotic agents.

Results: All patients responded to the management and, within 3 days, restored clarity of the cornea. Post op procedure, anterior segment OCT revealed attachment of the Descemet membrane.

Conclusions: A safe, easy, and effective technique of air bubble instillation with perpendicular slit incisions can manage corneal edema due to Descemet membrane detachment, preventing corneal blindness. This procedure can be done by any beginner surgeon with ease.

Abstract No.: 200869

Precision Microneedle-Enhanced Riboflavin Delivery for Customized Corneal Cross-Linking in Keratoconus Therapy

First Author: Jinhai HUANG

Co-Author(s): Zhongxing CHEN, Mei YANG, Xinning YANG, Xingtao ZHOU

Purpose: This study is to develop a customized CXL treatment for keratoconus, utilizing microneedles to precisely deliver riboflavin directly into the cornea, thereby improving the precision and efficacy of the treatment compared to conventional methods.

Methods: The study encompassed crafting of four unique microneedle mold, namely circular, semi-circular, annular, and butterfly-shaped. These molds served as templates for fabricating microneedle arrays that were preloaded with an optimized solution of riboflavin and hyaluronic acid. The microneedles were subsequently employed to gently penetrate the corneal epithelium while preserving the integrity of the underlying stromal layer. Following the application of the microneedles, the riboflavin (RF) solution was replenished to augment the RF concentration within the stroma, leveraging the punctures created by the microneedles. Microneedles were applied to A-CXL and efficacy was evaluated compared with conventional RF A-CXL protocol.

Results: The application of the customized microneedles led to a notable flattening of the corneal curvature in the treated zone. Replenishing the RF solution enhanced the stromal riboflavin content, which is crucial for effective cross-linking. Moreover, the treatment facilitated a swift postoperative recovery of corneal tissue, demonstrating the potential to reduce healing durations. Importantly, the customized corneal cross-linking effects proved to be comparable to those achieved through the conventional epi-off CXL protocol.

Conclusions: The integration of customized microneedle riboflavin delivery with CXL presents an innovative treatment modality for keratoconus. This approach offers a more precise and efficient alternative

to conventional methods, affording the possibility to customize treatments according to individual patient requirements.

Predicting Trouble: What Drives Graft Infections After TPK? A Prospective Study at Tertiary Eye Hospital

First Author: Tejaswi PRASAD

Co-Author(s): Tejaswi PRASAD

Purpose: To determine the incidence and timing of graft infections following TPK, and evaluate the influence of preoperative microbial flora, donor-related, and surgery-related factors on their development.

Methods: A prospective observational study of 84 patients who developed graft infections. Data on demographics, systemic illness, compliance, infiltrate size, microbiological profile, limbal involvement, and surgical parameters were analysed among 249 TPKs from January to December 2024.

Results: The graft infection rate was 34.53%. Major preoperative risk factors included infiltrates ≥ 7 mm (73.49%), limbal involvement (51.02%), and corneal perforation (44.90%); diabetes was present in 32.65% and 24.49% were non-compliant preoperatively. Microbiology showed fungal predominance: *Fusarium* spp. (38.78%) and *Aspergillus flavus* (20.41%) predominated; no growth in 12.24%. *Pythium insidiosum* accounted for 6.12%, while *Streptococcus pneumoniae* and dematiaceous fungi were each 4.08%; other rare isolates were 2.04% each. Overall, 73.47% were fungal, 8.16% bacterial, 6.12% pythium, and 12.24% culture-negative. Infections presented between 7–82 days postoperatively and clustered in larger grafts (>10 mm: 42.86%; 9–10 mm: 28.57%; 8–9 mm: 22.45%; <8 mm: 6.12%). Outcomes were poor: 97.96% attained $\leq$ CFCF vision; total graft infection occurred in 57.14%, partial in 26.53%, and 6.12% progressed to phthisis or required evisceration.

Conclusions: Post-TPK graft infections were predominantly associated with fungal keratitis, large infiltrates, and cases with limbal involvement or perforation. Early microbiological diagnosis, strict adherence to therapy, and timely intervention are crucial to minimizing infection risk and optimizing surgical outcomes.

Preliminary Analysis of the Efficacy of Traditional Chinese Medicine Ultrasonic Atomization Treatment for Dry Eye Disease: A Randomized Controlled Trial

First Author: Zhichao HU

Co-Author(s): Kelvin Kam Lung CHONG, Yiu Man WONG

Purpose: To investigate the efficacy of traditional Chinese medicine (TCM) atomization for Dry Eye Disease (DED).

Methods: Two hundred participants were allocated (1:1:1:1:1) to compound decoction (CD), dendrobium caulis (DC), houttuynia cordata (HC), placebo atomization (PA), or artificial tear (AT) group randomly. Ocular Surface Disease Index (OSDI) and non-invasive tear break-up time (NIBUT) from baseline (m0) to week 4 (w4) and month 4 (m4) were analyzed by generalized estimating equations on SPSS 29. (Clinicaltrials.gov: NCT06089317)

Results: 199 subjects (154 females) aged 54.53 ± 14.72 were analyzed. At w4, only the first NIBUT in DC group was significantly different from m0 (3.06, $P=0.027$), while no significant NIBUT change in m4 compared to m0, and among all groups at w4 and m4. There was a significant change of OSDI in CD (-7.57, $P<0.001$), DC (-8.52, $P<0.001$), HC (-12.85, $P<0.001$), and PA (-8.49, $P<0.001$) from m0 to w4, and also in CD (-5.03, $P=0.023$), DC (-7.65, $P<0.001$), HC (-8.98, $P<0.001$), PA (-7.91, $P<0.001$), and AT (-3.78, $P=0.031$) from m0 to m4. OSDI in the HC group was significantly lower than CD and DC.

Conclusions: TCM atomization could improve OSDI and NIBUT, and act as an effective DED treatment.

Prevalence and Management of Allergic Sensitizations in a Pediatric Population: Demographic and Clinical Insights

First Author: Divya KATTA

Co-Author(s): Mahathi VANKIREDDI

Purpose: This study aimed to investigate the prevalence of allergic sensitizations among pediatric patients, focusing on demographic characteristics, diagnosis severity, healthcare engagement, and the distribution of allergens. It also explored associations between allergen sensitization and clinical outcomes such as astigmatism.

Methods: A cohort of 74 pediatric participants aged 3 to 23 years was assessed for demographic data, allergy diagnosis severity, frequency of clinical visits, medication use, and results from skin prick tests. Allergen distribution was specifically evaluated, with statistical analyses including Chi-square and Fisher's

Exact Test performed to evaluate associations among variables.

Results: The findings revealed that 98.6% of participants tested positive for allergies, with significant sensitization to common indoor allergens such as cockroach (25 cases) and house dust mites (*Dermatophagoides pteronyssinus* at 26 cases, *D. farinae* at 15 cases). The study also identified associations between positive skin prick test results and higher rates of astigmatism ($X^2 = 17.74$, $p < 0.001$). Furthermore, 51.4% of participants reported using three medications annually, reflecting a strong reliance on ongoing medication management. Notably, 80.0% of participants engaged in follow-up visits post-testing, with 72.7% adjusting their medication regimens accordingly.

Conclusions: This study underscores the urgent need for thorough assessments and tailored management strategies in pediatric populations affected by allergies, emphasizing the significant prevalence of sensitizations and the implications for clinical practice. The high engagement in follow-up care suggests an opportunity to improve outcomes through targeted interventions that address both allergen exposure and associated clinical conditions.

Primary Results of the MIHE Keratoprosthesis Surgery

First Author: Jie BAI

Co-Author(s): Zexia DOU, Yifei HUANG, Ling LI, Shaowei LI, Chang LIU, Lin ZHAO

Purpose: To evaluate the primary anatomical and functional results of MIHE keratoprosthesis (KPro) for bilateral end-stage corneal blindness.

Methods: Retrospective consecutive case series of 16 (16 eyes) patients with end-stage corneal blindness who underwent MIHE KPro implantation. Preoperative characteristics, surgical details, and postoperative data, including best-corrected visual acuity (BCVA), KPro retention, and complications, were collected.

Results: Surgical indications included chemical injury (4 eyes), multi-penetrating keratoplasty failure (4 eyes), mucous membrane pemphigoid (3 eyes), graft-versus-host disease (2 eyes), explosive injury (1 eye), Stevens-Johnson syndrome (1 eye), and severe dry eye caused by cytomegalovirus keratitis secondary to HIV (1 eye). Mean follow-up was 11.81 ± 6.56 months (range: 3 to 24 months). Fifteen of the 16 eyes underwent simultaneous implantation of the MIHE KPro's frame and optical cylinder, while 1 eye required a two-stage procedure due to corneal perforation that occurred during lamellar corneal dissection. Autologous auricular cartilage reinforcement was performed in all patients. At last follow-up, all 16 eyes achieved postoperative

BCVA of 20/200 or better, with 7 eyes reaching 20/40 or better. Postoperative complications included surface mucosa overgrowth (4 eyes), conjunctival defect (2 eyes), and one case each of retro-prosthetic membrane, trauma-induced displacement of the KPro, retinal detachment, and aqueous humour leakage. All 16 eyes retained their initial KPro at the latest follow-up.

Conclusions: MIHE KPro, no allogeneic corneal donor needed, is an effective treatment for end-stage corneal blindness. It offers broad indications and a favorable safety profile. The procedure is highly feasible, with most patients eligible for simultaneous implantation of the frame and optical cylinder.

Panel No.: CDE-0262

Quality of Life in Patients With Mild to Moderate Dry Eye Disease in a Hong Kong Cohort

First Author: Zhichao HU

Co-Author(s): Kelvin Kam Lung CHONG, Chi Pui Calvin PANG, Clement Chee Yung THAM, Yiu Man WONG

Purpose: This study aimed to investigate the quality of life (QoL) in patients with mild to moderate dry eye disease (DED) in a Hong Kong cohort.

Methods: QoL was assessed via the Short Form Health Survey (SF-36), which evaluates eight domains: Physical Functioning (PF), Role-Physical (RP), Bodily Pain (BP), General Health (GH), Vitality (VT), Social Functioning (SF), Role-Emotional (RE), and Mental Health (MH). Clinical measures of DED included Tear Break-Up Time (TBUT) and the Ocular Surface Disease Index (OSDI). The correlations between the SF-36 domains and the DED outcomes were analyzed using Spearman's correlation analysis in SPSS Version 29. (ClinicalTrials.gov ID: NCT06089317)

Results: A total of 198 subjects (153 females, 76.9%), with a mean age of 54.69 ± 14.58 years, were included. The mean scores for the eight SF-36 domains were as follows: PF (86.31 ± 14.47), RP (77.40 ± 33.94), BP (79.86 ± 13.93), GH (60.45 ± 16.08), VT (68.18 ± 17.95), SF (90.21 ± 12.13), RE (79.80 ± 33.69), and MH (68.81 ± 16.12). The means of OSDI and TBUT were 22.99 ± 11.92 and 3.65 ± 2.36 , respectively. Significant negative correlations with the OSDI score were observed for RP ($P < 0.001$, $r = -2.87$), BP ($P = 0.010$, $r = -0.183$), VT ($P = 0.027$, $r = -0.158$), SF ($P < 0.001$, $r = -0.234$), RE ($P < 0.001$, $r = -0.252$), MH ($P = 0.02$, $r = -0.165$), and. A significant positive correlation with TBUT was found only for VT ($P = 0.036$, $r = 0.015$).

Conclusions: The findings indicated that the impact of DED on QoL is more strongly and broadly associated with patient-reported symptom severity (OSDI) than with the objective measure of tear film stability (TBUT).

Abstract No.: 204877**Panel No.: CDE-0257****Quality of Life in Patients with Ocular Herpes Simplex Virus Disease***First Author: Hei Tung SHEK**Co-Author(s): Yan Yu Julia CHAN*

Purpose: To compare the quality of life (QoL) in active ocular herpes simplex virus disease patients with inactive ocular herpes simplex virus disease patients.

Methods: A prospective case-control study was carried out. 59 patients with ocular herpes simplex virus disease were recruited. Patient demographics, including age, gender, treatment and disease state, were collected for analysis. Three previously validated QoL questionnaires were used: National Eye Institute Visual Functioning Questionnaire, 28-item, Rasch-based revised (VFQ-28R), Glaucoma Quality of Life 17 (Glau-QoL17) questionnaire, and European Quality of Life 5 Dimensions 5 Level Version (EQ-5D-5L) questionnaire. Each questionnaire covered various aspects of the disease. An independent t-test was done to evaluate statistical significance.

Results: The results of the 3 questionnaires were compared. The total VFQ-28R score did not differ significantly in patients with active and inactive disease (64.5 ± 30.7 vs. 83.3 ± 20.5 , $p = 0.065$). For Glau-QoL17, patients with active disease had lower scores in the constraint (5.56 ± 2.40 vs. 7.09 ± 1.52 , $p < 0.05$) and self-care (3.25 ± 1.14 vs. 4.15 ± 1.38 , $p < 0.05$) domains when compared to patients with inactive disease. For EQ-5D-5L, the overall health score in patients with active disease was significantly lower than patients with inactive disease (54.6 ± 19.7 vs. 66.5 ± 14.1 , $p < 0.05$).

Conclusions: Patients with active ocular herpes simplex virus disease had worse overall health when compared to patients with inactive disease. They had a significantly lower QoL in constraints and self-care domains.

Abstract No.: 202092**Panel No.: CDE-0206****Quantitative Assessment of the Biomechanical Properties of Normal Human Eyes Using Brillouin Spectroscopy***First Author: Jiwon JEONG*

Purpose: With testing of a large normal population, we explored factors such as patient age, sex, and corneal thickness that might be associated with Brillouin spectroscopy measurements of corneal stiffness.

Methods: Preoperative data from 1,763 eyes of 888 refractive surgery patients (17–52 years old; 424 females) were retrospectively collected. These included V/A, IOP, MRSE, and Pentacam measurements (central corneal thickness (CCT), K1, and K2). Corneal

scans were recorded on a Brillouin Optical Scanning System (BOSS) using an automated 10-point pattern. The device measures the Central, Mean, Minimum, and Maximum Brillouin modulus (BM) values from the multiple localized values per scan. Non-parametric methods, such as Spearman rank correlations and Wilcoxon tests, were used in the data analyses.

Results: There were no significant interocular differences in the clinical measurements or in 3 of the 4.; however, the Max BM was greater for OS than OD ($P=0.03$). There were significant differences between the sexes in CCT, K1, K2 ($P \leq 0.0001$), and MRSE ($P=0.03$). Age correlated with MRSE, IOP and CCT ($P \leq 0.002$). BM values correlated significantly with CCT ($P \leq 0.04$) but not with IOP, K1, K2 or MRSE ($P \geq 0.11$). Corneal stiffness tended to increase with age ($P \leq 0.01$), but the increase was slow and slightly nonmonotonic, with variability between patients of the same age. The scans showed significantly greater Brillouin moduli for males than for females.

Conclusions: Non-contacting Brillouin scans of normal eyes showed associations between corneal stiffness and age, sex, and CCT of patients, suggesting that these factors should be considered in refractive surgery planning.

Abstract No.: 205247**Panel No.: CDE-0266****Recent Data of Keratitis/Scleritis-Related Endophthalmitis at a Tertiary Hospital in Thailand***First Author: Natasha YINGSAKMONGKOL**Co-Author(s): Thipsukon AMNARTPANICH, Pitipol CHOOPONG, Dhanach DHIRACHAIKULPANICH, Sathiya KENGPNPANICH*

Purpose: To report 9-year data in epidemiology, prognostic factors, clinical features, microbiology, treatment, visual outcomes, and ocular complications of keratitis/scleritis-related endophthalmitis (KSE).

Methods: We retrospectively reviewed KSE cases in a single-center tertiary hospital from January 2014 to December 2022. Demographics, associated factors, clinical presentation, microbiology, treatment, visual outcomes and ocular complications were collected. Data were analyzed for prognostic factors of poor visual outcomes (final visual acuity worse than hand motion) using univariable and multivariable logistic regression.

Results: Of 295 endophthalmitis cases, 48 (16.3%) were KSE with a mean follow-up of 8.25 months (interquartile range [IQR] 0.96–28.37). Mean age was 69.61 ± 14.99 years. Cultures were positive in 66.7%. The most commonly identified pathogen was *Pseudomonas aeruginosa* (20.8%), followed by fungi (4.2%) and mixed infections (12.5%). Median symptom-to-treatment time was 3.5 days (IQR 1.0–8.75). Initially, 54.3% of patients had visual acuity worse than hand

motion. The poor visual outcomes (visual acuity worse than hand motion) increased to 70.2% at final follow-up. Enucleation/evisceration was performed in 62.5%. Only 14.9% achieved functional vision (equal or better 6/60). Univariable and multivariable analysis identified intravitreal antimicrobial therapy (univariable analysis: crude odds ratio (OR) 0.08, 95% confidence interval [CI] 0.02-0.44, $p=0.003$; multivariable analysis: adjusted OR 0.09, 95% CI 0.015-0.529, $p=0.008$) as a protective factor of poor visual outcomes.

Conclusions: KSE remains sight-threatening with high enucleation rates. *Pseudomonas aeruginosa* represents the key target for empiric antibiotics. Low fungal detection emphasizes comprehensive microbiological work-up in suspected cases. Intravitreal antimicrobial therapy is a protective factor for visual outcomes. These findings could guide KSE management.

Restoring Vision With Descemetopexy in Descemet Membrane Detachment Following Cataract Surgery

First Author: Dhiny LIDINILLAH

Co-Author(s): Budiman, Ludwig TJOKROVONCO

Purpose: This case report aims to highlight the role of descemetopexy as an effective treatment for Descemet membrane detachment (DMD) following cataract surgery, emphasizing its potential in restoring corneal clarity and achieving significant visual improvement.

Methods: We report a case of a 74-year-old male who presented with blurred vision in the right eye (RE) one week after cataract surgery. On examination, the uncorrected visual acuity (UCVA) was 0.25 in the RE and the best-corrected visual acuity (BCVA) was 0.32 in the RE (S+1.50 C-1.50 $\times$ 35). Anterior segment examination of the RE revealed corneal edema, Descemet membrane folds extending from the temporal to central cornea, guttata, and a beaten metal appearance. Anterior Segment Optical Coherence Tomography (AS-OCT) confirmed DMD, while specular microscopy demonstrated polymegathism and pleomorphism in both eyes, suggesting Fuchs endothelial corneal dystrophy. Descemetopexy with 20% sulfur hexafluoride (SF6) gas was performed to achieve anatomical reattachment and visual rehabilitation.

Results: One day postoperatively, the cornea appeared clearer with attached Descemet membrane on AS-OCT, and intraocular pressure remained within normal limits. By one week, the patient reported markedly improved vision without discomfort. The cornea was transparent, anterior chamber was stable, and the intraocular lens was well positioned in the capsular bag. BCVA in the RE improved significantly to 0.8 with no postoperative complications observed.

Conclusions: Descemetopexy is a safe and effective treatment for DMD following cataract surgery, enabling rapid anatomical recovery and significant restoration of visual function.

Retention Cyst Mimicking Lacrimal Gland Cyst in a Patient of Mycoplasma-Induced Rash and Mucositis (MIRM)

First Author: Mariya DOCTOR

Purpose: To report the development of a large palpebral cyst mimicking lacrimal gland cystic swelling, in a patient with mycoplasma-induced rash and mucositis (MIRM).

Methods: A 25-year-old male presented with foreign body sensation and severe photophobia in both eyes for the past 1 month after an episode of sore throat, fever, and recurrent multiple oral ulcers. On examination, a large cystic swelling was noted in the upper temporal quadrant of the right eye, which appeared to be arising from the lacrimal gland. Slit lamp examination showed an extremely dry ocular surface, forniceal shortening, early nasal symblepharon, diffuse corneal punctate keratitis, and atrophic meibomian gland with lower lid keratinisation. The left eye showed central corneal thinning. Given the history, a suspicion of MIRM-induced cicatrizing conjunctivitis was made.

Results: He was subjected to Serum IgG and IgM for Mycoplasma, which came positive. MRI orbit confirmed the presence of a palpebral cyst. The patient was planned for a cyst biopsy. He was started on oral azithromycin 500mg for two weeks. When he came for the biopsy, the lesion had completely resolved, with fibrosis noted in the lacrimal gland region. After two weeks of systemic antibiotic cover, the patient was started on topical steroids, following which he was better symptomatically. Scleral contact lenses were prescribed to him at 2 months, which helped his vision to improve to 20/20p and also provided symptomatic improvement.

Conclusions: Retention cysts are common in conditions of cicatrizing conjunctivitis. Ophthalmologists should be aware of its various presentations and association with cases of MIRM.

Risk Factors and Patterns of Recurrence of Lid Margin Keratinization After Mucous Membrane Grafting in Stevens–Johnson Syndrome: A Case Series

First Author: Swetha **BUGGAREDDIGARI**Co-Author(s): Pragnya Rao **DONTHINENI**

Purpose: To identify the patterns of recurrence of lid margin keratinization (LMK) and risk factors associated with it in patients undergoing repeat mucous membrane grafting (MMG) in chronic Stevens–Johnson Syndrome sequelae (SJS) patients.

Methods: In this retrospective review of 89 patients who underwent MMG, operated by a single surgeon between 2018 and 2025 at a tertiary care centre, we identified 6 eyes of 5 patients who presented with LMK recurrence and underwent repeat MMG. Demographics, graft size, timing and location of recurrence, graft behaviour, associated keratopathy, donor-site morbidity, and clinical outcomes were recorded. Recurrence was defined as significant lid margin keratinization causing lid-related keratopathy requiring repeat surgery.

Results: The mean age was 34.2 years (range 11–64). Out of 5 patients, 4 had unilateral recurrence of LMK 1 had bilateral recurrence. The mean interval between surgery to recurrence was 5.3 months (range 3.5–7 months), with one late recurrence at 2.5 years. Recurrences predominantly involved the lower eyelid margin, particularly over the medial half. All grafts were well taken up; no displacement was observed in any of the eyes. However, horizontal graft shortening with epithelial breakdown at graft edges was seen in two cases. All eyes had associated keratopathy due to the LMK recurrence.

Conclusions: In chronic SJS, recurrence of LMK was typically seen within 6 months, more commonly over the medial half of the eyelid and commonly associated with horizontal graft shortening. Thus, optimizing graft dimensions, ensuring solid edge apposition, and managing ocular surface risk factors are crucial to reducing recurrence.

Safety and Efficacy of 30 mV/cm² Epi-Off Corneal Collagen Crosslinking in Eyes Affected by Progressive Keratoconus After 2 Years

First Author: Luigi **SERRA**Co-Author(s): Francesco **ABBATE**, Francesca **AGRICOLA**, Salvatore **AMBROSIO**, Rosa **BOCCIA**, Teresa **CANGIANO**, Italo **FATTORE**, Michele **LANZA**, Francesca **SIMONELLI**

Purpose: To investigate efficacy, safety, and outcomes of epi-off accelerated corneal collagen crosslinking (ACCC) in eyes affected by progressive keratoconus (KC) 2 years after treatment.

Methods: Epi off ACCC procedures using an energy of 30 mV/cm² were performed in 28 progressive KC eyes of 22 patients with a mean age of 24.07 ± 5.78 years (ranging from 17 to 36 years). A complete eye visit, including Scheimpflug camera scan, was performed in every patient at baseline and at 1, 3, 6, 12, and 24 months follow-up. Mean anterior (AMK) and posterior (PMK) keratometry, anterior maximum keratometry (Kmax), thinnest corneal point (TCP) changes were evaluated.

Results: After 2 years, no significant variations were observed in best corrected visual acuity (-0.04 ± 0.16 logMAR, $p = 0.07$), AMK (-0.08 ± 0.58 D), PMK (-0.06 ± 0.16 D), Kmax ($+0.06 \pm 0.22$ D, and TCP (-4.13 ± 9.31 μ m). Moreover, no complications were detected in every patient treated.

Conclusions: According to data observed in this study, even if they need to be confirmed in a larger population and longer follow-up, ACCC using an energy of 30 mV/cm² could be a safe and effective procedure aiming to stabilize the clinical conditions of eyes affected by progressive KC.

Scleral Contact Lens in Complex Corneal Situations in a Tertiary Eye Center

First Author: Nandita **TRIVEDI**Co-Author(s): Avani **HARIANI**, Parul **JAIN**

Purpose: To showcase a myriad of complex scenarios where scleral contact lenses (SCL) were used as a treatment choice in patients for better quality of vision and comfort.

Methods: This is a retrospective analysis of SCL fitting done in complex corneal situations in a contact lens clinic in a tertiary eye center in Delhi.

Results: The most common indication for the use of SCL in our setup was keratoconus. Other complex situations that were corrected include post-RK, post-Lasik Ectasia, operated Keratoplasty, surface

irregularities like Epithelial Basement Membrane Dystrophy, Pellucid Marginal Degeneration, Terrien's Degeneration, and Salzmann Nodular Keratopathy.

Conclusions: There has been a shifting trend to manage various degrees of irregular corneas due to varied etiology with scleral contact lens (SCLs) hence adopting a more conservative approach which is reversible and more acceptable to the patients. These lenses have become a useful tool in ocular surface abnormalities, providing a protective interface as well as improving the visual acuity and quality of life.

Screening and Identification of Basement Membrane-Related Gene Signatures for Diagnosis in Keratoconus Through WGCNA and Machine Learning

First Author: Peiyun XIE

Co-Author(s): Ding CHEN, Zhanhao GU, Bowei YUAN

Purpose: Keratoconus (KC) can lead to severe vision loss, impacting daily life. The etiology of KC is not yet clear, and early diagnosis and treatment are crucial for prognosis. This study aimed to explore basement membrane (BM)-related gene signatures for the diagnosis and therapy of KC and provide novel insights into its pathogenesis.

Methods: Based on the public datasets GSE112155 and GSE151631 in the GEO database, we obtained the DEGs of KC, and downloaded BM-related genes based on the GeneCard database. Through a combination of bioinformatics methods, primarily WGCNA and machine learning such as RF and SVM, BM-related genes were identified as biomarkers for KC diagnosis. Subsequently, we further validated these findings using unsupervised clustering analysis, a nomogram, and ROC curve analysis.

Results: Through the analysis of two KC-related datasets, 227 DEGs were screened out and intersected with BM-related genes to obtain 195 intersecting genes. By WGCNA and two machine learning algorithms, we identified four genes, namely CRY2, RNF19B, PPP1R18 and PFKFB3. These genes were significantly expressed in the normal group. By the ROC analysis, four genes demonstrated excellent diagnostic performance in internal validation. In external validation, CRY2, RNF19B, and PPP1R18 showed good predictive performance, each with AUC values greater than 0.6. Unsupervised clustering and nomogram also supported the good diagnostic capabilities of these genes. Immune infiltration analysis and functional enrichment analysis further suggested that immune inflammation, metabolism, and apoptosis were also involved in KC.

Conclusions: Using bioinformatics analysis, we found that three novel hub genes, CRY2, RNF19B, and

PPP1R18, are beneficial for the diagnosis and therapy of KC.

Simple Limbal Epithelial Transplant (SLET) in Chinese Patients With Limbal Stem Cell Deficiency

First Author: Jeffrey Kai Chun MAK

Co-Author(s): Ka Wai KAM, Stephanie KWOK, Eugenie MOK, Alvin Lerrmann YOUNG

Purpose: Simple limbal epithelial transplant (SLET) is a promising surgical technique for treating limbal stem cell deficiency. This study reports our experiences at a tertiary eye center in Hong Kong with SLET for LSCD of various etiologies since 2018.

Methods: We reviewed medical records of patients who underwent SLET for LSCD, collecting demographic data, visual outcomes, ocular parameters, etiology of LSCD, and type of SLET performed. We measured follow-up duration, recurrence of LSCD, days to re-epithelization, and the proportion of eyes with a 2-line increase in Snellen acuity.

Results: Eleven eyes from 4 males and 4 females were analysed. Five eyes suffered from an autoimmune cause, five from chemical burns, and one from treatment of ocular surface squamous neoplasia. The mean follow-up duration was 2.4 years (0.3 to 6.3). Five SLETs were autologous, while 6 allogenic SLETs were performed on both eyes of two patients and twice in one eye of one patient with bilateral LSCD. One eye received subsequent cataract and penetrating keratoplasty, and two eyes underwent cataract surgery with implantation of an intraocular lens following SLET. Nine of eleven eyes (81.8%) showed no recurrence of LSCD at the last follow-up. Excluding one bilateral allogeneic SLET performed for acute chemical burn, five out of nine eyes (55.5%) achieved a 2-line increase in visual acuity. None of the donor eyes in autologous SLET exhibited focal LSCD.

Conclusions: SLET is an effective and safe surgical option for Chinese patients with LSCD of various etiologies.

Six-Month Comparison of Clinician-Guided Thermal Pulsation With Warm Compress Therapy for Managing Meibomian Gland Dysfunction

First Author: Dian ZHUANG

Co-Author(s): Jennifer CRAIG, Catherine JENNINGS, Stuti MISRA, Alex MUNTZ, Michael WANG

Purpose: Patient compliance limits the effectiveness of standard therapy for meibomian gland dysfunction

(MGD). This study compared the therapeutic efficacy of in-office clinician-guided thermal pulsation (Systane iLux®, Alcon) to daily warm compress therapy as standard of care.

Methods: In this prospective, investigator-masked, parallel-group trial, participants with MGD and DED meeting TFOS DEWS II criteria were randomised to receive in-office thermal pulsation at day 0, or 6 months of daily self-applied warm compress and eyelid massage. Symptoms and clinical measures of tear film, ocular surface, and meibomian glands were assessed at baseline and monthly for 6 months. Conjunctival impression cytology samples (EYEPRIM®, Opia) were analysed for IL-1 β , -8, -18, caspase-1, NLRP3, and MMP-9 gene expression using digital droplet PCR (ddPCR) and compared between groups at baseline and month 6 in a subset of participants.

Results: A total of 77 participants (aged 58 $\pm$ 18 years; 82% female) were included (thermal pulsation n=38, warm compress n=39). A total of 36 (thermal pulsation n=19, warm compress n=17) underwent inflammatory marker analysis. Both groups showed sustained improvements in DEQ-5, OSDI and SANDE symptomology scores, lipid layer grade, and lid wiper epitheliopathy from day 30 ($p<0.05$). Expressed meibum quality improved from day 90 only following thermal pulsation ($p<0.01$). SPEED scores improved earlier with thermal pulsation (day 30) than with warm compress (day 60, $p<0.01$). Caspase-1 expression significantly increased from baseline to month 6 in the warm compress group ($p<0.05$), while other markers showed no significant change in either group.

Conclusions: Both thermal pulsation and standard of care resulted in significant improvements in clinical outcomes, with the former providing a slightly more rapid and greater effect. Biomarker findings suggest comparable inflammatory control between groups. Outcomes suggest clinician-guided thermal pulsation therapy is effective, and the efficient in-clinic treatment may mitigate poor compliance with daily standard-of-care.

Somatostatin Analog Pasireotide Reestablishes Corneal Neuro-Immune Homeostasis and Promotes Nerve Regeneration in Dry Eye Disease

First Author: Xujiao ZHOU

Co-Author(s): Jiaxu HONG

Purpose: Dysregulated neuro-immune crosstalk perpetuates chronic dry eye disease (DED), yet targeted interventions remain limited. While somatostatin signaling—a pleiotropic neuro-immune modulator—holds therapeutic potential, its role in DED is uncharted. This study investigates whether the long-acting analog pasireotide (SOM230) promotes corneal

nerve repair and alleviates pain by modulating neuro-immune interactions.

Methods: In a murine DED model induced by lacrimal gland excision, pasireotide or vehicle was administered topically. Corneal integrity, neuropathic pain, and sensitivity were assessed via fluorescein staining, behavioral tests, and esthesiometry. Unbiased RNA sequencing, flow cytometry, immunofluorescence, and qPCR were employed to delineate mechanisms and evaluate macrophage polarization.

Results: Pasireotide accelerated epithelial healing, reversed mechanical allodynia, and restored corneal nerve density. Transcriptomic analysis revealed suppression of key inflammatory pathways, including TNF- α , NF- κ B, and IL-17. Crucially, pasireotide directly modulated ocular surface immunity by skewing macrophage polarization—diminishing M1 pro-inflammatory populations (reducing IL-1 β , TNF- α) while expanding reparative M2 macrophages (elevating Arg1, IL-10)—thereby transitioning the immune milieu from destructive inflammation to tissue repair.

Conclusions: We identify somatostatin signaling as a critical regulator of neuro-immune homeostasis in DED. Pasireotide reprograms macrophage plasticity via direct immunomodulation, curbing neurogenic inflammation and fostering a regenerative niche. These findings unveil a novel therapeutic axis, positioning pasireotide as a pioneering dual neuro-immune modulator with transformative potential for treating DED-associated neuropathic pain and corneal neuropathy.

Spark Plasma Sintered Titania-Graphene Oxide: A Toothless Keratoprosthesis for End-Stage Corneal Blindness

First Author: Sean NG

Co-Author(s): Evelina HAN, Jodhbir MEHTA, Hon Shing ONG, Andri K. RIAU, Yoke-rung WONG

Purpose: The osteo-odonto keratoprosthesis (OOKP) remains a groundbreaking treatment for end-stage corneal blindness after 50 years, but it is surgically complex and unsuitable for certain patients, particularly those without healthy teeth. We developed a novel keratoprosthesis (KPro) comprising spark plasma sintered titania-graphene oxide (TiGO) and a 5-mm PMMA optical cylinder, and evaluated its performance as an alternative to the tooth in the OOKP.

Methods: The KPro's suitability for implantation was demonstrated through the preservation of surface integrity, chemical structure, and mechanical strength following ethylene oxide sterilization. Mechanical pull-out tests showed that PMMA adhered more strongly to TiGO than to primate teeth after bonding with dental cement, suggesting that the same cement used in OOKP procedures can be used with TiGO

skirts. In addition, in-vitro studies confirmed TiGO's biocompatibility, supporting adhesion, proliferation, and viability of human corneal stromal fibroblasts.

Results: In a rabbit model of OOKP stage 1 surgery, the TiGO integrated successfully into dermal tissue, showing vascularized connective tissue with positive staining for collagen I and III and CD31. In stage 2 simulation, implantation of fibrovascularized KPro onto the ocular surface was uneventful with no evidence of tissue melt, PMMA detachment, or adverse inflammatory response over six months. Immunohistological analyses revealed minimal fibrosis and immune reactions in the nictitating membrane, with even less reaction in the rabbit host corneas.

Conclusions: In conclusion, our TiGO-based KPro offers a promising alternative to OOKP, with advantages including a larger PMMA optical cylinder, less complex surgery, and much broader surgical indications.

Splicing Dysregulation Associated with Trinucleotide Repeat Expansion in Fuchs Endothelial Corneal Dystrophy

First Author: Yuma YATA

Co-Author(s): Kruse FRIEDRICH, Noriko KOIZUMI, Taisuke NUMAO, Naoki OKUMURA

Purpose: Most Fuchs endothelial corneal dystrophy (FECD) patients carry trinucleotide repeat (TNR) expansions in the TCF4 gene, which cause splicing abnormalities through MBNL protein sequestration. Previous studies using short-read RNA sequencing could not fully resolve isoform structures. This study used long-read sequencing to comprehensively characterize isoform dynamics associated with TNR expansion in FECD.

Methods: Long-read RNA sequencing was performed on corneal endothelial cells obtained from FECD patients with TNR expansion (n=7) and healthy controls (n=5). Isoforms were classified into annotated and novel categories. In addition, three independent short-read RNA-seq datasets were analyzed to validate differential expression patterns of the identified isoforms.

Results: Long-read RNA sequencing revealed that both FECD and control samples contained 39~49% annotated isoforms and 18~31% novel isoforms. Differential expression analysis demonstrated that FECD patients with TNR expansion exhibited 318 upregulated isoforms (42 genes) and 203 downregulated isoforms (15 genes) across three datasets. Notably, a previously uncharacterized TCF4 isoform was consistently upregulated in FECD, terminating upstream of the TNR region and containing a functional poly(A) signal at the 3' end, supporting its biological relevance.

Conclusions: This study provides the first comprehensive long-read RNA sequencing analysis of FECD, revealing altered isoform expression dynamics associated with TNR expansion. The consistent upregulation of a novel TCF4 isoform highlights a potential mechanistic link to pathogenesis. Further validation using patient-derived samples and functional studies will be essential to clarify its pathogenic significance and contribution to FECD progression.

Standard Induction Chemotherapy Regimen Before Allogeneic Hematopoietic Stem Cell Transplantation Induces Functional and Morphological Damage to Ocular Surface Tissues

First Author: Jianwen XUE

Co-Author(s): Jiaxu HAN, Lingyi LIANG, Ren LIU, Caizhen QIU

Purpose: Prevalent ocular discomfort in patients before hematopoietic stem cell transplantation implied that the pretreatment conditioning regimens may contribute to ocular surface dysfunction, yet causality remains unproven. This study explored the effects of cytarabine (Ara-C) chemotherapy conditioning regimens on ocular surface tissues.

Methods: Mice received Ara-C with or without rosiglitazone (PPAR γ agonist) for 7 days. Slit-lamp biomicroscope was used for ocular examinations. Immunofluorescence detected acinar cell proliferation, differentiation, and ductal keratinization in the meibomian gland (MG) and the lacrimal gland (LG). Lipid accumulation was evaluated by LipidTox staining. Lipogenic status, FoxO1/FoxO3a cellular localization, and oxidative stress were visualized via immunohistochemistry. Western blotting assessed relative protein expression and AKT/FoxO1/FoxO3a pathway phosphorylation.

Results: Ara-C (50 mg/kg) did not affect mouse survival but induced damage to ocular surface, including corneal epithelial defects, MG obstruction and acinar dropout, and LG dysfunction. Ara-C caused progenitor loss in MG, as evidenced by reduced P63+/Lrig1+ acinar cells. Ducts of Ara-C-treated mice exhibited marked dilatation, lipid deposition, and hyperkeratinization. Ara-C disrupted MG lipid metabolism by downregulating PPAR γ and its downstream lipogenic targets AWAT2/SOAT1/ELOVL4 and upregulating HMGCR. Dephosphorylation of AKT and the subsequent nuclear translocation of FoxO1/FoxO3a contributed to Ara-C-induced PPAR γ downregulation. Ara-C triggered oxidative stress with increases in 4-HNE/8-OHdG and Keap1/Nrf2/HO-1/SOD1 axis dysregulation. Rosiglitazone treatment ameliorated MGD-associated pathological manifestations, LG function, MG lipid

metabolism, and oxidative stress in Ara-C-exposed mice.

Conclusions: Ara-C chemotherapy exerted topical cytotoxic effects on ocular surface, and PPAR γ restoration mitigated Ara-C-induced MGD alterations.

Starting From Schwalbe's Line With a Sharp Blade: A New Technique for Descemet's Membrane Endothelial Keratoplasty Graft Preparation

First Author: Guigang LI

Purpose: To introduce a new Starting from Schwalbe's line with a sharp blade (SSS) technique for DMEK graft preparation.

Methods: We performed a retrospective, uncontrolled study involving 109 patients (114 donors) who underwent DMEK over eight years (from October 2017 to December 2024). Starting from Schwalbe's line with a sharp blade (SSS) technique was used for donor graft preparation in all cases. A total of 109 patients were divided into two groups based on surgical timing: the earlier 54 cases and the later 55 cases. We compared DMEK graft preparation success rate (SR), complication rate (CR), and time used for graft preparation. For the last 19 cases in 2024, we analyzed corneal endothelial cell density (ECD) loss ratio by comparing donor cornea ECD before and after transplantation.

Results: In this study, 109 patients underwent DMEK surgery using 114 donor corneas. The first ($n = 54$) and second ($n = 55$) groups showed no significant differences in donor age, preservation time, graft diameter, or preparation time ($P > 0.05$). The overall graft preparation success rate was 97.37%, with no significant differences ($P = 1.000$). Complications varied, with eccentric punch showing a significant difference between groups ($P = 0.01$). Postoperative ECD measurements revealed no significant difference in ECD between groups ($P = 0.930$). In 2024, the post-transplantation ECD loss rate averaged $50.0 \pm 22.5\%$, indicating moderate endothelial cell loss.

Conclusions: SSS technique can guarantee a nearly 100% success rate (97.37%) for Descemet's membrane endothelial keratoplasty graft preparation. It is a time-efficient, easy-to-learn, and donor-cornea-saving method for donor graft preparation.

Surgical Management of Sclerocorneal Cyst Secondary to Ciliary Body–Scleral Fistula: Two-Year Follow-Up

First Author: Tu Nga NGUYEN

Co-Author(s): Hoang Viet Chi VU

Purpose: A primary sclerocorneal cyst represents a rare entity, with only a few cases documented in the literature. We report two cases of sclerocorneal epithelial cyst with emphasis on underlying etiology, surgical approach, and long-term outcomes.

Methods: Two patients with subconjunctival cystic lesions present since early childhood were evaluated. Neither patient had a history of ocular trauma or surgery. In both cases, the cysts had enlarged rapidly in recent months, causing visual impairment. Ophthalmic examination revealed fluid-filled sclerocorneal cysts extending into the corneal stroma and involving the visual axis. Surgical excision of the cysts was performed. During removal of the anterior cyst wall, a scleral fistula overlying the ciliary body was identified, with evident leakage of aqueous humor. The fistula was cauterized and closed with sutures, followed by placement of a tectonic lamellar kerato-scleral graft at the excised area.

Results: Histopathology confirmed the epithelial-lined cysts with minimal epithelial debris. Postoperative follow-up demonstrated restoration of corneal clarity, improvement of visual acuity, and no evidence of recurrence over a two-year period.

Conclusions: These cases suggest that a congenital ciliary body–scleral fistula may act as a conduit for aqueous humor, leading to the formation of a sclerocorneal epithelial cyst. Complete excision of the cyst, closure of the fistula, and tectonic kerato-scleral grafting can result in favorable anatomical and visual outcomes with minimal risk of recurrence.

Tacrolimus Prolongs Corneal Allograft Survival and Prevents Dendritic Cell Infiltration in a Myeloid-Derived Suppressor Cell-Dependent Manner

First Author: Yingyi LIU

Co-Author(s): Yan HE

Purpose: To clarify the cellular mechanism by which tacrolimus (FK506) suppresses immune activation and elongates allograft survival, with a focus on understanding its effects on immune regulation via myeloid-derived suppressor cells (MDSC).

Methods: A mouse model of corneal penetrating keratoplasty was utilized, with recipient mice receiving FK506 treatment and MDSC depletion using anti–

Gr-1 antibody at different time points post-transplant. Flow cytometry was used to evaluate the proportion of MDSC and dendritic cells (DC) in immune organs. Single-cell RNA sequencing and immunofluorescence staining were performed on corneal graft to analyze immune cell populations within the graft microenvironment. Ex vivo-generated MDSCs were cocultured with immature DCs, and RNA sequencing was performed to determine how FK506 modulates MDSC immunosuppressive activity.

Results: Administration of FK506 led to increased expansion of MDSC in recipient mice and prolonged survival of corneal allografts. In contrast, antibody-mediated depletion of MDSC abolished the FK506-mediated beneficial effects, which were associated with increased DC activation and recruitment to the graft bed and allografts. Notably, unlike continuous depletion and temporary early depletion, delayed depletion beginning on day 8 post-transplant failed to disrupt the FK506-induced elongation of corneal allograft survival. Single-cell RNA sequencing analysis and immunofluorescence staining of corneal grafts revealed that FK506 reduced graft infiltration of immune cells, including DC and T cells, in an MDSC-dependent and temporal fashion. Moreover, depletion of MDSC reverted FK506's suppression of DC maturation in the draining lymph node on day 7.

Conclusions: These findings indicate that FK506 prolongs allograft survival through induction of MDSC-mediated suppression of early DC activation.

Panel No.: CDE-0232

Tear Cytokines and Ocular Surface Damage in Pemphigus: A Triphasic Dry Eye Mode

First Author: Hui ZHANG

Purpose: To investigate the progression of pemphigus-associated dry eye and its correlation with tear cytokines.

Methods: In this cross-sectional study, 45 pemphigus patients (90 eyes) and 28 healthy controls (56 eyes) were evaluated using ocular surface parameters and tear cytokine analysis.

Results: Pemphigus patients showed significantly worse ocular surface metrics and higher dry eye prevalence (71.11% vs 46.43%) than controls. A three-phase progression was identified: early (disease duration with pemphigus ≤ 3 months) with tear film deficiency, intermediate (3–12 months) with conjunctival injury, and late (>12 months) with Meibomian glandular atrophy and corneal damage. Tear levels of IL-1 β , IL-2, IL-4, IL-5, IL-6, IL-8, IL-10, TNF- α , IFN- α , and IFN- γ were significantly elevated (all $p < 0.05$), with IL-6 and IL-8 positively correlating with conjunctival damage and disease duration.

Conclusions: These findings suggest that pemphigus-related dry eye progresses through inflammatory phases, supporting early anti-inflammatory intervention targeting IL-6/IL-8.

Abstract No.: 201334

Tear Proteome Alterations Over One Year With Topical 0.1% Cyclosporine a Emulsion in Patients Undergoing Allogeneic Stem Cell Transplantation

First Author: Jingwen YU

Co-Author(s): Lim LI, Yuchi LIU, Louis TONG, Lei ZHOU

Purpose: To profile longitudinal tear proteomics in allo-HSCT patients receiving daily 0.1% cyclosporine-A cationic emulsion and explore its relationship with clinical phenotypes.

Methods: This study included 24 participants using cyclosporine eye drops from 3–5 weeks pre-HSCT to 12 months post-HSCT. Ocular surface examinations and tear collection were done at pre-HSCT, HSCT, and 3/6/12 months post-HSCT. Patients were grouped into Responders (R) and non-Responders (NR) via impression cytology flow analysis. Tear proteomics was analyzed by LC-MS/MS with data-independent acquisition, followed by linear mixed model regression.

Results: None of the patients developed ocular GVHD in the first year after HSCT. The overall OSDI, Schirmer, TBUT and conjunctival redness did not change significantly from baseline (pre HSCT). 2570 proteins were identified. Pre-HSCT, AGT, HRG, and SERPIND1 differed between R and NR (all $P < 0.05$). Post-HSCT, COL6A1, RAB11B, XRCC6, etc., showed significant differences. WGCNA clustered these proteins into 6 modules linked to immune response, lysosome, etc., correlating with Schirmer test, tear osmolarity, and conjunctival redness.

Conclusions: Prophylactic 0.1% cyclosporine-A cationic emulsion may prevent ocular GVHD post-allo-HSCT in one year by modulating immunoinflammatory proteins and pathways.

The Correlation of Corneal Endothelial Cell Parameters and Anthropometry in Children With Diabetes Mellitus

First Author: Aisha ANDRIANA

Co-Author(s): Nanda Wahyu ANINDITA, Lely Retno WULANDARI

Purpose: Studies on corneal endothelial morphology in children with diabetes are limited. This study aimed to analyze the relationship between anthropometric measures and corneal endothelial parameters in

children with diabetes, to clarify whether growth-related factors influence corneal health.

Methods: This cross-sectional study included children with diabetes at Dr Saiful Anwar Hospital, Malang, Indonesia, in October 2024. We analyzed cell density (CD), coefficient of variation (CV), and hexagonality (HEX) as the corneal endothelial parameters with a non-contact specular microscope. Height, weight, and BMI were measured. Their associations were analyzed with Spearman's correlation and simple linear regression (two-tailed, $p < 0.05$). Ethics approval and informed consent were obtained.

Results: A total of 80 eyes from 40 children aged 7-18 years old were examined; 67.5% were female. We categorized BMI as underweight (45%), normal (30%), overweight (10%), and obese (15%). Specular microscope showed the mean CD of 3198.7 cells/mm², CV 24.0%, HEX 68.4%. BMI showed no significant correlation with CD, CV, or HEX. No significant correlations were observed between anthropometric measures and CV or HEX. CD correlated negatively with height ($p = 0.015$) and weight ($p = 0.029$), decreasing by 3.81 cells/mm² for each additional centimeter in height ($R^2 = 6\%$) and by 3.48 cells/mm² for each additional kilogram in weight ($R^2 = 5.5\%$).

Conclusions: There was no correlation between corneal endothelial cell parameters and BMI. Greater height and weight were associated with lower CD. Clinically, these findings suggest that growth parameters may influence corneal endothelial status. Incorporating anthropometry in ocular monitoring and conducting longitudinal studies is recommended to inform surgical planning and follow-up strategies.

The Efficacy of Topical Treatments for Vernal Keratoconjunctivitis: A Network Meta-Analysis

First Author: Ziming XU

Purpose: This meta-analysis aims to evaluate the efficacy and safety of topical cyclosporine on the management of vernal keratoconjunctivitis compared to placebo, tacrolimus and dexamethasone.

Methods: This meta-analysis was conducted in accordance with the 2020 PRISMA guidelines. We searched PubMed, Cochrane, Embase and Web of Science for relevant randomized controlled trials (RCTs) that had been published by August 2025. Studies that compared topical cyclosporine, tacrolimus and dexamethasone with a control were included. Direct and indirect comparisons were evaluated using network meta-analysis. Outcomes for efficacy evaluation include sign score, symptom score, and corneal fluorescein staining score. The Bayesian NMA

was conducted using the R-package, gemtc (version 1.0-1).

Results: Among 1,209 studies assessed, we identified 9 eligible RCTs involving 1,041 children aged 4 to 18 years. Cyclosporine was more effective than placebo in managing vernal keratoconjunctivitis, with a higher reduction in symptom score (standardised mean difference [SMD] = -1.57, 95% CI [-2.54; -0.61]), sign score (SMD = -0.95, 95% CI [-2.13; 0.23]) and corneal fluorescein staining score. There was no statistically significant difference between 0.05% cyclosporine and 0.01% dexamethasone ($p > 0.05$), and between 0.05% cyclosporine and 0.03% tacrolimus ($p > 0.05$).

Conclusions: This study indicates that cyclosporine was effective drug for the management of vernal keratoconjunctivitis, and its efficacy was similar to 0.01% dexamethasone to tacrolimus. More doses of cyclosporine were warranted to investigate the relationships between different doses.

The Impact of Extraocular Muscle Hypertrophy on Intraocular Pressure in the Primary Position and Special Positions of Gaze in Patients With Thyroid Eye Disease

First Author: Zijing SUN

Co-Author(s): Wei LU

Purpose: This study evaluates the effect of medial and inferior rectus muscle hypertrophy on intraocular pressure (IOP) in thyroid eye disease (TED) patients and its association with extraocular muscle involvement to facilitate clinical management.

Methods: A retrospective analysis was conducted on TED patients diagnosed with extraocular muscle hypertrophy at the Second Hospital of Dalian Medical University from September 2023 to September 2024. Patients were categorized into two groups based on the presence of muscle involvement: isolated inferior rectus hypertrophy and combined medial and inferior rectus hypertrophy. A control group comprising healthy individuals without orbital disease was also incorporated. IOP measurements were taken in the primary position and during temporal-superior gaze using the Icare Pro tonometer. Statistical comparisons of IOP among the groups were performed, along with correlation analyses between IOP changes and the number of affected muscles.

Results: The study comprised 24 TED patients (40 eyes), including 34 eyes with varying degrees of restrictive strabismus. The control group exhibited IOP values of 15.6 ± 1.9 mmHg and 18 ± 2.3 mmHg in the primary position and temporal-superior gaze, respectively. The isolated inferior rectus hypertrophy group presented IOP values of 17.4 ± 1.9 mmHg and 25 ± 2.9 mmHg, while the combined medial and inferior rectus hypertrophy

group showed IOP values of 17.2 ± 2.1 mmHg and 26.7 ± 3.0 mmHg. Significant differences in IOP were noted among the groups ($P < 0.001$ for all comparisons). A positive correlation was established between the degree of IOP change during temporal-superior gaze and the number of affected extraocular muscles ($r = 0.345$; $P < 0.001$).

Conclusions: TED patients exhibit normal primary position IOP. Inferior rectus hypertrophy raises IOP during temporal-superior gaze, exacerbated by medial rectus hypertrophy. Further research is needed on IOP management for TED patients with gaze-dependent IOP elevations.

Abstract No.: 206548

The Relationship Between Sedentary Behaviour, Dry Eye Disease and Retinal Microvascular Dysfunction in Elderly Patients

First Author: Kelly WONG

Purpose: To determine the impact of sedentary behaviour on ocular surface and retinal microvascular health in Chinese subjects aged 50 or above.

Methods: This cross-sectional study included 1,230 Chinese subjects aged ≥ 50 . All subjects underwent comprehensive dry eye assessment (OSDI, tear breakup time, meiboscore, etc.) and retinal imaging via OCT-Angiography to quantify vascular parameters. Physical activity was categorised using the Metabolic Equivalent of Task (MET) minutes per week.

Results: The prevalence of dry eye disease (DED) was 20.2%. Lower physical activity levels were significantly associated with a higher prevalence of DED. Subjects with DED had significantly worse retinal vascular parameters (e.g., central subfield thickness, capillary flux) than those without DED. OCT-A parameters also correlated with dry eye signs, like meiboscore and OSDI.

Conclusions: Sedentary behaviour is significantly associated with both DED and retinal microvascular dysfunction in elderly subjects. DED may serve as an indicator for lower exercise levels and poorer vascular health. Ophthalmologists should counsel DED patients on adopting healthy habits to improve vascular health.

The Study of PPBP in Fungal Keratitis

First Author: Xiaoxin GUO

Co-Author(s): Bo GONG, Weijia WU, Jialing XIAO

Purpose: To clarify the pathogenesis of fungal keratitis (FK) and identify new therapeutic targets.

Methods: • Intrastromal injection of *Aspergillus fumigatus* to induce FK mouse model. • Single-cell RNA-seq of infected corneas to map cellular

composition and transcriptional changes. • Human FK corneal transcriptome validation. • AAV-mediated Pbp knockdown in vivo.

Results: • FK corneas showed immune-cell infiltration, and reduced epithelial cell. • PPBP was the top differentially expressed gene across corneal epithelial cell. • Human corneal RNA-seq confirmed PPBP elevation. • Pbp knockdown attenuated corneal opacity, edema, epithelial defects, and decreased IL-1 β , IL-6, TNF- α expression.

Conclusions: PPBP is a critical pro-inflammatory mediator in FK. Targeting PPBP offers a promising therapeutic strategy to improve FK management.

Panel No.: CDE-0268

Three-Year Outcomes of Accelerated Cross-Linking Techniques for Thin Keratoconic Corneas: A Comparison of Standard, Contact Lens-Assisted, and Lenticule-On Approaches

First Author: Anastasiya INSAPOVA

Co-Author(s): Mukharram BIKBOV, Giulli KAZAKBAEVA, Iulia RUSAKOVA, Karine TITOIAN

Purpose: To evaluate the safety and efficacy of accelerated corneal collagen cross-linking (CXL) with an overlaying corneal lenticule (A-LACXL) for thin corneas in progressive keratoconus (KC), and to compare the outcomes with accelerated contact lens-assisted CXL (A-CACXL) and accelerated CXL (A-CXL).

Methods: This study enrolled eyes with progressive KC and a corneal thickness of less than 400 μ m after epithelial removal. Patients were divided into three groups: the A-LACXL group (12 patients/14 eyes) received a femtosecond laser-prepared lenticule on which accelerated CXL was performed; the A-CACXL group (22 patients/26 eyes) underwent accelerated CXL using contact lens; and the control group (20 patients/24 eyes) underwent standard A-CXL. The mean patient age was 27.0 ± 7.2 years, with a follow-up period of 3 years. Uncorrected (UDVA) and corrected (CDVA) distance visual acuity, manifest refraction, corneal topography, and endothelial cell density (ECD) were evaluated preoperatively and postoperatively.

Results: Mean UDVA improved significantly in all three groups at 12 months ($p < 0.05$) and remained stable throughout the follow-up period. Maximum keratometry (Kmax) decreased by 1.05 ± 1.84 D in the A-CACXL group and by 0.86 ± 1.57 D in the A-CXL group, though these changes were not statistically significant compared to baseline ($p > 0.05$). ECD remained stable in all groups ($p > 0.05$). There were no statistically significant differences in the mean changes in UDVA, CDVA, Kmax, mean keratometry (Kmean), or ECD between the three groups (all $p > 0.05$).

Conclusions: A-CACXL and A-LACXL are effective and safe techniques for managing progressive KC in thin

corneas, demonstrating outcomes comparable to standard A-CXL. A-CACXL halted progression in 76.7% of eyes and induced regression in 33.3%. A-LACXL represents a viable therapeutic option for patients with thin corneas where standard CXL is not indicated.

Topical Insulin (25 IU/ML) Combined With Propylene Glycol-Based Artificial Tears in the Management of Persistent Corneal Epithelial Defects: A Case Series

First Author: Hong Ngoc NGUYEN THI

Purpose: To evaluate the effectiveness of topical insulin (25 IU/mL) prepared with Propylene glycol-based artificial tears in treating persistent corneal epithelial defects (PCEDs) of various etiologies.

Methods: This case series included six patients with PCEDs unresponsive to standard therapy. Etiologies were: delayed epithelial healing after viral keratitis ($n = 2$), chemical burn ($n = 1$), infectious keratitis ($n = 1$), severe dry eye with suspected Sjögren's syndrome ($n = 1$), and persistent epithelial bullae following phacoemulsification in a diabetic patient ($n = 1$). Persistent epithelial defects were defined as lasting beyond complete resolution of infection or initial injury, with a mean duration of 23 ± 3.5 days before initiating insulin therapy. Topical insulin (25 IU/mL) was prepared by mixing insulin with Propylene glycol-based artificial tears and applied until complete re-epithelialization.

Results: All six cases achieved complete epithelial closure with a mean healing time of 9 ± 2.6 days after initiating topical insulin. No recurrences were observed during follow-up. No local or systemic adverse effects related to insulin were recorded.

Conclusions: Topical insulin (25 IU/mL) combined with Propylene glycol-based artificial tears is a safe, effective, and low-cost treatment option for PCEDs from various causes. It may be considered as an adjunctive therapy in cases unresponsive to conventional management.

Abstract No.: 205171

Panel No.: CDE-0259

Translation, Adaptation and Validation of the Malay Version of the Standard Patient Evaluation of Eye Dryness: In a Non-Clinical Sample

First Author: Mohd Asyraf ABDUL KADIR

Purpose: Dry eye disease (DED) is a multifactorial condition where symptoms often poorly correlate with clinical signs, necessitating validated patient-reported outcome measures. The Standard Patient Evaluation of Eye Dryness (SPEED) questionnaire is a concise, reliable tool for assessing DED symptom frequency

and severity. This study aimed to translate, culturally adapt, and validate the SPEED questionnaire into the Malay language (mSPEED) to address a critical gap in ophthalmic care for the Malay-speaking population in Malaysia.

Methods: The translation followed a rigorous cross-cultural adaptation process, including forward and backward translation, expert panel review, and cognitive debriefing. Participants completed the mSPEED questionnaire at baseline (T1) and one week later (T2) to assess reliability. Internal consistency was evaluated using Cronbach's alpha, and repeatability was assessed with intraclass correlation coefficients (ICC) and Bland-Altman plots.

Results: A total of 250 participants completed first assessment but only 180 completed both assessments. The mSPEED demonstrated excellent internal consistency, with a Cronbach's alpha of 0.866 for the SPEED score and 0.880 for the full score. Test-retest reliability was high, with an ICC of 0.974 (95% CI: 0.966–0.981) for the SPEED score and 0.986 (95% CI: 0.976–0.991) for the full score. Bland-Altman analyses showed good agreement between the two time points.

Conclusions: The Malay version of the SPEED questionnaire is a valid and reliable instrument with strong psychometric properties. The mSPEED is an indispensable tool for both clinical practice and epidemiological research, enabling standardised assessment of DED symptoms in Malay-speaking populations and promoting health equity.

Panel No.: CDE-0215

Trends in Surgical Procedures and Timing for Keratoconus at a Tertiary Referral Center in Northern China Over 20 Years

First Author: Yu SUN

Purpose: To analyze the trends in surgical procedures and timing in patients diagnosed with keratoconus (KC) over 20 years in a tertiary referral center in northern China.

Methods: This retrospective descriptive study included all patients who underwent surgical procedures for KC between January 2004 and December 2023. The categories of surgical procedures included penetrating keratoplasty (PK), lamellar keratoplasty (LK), and corneal crosslinking (CXL). Statistical analyses were performed on procedure types, surgery timing, and KC clinical stages. Trends in surgical procedures and timing changes were evaluated.

Results: A total of 1,497 patients (2,093 eyes) with KC underwent surgery. Regarding the category of keratoplasty, conventional PK decreased significantly from 22.2% to 1.0% over the study period, while LK decreased from 77.8% to 49.2%. As for different types of LK, femtosecond laser-assisted surgeries increased

from 0 to 76.2%. CXL rose from 0% to 49.6% following its introduction. Femtosecond laser-assisted surgeries and CXL dominated the fourth period, comprising 87.3% of the total surgical volume. The proportion of patients undergoing surgeries at early stages (I~II) of KC increased continuously (from 18.5% to 79.6%). Surgical procedures performed at different periods within the same KC stage varied significantly ($p < 0.001$).

Conclusions: Over the past 20 years, the main surgical procedure for KC has shifted from PK to more minimally invasive femtosecond laser-assisted lamellar keratoplasty and CXL. Femtosecond laser-assisted surgeries and CXL now occupy an increasingly important role. The timing of surgery for KC patients has shifted to earlier stages.

U-Shaped Association Between Residential Greenness and Keratoconus

First Author: Longyue LI

Co-Author(s): Weijing CHENG, Lingyi LIANG

Purpose: Keratoconus is a leading cause of corneal blindness in adolescents influenced by genetic factors. Whether environmental factors influence it remains unclear. This study explores the association between residential greenness and keratoconus risk.

Methods: We conducted a case-control study within the Chinese Environment-Ocular Surface (EOS) study, comprising 4341 keratoconus cases and 3723 controls. Validation was performed with data from the United Kingdom Biobank (UKB), a prospective cohort of 502,367 participants. The relationship between keratoconus and residential greenness, measured by the normalized difference vegetation index (NDVI) at a 300 m buffer, was assessed using multivariate-adjusted odds ratios (ORs) and spline analysis.

Results: Both studies revealed a U-shaped association between residential greenness and keratoconus. In the EOS study, participants in the lowest and highest quartiles of greenness had ORs (95% CIs) of 1.33 (1.23, 1.55) and 1.54 (1.37, 1.72), respectively, compared to the intermediate quartile. The lowest odds of keratoconus were observed at 0.42 NDVI. A similar pattern was found in the UKB cohort, where the first quartile of greenness was associated with 1.8 times higher odds (1.12, 2.91) of keratoconus compared to the intermediate quartile.

Conclusions: Our findings indicate a U-shaped relationship between residential greenness and keratoconus, with both low and high levels of greenness associated with increased keratoconus risk. These results underscore the complex interplay between environmental factors and keratoconus, offering insights for urban planning and environmental health policies.

Abstract No.: 206746

Panel No.: CDE-0285

Uncovering the Impact of Aging on Corneal Endothelial Cells in Older Adults of West Java, Indonesia

First Author: Rafida KAMILA

Co-Author(s): Nadhira AUGUSTRIA, Aurilia BHARATA, Isma SUHAIMA, Syska WIDYAWATI

Purpose: This study aims to evaluate the correlation between age and Corneal Endothelial Cells (CEC) characteristics, specifically endothelial cell density (ECD), coefficient of variation (COV), and Hexagonality (HEX), among the older population in Cianjur, West Java, Indonesia.

Methods: A cross-sectional observational study was conducted during a cataract surgery social service screening event. One eye from each patient aged over 50 years scheduled for cataract surgery was enrolled in this study. Data was collected from the CEC obtained using a specular microscope. Three parameters were selected for analysis: ECD, HEX, and COV. Descriptive statistics analysis was provided to illustrate corneal endothelial characteristics across age groups, followed by an analysis of their correlation with age.

Results: A total of 136 eyes were examined (mean age 65.18 ± 7.58). The mean ECD demonstrated a decreasing trend with advancing age, although not significantly correlated ($r = -0.122$, $p = 0.159$). The lowest mean of ECD was in the >80 year group (2198.40 ± 479.287 cells/mm²). No significant correlation was found between age and HEX ($r = -0.055$, $p = 0.536$). In contrast, age showed a moderate positive correlation with COV ($r = 0.275$, $p = 0.001$), indicating increased polymegathism in older individuals.

Conclusions: Aging demonstrates a trend of decreased values of corneal ECD although statistically insignificant. In contrast, the COV showed a significant positive correlation with age. This suggests that changes in cell size variation may serve as an early marker of age-related endothelial stress, rather than ECD or HEX.

Abstract No.: 203920

Panel No.: CDE-0234

Uncovering the Role of Transient Receptor Potential Channels in Pterygium: A Machine Learning Approach

First Author: Yuchen CAI

Purpose: We aimed at identifying the role of transient receptor potential (TRP) channels in pterygium.

Methods: Based on microarray data GSE83627 and GSE2513, differentially expressed genes (DEGs) were screened and 20 hub genes were selected. After gene correlation analysis, 5 TRP-related genes were obtained and functional analyses of gene ontology (GO) and Kyoto Encyclopedia of Genes and Genomes

(KEGG) were performed. Multifactor regulatory network including mRNA, microRNAs (miRNAs) and transcription factors (TFs) was constructed. The 5 gene TRP signature for pterygium was validated by multiple machine learning (ML) programs including support vector classifiers (SVC), random forest (RF), and k-nearest neighbors (KNN). Additionally, we outlined the immune microenvironment and analyzed the candidate drugs. Finally, in vitro experiments were performed using human conjunctival epithelial cells (CjECs) to confirm the bioinformatics results.

Results: Five TRP-related genes (MCOLN1, MCOLN3, TRPM3, TRPM6, and TRPM8) were validated by ML algorithms. Functional analyses revealed the participation of lysosome and TRP-regulated inflammatory pathways. A comprehensive immune infiltration landscape and TFs-miRNAs-mRNAs network was studied, which indicated several therapeutic targets (LEF1 and hsa-miR-455-3p). Through correlation analysis, MCOLN3 was proposed as the most promising immune-related biomarker. In vitro experiments further verified the reliability of our in silico results and demonstrated that the 5 TRP-related genes could influence the proliferation and proinflammatory signaling in conjunctival tissue, contributing to the pathogenesis of pterygium.

Conclusions: Our study suggested that TRP channels played an essential role in the pathogenesis of pterygium. The identified pivotal biomarkers (especially MCOLN3) and pathways provide novel directions for future mechanistic and therapeutic studies.

Panel No.: CDE-0298

Unilateral Pigmented Papillomatosis With Acanthosis: Ophthalmological Diagnosis and Management

First Author: Inchara **NAGARAJ**

Co-Author(s): Asam **NAVEENA**

Purpose: Eyelid papillomas are common benign lesions, typically presenting as smooth, rounded, or pedunculated growths. Squamous papilloma is the most common subtype, predominantly seen in individuals over 30 years of age. While usually innocuous, their clinical appearance can mimic that of other benign or malignant eyelid lesions, including squamous cell carcinoma, necessitating an accurate diagnosis and management.

Methods: We report a rare case of an unusual presentation of squamous papilloma in a 35-year-old female from a rural background. She presented with blackish, progressive swellings involving both the upper and lower eyelids since childhood, which had increased in size in recent years, causing cosmetic concerns.

Results: Surgical excision with 2 mm margins was performed, followed by lid reconstruction. The lower

eyelid was reconstructed using Mustarde's cheek rotation flap, and the upper eyelid with a postauricular split-thickness skin graft. Histopathological examination revealed squamous epithelial proliferation with acanthosis, papillomatosis, and pseudo-cysts, confirming the diagnosis of squamous papilloma. The patient was monitored for two years postoperatively and remained recurrence-free.

Conclusions: Squamous papilloma, although benign, can present with unusual clinical features that mimic malignancy. Comprehensive evaluation, meticulous excision, and appropriate reconstructive procedures are crucial for achieving both curative and cosmetically favourable results. Successful lid reconstruction techniques can achieve satisfactory anatomical and aesthetic outcomes. Long-term follow-up is crucial for monitoring recurrence.

Panel No.: CDE-0237

Unravelling the Unknown: A Retrospective Study of Ocular Hypertension (OHT) and Glaucoma After Pre-Descemet Endothelial Keratoplasty (PDEK)

First Author: Sarah **GEORGE**

Co-Author(s): Murali **ARIGA**, Soosan **JACOB**, Preethi **NAVEEN**

Purpose: To evaluate the incidence and risk factors of ocular hypertension (OHT) and glaucoma following PDEK, and to assess the temporal profile of patients developing OHT or glaucoma, and those with pre-existing glaucoma.

Methods: A retrospective review of 525 patients who underwent PDEK over 18 months at a tertiary eye care center was performed. Comprehensive ocular evaluation, including glaucoma assessment, was undertaken. Variables analyzed were demographics, pre-existing glaucoma, plain PDEK, combined PDEK with IOL surgery, repeat PDEK, pre-operative IOP, timing of IOP spikes, steroid regimen, anti-glaucoma medications (AGMs), response to AGMs, optic nerve head changes, OCT RNFL findings, and Humphrey visual fields. Statistical analysis included Mann-Whitney U, Kruskal-Wallis, Pearson Correlation, and Chi-square tests.

Results: OHT occurred in 12.5% and new-onset glaucoma in 1.33% of cases. Steroid response was the leading cause of raised IOP, with spikes correlating with steroid dosage and the number of steroid used. Although pseudophakic bullous keratopathy showed the highest mean IOP spike, no significant correlation was found between diagnosis or surgical procedure and IOP spikes. 8.9% patients used 1 AGM, 3.6% used 2 AGMs, and 5.14 % used 3 or above AGMs for IOP control. 14.6% continued AGMs at final follow-up. Surgical IOP control (AGV or trabeculectomy) was

needed in 3.04%. Importantly, OHT did not adversely affect postoperative BCVA.

Conclusions: PDEK demonstrates lower OHT and glaucoma incidence compared to DMEK and DSAEK, supporting its role as a reliable endothelial keratoplasty technique.

Urban Particulate Matter Triggers Meibomian Gland Dysfunction via PANoptosis Pathway

First Author: Caizhen QIU

Co-Author(s): Jiaxu HAN, Lingyi LIANG, Ren LIU, Jianwen XUE

Purpose: The meibomian gland (MG) is potentially damaged by urban particulate matter (UPM) based on epidemiological evidence, but the specific experimental mechanisms remain unknown. This study investigated the effects of UPM on MG dysfunction (MGD) in rodent models.

Methods: Female C57BL/6J mice received eye drops containing UPM suspension or PBS for 14 days. The proliferative capacity and progenitor of MG were evaluated by immunofluorescence. Cell apoptosis was confirmed by the TUNEL assay. Lipid accumulation was visualized by Oil Red O staining and LipidTox staining. Ductal hyperkeratinization, inflammatory cell infiltration, and PANoptosome activation were detected through immunostaining. The relative gene expression and PANoptosis signaling pathway activation were determined by Western blot analysis.

Results: Administration of UPM caused MGD-like clinical signs, manifested as distinct corneal epithelial erosion, increased MG orifice occlusion, and glandular dropout. UPM exposure significantly induced progenitor loss and lipogenic disorder in MG by reducing P63/Lrig1 expression and increasing meibum lipogenic protein (HMGCR/SREBP-1) expression. UPM-treated mice exhibited ductal hyperkeratinization and inflammatory cell recruitment. Simultaneously, PANoptosis was motivated, as indicated by the heightened expression of NLRP3/ZBP1/RIPK1 and the cleavage of caspase-3, -8, and -1 and gasdermin D, as well as the phosphorylation of MLKL. The underlying pathological mechanisms of UPM involve the phosphorylation of mitogen-activated protein kinase and nuclear factor- κ B.

Conclusions: These results provided direct evidence for the toxicity of UPM in MG. UPM-induced activation of PANoptosis and the MAPKs/NF- κ B signaling pathway might account for the inflammatory MGD.

Validity of the OSDI-6 Questionnaire in a Japanese Population: The First Report of the J-OSDI-6

First Author: Hiroki NISHIMURA

Co-Author(s): Rohan KHEMLANI, Shintaro NAKAYAMA, Eisuke SHIMIZU, Hirotsugu SOGA, Yuji TAKAYANAGI, Koharu TOZAWA

Purpose: The TFOS DEWS III report recommends the use of OSDI-6, a shortened six-item version of the OSDI questionnaire, to assess dry eye symptoms. While OSDI-6 has been validated in Chinese, no Japanese version existed. This study aimed to translate and validate the OSDI-6 in Japanese (J-OSDI-6) for use in Japanese clinical settings.

Methods: This single-center, prospective observational study was approved by the Human Sciences Ethics Committee of the Japan Orthoptic Vision Society. From June to August 2025, 100 Japanese adults (mean age 42.37 ± 14.42 years) who visited Yokohama Keiai Eye Clinic were enrolled. All participants completed the 12-item J-OSDI questionnaire. The J-OSDI-6 was extracted as a subset, and its total score was compared with the full J-OSDI-12. Cutoff values of 4 for J-OSDI-6 and 13 for J-OSDI-12 were applied based on previous literature.

Results: The J-OSDI-6 showed excellent correlation with J-OSDI-12 ($r = 0.952$). Sensitivity and specificity were 0.977 and 0.913, respectively. The AUC for detecting dry eye symptoms was 0.945. No significant associations were found between J-OSDI-6 scores and age, visual acuity, intraocular pressure, or screen time.

Conclusions: The J-OSDI-6 demonstrated strong validity and high diagnostic performance in comparison with the full J-OSDI-12. This tool provides a simple, efficient, and reliable option for assessing dry eye symptoms in Japanese clinical practice. This study was conducted at a single center and future multicenter studies are needed to validate the generalizability of the J-OSDI-6 across diverse populations.

Panel No.: CDE-0294

Visual and Therapeutic Impact of Scleral Lenses in Diverse Eye Diseases

First Author: Smruti PRIYADARSHINI

Co-Author(s): Shalvika GUPTA

Purpose: To study the indications and benefits of scleral contact lenses in various ocular conditions.

Methods: A retrospective, observational study was conducted at a tertiary eye care center between January 2019 and December 2024. Patients who underwent a scleral lens trial and were dispensed BostonSight Scleral contact lenses (BSS) were included,

and those with incomplete records and those who were unwilling were excluded.

Results: A total of 179 eyes from 146 patients were included in the study, with a mean age of 29.25 ± 11.38 years, male predominance (62%), and first-time scleral lens users (64.2%). Common indications were corneal ectasia (62.6%), Stevens–Johnson syndrome (SJS) sequelae (22.9%), corneal scars (12.3%), and dry eye disease (4.5%). The purpose of scleral lenses was visual rehabilitation (96%), dry eyes (18.4%), comfort (18.4%), and cosmesis (4.5%). About 40.2% underwent prior surgical interventions before scleral lens fitting. The mean improvement in vision compared with spectacles was 0.71 logMAR units ($p < 0.001$) and 9.52 ± 5.57 lines on the logMAR chart. Symptomatic relief was experienced in the form of reduced ocular discomfort (24.7%), decreased dependency on topical lubricants (17.4%), reduction in epithelial breakdown (14.6%). Complications included sterile infiltrates (3 eyes) and non-sterile infections (2 eyes).

Conclusions: Scleral contact lenses (SCLs) have emerged as an important tool for both visual rehabilitation and ocular surface protection. This study reaffirms SCLs' efficacy in visual rehabilitation and OSD protection.

Abstract No.: 204486

Panel No.: CDE-0242

Washed Microbiota Transplantation in the Effective Treatment of Dry Eye Disease

First Author: Huiyi WU

Co-Author(s): Shengyu HE

Purpose: Currently, the treatment of DED mainly focuses on symptom relief and has a limited effect in regulating the immune-inflammatory imbalance of the disease. Previous studies have indicated that patients with DED exhibit ocular surface dysbiosis, manifesting as alterations in microbial diversity and abnormal abundance of specific taxa. The «Gut-Eye Axis» reveals that the gut microbiome can influence the eye by modulating systemic immune and inflammatory status. Gut dysbiosis has been linked to various ocular diseases, and its role in DED is being actively uncovered.

Methods: Analyzed and compared OSDI, TBUT, and TMH of patients who underwent WMT (Washed Microbiota Transplantation) and those who underwent TAT (Topical Artificial Tears). Furthermore, 16S sRNA sequencing of patients' ocular surface and gut microbiota was performed, and the composition at the Phylum and Genus levels was compared.

Results: The target and control patients' condition improved with WMT treatment. The characteristics of the target patient's ocular surface and gut microbiota changed after WMT, while the ocular surface microbiota of the control patient remained unchanged.

The characteristics of the patient's gut microbiota changed after WMT treatment, mainly presenting an increase of beneficial bacteria, *Bacteroides* and *Prevotella*, while a decreased abundance of *Ruminococcus* and *Faecalibacterium*.

Conclusions: Our results supported that WMT may be an effective and safe choice for the treatment of patients with DED by changing ocular surface and gut microbiota characteristics of the host.

What The Fluff: Fungal Keratitis In A 9-Year Old Treated With Intrastromal Voriconazole

First Author: Nikolai Thadeus MAPPATAO

Co-Author(s): Pia Regina GALVANTE

Purpose: To report a case of presumed fungal keratitis in a pediatric patient treated with intrastromal and intracameral Voriconazole.

Methods: AS-OCT revealed a hyperreflective mass with fuzzy borders adherent to the paracentral endothelium and hyperreflective dots in the anterior chamber (AC). The patient was initially treated with topical Natamycin, Atropine, and Levofloxacin for 18 days, but showed limited improvement and worsening corneal infiltrates, with vision deteriorating to 20/200. Due to the absence of epithelial defects and involvement of Descemet's membrane, a therapeutic cleanup of the fungal ball in the AC through irrigation and aspiration followed by intracameral and intrastromal injection of Voriconazole (50 µg/0.1ml) were performed under general anesthesia. Post-operatively, the patient continued with topical Levofloxacin and Voriconazole.

Results: The corneal infiltrate density gradually resolved, and the fungal ball did not recur. Visual acuity improved (20/250 pre-op, 20/100 day 1, 20/20 day 25). Though there was no apparent post-procedure endothelial cell loss, there was a note of scarified endothelial opacity in the area of the Descemet's break, and an anterior sub-capsular cataract at day 18 post-op.

Conclusions: This is the first documented local case of presumed fungal keratitis in a pediatric patient treated with intrastromal Voriconazole. The treatment, including the evacuation of the fungal ball and Voriconazole injections, was more effective than topical antifungals alone. Clinical trials are needed to further evaluate the safety and efficacy of intrastromal and intracameral Voriconazole injections in pediatric fungal keratitis.

When Brittle Bones Meet Fragile Eyes: Osteogenesis Imperfecta With Corneal Ectasia

First Author: Sri Satviki POSINA

Co-Author(s): Inchara NAGRAJ, Asam NAVEENA

Purpose: To report a rare case of osteogenesis imperfecta with corneal ectasia and cataract, emphasizing the need for comprehensive ophthalmic evaluation in systemic collagen disorders.

Methods: We present the case of a 65-year-old female, a known case of osteogenesis imperfecta, who reported gradual, painless diminution of vision in the left eye for two months and poor vision in the right eye since childhood. Detailed ophthalmic evaluation included visual acuity, slit-lamp examination, and fundus assessment.

Results: Visual acuity was counting fingers at 1 m in both eyes. The anterior segment showed bluish scleral discoloration bilaterally. The right eye demonstrated a deep anterior chamber with corneal edema and a descemetocoele, suggestive of corneal ectasia with impending perforation, along with a mature cataract. The left eye revealed a senile immature cataract. Fundus evaluation of the right eye was not possible due to media opacity, while the left eye showed a healthy optic disc (cup-disc ratio 0.3) with normal vasculature and dull foveal reflex.

Conclusions: This case highlights the rare association of osteogenesis imperfecta with corneal ectasia and cataract. Vigilant ophthalmic evaluation in systemic connective tissue disorders is essential, as timely detection and intervention can prevent vision-threatening complications and preserve quality of life.

Abstract No.: 203045

Panel No.: CDE-0223

When the Fellow Eye Has Almost Nothing Left: Autokeratoplasty for Sudden Corneal Perforation

First Author: Kiara NURMATHIAS

Co-Author(s): Rio RHENDY

Purpose: To highlight a globe-preserving technique using manual lamellar autokeratoplasty harvested from a phthisical fellow eye in acute corneal perforation.

Methods: A 56-year-old woman presented with acute full-thickness corneal perforation (2 × 1.5 mm, paracentral) in the left eye. The fellow right eye was phthisical, with a long history of corneal ulcer and epithelialized iris prolapse. The visual acuity pre-operative were 1/300 in left eye. Examination revealed 180° conjunctivalization and dense corneal scarring, leaving only a minimal residual clear cornea. Emergency surgery involved manual lamellar graft

harvesting from the fellow eye, transplantation to the left eye, intracameral triamcinolone injection, and anterior chamber reformation. The donor site was reinforced with multilayer amniotic membrane transplantation (AMT).

Results: At 2-month follow-up, the left eye showed a stable graft, reformed anterior chamber, and visual acuity of 0.5/60. The donor site in the right eye healed without further complications. Systemic work-up revealed rheumatoid factor positivity and digital ulcers, suggesting a possible autoimmune background as a risk factor for corneal thinning and perforation.

Conclusions: This case illustrates that even a compromised fellow eye can serve as a source of life-saving tissue. Manual lamellar autokeratoplasty from a minimally viable fellow eye may offer a globe-preserving solution in cases of sudden corneal perforation. It also highlights the importance of systemic evaluation in patients with corneal melting, which in this case was presumed to have an autoimmune background.

ΔNp63α as a Master Regulator of Meibomian Gland Progenitors and Age-Associated Decline

First Author: Naiwen FAN

Co-Author(s): Hsu CHIA-AN, Ya-shan YU, Yih-shiuan KUO

Purpose: Meibomian gland atrophy and dysfunction are common features of aging, leading to reduced lipid secretion and ocular surface disorders. This study investigated the role of ΔNp63α in meibomian gland epithelial progenitors, focusing on its impact on cell proliferation, differentiation, and age-associated changes.

Methods: Meibomian glands were harvested from C57BL/6 mice at 2, 7, and 12 months. ΔNp63α expression was assessed by immunohistochemistry and western blotting. Human immortalized meibomian gland epithelial cells (HMGECS) were cultured under proliferative, basal, and differentiation conditions to evaluate ΔNp63 isoform expression. Nuclear fractionation determined subcellular localization. LipidTOX staining was used to assess differentiation. Functional assays were conducted following ΔNp63α overexpression or knockdown, with cell proliferation measured by proliferation assays and Cyclin D1 levels. RNA sequencing (RNA-seq) was performed to profile transcriptomic changes associated with ΔNp63α overexpression.

Results: ΔNp63α was predominantly expressed in the basal layer of meibomian glands and significantly decreased in aged mice (P < 0.05). In HMGECS, ΔNp63α was the major isoform in progenitors, localized mainly

to the nucleus, and diminished during differentiation. Overexpression of $\Delta Np63\alpha$ promoted proliferation ($P < 0.05$), whereas knockdown reduced cell number and Cyclin D1 expression ($P < 0.001$). RNA-seq analysis revealed broad transcriptional reprogramming, with upregulation of gene clusters related to epithelial morphogenesis, stratified epithelium differentiation, and p53-family signaling, alongside downregulation of lipid metabolism and inflammatory pathways. These findings suggest that $\Delta Np63\alpha$ can both sustain progenitor programs and activate epithelial lineage networks when overexpressed.

Conclusions: $\Delta Np63\alpha$ is essential for maintaining progenitor identity and proliferation in meibomian gland epithelial cells. Its age-associated decline may contribute to impaired gland regeneration and lipid homeostasis. The dual ability of $\Delta Np63\alpha$ to support progenitor renewal and influence epithelial differentiation highlights its central role in meibomian gland aging and dysfunction.

1% Atropine for Treatment of Idiopathic Orbital Inflammation With Acute Angle Closure

First Author: Zhaole LI

Co-Author(s): Jianhao CAI, Zeyi LI

Purpose: To report a rare case presented with idiopathic orbital inflammation (IOI) with acute angle closure (AAC), who was treated with 1% atropine instead of pilocarpine with excellent effect.

Methods: A 21-year-old male presented with redness and swelling with exophthalmos in his left eye for 6 days, and was diagnosed with IOI. After receiving intravenous methylprednisolone (IVMP) treatment for 5 days, the symptoms of IOI resolved, and the visual acuity improved from 1/25 to 16/20 OS, while the intraocular pressure (IOP) increased from 25 mm Hg to 32 mm Hg OS with a shallow anterior chamber. Ultrasound biomicroscopy revealed a 360-degree angle closure and ciliary body thickening, which confirmed the diagnosis of IOI with involvement of ciliary body edema and thickening to cause anterior rotation of the lens-iris diaphragm, resulting in AAC. Thus, 1% atropine was administered to paralyze the ciliary muscle, and IOP-lowering treatment was also adopted.

Results: The IOP reduced to 22 mm Hg OS 3 days later, and the visual acuity increased to 20/20 with a decline in IOP to 12 mm Hg 2 week later. Slit-lamp examination revealed that the ACD improved to 3.0 times the corneal thickness and the macular edema disappeared. UBM showed open angle and ciliary body with clear

boundaries and homogeneous echo. Besides, the ACD increased to 2.91mm.

Conclusions: IOI involved ciliary body to cause AAC, which had different pathogenesis from frequently encountered AAC. Therefore, 1% atropine was administered instead of pilocarpine with excellent effect.

A Case Report: A Complex Case of Secondary Glaucoma Drainage Device Implantation in a Post Penetrating Keratoplasty Patient With Secondary Angle Closure From Ice Syndrome

First Author: Lee Tomas TAN

Co-Author(s): Nilo Vincent FLORCRUZ, Anna Victoria SAN PEDRO

Purpose: A Case Report of a Complex Case of Secondary GDD Implantation that resulted in post operative hypotony and hemorrhagic choroidal detachment. The patient underwent external drainage and old tube explantation resulting in the resolution of the choroidal detachment.

Methods: 76 year old female diagnosed Bilateral ICE Syndrome and Secondary Angle Closure Glaucoma Underwent penetrating keratoplasty and multiple glaucoma surgeries on the left eye including a primary GDD implantation IOP uncontrolled on maximum tolerated medications at 31

Results: The first surgery done was a secondary GDD implantation using an Ahmed FP7 placed superonasally to control the IOP. The surgery was unremarkable 1 Day post op, the VA dropped to hand movement, the anterior chamber was shallow and hypotony noted Ocular UTZ revealed serous choroidal detachment. On the 7th day post op, the patient underwent external drainage of the the left eye and ligation of the secondary tube. On the 1st day post op from the external drainage, the patient was still hypotonic at 2 but there still a view of the macula. The patient then underwent, tube explantation of the old tube and ligation of the new GDD OP increased to 10 and there was noted resolution of the choroidal detachment.

Conclusions: There are multiple factors that may cause post op hypotony in complex cases of secondary glaucoma for GDD implantation. In placement of a secondary GDD, checking the flow of the primary GDD is important. The timely co-management of hemorrhagic choroidal detachment is important in complex cases

A Case of Free Conjunctival Autograft for the Ruptured Avascular Bleb Following Descemet Membrane Endothelial Keratoplasty

First Author: Mari **MIMURA**

Co-Author(s): Masashi **FUJIHARA**, Yasuhiko **HIRAMI**, Shin-ichiro **ITO**, Yasuo **KURIMOTO**, Takahiro **NAKAMURA**

Purpose: To report a case of avascular bleb rupture caused by postoperative anterior chamber air migration following Descemet Membrane Endothelial Keratoplasty (DMEK) and to evaluate the effectiveness of a free conjunctival autograft.

Methods: A 73-year-old man with exfoliation glaucoma in his left eye had previously undergone Ex-PRESS implantation and trabeculectomy, resulting in the formation of an avascular filtering bleb with intraocular pressure (IOP) maintained in the low teens. Subsequently, the patient developed bullous keratopathy and underwent DMEK. On postoperative day (POD) 3, air from the anterior chamber migrated into the filtering bleb, resulting in bleb rupture, aqueous leakage, and ocular hypotony. A 3×3 mm free conjunctival graft was harvested from the inferonasal quadrant and secured to the rupture site using blocking sutures. Due to inadequate air tamponade and persistent hypotony, the DMEK graft underwent primary failure. Therefore, repeat endothelial keratoplasty (DSAEK) was performed.

Results: After free conjunctival autografting, aqueous leakage decreased and ceased on POD4. The filtering bleb remained intact, and the IOP stabilized in the lower teens. Although air from the anterior chamber again migrated into the filtering bleb immediately after DSAEK, the bleb wall remained undamaged. The graft firmly adhered to the host cornea, and corneal transparency was restored.

Conclusions: Air in the anterior chamber may migrate to an avascular filtering bleb immediately after DMEK, potentially causing bleb wall rupture. Free conjunctival autografting with blocking sutures appears to be an effective and straightforward technique for bleb repair.

A Complex Case of Secondary Glaucoma Drainage Device Implantation in a Post Penetrating Keratoplasty Patient With Secondary Angle Closure Glaucoma From Ice Syndrome

First Author: Lee Tomas **TAN**

Co-Author(s): Nilo Vincent **FLORCRUZ**, Anna Victoria **SAN PEDRO**

Purpose: The presentation of a case report on a complex case of secondary GDD implantation that resulted in hypotony and hemorrhagic choroidal detachment.

Methods: A 76-year-old female diagnosed with bilateral ICE syndrome and secondary angle closure glaucoma. She underwent penetrating keratoplasty and multiple glaucoma surgeries on the left eye, including a primary GDD implantation (AADI). Her IOP on the left eye was still uncontrolled on maximum tolerated medications. The planned procedure was a secondary GDD implantation using an Ahmed FP7 placed superonasally to control the IOP.

Results: On the first day post-secondary GDD implantation, the VA decreased, the anterior chamber was shallow, and the IOP was hypotonic. The patient was noted to have a hemorrhagic choroidal detachment. 3 Days postoperatively, Ocular UTZ revealed persistence of choroidal detachment. The patient underwent external drainage of the left eye and ligation of the secondary tube. Due to the recurrence of the choroidal detachment, tube explantation of the old tube and ligation of the new GDD with absorbable vicryl suture. There was then noted resolution of choroidal detachment, an increase in IOP to 10, and return to pre op vision.

Conclusions: There are multiple factors that may cause post op hypotony in complex cases of secondary glaucoma for GDD implantation. In the placement of a secondary GDD, checking the flow of the primary GDD is important. In patients with a previous trabeculectomy site, careful manipulation of the conjunctiva must be performed. The timely co-management of hemorrhagic choroidal detachment with fellow subspecialty colleagues is important in complex cases

A Dilemma: Managing Secondary Glaucoma in Microspherophakia During Pregnancy

First Author: Veronica **SINURAT**

Co-Author(s): Elsa **GUSTIANTY**, Maula **RIFADA**, Sonie **UMBARA**

Purpose: It is reported that 31% of ophthalmologists were unsure about dealing with glaucoma management

during pregnancy. The management of glaucoma in women planning pregnancy, during pregnancy, and during the breastfeeding period, presents a number of challenges and uncertainties. The choices of glaucoma medication and surgery need to be considered at every stage of pregnancy. This case report aims to describe the management of pregnant woman with secondary glaucoma due to microspherophakia.

Methods: A case of a 29-year-old woman presented in the sixteenth week of pregnancy with chief complaints of blurred vision and glare on both eyes. She had history of wearing S-14.00 glasses. Intraocular pressure were 34 mmHg and 28 mmHg, with cup disc ratio of 0.9 both eyes. Subluxation of lens revealed on both eyes, with diameter of lens was 6.0 mm. She was treated with a non-selective beta-blocker glaucoma medication, given with punctal occlusion. The patient underwent intracapsular cataract extraction followed by implantation of retropupillary iris-claw intraocular lens. After surgeries, glaucoma medication was still given with a great attention to her baby's condition.

Results: Presenting visual acuity (VA) improved from finger counting on both eyes pre-operatively to 0.63 and 0.5 (best corrected VA) post-operatively. Intraocular pressure reduced to 14 mmHg and 13 mmHg with glaucoma medications. There was no sign of complications during and after surgery within the three-month follow-up.

Conclusions: Managing glaucoma in pregnancy requires a holistic and multidisciplinary approach to avoid negative impacts on the mother and fetus.

A Pilot Case Series of iStent Inject W Implantation in Asian Eyes With Uveitic Glaucoma and Ocular Hypertension – 12-Month Outcomes

First Author: Bryan ANG

Co-Author(s): Rupesh AGRAWAL, Elizabeth CHEN, Celyn CHNG

Purpose: To evaluate the 12-month safety and efficacy outcomes of combined phacoemulsification and iStent inject W implantation in Asian eyes with uveitic glaucoma (UG) or uveitis-related ocular hypertension (OHT).

Methods: A pilot, single-surgeon, prospective case series was conducted from September 2022 to March 2024 in a tertiary eye centre in Singapore. Primary outcomes included change in intraocular pressure (IOP) and anti-glaucoma medications up to 12 months post-operatively (POM12). Secondary outcome measures included visual acuity (VA), Humphrey Visual Field (HVF) progression and intra- and post-operative complications.

Results: Five eyes with quiescent UG or uveitis-related OHT underwent combined phacoemulsification with iStent inject W implantation. 100% (5 eyes) were from Chinese subjects, and 60% (3 eyes) were from male subjects. Mean age was 68.8 (range 57-74) years. Mean pre-operative IOP was 12.8 (range 11-16) mmHg, maintained at 13.4 (range 11-16) mmHg at POM12. The median number of anti-glaucoma medications reduced from 2 preoperatively to 0 at POM12. In 3 eyes with reliable HVFs, the mean baseline VF MD of -6.87 dB improved to -3.98dB by POM12. There was no loss in best corrected VA and no eyes required secondary glaucoma procedures. One eye with UG secondary to cytomegalovirus anterior uveitis with prior steroid response maintained stable IOP with reduction of one glaucoma medication, despite ongoing use of topical corticosteroids.

Conclusions: In this pilot case series, combined phacoemulsification and iStent inject W implantation demonstrated glaucoma medication burden reduction with stable IOP control and good safety outcomes, up to 12 months post-operatively.

A Stiff Prediction: Corneal Hysteresis and the Risk of Visual Field Progression in Open-Angle Glaucoma Patients of South India

First Author: Shubham DARADE

Co-Author(s): Sathi DEVI, Zia PRADHAN, Harsha RAO

Purpose: To evaluate the association between baseline ocular response analyser (ORA) measurements and progressive visual field (VF) loss in patients with open-angle glaucoma (OAG) from South India.

Methods: Prospective, longitudinal study of OAG patients who had undergone a baseline ORA and were followed up for a minimum of 3 years with at least 5 reliable visual fields. Eyes with retinal pathology, neurological disorders and poor-quality ORA measurements (Waveform Score <4) were excluded from the analysis. Progression was determined by the rate of change of visual field index (VFI) over time (VFI slope). Effect of demographic (age, gender, etc), clinical (intraocular pressure IOP variables, corneal pachymetry, presence of disc haemorrhage, baseline visual field parameters), and baseline ORA parameters (CH, and corneal resistance factor CRF) on VFI slope was analysed using linear mixed models.

Results: Eighty eyes of 59 OAG patients were included in the analysis. The mean age of the participants was 62.57 ± 10.9 years. The mean follow-up duration was 6.6 ± 1.8 years. Mean baseline VFI was $78.2 \pm 22\%$ and final VFI was $73.7 \pm 26\%$ (VFI slope $-0.93 \pm 0.2\%$ /year, $p=0.001$). On univariate analysis, eyes with greater IOP fluctuation (co-efficient -0.27 , $SE=0.16$) and higher baseline pattern standard deviation (PSD) on visual fields (-0.08 , $SE=0.05$) showed faster VF progression.

However, on multivariate analysis which included these variables and other factors shown previously to be associated with glaucoma progression such as mean IOP during follow-up, CH, and presence of disc haemorrhages, only great baseline PSD was associated with a faster VFI decline (-0.1 , $SE=0.05$, $p=0.049$).

Conclusions: Hence, higher PSD on a baseline visual field is a risk factor for progression in open-angle glaucoma. This study in a cohort of OAG eyes from South India did not find any association between CH and glaucoma progression.

Abstract No.: 205504

Panel No.: GLA-0394

Ahmed Glaucoma Valve Implant – Clinical Outcomes in Pars Plana Versus Anterior Chamber Entry in Refractory Glaucoma

First Author: Salwa KAIDAKATH

Co-Author(s): Meena GOPINATH MENON, Shalini

Purpose: To compare the clinical outcomes, intraocular pressure (IOP) control, and complication rates of Ahmed Glaucoma Valve (AGV) implantation with tube placement in the anterior chamber (AC) versus pars plana (PP) in eyes with refractory glaucoma.

Methods: This single-centre, retrospective study included 60 eyes that underwent AGV implantation (FFP 7/8). 38 eyes received AC tube placement, and 31 received PP tube placement. Pre- and postoperative data, including intraocular pressure, best-corrected visual acuity, number of anti-glaucoma medications, and complications, were analyzed. Surgical success was defined as IOP between 6–21 mmHg with or without AGM, no additional glaucoma surgery or implant removal, and maintenance of light perception vision. Statistical significance was set at $P < 0.05$.

Results: Both groups showed significant IOP reduction from preoperative levels (AC: 35.00 to 16.37 mmHg; PP: 38.96 to 16.90 mmHg; $P < 0.001$) and a decrease in AGM use. Final IOP, AGM use, and visual outcomes were comparable ($P > 0.05$). Overall success rates were 78.9% in the AC group and 67.7% in the pars plana group ($P = 0.170$). Complication rates did not differ significantly between groups ($P = 0.683$).

Conclusions: AGV implantation via either anterior chamber or pars plana is effective in lowering IOP, reducing medication burden, and maintaining vision in refractory glaucoma, with comparable safety profiles and complication rates. Both approaches remain viable options depending on ocular anatomy and surgical indications.

Panel No.: GLA-0313

Analysis of Lens Zonular Ligament Relaxation in Primary Angle Closure Disease by Pentacam

First Author: Hui LIU

Co-Author(s): Danyan LIU

Purpose: To explore the differences in lens zonular ligament relaxation among patients with various types of primary angle-closure disease (PACD).

Methods: A total of 86 PACD patients (consisting of primary angle-closure suspects (PACS), acute primary angle-closure (APAC), chronic primary angle-closure (CPAC), and primary angle-closure glaucoma (PACG)) and 40 controls were recruited. The central anterior chamber depth (CADC) and peripheral anterior chamber depth (peri-ACD) in 8 directions under normal pupil condition, changes in CADC after mydriasis and miosis (Δ CADC), and changes in peri-ACD after mydriasis (Δ peri-ACD) of all patients were measured and compared by using the Pentacam. Δ CADC and Δ peri-ACD could show the degree of zonular ligament laxity.

Results: The CADC and peri-ACD in all 8 directions were significantly lower in PACD patients as compared to controls under normal pupil state, and APAC group concerning CADC and peri-ACD was significantly lower than the other three types of PACD (all $P < 0.0001$). The Δ CADC and Δ peri-ACD in all 8 directions were distinctly different between PACD patients and controls (all $P < 0.05$). Further comparisons revealed that lower Δ CADC and Δ peri-ACD in superior and temporal directions were observed in APAC patients as compared to PACS, CPAC and PACG patients (all $P < 0.05$).

Conclusions: The four types of PACD may be associated with a certain degree of zonular relaxation. Lens zonular relaxation was most significant in APAC eyes, and the degree of relaxation was greater than that of the contralateral eyes.

Antibody-Mediated GFAP Targeting Protects Retinal Neurons in Experimental Glaucoma and Inhibits Astrocyte Reactivity In Vitro

First Author: Chaoqiang GUAN

Co-Author(s): Zhijie LI, Linglin ZHANG

Purpose: Glaucoma causes progressive retinal ganglion cell (RGC) loss and irreversible vision loss. Astrocyte reactivity, marked by elevated GFAP, promotes neuroinflammation and RGC degeneration. This study tested the neuroprotective potential of a GFAP-targeting monoclonal antibody in vivo and its effects on astrocyte reactivity in vitro.

Methods: Glaucoma was induced in female Sprague-Dawley rats by episcleral vein occlusion to establish sustained ocular hypertension (OHT), followed by an intravitreal injection of either a GFAP monoclonal antibody (mAb) or an IgG control. Retinal nerve fiber layer (RNFL) thickness was measured using optical coherence tomography, and retinal ganglion cell (RGC) survival was assessed by Brn3a immunostaining. In vitro, primary mouse astrocytes were stimulated with lipopolysaccharide (LPS) with or without GFAP mAb treatment, and astrocyte reactivity was evaluated by GFAP expression and morphology, while neurotoxic activation was determined by lipocalin-2 (LCN2) expression. GFAP mAb internalization was visualized by fluorescence labeling.

Results: GFAP mAb treatment significantly preserved RNFL thickness and enhanced RGC survival in vivo. In vitro, it attenuated astrocyte reactivity by reducing GFAP and LCN2 expression, normalizing reactive morphology, and suppressing the pro-inflammatory mediators TNF- α and IL-1 β . Fluorescence imaging further confirmed astrocytic uptake of GFAP mAb, which was increased under LPS-induced inflammatory conditions.

Conclusions: GFAP mAb provides neuroprotection in experimental glaucoma and reduces astrocyte reactivity and inflammation in vitro, highlighting its potential as a novel immunotherapeutic strategy targeting glial dysfunction in glaucoma.

Association Between Sleep Disturbances and Glaucoma: A Cross-Sectional Study

First Author: Noriko **HIMORI**

Co-Author(s): Maki **FUKUMOTO**, Makoto **ISHIKAWA**, Toru **NAKAZAWA**, Takahiro **NINOMIYA**, Satoru **TSUDA**, Mitsuhide **YOSHIDA**

Purpose: Sleep disturbances have recently been implicated in the pathogenesis of glaucoma, but the mechanisms remain unclear. This study aimed to explore whether sleep quality is associated with glaucomatous damage via systemic physiological changes, such as reduced antioxidant capacity.

Methods: We enrolled 151 patients (79 men, 72 women; mean age: 57.1 $\pm$ 10.6 years) with open-angle glaucoma treated at our clinic. The primary endpoint was circumpapillary retinal nerve fiber layer thickness (cpRNFLT) measured with optical coherence tomography (OCT). The secondary endpoint was biological antioxidant potential (BAP) assessed with a free radical analyzer. Sleep quality was evaluated using sleep duration and the Pittsburgh Sleep Quality Index (PSQI). Multiple regression analyses were conducted to assess the associations among these parameters.

Results: The cpRNFLT was significantly reduced in patients with poor sleep quality (PSQI $\geq$ 6, n=67) compared to those with better sleep (PSQI <6, n=84) (p=0.04). In multiple regression, PSQI score (p<0.01) and age (p<0.01) were significant predictors of cpRNFLT. Sleep duration was significantly associated with BAP (p=0.04).

Conclusions: Poor sleep quality and short sleep duration were significantly associated with reduced cpRNFLT and lower antioxidant capacity. These findings suggest that adequate sleep may play an important preventive role in the pathophysiology of glaucoma, potentially via its influence on systemic antioxidant capacity.

Association of Serum Complement C3 With Primary Open Angle Glaucoma

First Author: Shams **NOMAN**

Purpose: Elevated intraocular pressure (IOP) is a key risk factor in POAG, some patients still experience vision loss despite IOP reduction. Evidence shows that low serum complement C3 is linked to early nerve damage and retinal ganglion cell (RGC) loss, implying C3's protective role against early glaucomatous damage.

Methods: This cross sectional comparative study was carried out into Department of Ophthalmology, Bangabandhu Sheikh Mujib Medical University (BSMMU) during January, 2022 to August, 2023. A total of 40 diagnosed cases of POAG were the study population and 40 patients were selected considering similar age group as comparison group without glaucoma. Serum complement C3 level was measured by immunonephelometry system in Department of Microbiology, BSMMU. Statistical analyses of the results were obtained by using Statistical Packages for Social Sciences (SPSS-26).

Results: The mean serum complement C3 level was 1.02 $\pm$ 0.12 (g/l) in POAG group and 1.09 $\pm$ 0.15 (g/l) in control group. The difference was statistically significant (p<0.05) between groups. The mean serum complement C3 level was 1.07 $\pm$ 0.12 (g/l) in mild glaucomatous damage, 1.03 $\pm$ 0.14 (g/l) in moderate glaucomatous damage and 0.99 $\pm$ 0.99 (g/l) in severe glaucomatous damage. The mean Serum complement C3 was not statistically significant (p>0.05) in different grading of severity of POAG patients.

Conclusions: The analysis revealed reduced serum concentrations of C3 in individuals diagnosed with POAG than comparison group. However, there was no correlation between serum complement C3 levels and the severity of POAG.

Calcified Glaucoma Implant in a Child With Secondary Glaucoma Due to Sturge Weber Syndrome: A Case Report

First Author: Rachel ETHELIND

Co-Author(s): Virna Dwi OKTARIANA

Purpose: Calcium deposits have been reported in several types of ocular implant such as silicone scleral buckles and intraocular lenses. However, to our knowledge, they have not been previously observed in connection with a glaucoma drainage device (GDD).

Methods: Observational case reports.

Results: A 12-year-old boy presented with uncontrolled intraocular pressure in the right eye. The patient had a history of Ahmed Glaucoma Implant placement in the right eye 12 years prior due to Secondary Glaucoma of the right eye due to Sturge Weber Syndrome. Upon examination, visual acuity was light perception (previously 1/300), intraocular pressure was 40 mmHg despite full medication, anterior chamber showed a flat area at the inferonasal quadrant, the tube tip at the 1 o'clock position was patent, whereas the tube at the 11 o'clock position was not visualized. The pupil was round, centrally located, and patent peripheral iridectomy. Posterior synechiae were present throughout all quadrants. The patient subsequently underwent an exchange surgery of the Ahmed Glaucoma Implant with a Virna Glaucoma Implant GL-52 (VGI GL-52). Intraoperatively, the Ahmed Glaucoma Implant was found to be calcified and strongly adherent to the sclera. Histopathological examination of the implant tissue revealed fibrotic connective tissue with calcification and ossification.

Conclusions: This rare case of calcification of glaucoma drainage device might be underrecognized because of the lack of signs or symptoms that might lead to the suspicion of calcification. Further consideration should be accounted.

Cataract Surgery in Primary Angle Closure Suspect (PACS) Subjects With Laser Peripheral Iridotomy (LPI): A 15-Year Cohort Study at the Hong Kong West Cluster (HKWC)

First Author: Rachel YIU

Co-Author(s): Yawen Philip GUO, Min Yu HUANG, Christopher Kai Shun LEUNG

Purpose: The Zhongshan Angle Closure Prevention trial recommends against LPI for all PACS patients. Meanwhile, data showed an association between rising cataract surgical rates and decreasing rates of acute angle closure. This study aimed to retrospectively review the performance of cataract surgery for PACS subjects after LPI.

Methods: Data from LPI clinics at the HKWC hospitals from 1 July 2010 to 30 June 2015 were obtained from the electronic medical records. All patients were followed up for 10 years after LPI. Detailed clinical information from 1 July 2010 to 30 June 2025 was reviewed.

Results: A total of 157 subjects received LPI for PACS at HKWC hospitals during 2011-2015. Among them, 35 (22.3%) and 54 (34.4%) subjects underwent cataract extraction within 5 and 10 years after LPI, respectively, with 80-100% indicated for visually significant cataract. The mean age of PACS subjects who underwent cataract surgery (75.3 years) was significantly higher than that of subjects who did not have cataract surgery (65.2 years) during the follow-up period ($P < 0.00001$). The median age of PACS subjects receiving LPI was 70 years. There was no conversion to PAC or occurrence of acute angle closure in all subjects.

Conclusions: More than 50% of patients were beyond the mean age of PACS subjects undergoing cataract extraction after LPI. Further cost-effectiveness analyses incorporating the pseudophakic factor could guide the management of PACS subjects in the public hospital setting.

Causal Effects of Plasma Proteins on Primary Open-Angle Glaucoma: Evidence From Mendelian Randomization, Single-Cell RNA Sequencing, and Network Pharmacology

First Author: Nachuan LUO

Co-Author(s): Xin MA, Chengguo ZUO

Purpose: To explore the causal role of circulating plasma proteins in the pathogenesis of primary open-angle glaucoma (POAG) and identify potential therapeutic targets.

Methods: We performed a two-sample, bidirectional Mendelian randomization (MR) analysis using genome-wide association study (GWAS) summary statistics to assess the causal effects of 4,907 plasma proteins on POAG risk. Single-cell transcriptomic data from retinal tissues were used to determine protein expression patterns across cell types. Drug enrichment analysis and molecular docking were employed to evaluate potential interactions between candidate proteins and small-molecule compounds.

Results: MR analysis identified 49 plasma proteins causally associated with POAG. Functional enrichment highlighted roles in endoplasmic reticulum lumen biology and cytokine-cytokine receptor interactions. Protein-protein interaction mapping revealed 10 hub proteins, including CLU and WNT5A. Single-cell data showed CLU was predominantly expressed in Müller glia, while WNT5A lacked cell-type specificity. Network pharmacology analysis identified gemcitabine

($P = 0.000195$), dacarbazine ($P = 0.000305$) and acrasin ($P = 0.000758$) as significantly enriched candidate compounds targeting the hub proteins. Docking simulations suggested high binding affinity of gemcitabine to CLU (vina score = -6.7 kcal/mol) and WNT5A (vina score = -6.8 kcal/mol) as well as dacarbazine to CLU (vina score = -5.7 kcal/mol) and acrasin to WNT5A (vina score = -7.6 kcal/mol).

Conclusions: The findings suggest that plasma proteins CLU and WNT5A contribute to the pathogenesis of POAG and may represent viable targets for therapeutic intervention. Gemcitabine, dacarbazine and acrasin warrant further investigation for potential repurposing in glaucoma treatment.

Cerium Single-Atom Nanozyme Penetrates the Corneal Barrier to Suppress Mitochondrial Damage and Pyroptosis in the Trabecular Meshwork for Glaucoma Intervention

First Author: Mengyang ZHAO

Co-Author(s): Jingguo LI, Zhanrong LI

Purpose: Glaucoma, the leading irreversible blinding eye disease worldwide, is characterized by abnormal accumulation of extracellular matrix in the trabecular meshwork (TM), which induces oxidative damage and exacerbates aqueous humor circulation disorders, forming a vicious cycle. Current topical eyedrops suffer from limited therapeutic efficacy due to the ocular drug delivery barrier, resulting in less than 2% bioavailability in the anterior chamber.

Methods: This project aims to develop a novel cerium single-atom nanozyme-based eyedrop (Ce-SAN/CDs). Firstly, Ce-SAN/CDs was prepared through hydrothermal synthesis. Further, the in vitro anti-inflammatory and antioxidant activities of the substance were verified through experiments on cells constructed in vitro to simulate oxidative stress conditions. Finally, a glaucoma model of oxidative damage to the mouse trabecular meshwork was established to verify the therapeutic effect of Ce-SAN/CDs on glaucoma in mice.

Results: The Ce-SAN/CDs structure were characterized to confirm the successful preparation of Ce-SAN/CDs. The formulation leverages positively charged carbon dots as carriers to reversibly open corneal epithelial tight junctions, effectively penetrating the corneal barrier without damaging the epithelial layer. Furthermore, the Ce-SAN/CDs mimics the synergistic effects of multiple antioxidant enzymes to efficiently scavenge reactive oxygen species, thereby inhibiting mitochondrial oxidative damage and pyroptosis in the TM. By establishing a glaucoma model of oxidative damage to the TM in mice, Ce-SAN/CDs showed significant therapeutic effects on glaucoma in mice,

successfully reducing the intraocular pressure (IOP) of the mice.

Conclusions: The system demonstrates restoring the redox homeostasis of TM mitochondria to reverse oxidative damage at its root and achieve IOP reduction.

Changes in Anterior Segment Configuration During Acute Angle Closure in Eyes With and Without Zonular Laxity

First Author: Jianrong JIANG

Co-Author(s): Jingjing HUANG, Litong YE

Purpose: To describe and compare the changes in anterior segment parameters in eyes with and without zonular laxity during an episode of acute angle closure (AAC).

Methods: We retrospectively reviewed the records of 931 patients with AAC treated at a single tertiary eye center between June 2019 and September 2025. Patients with available detailed anterior biometric data from both before and during the AAC were included. The diagnosis of zonular laxity was confirmed via intraoperative findings. Anterior segment parameters were compared between groups using the Mann-Whitney U test.

Results: At baseline, compared to the AAC without zonular laxity eyes ($n=4$), the eyes with zonular laxity ($n=4$) had a significantly shallower anterior chamber depth (ACD) but a wider superior angle opening distance (AOD) and anterior chamber angle (ACA) (all $P < 0.05$). During the AAC, the magnitude of change was significantly greater in the zonular laxity group for ACD, lens vault, inferior AOD, inferior ACA, and superior iris-ciliary process distance (all $P < 0.05$). No significant inter-group differences were found for the baseline and change in lens thickness, iris curvature and trabecular meshwork-ciliary process distance.

Conclusions: AAC Eyes with zonular laxity present with a unique baseline anatomy and undergo significantly greater changes in anterior segment configuration during episode of AAC. Zonular integrity appears to be a critical factor influencing the stability of the anterior segment during AAC.

Climbing the MIGS Learning Curve: Surgical Confidence With Hydrus® and iStent Inject®

First Author: Aditi KOCHAR

Co-Author(s): Shamira PERERA

Purpose: To analyse the early learning curve of minimally invasive glaucoma surgery (MIGS) using Hydrus® Microstent ($n = 24$) and iStent inject® ($n = 19$), performed in combination with phacoemulsification

between January 2024 and January 2025 at the Singapore National Eye Centre (SNEC).

Methods: A retrospective comparative study. All procedures were conducted by a single surgeon under mentor supervision.

Results: First-attempt correct placement was achieved in 80% of early Hydrus cases and 90% of iStent cases, improving to 93.75% and 95%, respectively, with increasing experience. Major challenges encountered included gonioscopic stabilization, consistent identification of Schlemm's canal, and controlled device deployment. Notable improvements in operative time and intraoperative handling were observed after approximately the 10th case in both groups, marking a transition in confidence and technical fluency.

Conclusions: The fellowship's exposure and structured mentorship accelerated surgical proficiency, leading to enhanced precision, consistency, and predictable outcomes. These findings underscore the importance of guided training and repetition in mastering angle-based MIGS techniques and provide practical insights into the transition from early novice performance to surgical confidence.

Clinical Profile and Surgical Outcomes of Lens-Induced Glaucoma Patients in a Tertiary Eye Hospital

First Author: Habiba SULTANA

Co-Author(s): Shajeda AZIZI, Md Sajidul HUQ, Khairul ISLAM

Purpose: To evaluate the clinical profile and surgical outcomes of Lens-Induced Glaucoma patients in a Tertiary Eye Hospital, Bangladesh.

Methods: This prospective study was conducted from July 2024 to July 2025. A total of 43 patients who underwent cataract surgery in the hospital with classic symptoms of lens-induced Glaucoma were taken into the study. Informed consent was obtained from all eligible participants before undertaking surgery. The institutional review board provided ethical approval for this study.

Results: Females comprised 74.4% of patients, with most aged 61–70 years (48.8%). Phacomorphic glaucoma was more frequent (62.8%), while Blurred vision (73.1%) and pain (62.5%) were the most common symptoms. Clinical signs in phacomorphic cases included edematous cornea (60.7%) and shallow anterior chamber (100%). Treatment delay was mainly due to good vision in the fellow eye (76.7%). Most patients (88.4%) underwent SICS with PCIOL surgery. Preoperative IOP >40 mmHg was higher in patients operated within 7 days (60.7%). Postoperative IOP ≤20 mmHg was achieved by most patients by day 7th and 30th. Early surgery presented better visual outcomes

compared to delayed surgery. Complications occurred in 27.9% of cases, with zonular dialysis being most common (41.7%). Moderate to severe optic nerve damage was noted in the majority based on cup-to-disc ratio assessment.

Conclusions: Early surgical intervention leads to improved visual recovery and effective IOP control. Increased awareness and timely management are vital to prevent vision loss in lens-induced glaucoma patients.

Clinical Profile of Secondary Glaucoma and Its Management in a Tertiary Eye Care Center: A Hospital-Based Prospective Study

First Author: Roopambara Singh RATHORE

Co-Author(s): Jaishree DWIVEDI, Alka GUPTA, R.c. GUPTA

Purpose: To study the clinical profile of secondary glaucoma and its management in a tertiary eye care center.

Methods: This hospital-based, prospective study was conducted for 1 year, including patients with high IOP >21mmHg, a history of ocular trauma, inflammation of the eye, long-term steroid use, any associated eye or systemic disease, and a history of ocular surgery. After proper history, detailed examination, including visual acuity, anterior segment, posterior segment examination, IOP, gonioscopy, and anterior chamber depth via A-Scan, and central corneal thickness were done for all the patients enrolled in the study.

Results: The prevalence of secondary glaucoma was 19.5%. The most common risk factor associated with secondary glaucoma was found to be hypermature & intumescent cataracts in 40.8% of total eyes. Phacomorphic glaucoma (38.8% eyes) was the most common cause, followed by inflammatory glaucoma (17%). The BCVA at presentation and post-treatment visual acuity at 6 months were recorded. At 6 months follow-up, phacomorphic (17.5% eyes) & steroid-induced glaucoma (66.66% eyes) showed the best visual recovery with 6/36-6/18 visual acuity. Mean IOP was recorded at 2 weeks, 3 months, and 6 months follow-up. Malignant glaucoma presented with the highest IOP at presentation, followed by phacomorphic glaucoma. The majority of eyes underwent medical treatment, followed by surgical treatment (57%).

Conclusions: The study showed that the prevalence of secondary glaucoma was 19.5%. The most common associated risk factors were intumescent and hypermature cataracts. The most common type of secondary glaucoma encountered was phacomorphic glaucoma. Significant reduction in IOP after treatment was found in 95% of eyes with p-value < 0.05. Visual acuity improvement was found to be best in steroid-

induced glaucoma. Medical management, followed by surgical management, was successful in controlling IOP in the majority of eyes.

Comparative Evaluation of Treatment Strategies for Advanced Glaucoma: A Systematic Review

First Author: Sarangerel ENKHTAIKHAN

Co-Author(s): Munkhtuya TSEGMID

Purpose: To compare key clinical outcomes across different medical, laser, and surgical treatment modalities for adult patients with advanced primary open-angle glaucoma (POAG) and primary angle-closure glaucoma (PACG).

Methods: A systematic search of PubMed, EMBASE, and Scopus was conducted for studies published from 2000 to 2025. The study selection process adhered to the PRISMA 2020 guideline. Eligible studies reported outcomes in adult patients with advanced POAG or PACG. Extracted outcomes included IOP reduction, medication burden, and complication rates. The risk of bias was assessed using the RoB 2, ROBINS-I, and the Newcastle–Ottawa Scale. Meta-analysis was not performed due to heterogeneity in study design and outcome definitions.

Results: The database search yielded 1,865 records. After screening based on predefined inclusion and exclusion criteria, 69 studies were included in the final analysis. Among the included studies, 20 standalone and 17 combined surgical treatment modalities were identified. Across all treatment modalities, mean IOP reduction ranged from as high as 51.3%, as seen with non-penetrating deep sclerectomy (NPDS), and filtering tube shunt surgeries, to as low as 2.5% with the Hydrus microstent. MicroShunt implant (83.5%) and trabeculectomy (82.8%), demonstrated high rates of postoperative medication reduction. Among combined surgical interventions, GATT combined with diode laser cyclophotocoagulation (DLCP) achieved the highest reported IOP reduction (55.6%) and medication reduction (91.7%).

Conclusions: Traditional filtering surgical treatments offer the greatest efficacy for both advanced POAG and PACG but come with increased risk. Treatment decisions should be individualized. Future research should aim to standardize success criteria and reporting methods to better guide clinical decision-making.

Comparative Long-Term Clinical Outcomes of a Novel Tube Flushing Technique Using Balanced Salt Solution Injection to Cyclophotocoagulation in Patients With Failed Glaucoma Tube-Shunt Devices

First Author: Alicia Hoi Ying LIU

Co-Author(s): Hussain ALUZRI, Velota SUNG, Tsz Chun Jason WONG

Purpose: Tube flushing (TF) and transscleral cyclophotocoagulation (CPC) are two surgical options for managing refractory glaucoma in patients with pre-existing tube shunts, yet their long-term outcomes remain poorly characterised.

Methods: A retrospective study was conducted in refractory glaucoma patients with prior tube shunts who had undergone either TF or CPC. The primary outcome was IOP reduction. Secondary outcomes included surgical success, best-corrected visual acuity (BCVA), number of glaucoma medications (NOM), complications, and further glaucoma surgeries.

Results: We included 23 eyes treated with TF and 8 eyes with CPC. Baseline mean IOP (standard deviation) for TF was 21.26 (6.43) mmHg on 2.39 (1.27) glaucoma medications which improved to 17.35 (6.26) mmHg on 2.30 (1.46) medications at final follow-up ($p=0.8640$), with an IOP reduction of 12.85% (33.76%). BCVA worsened from 0.76 (0.69) to 1.02 (0.82) ($p=0.5871$). For CPC, baseline mean IOP was 32.5 (10.57) mmHg, on 3.63 (0.92) medications, which improved to 17 (11.97) mmHg on 2.5 (1.20) medications at final follow-up, with IOP reduction of 45.88% (37.07%) ($p=0.1859$). BCVA worsened from 0.63 (0.37) to 0.82 (0.66) at final follow-up ($p=0.5871$). Surgical success was higher in the CPC cohort (50% vs. 13.04%, $p=0.0497$). Additional glaucoma surgeries were required in 26.08% of TF and 50% of CPC cohort.

Conclusions: Both TF and CPC offer limited long-term clinical effectiveness. CPC affords a deeper and longer IOP drop but at 2-fold higher odds of re-operation; TF offers a modest pressure benefit with fewer sight-threatening sequelae. We highlighted the need for more effective solutions in this challenging population.

Comparative Outcomes of Microinvasive Glaucoma Surgery Alone Versus Combined With Phacoemulsification in Normal-Tension Glaucoma

First Author: Ulil Albab HABIBAH

Purpose: Normal-tension glaucoma (NTG) remains a therapeutic challenge, as optic nerve damage progresses despite statistically normal intraocular

pressure (IOP). Microinvasive glaucoma surgery (MIGS) is increasingly used, often with phacoemulsification in eyes with cataract. However, evidence specific to NTG and direct comparisons with standalone MIGS remain limited. To systematically review the clinical outcomes of MIGS in NTG, with particular focus on procedures combined with phacoemulsification, and to identify evidence gaps regarding MIGS performed alone.

Methods: A systematic search of PubMed, Embase, Scopus, and Cochrane Library was performed up to January 2025. Eligible studies included clinical trials, cohort studies, and case series reporting MIGS outcomes in NTG. Primary endpoints were mean IOP and medication reduction; secondary outcomes included visual acuity, surgical success, and safety.

Results: Three studies (367 eyes, 310 patients) met inclusion criteria. All evaluated trabecular micro-bypass stents (iStent or iStent inject) were combined with phacoemulsification. Across studies, combined procedures achieved meaningful IOP reduction (20–22% from baseline) and substantial decreases in medication use (60–87%), with 67–81% of NTG eyes medication-free at 12–24 months. Visual acuity improved primarily due to cataract extraction. Safety profiles were favorable, with transient hyphema and occasional stent occlusion being the most reported events; <2% required subsequent filtering surgery. Notably, no included study assessed MIGS alone in NTG.

Conclusions: MIGS combined with phacoemulsification appears safe and effective for NTG, providing sustained IOP and medication reduction with minimal complications. However, the absence of standalone MIGS data highlights the need for well-designed comparative studies to clarify the relative benefits of different surgical strategies in NTG.

Panel No.: GLA-0332

Comparative Study of Netarsudil As Adjunctive Therapy in Angle Closure and Mixed Mechanism Glaucoma

First Author: Elizabeth SUN

Co-Author(s): Maral AIBYEK, Andrew IWACH, Shan LIN, Terri-diann PICKERING, Sunita RADHAKRISHNAN

Purpose: To evaluate the real-world efficacy of netarsudil in reducing intraocular pressure (IOP) among patients with angle closure (ACG), mixed mechanism (MMG), and primary open-angle glaucoma (POAG).

Methods: Medical charts from a single clinical site (Glaucoma Center of San Francisco) were reviewed. Adult patients were included if they were initiated on netarsudil between January 2018 and June 2024, and had a diagnosis of ACG, MMG, or POAG. ACG was defined as ≥ 180 degrees of iridotrabecular contact on gonioscopy or Shaffer grade 0-1. MMG was

defined as prior angle closure with open angles after laser iridotomy, with persistent IOP elevation and/or glaucomatous optic neuropathy necessitating glaucoma therapy. Outcomes included IOP and discontinuation due to side effects.

Results: There were 396 and 109 eyes in the POAG and ACG/MMG groups, respectively. The ACG/MMG group was significant for having older age, more females, and different race distribution, with a higher proportion of Asians, compared to the POAG group. Other baseline characteristics were similar. Mean IOP reduction was comparable between groups at all timepoints. Discontinuation due to side effects was also similar, occurring in 40.7% of POAG and 48.6% of ACG/MMG eyes.

Conclusions: Netarsudil showed similar IOP reduction in POAG and ACG/MMG eyes. Discontinuation rates due to tolerability were also similar. These findings support its role as an adjunctive therapy for both angle closure and mixed mechanism glaucoma in real-world clinical practice.

Abstract No.: 206346

Comparing Biomechanically Corrected Intraocular Pressure (IOP) by Corvis ST With Intraocular Pressure by iCare IC200 Across Axial Lengths

First Author: Tsun Hin NG

Purpose: To evaluate the utility of biomechanically-corrected non-contact tonometry intraocular pressure measurement (bIOP), as calculated using Corvis-ST (Oculus, Germany), across different axial lengths, with reference to iCare tonometry measurements.

Methods: Right eye data from 2,138 consecutive subjects were obtained from a cross-sectional random population study of Chinese subjects, aged 50 and above, between 1st of May 2019 to 30th of April 2020. Parameters, including IOP, bIOP and Corvis Biomechanical Index (CBI) were measured for all subjects. IOP was measured using iCare and Corvis ST devices. Data were grouped according to axial length (AXL), and correlations between IOP and bIOP values were examined across groups.

Results: Correlations between iCare IOP and bIOP (0.367 in 20-22mm, $p=0.002$ to 0.643 in 26-30mm, $p<0.001$) as well as iCare IOP and uncorrected IOP (0.542 in 20-22mm, $p<0.001$ to 0.729 in 26-30mm, $p<0.001$), as measured by CORVIS-ST, significantly increased with axial length. Compared to iCare IOP, uncorrected IOP tended to be overestimated (74.5% overestimated), while bIOP values were equally overestimated and underestimated (51.0% overestimated). Mean CBI was significantly lower in eyes with higher axial lengths [0.168(± 0.291), 0.133($\pm$

0.262), 0.089($\pm$ 0.220), 0.063($\pm$ 0.207), 0.110($\pm$ 0.245), $F(3,2102)=9.643$, $p<0.001$].

Conclusions: Correlation between bIOP and iCare IOP increased with higher axial lengths. The observed findings may be related to differences in corneal biomechanical properties across axial lengths. Thus, bIOP may be more relevant in high myopic patients with longer axial lengths and lower CBIs.

Abstract No.: 205945

Comparison of Surgical Outcomes of Tanito Microhook Trabeculotomy With Bent Ab Interno Needle Goniectomy in Open Angle Glaucoma at 12 Months

First Author: Nimrita NAGDEV

Co-Author(s): Devendra MAHESHWARI, Madhavi PILLAI

Purpose: To compare the safety and efficacy of Tanito microhook trabeculotomy (TMH) versus Bent ab interno needle goniectomy with phacoemulsification in eyes with primary open-angle glaucoma.

Methods: A retrospective and comparative study included 70 eyes (35 TMH-Phaco group 1 and 35 BANG-Phaco group 2). Baseline characteristics like Intraocular pressure (IOP), Best corrected visual acuity (BCVA), and anti-glaucoma medications (AGMs) were compared at each post-operative visit. Data were collected at 2 weeks, 1 month, 3,6, and 12 months. Surgical success was defined as IOP ≤ 21 / ≤ 18 / ≤ 15 mmHg with $> 20\%/25\%/30\%$ reduction from baseline, respectively (Criteria 1, 2 and 3). Complications, secondary interventions, and surgical risk factors were also analyzed.

Results: The mean (SD) IOP decreased from 24.69 ± 7.09 to 14.14 ± 2.33 and from 23.20 ± 7.90 to 13.09 ± 2.87 in groups 1 and 2 respectively at the end of 12 months ($p<0.001$). AGM reduced from 1.57 ± 1.07 to 0.20 ± 0.58 and from 1.46 ± 0.85 to 0.14 ± 0.36 in groups 1 and 2 respectively at the end of 12 months ($p<0.001$). Complete and Qualified success was 80%,71.4%,65.7% and 14.3%,11.4%, 8.6% in group 1, respectively. In group 2, it was 71.4%,65.7%,62.9% and 14.3%,14.3%, 5.7%. Micro hyphemas were seen in 5 patients (3 group 1, 2 group 2), and 6 patients had IOP spikes (4 group 1, 2 group 2).

Conclusions: Both TMH and BANG achieved significant IOP and medication reduction, with TMH showing superior outcomes and higher success at 12 months.

Panel No.: GLA-0382

Comparison of Surgical and Patient-Related Outcomes of Phaco-GATT Versus Phaco-Trabeculectomy in Open-Angle Glaucoma

First Author: Madhavi PILLAI

Co-Author(s): Shivam GUPTA, Devendra MAHESHWARI

Purpose: To compare outcomes (Surgical & patient related) of phaco-GATT&Phaco-Trabeculectomy in Open angle glaucoma

Methods: Prospective, non-randomised interventional, comparative study. Consecutive patients with POAG and PXFG and visually significant cataract were divided into PhacoGATT (Grp1-75) & PhacoTrab (Grp2-77) & followed up for 1 year. Outcome measures included were IOP, AGM, surgical success, complications & interventions. Success was defined as at least 20%/25%IOP reduction and IOP < 21 or 18 mm Hg(Criteria 1/2). The quality of life post-surgery was assessed with the help of a questionnaire at the end of 12 months.

Results: In Group 1, mean IOP reduced significantly from 17.93 ± 4.29 mmHg to 13 ± 3.18 mmHg, and in Group 2 from 17.81 ± 4.52 mmHg to 12.16 ± 3.28 mmHg at 12 months($p<0.001$), with no significant difference between the groups($p=0.135$).AGM significantly reduced from 1.03 ± 0.43 to 0.09 ± 0.29 in group 1 and from 1.04 ± 0.41 to 0.16 ± 0.37 in group 2 ($p<0.001$), without a significant difference between the groups ($p=0.244$). The cumulative probability of success was 68%,60% in group 1, and 63.6%,50.7% in group 2 (Criteria 1,2). The number of postoperative visits was significantly less in Group 1 ($p<0.001$). Group 1 had a significantly higher patient satisfaction score (8.37) when compared to Group 2 (7.14) ($p<0.001$). Macrohyphema (>1 mm) was seen in 10 patients in Group 1, and two patients required an anterior chamber wash.

Conclusions: Phaco-GATT is safe, efficacious, and comparable to Phaco-Trabeculectomy.Phaco-GATT performed better in terms of quality of life and required fewer postoperative visits and interventions.

Conjunctival Peritomy in Trabeculectomy: All "Frills", Nothing Fancy

First Author: Shubham DARADE

Co-Author(s): Zia PRADHAN, Sujani SHROFF

Purpose: To compare the incidence of bleb leaks following trabeculectomy in eyes which underwent the Frill peritomy vs a conventional fornix-based peritomy.

Methods: Eighty-one eyes underwent Frill peritomy (conjunctiva cut 1mm away from limbus) and 79 eyes underwent conventional peritomy (conjunctiva cut

flush with limbus). The incidence of leaks and their management were compared between the techniques.

Results: Incidence of leaks was significantly lower in the Frill group (2 vs 10 eyes, $p=0.01$). In the Frill group, both leaks resolved with conservative management, while in the conventional group, 4 eyes needed conjunctival re-suturing.

Conclusions: The Frill peritomy has fewer conjunctival complications compared to the conventional peritomy. The Frill peritomy combines the benefits of limbus-based flaps (water-tight closure of anatomically similar tissues) and fornix-based flaps (diffuse posterior blebs) in a single procedure.

Cost-Effectiveness Analysis of Population-Based Glaucoma Screening Using OCT-Based AI System in China

First Author: Jiaying ZHOU

Co-Author(s): Carol Y. CHEUNG, Xin LIU, Anran RAN, Clement THAM, Shuyi ZHANG

Purpose: Glaucoma is frequently diagnosed at advanced stages and relies on opportunistic finding in clinical practice given its asymptomatic nature in early stages, while the high diagnostic costs of conventional approaches have prevented the implementation of population-based screening for early glaucoma. We aim to evaluate the cost-effectiveness of population-based screening using an optical coherence tomography (OCT)-based AI system in China.

Methods: We developed a Markov model comparing OCT-based AI screening for primary angle-closure (PACG) and open-angle glaucoma (POAG) versus opportunistic finding from a societal perspective. A cohort of 100,000 individuals aged 50 through 35 1-year Markov cycles. Parameters were derived from literature, with costs from Beijing Haidian Hospital converted to USD (2024 exchange rate: 7.1 HKD/USD). Primary outcomes were incremental cost-utility (ICURs) using quality-adjusted life years (QALYs) and incremental cost-effectiveness ratios (ICERs) using years of blindness avoided. To reflect the uncertainty around ICURs and ICERs, both one-way deterministic and simulated probabilistic sensitivity analysis were done. Willingness-to-pay (WTP) thresholds used three-times local per capita gross domestic product (GDP).

Results: Over 35 years, opportunistic finding cost US\$ 6,535.34 per person (16.73 QALYs), while OCT-based AI screening cost US\$1,820.26 (17.91 QALYs). OCT-Based AI screening achieved 62,000 years of blindness avoided among 100,000 individuals, with ICUR of -US\$3,996 and ICER of -US\$7,605. One-way sensitivity analysis demonstrated AI performance as the most influential factor. Probabilistic sensitivity analysis confirmed robust ICURs and ICERs.

Conclusions: The OCT-based AI system for population-based glaucoma screening is highly cost-effective compared to opportunistic finding, offering evidence for implementing the AI system in real-world.

Cost-Effectiveness and Cost-Utility of Angle-Based Minimally Invasive Glaucoma Surgery in Primary Open Angle Glaucoma – a Systematic Review

First Author: Eleanor Jia Xin CHONG

Co-Author(s): Bryan Chin Hou ANG, Kevin Kun Peng WANG

Purpose: This study aims to evaluate current economic evidence on cost-effectiveness and cost-utility of angle-based minimally invasive glaucoma surgery (MIGS), compared to conventional treatments, for primary open-angle glaucoma (POAG).

Methods: Database searches on MEDLINE, Cochrane Library, and International Health Technology Assessment identified economic evaluations of angle-based MIGS, with or without concurrent cataract surgery, compared with standalone cataract surgery, medical or laser therapy, or traditional incisional surgery in POAG. Primary outcome measures include costs, quality-adjusted life years (QALYs), incremental cost-effectiveness ratios (ICER), and incremental cost-utility ratios (ICUR) — stratified by MIGS device types, comparators, and economic model scenarios.

Results: Fourteen out of 321 screened studies were included for final analysis. Studies employed Markov models with varying factors such as time horizons and glaucoma severity, adopting healthcare or societal perspectives. Across all studies, base case analyses demonstrated cost-effectiveness in MIGS, with the ICER or ICUR below willingness-to-pay thresholds and supported by sensitivity analyses. From the ten studies comparing MIGS with cataract surgery versus cataract surgery alone, MIGS was found to have limited advantage in the context of short time horizons or in advanced disease. Five studies comparing MIGS to medical or laser therapy, and one study comparing MIGS to incisional surgery, found higher initial costs of MIGS offset by QALYs gained and reduced long-term direct and indirect treatment-related costs, making MIGS cost-effective in the long term.

Conclusions: Angle-based MIGS is cost-effective compared to conventional POAG treatments. Standardised methodologies and longer-term data will strengthen future economic evaluations to guide health technology assessment decisions.

Cost-Utility Analysis of Preservative-Free Latanoprost Eye Drop Cationic Emulsion Versus Preserved First-Line Treatments for Open-Angle Glaucoma or Ocular Hypertension in the Philippines

First Author: David **CHAMPION**Co-Author(s): Amish **CHATURVEDI**, Jieyi **LI**, Vrinda **MATHUR**, Kun **SHI-VAN WIELINK**, Prachi **SINGH**

Purpose: To evaluate the economic value of preservative-free latanoprost eye drop cationic emulsion (PF-LAT E) versus preserved first-line treatments for open-angle glaucoma (OAG)/ocular hypertension (OHT) in the Philippines context to inform resource-allocation (policymakers) and treatment-choice (clinicians) decisions.

Methods: A lifetime (46-year) Markov model (6 states; 30-day cycle) estimated the cost-utility of PF-LAT E versus preserved latanoprost, bimatoprost, tafluprost, brimonidine, and dorzolamide. Analyses used a Philippine societal perspective and 7% annual discounting (cost in 2025 ₱). Outcomes included incremental total costs, incremental quality-adjusted life years (QALYs), and net monetary benefits (NMBs). Model inputs for efficacy, safety, adherence, utility values, and disease progression were sourced from published literature, while healthcare resource utilization was gathered from glaucoma specialists. An informal willingness-to-pay (WTP) threshold of ₱160,890 per QALY was applied. One-way (OWSA) and probabilistic sensitivity (PSA) analyses tested robustness.

Results: PF-LAT E consistently delivered additional health gains (+0.025 to +0.132 QALYs per patient) versus preserved therapies while reducing lifetime costs by ₱12,747-₱40,750. Net monetary benefit was uniformly positive (₱16,784-₱54,813 per patient at the accepted WTP). Results were robust in both OWSA and PSA. PF-LAT E benefits were driven by fewer adverse-event costs, reduced need for treatment escalation, and better tolerability.

Conclusions: Findings suggest PF-LAT E offers a more favourable tolerability profile, and enhanced cost-effectiveness compared to preserved formulations, supporting its adoption as a clinically and economically advantageous option within the Philippine healthcare system.

Abstract No.: 205437

Dead Bags, Elevated Pressures: A Case Series on Late in-the Bag IOL Complications With Secondary Glaucoma

First Author: Amrita **PUGALENTHI**Co-Author(s): Rathini **DAVID**, Ronnie **GEORGE**, Baskaran **MANI**, Smita **PANDA**

Purpose: To describe the clinical presentation of patients with dead bag syndrome associated with posterior capsular tear, vitreous prolapse and secondary ocular hypertension.

Methods: A case series of six pseudophakic patients presenting with high intraocular pressure (IOP) and vitreous prolapse into the anterior chamber due to posterior capsular tear and late IOL-bag complex instability. Clinical records were reviewed for demographics, visual acuity, Intraocular pressure (IOP), gonioscopy, optic nerve evaluation, visual fields, and management.

Results: All patients had a history of uncomplicated phacoemulsification with in-the-bag posterior chamber IOL implantation. The latency period ranged from 4 - 12 years after cataract surgery. Clinical findings included posterior capsular tear with vitreous in the anterior chamber, IOL decentration in some cases, raised IOP (22–32 mmHg) at presentation, and optic nerve changes consistent with glaucomatous optic neuropathy were seen in three patients, while two developed additional complications, including cystoid macular oedema and retinal detachment. Management included topical antiglaucoma medications in all cases, with one patient requiring filtration surgery.

Conclusions: The clinical entity “Dead bag syndrome” is still a mystery that can present several years after routine phacoemulsification with sequelae such as capsular bag instability with vitreous prolapse that can lead to secondary glaucoma and vision-threatening complications. Long-term surveillance of pseudophakic patients is essential for early recognition and timely management.

Development and Validation of a Predictive Model for Blindness After Lens Extraction Surgery in Acute Primary Angle Closure: A Multicenter Longitudinal Study

First Author: Yining **GUO**Co-Author(s): Chendi **LI**, Xuemin **LI**, Zhongping **LUO**, Chun **ZHANG**

Purpose: To develop and validate a nomogram for predicting blindness in patients with acute primary angle closure (APAC) treated with lens extraction (LE) surgery.

Methods: This multicenter retrospective longitudinal study included 254 eyes in the training cohort and 111 eyes from three centers in the validation cohort. Univariate and multivariate Cox regression analyses were performed to identify predictors of blindness. Nomogram performance was assessed using time-dependent receiver operating characteristic (ROC) curves, area under the curve (AUC), and concordance index (C-index). Kaplan-Meier curves were used to compare the blindness incidence between risk groups.

Results: Cox regression identified significant predictors including logMAR visual acuity (VA) at attack (HR, 1.935; 95% CI, 0.966-3.879), intravenous mannitol use during the acute phase (HR, 0.453; 95% CI, 0.231-0.887), timing of surgery (linear term: HR, 0.771; 95% CI, 0.315-1.887; quadratic term: HR, 0.304; 95% CI, 0.144-0.646; cubic term: HR, 0.792; 95% CI, 0.419-1.498), preoperative logMAR VA (HR, 1.886; 95% CI, 1.174-3.028), and preoperative intraocular pressure (HR, 1.047; 95% CI, 1.022-1.073). The C-index was 0.860 and 0.826 in the training and validation cohorts, respectively. The 1-year and 5-year AUC values were 0.906 and 0.875 in the training cohort, and 0.947 and 0.894 in the validation cohort, respectively. Kaplan-Meier analysis revealed significant differences in blindness probability between low- and high-risk groups ($P < 0.0001$).

Conclusions: The nomogram provides an effective tool for predicting blindness in APAC patients treated with LE surgery, enabling risk stratification and aiding clinical decision-making.

Abstract No.: 201949

Panel No.: GLA-0334

Development of Peripheral Anterior Synechiae Following Combined Bent Ab Interno Needle Goniectomy and Phacoemulsification

First Author: Samyak KHETAN

Co-Author(s): Sarita BERI, Poonam, Rhea BHARTI, Mukund GARG, Piyush Kumar R RAMAVAT

Purpose: To study the 3-month incidence of Peripheral Anterior Synechiae after combined Bent Ab Interno Needle Goniectomy and Phacoemulsification.

Methods: A hospital-based, prospective, observational study in which 30 eyes of Primary open-angle glaucoma patients having visually significant cataract underwent uneventful phacoemulsification followed by Bent Ab Interno Needle Goniectomy (BANG) with a bent-tipped 25-G needle. Preoperative Gonioscopy was done, followed by gonioscopy at post-op 3 months.

Results: Eight eyes out of the 30 eyes developed Peripheral Anterior Synechiae (PAS) at 3 months of follow-up. There was statistically significant when comparing different degree of treatment of BANG i.e. 30°, 45° and 60° and relation with PAS. There were

3 eyes that had mild hyphema on post-operative day 1 and all these eyes developed PAS at the end of 3 months follow-up period, indicating a positive correlation between postoperative hyphema and incidence of PAS. When comparing post-operative IOP change in the PAS and non-PAS groups at 3 months post-op there was no statistical significance, indicating that in a follow-up period of 3 months, PAS didn't cause an increase in IOP.

Conclusions: The findings suggest that while PAS formation after combined phacoemulsification with BANG is 26%, the risk is increased in cases with postoperative hyphema. The absence of correlation with the treatment extent highlights that factors other than the degree of trabecular meshwork removal may influence PAS development. Thus, emphasis should be given more on significance of controlling inflammation and developing specialized follow-up plans for BANG patients.

Abstract No.: 206107

Diverse Presentations of ICE Syndrome: A Case Series of Experience With Trabeculectomy and Various Implant Devices

First Author: Maula RIFADA

Co-Author(s): Elsa GUSTIANTY, Andika PRAHASTA, Indriyani RIFANDI, Sonie UMBARA

Purpose: To present the clinical spectrum of iridocorneal endothelial (ICE) syndrome and report surgical outcomes of glaucoma management using trabeculectomy and various glaucoma drainage implants.

Methods: Four patients with different ICE variants—progressive iris atrophy (32-year-old man), Chandler syndrome (30-year-old man), Cogan–Reese syndrome (44-year-old woman), and a mixed-type variant (52-year-old woman)—were included. All patients developed secondary glaucoma with uncontrolled intraocular pressure (IOP) despite maximal medical therapy and had advanced glaucoma. Surgical interventions consisted of trabeculectomy with 5-fluorouracil, Aurolab Aqueous Drainage Implant (AADI), Virna Glaucoma Implant (VGI), and Paul Glaucoma Implant (PGI). Pre- and postoperative IOP and visual acuity (VA) were analyzed.

Results: • Progressive iris atrophy: trabeculectomy reduced IOP from 40 to 18 mmHg in 2 months post-surgery, VA remained hand movement (HM). • Chandler syndrome: AADI decreased IOP from 37 to 12 mmHg in 10 month post-surgery, VA remained 0.2. • Cogan–Reese syndrome: VGI lowered IOP from 56 to 11 mmHg in 5 months post-surgery, VA from HM to 0.1 • Mixed variant: despite prior trabeculectomy and cataract surgery, IOP remained at 30 mmHg; subsequent PGI reduced IOP to 11 mmHg at one week

and maintained 16 mmHg after ripcord removal at 1 month with VA from 0.1 to 0.4

Conclusions: ICE syndrome represents a rare and heterogeneous disorder often associated with refractory glaucoma. Surgical management is challenging; trabeculectomy provide short term reduction, but glaucoma drainage implants appear more effective in long-term control. Individualized surgical selection tailored to ICE subtype and disease course is essential for optimal outcomes.

Abstract No.: 206557

Panel No.: GLA-0423

Effect of Navigation Rehabilitation Module for Stroke on Physical Activities, Quality of Life and Serum Total Anti-Oxidant Capacity in Patients With Primary Glaucoma

First Author: Damia Faiqah MOHAMAD SHAHBODIN
Co-Author(s): Liza-sharmini AHMAD TAJUDIN, Muhammad Hafiz HANAFI

Purpose: To determine the effect of Chessington Occupational Therapy Neurological Assessment Battery on physical activities, serum total anti-oxidant capacity (TAC) and quality of life (QoL) in patients with primary glaucoma.

Methods: A randomized, single-blinded controlled trial involving 72 primary glaucoma patients was conducted at Hospital Pakar Universiti Sains Malaysia (HPUSM) from March 2019 to December 2020. Patients were recruited by simple random sampling and randomized using sequentially numbered, opaque sealed envelopes (SNOSE). Group A attended a visual occupational rehabilitation programme based on the Chessington Occupational Therapy Neurological Assessment Battery (COTNAB): once fortnightly for 2 months, monthly for 2 months, followed by 2 months of self-directed home practice. Physical activity was measured using an accelerometer, quality of life (QOL) using the Malay GlauQOL-36 questionnaire, and serum total antioxidant capacity (TAC) using the QuantiChrom™ Assay. Assessments were performed at baseline and 6 months.

Results: Of 72 recruited patients however 4 drop-out and 1 deceased, 67 patients completed the study (32 in group A, 35 in group B); mean age was 63.3 ± 6.7 years. Mean daily steps were 2128.0 ± 1824.0 . Group A showed increased steps, lower GlauQOL-36 scores, and higher serum TAC post-intervention, but differences were not statistically significant ($p > 0.05$). Repeated measures ANOVA showed no significant between-group effects.

Conclusions: Visual rehabilitation based on COTNAB has no significant effects on mobility, QoL and serum TAC level. However, patients with glaucoma are encouraged to be physically active and independent. An easy and user-friendly visual rehabilitation module

specific for patients with glaucoma needs to be developed in the future.

Abstract No.: 203433

Panel No.: GLA-0357

Effect of Pre-Operative 0.1% Brimonidine on Post-Operative Conjunctival Hyperemia, Subconjunctival Hemorrhage and Surgical Outcomes of Trabeculectomy With MMC: A Pilot, Triple-Blind Randomized Placebo-Controlled Trial

First Author: Methaphon CHAINAKUL

Co-Author(s): Nucharee PARIVISUTT, Vasu THAKAEW

Purpose: To assess efficacy of 0.1% Brimonidine on reducing post-operative conjunctival redness and bleeding, and to evaluate surgical outcomes, specifically in terms of intraocular pressure (IOP) control and bleb survival.

Methods: Thirty-six eyes from 35 glaucoma patients were analyzed. Post-operative conjunctival bleeding was evaluated using Keratograph 5M imaging. The automated Redness Score (RS) was used to assess conjunctival hemorrhage in position 1 (look straightforward). Additionally, grayscale images in position 2 (look downward to expose the bleb area) were enhanced, followed by conjunctival segmentation using a U-Net deep learning model. Finally, bleeding in the upper quadrant around the bleb area was quantitatively analyzed using an adaptive threshold pixel measurement technique. Clinical outcomes were also compared between groups.

Results: The treatment group had a significantly lower post-operative RS compared to controls (2.84 ± 0.58 vs. 4.26 ± 0.82 ; $p < 0.001$), with a significantly smaller increase from baseline ($p < 0.001$). Percentage pixel analysis of conjunctival bleeding in position 2 from treatment group tended to be lower in post-operative ($46.42 \pm 3.93\%$ vs. $48.82 \pm 6.54\%$; $p = 0.216$) and in the change from baseline ($17.00 \pm 7.20\%$ vs. $19.60 \pm 7.43\%$; $p = 0.315$). Intraoperative complications occurred only in the control group (12.5%). Post-operatively, the treatment group showed trends toward a lower bleb failure rate (5.9% vs. 25%; $p = 0.174$) and required fewer interventions. IOP reduction from baseline was higher in treatment group (14.66 ± 14.01 vs. 12.02 ± 14.55 ; $p = 0.601$).

Conclusions: 0.1% Brimonidine appears to be an effective method to reduce early postoperative conjunctival hyperemia and bleeding following Trabeculectomy surgery and implicates that it can also minimize intraoperative bleeding. As reduced inflammation and bleeding can potentially improves patient's early post-operative experience and may contribute to a more successful bleb function. Consequently, this study provides evidence to support Brimonidine's novel indication in mitigating inflammation and bleeding postoperatively.

Effectiveness of Standalone iStent Technologies for Glaucoma: A Systematic Literature Review

First Author: Kyoko ISHIDA

Co-Author(s): Geoffrey CHAN, Alice CHU, Colin CLEMENT, Jennifer EVANS, Masaru INATANI

Purpose: To investigate clinical outcomes following implantation of second- and third-generation iStent as a standalone surgery in glaucoma patients.

Methods: Searches were conducted in MEDLINE, Embase, Cochrane Database of Systematic Reviews and Cochrane Central Register of Controlled Trials. Interventional and observational studies reporting ≥ 6 months of follow-up, enrolling adult glaucoma patients regardless of treatment history, receiving standalone iStent technologies (iStent inject®, iStent inject® W or iStent infinite®), and reporting change from baseline (CfB) in intraocular pressure (IOP) and glaucoma medications, and eyes achieving success criteria, were included.

Results: Eighteen unique studies, including 1,810 eyes, were identified. Despite varied baseline IOP, number of IOP-lowering medications, and surgical history, a reduction in mean IOP from baseline was observed in all studies reporting this outcome. CfB in mean IOP at Month 12 ranged from -0.5 mmHg to -12.2 mmHg. Eyes achieving unmedicated IOP ≤ 18 mmHg at Month 12 ranged from 12.8% to 100% in four reporting studies. A decrease in IOP-lowering medication burden was observed following iStent implantation in 9 of 12 studies reporting this outcome; CfB in mean medication number at Month 12 ranged from -0.1 to -2.1. No change was observed in the remaining 3 studies.

Conclusions: This review summarised evidence for the effectiveness of newer generation iStent standalone surgeries in reducing IOP and medication burden in patients with glaucoma, regardless of baseline IOP, medication burden, and surgical history. Meta-analysis to account for observed between-study heterogeneity in baseline characteristics is recommended for future investigation.

Abstract No.: 206394

Effectivity of Selective Laser Trabeculoplasty in Open Angle Glaucoma in a Tertiary Hospital

First Author: Tommy WIBOWO

Co-Author(s): Elsa GUSTIANTY, Andika PRAHASTA, Maula RIFADA, Sonie UMBARA

Purpose: To evaluate efficacy of selective laser trabeculoplasty (SLT) in lowering intraocular pressure (IOP) and decreasing glaucoma medication in open-

angle glaucoma (OAG). And to correlate its laser parameter and history of surgery to its success rate.

Methods: This study is a retrospective study. The sample is 23 eyes from 17 patients with OAG in Cicendo Eye Hospital from 1st November 2023 to 31st June 2023. Inclusion criteria were OAG patient with IOP > 21 mmHg. Patient with history of uveitis, steroid, trauma, absence in follow up period, and surgery during follow up period was excluded. The main parameter was IOP pre SLT, one week, one month, two months, and three months after SLT. Successful criteria determined as $> 20\%$ IOP reduction from Pre SLT IOP. The data was analyzed using SPSS 20.

Results: A total of 23 eyes from 17 patients underwent SLT. Mean baseline IOP was $20,74 \pm 4,58$ mmHg. During follow up period IOP is reduced $18,17 \pm 5,47$ mmHg at one week, $15,87 \pm 4,43$ mmHg at one month, $16,61 \pm 4,91$ mmHg at two months, and $17,48 \pm 4,78$ mmHg at three months. The highest successful rate was 65,21%. There was correlation between total energy used with IOP reduction in one month with correlation coefficient of 0,361 and P value 0,046.

Conclusions: Selective laser trabeculoplasty is effective to reducing IOP and number of glaucoma medication in open angle glaucoma whether there is history of surgery prior to SLT or not.

Abstract No.: 206091

Panel No.: GLA-0413

Effects of Daily Ambient Temperature on Intraocular Pressure: A Time-Series Analysis Using Generalized Additive and Distributed Lag Nonlinear Models

First Author: Yuto YOSHIDA

Co-Author(s): Yuuri FUJINO, Noriko KOIZUMI, Nobuaki MICHIIHATA, Naoki OKUMURA, Masaki TANITO

Purpose: To investigate the previously underexplored non-linear association between ambient temperature and intraocular pressure (IOP), as well as the short- to medium-term lagged effects of temperature exposure on IOP.

Methods: A time-series study was conducted using 2018–2023 outpatient data from Shimane University Hospital in Izumo, Japan. Daily meteorological data were obtained from the Japan Meteorological Agency. We analyzed the association between ambient temperature and IOP using generalized additive models (GAMs) to assess nonlinearity, and distributed lag nonlinear models (DLNMs) to evaluate cumulative lag-effects. Models were adjusted for time-related confounders (timeline, day of the week, public holidays, season).

Results: We analyzed 1,269 observation days comprising 33,979 IOP measurements: 921 days with 8,756 measurements in the non-glaucoma group and 1,182 days with 25,173 measurements

in the glaucoma group. In the non-glaucoma group, nonlinear associations with IOP were suggested for daily temperatures, with significant increase at average temperatures between 2.2 °C and 12.2 °C. In the glaucoma group, no nonlinear associations were detected. Cumulative exposure to warm average temperatures was associated with lower IOP in the non-glaucoma group (lag 0–6: 15.6–21.1 °C; lag 0–13: 15.6–29.6 °C), whereas colder ranges (lag 0–6: 14.6–15.1 °C; lag 0–13: 13.1–15.1 °C) increased IOP in the same group; no significant cumulative effects were observed for lag 0–30.

Conclusions: This study provides novel epidemiological evidence that ambient temperature is associated with IOP through nonlinear relationships and short-term cumulative effects, particularly in the non-glaucoma group. These findings suggest that monitoring ambient temperature is important for IOP management.

Abstract No.: 203991

Panel No.: GLA-0366

Efficacy and Safety of Ahmed Glaucoma Valve in Inpatients With Neovascular Glaucoma: A Retrospective Study

First Author: Lei FANG

Co-Author(s): Keith BARTON, Jingjing HUANG, Zhishu LIANG, Xing LIU

Purpose: To evaluate the efficacy and safety of the Ahmed glaucoma valve (AGV) implantation in the management of neovascular glaucoma (NVG).

Methods: This retrospective study analyzed 190 eyes of 184 inpatients with NVG who underwent AGV implantation at Zhongshan Ophthalmic Center between January 2020 and February 2024. Data collected included demographic characteristics, preoperative and postoperative intraocular (IOP), number of glaucoma medications, best-corrected visual acuity (BCVA), surgical success rates, and complications were recorded. Potential preoperative characteristics that influence success rates were assessed using Cox proportional hazards regression models.

Results: The most common etiology was diabetic retinopathy (54.7%, 104/190 eyes). The mean patients age was 50.9±13.6 years, with a mean follow-up 15.4±5.2 months. Among 190 eyes, prior treatments included anti-VEGF (73.7%), panretinal photocoagulation (41.6%), vitrectomy (21.1%), and cataract surgery (34.7%). Postoperatively, IOP significantly decreased from 41.0±8.5 mm Hg to 15.3±6.4 mm Hg, along with a reduction in the number of glaucoma medications from 2.8±1.6 to 1.4±1.2 (both $P<0.001$). Preoperatively, 64.2% of eyes had a BCVA of $<20/400$; postoperative BCVA remained stable (2.2 ±0.7 vs 2.2 ±0.8, $P=0.091$). The cumulative surgical success rates at 12 and 24 months postoperatively were 86.7% and 68.5%, respectively. No factors were found to be significantly associated with the success

rate. Postoperative complications were observed in 31.6% of eyes, primarily shallow anterior chamber (9%) and hypotony (8%), all of which resolved spontaneously without any vision-threatening events.

Conclusions: AGV implantation was a safe and effective procedure in NVG which could be considered as one of the first choices for management of NVG.

Abstract No.: 202429

Panel No.: GLA-0342

Efficacy and Safety of Combined Phacoemulsification and iStent Implantation in Primary Angle Closure Disease: A Systematic Review and Meta-Analysis

First Author: Sheng Yang LIM

Co-Author(s): Bryan Chin Hou ANG, Bjorn Kaijun BETZLER, Kai En CHAN, Eric Yihao JIN

Purpose: This systematic review and meta-analysis (SRMA) aims to evaluate the efficacy and safety of combining phacoemulsification and the iStent trabecular micro-bypass (phaco-iStent) in patients with primary angle-closure disease (PACD), a procedure that, while commonly performed, remains 'off-label'.

Methods: A comprehensive search of Medline, Embase, and CENTRAL databases through August 18, 2024, identified studies evaluating the efficacy of Phaco-iStent (all generations) in PACD patients. Meta-analyses of single means and binary outcomes were conducted, including pairwise comparisons with standalone phacoemulsification.

Results: Four studies involving 219 eyes were included. At 12 months postoperatively, the procedure achieved a mean intraocular pressure (IOP) reduction of 2.69 mmHg (95% CI: 4.72-0.66; $p<0.001$) and a mean reduction of 1.33 IOP-lowering medications (95% CI: 1.60 –1.06; $p<0.001$). Compared to standalone phacoemulsification, Phaco-iStent showed greater reductions in both IOP ($p=0.314$) and medication use ($p<0.001$, statistically significant). The most frequent complication was stent occlusion (9.69%, 95% CI: 0.00–31.47%), followed by transient hyphema (3.50%, 95% CI: 0.00–20.72%). The odds of transient hyphema were 10 times higher with Phaco-iStent compared to phaco alone (OR: 10.01; 95% CI: 1.24–81.15; $p=0.031$). Conversely, the odds of postoperative IOP spikes were six times lower in the Phaco-iStent group (OR: 0.16; 95% CI: 0.05–0.52; $p=0.002$).

Conclusions: This SRMA quantitatively supports the potential use of Phaco-iStent surgery in PACD. Future studies are needed to establish comparative efficacy against standalone phacoemulsification, as well as its longer-term outcomes.

Abstract No.: 201468

Panel No.: GLA-0330

Efficacy and Tolerability of Rocklatan in Asian Eyes With Primary Open Angle and Normal Tension Glaucoma: 3 Week Results

First Author: Claire Lixian PETERSON

Co-Author(s): Nur Insyirah Binte AZNAN, Rachel CHONG, Samantha LOR, Tina WONG

Purpose: Studies on Rocklatan in Asian eyes are limited. We evaluated the efficacy, safety, and tolerability of Rocklatan (Netarsudil0.02% + Latanoprost0.005%) in Asian patients with primary open-angle glaucoma (POAG) or normal-tension glaucoma (NTG).

Methods: Prospective single-arm study at a tertiary eye centre. POAG/NTG patients on prostaglandin mono- or combination therapy were switched to once-daily Rocklatan in one eye for 12 weeks. Enrollment began in June 2025. Baseline and 3-week data were analyzed. Assessments included Goldmann applanation tonometry, visual acuity, Humphrey visual field, biometry, and patient-reported comfort/tolerability questionnaire (baseline and week 12). Masked anterior segment photos were graded on the Cornea and Contact Lens Research Unit (CCLRU) scale at each visit.

Results: Eighteen patients (70.8±6.8years) completed baseline and 3-week visits, 2 months from study initiation. 5 had POAG, 13 NTG, most were myopic (axial length26.9±2.3mm), with early-moderate disease (mean deviation -5.8±3.3dB). 13 were on prostaglandin monotherapy and 3 on prostaglandin-combination therapy. Baseline mean intraocular pressure (IOP) was 13.3±2.7mmHg, decreasing to 10.5±2.5mmHg at 3 weeks, reflecting a mean 20.4%±13.0% (-2.8±2.1mmHg, p<0.001) reduction in IOP. 44.4% achieved ≥20% reduction. The most common side effect was conjunctival hyperaemia: 10 had 1-point; 2 had 2-point bulbar redness worsening on the CCLRU scale. 1 discontinued due to intolerance; no serious ocular or systemic adverse events were reported.

Conclusions: Interim analysis suggests Rocklatan provides effective short-term IOP reduction with acceptable tolerability in Asian eyes with POAG/NTG. A 12-week follow-up is ongoing.

Abstract No.: 202487

Panel No.: GLA-0345

Efficacy of Rho Kinase Inhibitors in Open and Closed Angle Glaucomas Within the Vietnamese Population

First Author: Dzuy TRUONG

Co-Author(s): Sunee CHANSANGPETCH, Andrew IWACH, Shan LIN, Eden NG, Kelly NGUYEN, Ngoc NGUYEN, Sunita RADHAKRISHNAN

Purpose: Rho kinase (ROCK) inhibitors are a class of glaucoma medications that may provide benefit across open and closed-angle types. This study evaluated the

efficacy of Netarsudil (a ROCK inhibitor) for both types within a predominantly Vietnamese population.

Methods: We performed a retrospective chart review of eyes diagnosed with primary open-angle glaucoma (OAG), combined mechanism glaucoma (CMG), or angle-closure glaucoma (ACG) that received Netarsudil for at least three months. OAG was defined as >180 degrees grade II or greater, CMG as closed angles subsequently opened after laser iridotomy, and PACG as ≥180 degrees grade I or lower or possessing any PAS. All patients were from a single clinical site (Ngoc Nguyen).

Results: 235 eyes were included, of which 210 (89%) were from Vietnamese patients. At baseline, mean intraocular pressure (IOP) was 17.7 mmHg in both OAG and CMG groups and 19.2 mmHg in ACG groups. At six months, mean IOP reduction did not significantly differ when comparing OAG to CMG (4.2 ± 3.9 mmHg in OAG, 3.4 ± 4.1 mmHg in CMG, p=0.254). This was similar when comparing OAG to ACG (4.3 ± 5.0 mmHg in ACG, p=0.739). Comparing discontinuation rates due to side effects, OAG did not differ from CMG [n=29 (25%) in OAG, n=13 (20%) in CMG, p=0.623]. This was similar when comparing OAG to ACG [n=10 (19%) in ACG, p=0.488].

Conclusions: Our findings suggest that Netarsudil is equally effective in reducing IOP across glaucoma subtypes of angle status. Furthermore, it appears to be a useful adjunctive therapy for glaucoma in Vietnamese patients.

Panel No.: GLA-0373

Evaluation of Intraocular Pressure and Optical Coherence Tomography Angiography Parameters in Preeclampsia

First Author: Ayush ARYA

Co-Author(s): Akshat ARYA, Kirti SINGH

Purpose: Understanding Intra Ocular Pressure (IOP) changes and ocular vascular complications in pre-eclampsia by determining differences in intraocular pressure (corrected), central corneal thickness (CCT), and retinal circulation (Optical Coherence Tomography Angiography) parameters between pregnant women with preeclampsia and uncomplicated pregnancy.

Methods: A cross-sectional comparative study was conducted comparing 40 pregnant females with pre-eclampsia in the study group to 40 healthy pregnant females in the control group. Clinical assessment with IOP measurement using Goldmann's Applanation Tonometer, CCT using Sonomed PACSCAN 300AP, and Optical Coherence Tomography Angiography using Cirrus HD-OCT 5000 version were performed and compared between the two groups.

Results: The CCT corrected IOP, and Mean ocular perfusion pressure were found to be significantly

higher in preeclampsia as compared to normotensive pregnancy. OCTA (Optical Coherence Tomography Angiography) parameters were suggestive of similar Foveal Avascular Zone (FAZ) and Superficial Capillary Plexus Vascular Density (SCPVD) despite significantly increased Radial Peripapillary Capillary Vessel Density (RPCVD) in preeclampsia patients as compared to normotensive pregnancy. Retinal Nerve Fibre Thickness (RNFL) was found to be similar in both groups.

Conclusions: Glaucoma control may be hampered in pregnancy with preeclampsia due to an increase in IOP, requiring close monitoring and changes in anti-glaucoma medications. Optic disc vasculature is vulnerable to systemic haemodynamic changes, as shown by a significant increase in RPCVD, but the underlying retinal autoregulatory mechanism prevents significant changes in the retinal vasculature, as shown by similar SCPVD values and RNFL thickness between the two groups.

Evaluation of Visual Outcomes in Patients With Concurrent Glaucoma and Cataract Following Multifocal Intraocular Lens Implantation

First Author: Guoxing LI

Co-Author(s): Lin FU, Shudan LI, Yuanbo LIANG, Yijing PING, Shumeng YAO

Purpose: To investigate the visual outcomes of multifocal intraocular lens implantation in patients with concurrent glaucoma and cataract.

Methods: We conducted a prospective study involving 90 eyes: 21 with glaucoma and cataract implanted with multifocal IOLs (Multifocal Glaucoma group), 38 with cataract-only receiving multifocal IOLs (Multifocal Cataract group), and 31 with glaucoma and cataract receiving monofocal IOLs (Monofocal Glaucoma group). Preoperative and three-month postoperative outcomes—including visual acuity, visual field, OQAS parameters, defocus curves, and contrast sensitivity—were compared using SPSS.

Results: The near visual acuity (NVA) of the Multifocal Glaucoma group was better than that of the Monofocal Glaucoma group at three months after surgery ($P=0.005$), and there was no difference compared with the Multifocal Cataract group ($P\geq 0.005$). In the Multifocal Glaucoma group, there was no decrease in visual field (VF) and contrast sensitivity after the operation ($P\geq 0.005$), and the objective visual quality (OQAS) remained unchanged. Postoperative NVA and contrast sensitivity in glaucoma patients had no significant correlation with the degree of VF defect ($P\geq 0.005$).

Conclusions: The NVA of the Multifocal Glaucoma group was significantly better than that of the

Monofocal Glaucoma group, and there was no difference compared with the Multifocal Cataract group. Postoperative VF, contrast sensitivity and OQAS did not decline significantly, and there was no significant correlation between the above visual function indicators and the degree of visual field defect.

Eyes on Adherence in Glaucoma Treatment: A Comparative Evaluation of Medication Reminder Apps

First Author: John Davis AKKARA

Purpose: To identify available medication reminder apps and analyze them quantitatively & qualitatively. To compare the features & usefulness of various medication reminder smartphone apps.

Methods: Cross-sectional observational study. Quantitative & qualitative analysis of medication reminders apps (especially eyedrops). Out of more than 100 medication reminder smartphone apps, the 26 best-rated apps were selected for further analysis. Analyzed for ratings, downloads, file size, essential features, user interface, ease of use, presence of advertisements, paid upgrades, paid app, reliability, and errors.

Results: Applying criteria, 26 apps were selected. Main reasons for exclusion were not being specific for medication, not having at least 1000 installs, and having rating less than 3.0. Tables show the detailed analysis for the selected 26 apps. Some apps were paid, some free and some had ads. A good number of the apps were made for all sorts of medications while a few (3 numbers = 12%) were dedicated for eyedrops and 1 for glaucoma specifically. Number of installs ranged from 1000 to 1 million installs. In addition, it is also important to look at the number of raters who rated the app. This ranged from 13 for the very specific "Glaucoma App" to 204908 for "MediSafe" which correspondingly had 1000 and 1 million installs. File size varied from 0.3MB for the simple Glaucoma App to 35MB for feature-rich MediSafe App.

Conclusions: Our study shows availability of medication reminder apps and their usability. Apps vary widely in file size, ratings and number of installs. Number of installs was better parameter for quality of app than rating. Apps can improve patients' adherence to medications.

Five-Year Cumulative Success Rates of Trabeculectomy Versus Tube Implantation in Advanced Glaucoma Management in Cambodia

First Author: Channdarith KITH

Co-Author(s): Kossama CHUKMOL, Baljean DHILLON, Piseth KONG, Bunseng SEA

Purpose: The aim is to evaluate the effectiveness of primary trabeculectomy with mitomycin-C and tube implant surgery in adult Cambodian patients with advanced stage glaucoma.

Methods: A retrospective chart study was conducted on adult patients who underwent primary trabeculectomy or primary tube implant surgery at national tertiary eye care centre between January 2017 and October 2024. Patients who had previous intraocular procedures were excluded. Demographics, intraocular pressure (IOP), use of anti-glaucoma medications (AGM), and complications were all documented. The complete success was defined as maintaining IOP control with or without medications while avoiding additional glaucoma surgery.

Results: A total of 216 eyes were examined from 197 patients. Of these, 35 eyes (16.20%) received tube implants, while 181 eyes (83.80%) had trabeculectomy. The mean IOPs of the trabeculectomy group decreased from 32.45 ± 12.54 mmHg to 13.10 ± 3.94 mmHg, while the tube group decreased from 32.80 ± 13.69 to 12.06 ± 3.08 mmHg following five years, with no significant difference between the two groups ($p = 0.93$). At five years, the trabeculectomy group had a slightly higher cumulative success rate (67.96%) than the tube group (62.86%), although the difference was not statistically significant ($p = 0.35$).

Conclusions: In Cambodia, while trabeculectomy continues to be the preferred treatment, tube implants are gaining popularity. Our findings revealed that, in this Cambodian cohort, trabeculectomy had a slightly higher five-year cumulative success rate than tube implantation for advanced glaucoma. Both treatments provided effective long-term IOP control, emphasising the importance of tailored surgical planning based on each patient's risk profile and available resources.

Frailty Syndrome and Its Impact on Intraocular Pressure Regulation: An Epidemiological Analysis

First Author: Jianqi CHEN

Co-Author(s): Zhidong LI, Yingting ZHU, Yehong ZHUO

Purpose: As populations age, the prevalence of frailty syndrome is expected to rise. Frailty is characterized by decreased resilience and increased susceptibility

to stressors, and is linked to various adverse health outcomes. Intraocular pressure (IOP) is a significant risk factor for glaucoma and may be influenced by mechanisms such as autonomic nervous dysfunction and inflammation, which share underlying mechanisms with frailty. This study aims to investigate whether frailty syndrome affects the regulation of IOP.

Methods: This study utilized a two-sample Mendelian randomization analysis. The genome-wide association study data for frailty were obtained from a meta-analysis conducted by Atkins et al., which incorporated data from the UK Biobank and TwinGene, encompassing 175,226 participants. The IOP data were sourced from a meta-analysis by Springelkamp et al., based on 19 cohorts comprising 29,578 participants, with no overlap between the two datasets. The inverse variance-weighted method served as the primary inference technique, supplemented by several sensitivity analyses to ensure robustness.

Results: The inverse variance-weighted method suggests that frailty syndrome may contribute to an increase in IOP ($\beta=1.05$, 95% CI: 0.58–1.52, $P<0.001$). This finding is corroborated by sensitivity analyses, as evidenced by the weighted median method ($\beta=1.16$, 95% CI: 0.49–1.82, $P=0.001$) and the weighted mode method ($\beta=1.25$, 95% CI: 0.14–2.37, $P=0.032$), both of which support this conclusion.

Conclusions: This study indicates that frailty syndrome may affect the regulation of IOP. Its potential impact should be considered in the management of IOP in patients with glaucoma, particularly in frail older adults.

From Hemorrhage to High Pressure: A Case Report of Ghost Cell Glaucoma Following Vitrectomy

First Author: Rahmah AMRAN

Co-Author(s): Rina La Distia NORA, Virna Dwi OKTARIANA, Faiz Alwan TAGAR

Purpose: To report a case of ghost cell glaucoma following vitrectomy for vitreous hemorrhage and emphasize the importance of differentiating it from postoperative endophthalmitis.

Methods: A 53-year-old patient presented with severe right eye pain, redness for three days, blurred vision, and photophobia two months post-vitrectomy. Endophthalmitis was initially suspected. However, ocular examination and intraocular pressure (IOP) assessment were performed to refine the diagnosis.

Results: The IOP was markedly elevated at 52 mmHg, associated with corneal edema, conjunctival injection, and a crescent-shaped pseudohypopyon. Further evaluation revealed a deep hazy anterior chamber containing ghost cells, confirming the

diagnosis of ghost cell glaucoma. Ghost cell glaucoma is a secondary open-angle glaucoma caused by degenerated red blood cells obstructing the trabecular meshwork, often developing weeks after vitreous hemorrhage or intraocular surgery. In this case, initial treatment with topical pressure-lowering agents and systemic acetazolamide successfully normalized IOP and alleviated pain. However, the pseudohypopyon persisted, requiring irrigation–aspiration for definitive management.

Conclusions: This case underscores that not all postoperative red and painful eyes represent infection. Early recognition of ghost cell glaucoma is crucial for timely management and preservation of vision.

Abstract No.: 203985

Functional Visual Parameters in Open-Angle Glaucoma Suspects (NTG) With and Without High Axial Myopia

First Author: Kaveri **BIRLA**

Co-Author(s): Zia **CHAUDHURI**, Sunil **KUMAR**, Om **PRAKASH**

Purpose: To compare functional visual performance—best corrected visual acuity (BCVA), contrast sensitivity, colour vision, stereopsis, speed of reading (SOR), and visual fields—in open-angle glaucoma (NTG) suspects with and without high axial myopia (HAM).

Methods: In this hospital-based cross-sectional study, 80 adults (40 NTG with HAM; 40 NTG without HAM) underwent standardized assessments: BCVA (ETDRS), contrast sensitivity (Pelli-Robson), colour vision (Hardy–Rand–Rittler and Farnsworth D-15), stereopsis (Lang I & II, Titmus Fly, TNO), speed of reading (MNREADS), and Humphrey 24-2/10-2 visual fields. Group differences were analyzed using t-tests or chi-square tests.

Results: NTG with HAM presented younger (mean 28.7 ± 13.5 yrs vs 40.3 ± 20.5 yrs, $p=0.003$) and had significantly poorer distance BCVA (logMAR 0.21 vs 0.12, $p=0.02$). Contrast sensitivity and colour vision did not differ significantly between groups ($p>0.3$). Stereopsis was consistently reduced in the HAM group, with higher mean thresholds on Lang I (876 arcsec vs 602 arcsec, $p=0.002$) and Lang II (457 arcsec vs 243 arcsec, $p<0.001$). Speed of reading and visual field defects showed no significant inter-group difference. The findings indicate that while overall visual function remains largely comparable, stereopsis and distance acuity are selectively impaired in NTG with HAM, reflecting the combined effects of myopic axial elongation and early glaucomatous damage.

Conclusions: Functional visual assessment reveals that NTG suspects with HAM exhibit significantly poorer stereopsis and slightly reduced distance visual acuity, despite similar contrast sensitivity and colour

vision. Early stereopsis testing may help identify subtle functional compromise in highly myopic NTG suspects.

Glaucoma Following Microincision Vitreous Surgery (MIVS) for Treatment Naïve Adult Rhegmatogenous Retinal Detachment

First Author: Akanksha **SHARMA**

Co-Author(s): Mohit **DOGRA**, Surinder **PANDAV**, Ramandeep **SINGH**, Faisal **THATTARUTHODY**

Purpose: To evaluate the incidence, clinical course, and management of ocular hypertension/ glaucoma following Microincision Vitreous Surgery (MIVS) for treatment-naïve adult rhegmatogenous retinal detachment (RRD) at a tertiary care centre in Northern India.

Methods: We conducted a retrospective observational non-comparative study of 148 adult patients who underwent MIVS with internal tamponade for RRD and completed a minimum follow-up of six months. Postoperative ocular hypertension/glaucoma was identified based on intraocular pressure (IOP) measurements and clinical findings. Management strategies included antiglaucoma medications, silicone oil removal (SOR), glaucoma drainage device implantation, and diode laser cyclophotocoagulation. Preoperative and postoperative IOP, timing of glaucoma onset, interventions required, and surgical outcomes were analysed.

Results: The mean age of patients was 52.2 years. Most patients (87%) underwent combined scleral band with pars plana vitrectomy and silicone oil tamponade (SB+PPV+SOT), while 10% had SB+PPV with gas tamponade, and 3% underwent PPV with silicone oil tamponade. A mean postoperative IOP rise of 24.4 mmHg was observed compared to baseline. Glaucoma or ocular hypertension developed in 27% of patients. Among these, 52.5% achieved IOP control with medications alone, while 37.5% required SOR to achieve target pressures. Patients undergoing glaucoma surgery, including drainage devices or cyclophotocoagulation, achieved a qualified success rate of 83%. No major vision-threatening complications were noted following secondary glaucoma interventions.

Conclusions: Postoperative glaucoma is a common and potentially sight-threatening complication after MIVS with internal tamponade for RRD. Early recognition and prompt, aggressive management—medical and surgical—are essential for optimal IOP control.

Goniotomy for Secondary Glaucoma in Post-Phacoemulsification Patients: A Way to Dodge the Tube

First Author: Widya ANANDITA

Purpose: This case series aims to report the successful use of goniotomy in secondary glaucoma patients due to complications in phacoemulsification.

Methods: A case series done by retrospective review of three patients.

Results: We have three cases, all of which have a history of phacoemulsification, and in all, we found foldable IOL in the sulcus with closed angle and significant synechiae. All underwent IOL exchange and goniotomy. First patient is 56 y.o. A female who underwent phacoemulsification 4 months before presentation, visual acuity (VA) was 2 meters, finger counting (mfc), and IOP was 45 mmHg. After intervention, VA was 20/60 and pressure decreased to 24, 11, 16, 15.5 mmHg in 1 day, 1 week, 1 month, and 1 year, respectively, without anti-glaucoma medication. Second was 60 y.o. male with history of phacoemulsification 2 years before, VA was 1/2 mfc, and IOP of 34 mmHg. After intervention, VA was 20/60, and IOP decreased to 16.6 and 8.9 mmHg in 1 week and 1 month without medication. The third patient is a female, 53 y.o. who underwent phacoemulsification 4 months before. Pressure was 51 mmHg, and VA was 3 mfc. Afterwards, VA was 20/50, and IOP was 29.3, 42, and 17 mmHg in 1 day, 1 month, and 3 months, with 2 topical anti-glaucoma medications.

Conclusions: Conventionally, secondary glaucoma in patient with history of phacoemulsification complication is primarily treated with glaucoma drainage device. This case series shows goniotomy can be a good alternative to control IOP in such patients.

Gut-Eye Axis in Action: Association of Probiotic Use With Major Glaucoma Subtypes

First Author: Chien-yun TSAI

Purpose: To investigate the association between probiotic use and the risk of developing ocular hypertension (OHT), primary open-angle glaucoma (POAG), normal-tension glaucoma (NTG), and primary angle-closure glaucoma (PACG).

Methods: We conducted a retrospective cohort study using the TriNetX multinational database. Adults aged ≥ 40 years with a diagnosis of dry eye and no prior glaucoma history were included. Participants were categorized into probiotic and non-probiotic groups according to prescription records. Propensity score matching (1:1) was applied to balance demographics,

comorbidities, and medication use. Cox proportional hazards models estimated hazard ratios (HRs) with 95% confidence intervals (CIs), and Kaplan–Meier analyses assessed five-year cumulative incidence. Sensitivity and subgroup analyses were performed to evaluate robustness across age, sex, race, diabetes, and obesity strata.

Results: A total of 15,613 matched pairs were analyzed. Probiotic use was associated with significantly lower risks of OHT (HR: 0.67, 95% CI: 0.54–0.85), POAG (HR: 0.44, 95% CI: 0.32–0.61), NTG (HR: 0.51, 95% CI: 0.27–0.97), and PACG (HR: 0.37, 95% CI: 0.19–0.75). These associations were consistent in sensitivity analyses and across multiple subgroups.

Conclusions: Probiotic use was associated with a reduced risk of multiple glaucoma subtypes in this large real-world cohort. These findings support a potential role of the gut–eye axis in glaucoma pathogenesis and underscore the need for prospective studies to confirm causality and elucidate underlying mechanisms.

Hong Kong Glaucoma Surgery Practice Patterns: A Survey Among Glaucoma Specialists

First Author: Rachel Lancey LAI

Co-Author(s): Virna ASRORY, Thomas Chi-ho LAM, Dexter LEUNG, Clement THAM

Purpose: To Characterize Current Glaucoma Surgical Practice Patterns Among Glaucoma Specialists in Hong Kong

Methods: An anonymous online survey was distributed to glaucoma specialists in Hong Kong via Google Forms, capturing demographic data and detailed preferences for surgical procedures.

Results: Among 27 respondents (44.4% public, 55.6% private), practice patterns for trabeculectomy included a preference for a superonasal site (51.9%), a fornix-based conjunctival flap (96.3%), a rectangular scleral flap (74.1%), and MMC 0.4mg/ml for 3 minutes (77.8%). Postoperative management showed varied use of NSAIDs, rare use of subconjunctival steroids, and no reported use of intracameral anti-VEGF. The Ahmed valve was the dominant tube shunt (81.5%), with a unanimous preference for a superotemporal initial site, followed by a superonasal site (63%). The usage of MIGS was highest for iStent (88.9%), followed by goniotomy (48.1%), and minimally invasive bleb surgeries (MIBS) such as the XEN Gel Stent and PRESERFLO Microshunt (37% each). Patient selection criteria varied: angle-based MIGS were primarily used for mild-moderate glaucoma (92.6%), whereas MIBS were favoured for medication intolerance (61.5%). Key barriers included narrow angles for angle-based MIGS (81.5%) and conjunctival scarring for MIBS (57.7%). In

the next five years, 40.7% of specialists foresee MIGS remaining primarily for mild-moderate disease, while 33.3% predicted broader earlier use.

Conclusions: The glaucoma surgical landscape in Hong Kong is characterized by a hybrid model, where well-established techniques are integrated with a cautious adoption of newer MIGS. Surgeon preference and specific patient factors heavily influence strategy. These patterns provide a valuable benchmark for regional comparison within the Asia-Pacific region.

Abstract No.: 204713

Panel No.: GLA-0374

Identification of a 2MB Plausible Novel Locus on Chromosome 7, and a Novel Mutation p.Ser464Pro in CYP1B1 in Primary Congenital Glaucoma Families of Pakistani Origin

First Author: Hamza KHAN

Co-Author(s): Nauman AHMAD, Humaira AYUB, Israr Ahmed BHUTTO, Sadia BUKHARI

Purpose: The current study was conducted to explore the genetic factors associated with PCG families of Pakistani origin.

Methods: The study participants comprised of nine large unrelated consanguineous PCG families and three trios families collected from Pakistan. Probandes were investigated for CYP1B1 mutations by Sanger sequencing, followed by segregation analysis of the identified variants. Moreover, one family (PCG02) not linked to CYP1B1 was further subjected to 250K SNP microarray, homozygosity mapping, and whole exome sequencing (WES).

Results: Nine recurrent and one previously unreported mutation was identified in the current cohort of nine families and three trios cases. The variant p.Ser464Pro was not found in any of online databases such as genomAD, ClinVar, and dbSNP, and was predicted to be deleterious by all the pathogenicity predicting tools. Six known missense mutations [p.Arg444Gln, p.Arg368His, p.Arg390His, p.Arg390Ser, p.Gly61Glu, and p.Arg469Trp], two frameshift mutations [p.Arg290Profs*37, and p.Pro442Glufs15*], and one hypomorphic allele [p.Glu229Lys] segregated with the disease phenotype in the respective families. In a trios family (PCGT02) compound heterozygous mutations p.Arg368His, and p.Arg390His were identified. Furthermore, In PCG02, a plausible 2Mb novel locus was identified on chromosome 7q34 (139,681,371-141,507,822) (GRCh38/hg38).

Conclusions: The current study expands the mutation spectrum of the CYP1B1 in Pakistani population with the identification of previously unreported mutation p.Ser464Pro. Additionally, the mapping of a 2MB novel locus mapped to chromosome 7 provides strong evidence of additional genetic contributors,

highlighting the genetic heterogeneity of the disease in Pakistani population.

Impact of Early Medication Discontinuation on Intraocular Pressure Outcomes Following Selective Laser Trabeculoplasty in Medicated Asian Patients

First Author: Ching Wen CHIU

Co-Author(s): Chia-an HSU, Yu-chieh KO

Purpose: Based on the hypothesis that a higher baseline intraocular pressure (IOP) is associated with better selective laser trabeculoplasty (SLT) outcomes, we investigated whether immediate medication reduction after SLT could improve IOP response in medicated primary open-angle glaucoma (POAG) patients.

Methods: This retrospective study enrolled medicated POAG patients who underwent SLT for additional IOP lowering at a medical center in Taiwan between 2023 and 2024. Patients were stratified by whether one glaucoma medication, typically the most effective one, was withdrawn immediately post-SLT. Primary outcomes were IOP changes, and secondary outcomes were predictors for an IOP reduction of $\geq 20\%$ over a 6-month follow-up period.

Results: A total of 178 eyes (mean baseline IOP 17.4 ± 4.82 mmHg) were analyzed. The mean IOP was significantly reduced by 13% at 7 days, 4.8% at 12 weeks, and 2.7% at 24 weeks. Patients with immediate medication discontinuation (n=76) showed similar IOP outcomes compared to those who continued prior medications (n=97). Predictors for better mid-term IOP control were a higher baseline IOP and a significant IOP drop at day 7, with an area under the receiver operating characteristic curve (AUC) of 0.903 and 0.809 for 12-week and 24-week outcomes, respectively.

Conclusions: Early withdrawal of medication after SLT is an effective approach to maximize the benefits of SLT, achieving additional IOP reduction while lowering the medication burden, with improvements evident as early as one week after treatment.

Abstract No.: 201609

Panel No.: GLA-0331

Impact of Sleep Apnea Syndrome on Lipid Oxidation in Patients With Glaucoma

First Author: Takahiro OHSHIMA

Co-Author(s): Noriko HIMORI, Shunji KATO, Kiyotaka NAKAGAWA, Toru NAKAZAWA, Yurika OTOKI

Purpose: Sleep apnea syndrome (SAS) has been reported to be associated with glaucoma, but the mechanisms underlying this association remain unclear. This study aimed to clarify the impact of SAS-induced lipid oxidation in patients with glaucoma.

Methods: Forty-five patients with normal-tension glaucoma (33 with SAS, 12 without SAS) were enrolled. Serum samples were collected, and phospholipid hydroperoxides (PLOOHs) were quantified as a lipid peroxidation marker using liquid chromatography–tandem mass spectrometry. Statistical comparisons between groups with and without SAS were performed using the Mann–Whitney U test.

Results: PLOOHs were consistently detected in the serum of the glaucoma patients. The patients with SAS had significantly higher levels of PLOOHs associated with radical-mediated oxidation compared to glaucoma patients without SAS (198.5 ± 64.4 vs. 124.7 ± 42.6 , $p < 0.001$). In contrast, PLOOHs associated with singlet oxygen-mediated oxidation showed no significant difference (20.7 ± 6.5 vs. 21.5 ± 7.9 , $p = 0.747$). These findings indicate that glaucoma patients with SAS have an increased oxidative burden that acts via radical-mediated oxidation pathways.

Conclusions: Our analysis using PLOOHs as a biomarker revealed that oxidative stress is closely linked with glaucoma, particularly in glaucoma patients with SAS. This finding indicates that monitoring oxidative stress could offer valuable insights into the underlying mechanisms of glaucoma and emphasizes the need to account for SAS in clinical practice.

Injectable Hyaluronic Acid Hydrogel for Sustained Pirenzepine Release Enhances Neuroprotection in Optic Nerve Crush Injury

First Author: Xuehan LIU

Co-Author(s): Yiqing LI, Jiahui TANG

Purpose: Glaucoma causes significant impairment of visual function, but the efficacy of current drug therapies remains limited. Sustained-release ophthalmic formulations offer the potential to enhance drug retention, decrease dosing frequency, and improve patient compliance. Hydrogels represent a class of materials with considerable versatility for ophthalmic applications. To investigate whether injectable intravitreal hydrogels can enhance the drug therapy in optic nerve crush (ONC) by sustaining drug release.

Methods: Pirenzepine, an M1 mAChR antagonist, was delivered via single/multiple intravitreal injections or encapsulated in an HA-based hydrogel. Retinal ganglion cell (RGC) survival was then quantified by immunofluorescence. Axon regeneration was assessed by manually counting CTB-labeled axons at specific distances in the whole-mount optic nerve.

Results: Pirenzepine enhanced both RGC survival and stimulated intense axonal regeneration compared to control in an optimal concentration of 100 μ M. Furthermore, injecting pirenzepine immediately after

injury and again 3 d later, was more effective than a single early injection to augment axon regeneration. Drug-loaded hydrogels demonstrated equivalent efficacy to repeated pirenzepine administration in promoting RGC survival and exceeded the protective effect of single-dose therapy.

Conclusions: Our findings demonstrate that the HA-A/HA-SH hydrogel is injectable, biocompatible, and enhances pirenzepine therapy in ONC by sustaining drug release. This approach represents a promising strategy for improving the therapeutic index of glaucoma medications by potentially reducing side effects associated with frequent dosing.

Injectable vs. Sponge Mitomycin C in Trabeculectomy: A Retrospective Comparative Study

First Author: Shalini SHALINI

Co-Author(s): Salwa KAIDAKATH, Meena MENON, Niharika PRASAD

Purpose: To compare the efficacy and safety of intraoperative subconjunctival injectable mitomycin C (MMC) versus sponge-applied MMC during trabeculectomy.

Methods: Retrospective analysis of patients who underwent trabeculectomy with injectable MMC ($n=58$) and sponge-applied MMC ($n=61$) with the concentration of 0.4mg/ml of MMC solution. The primary outcomes measured were intraocular pressure (IOP) and the number of anti-glaucoma medications (AGM) at various time points, including pre-operatively and post-operatively.

Results: Both the injectable and sponge-based groups showed a significant reduction in mean IOP from pre-operative levels over a six-month follow-up period ($p=0.001$ for both groups). The mean pre-operative IOP of the injectable group was 20.78mmhg (SD 9.35), which decreased to 12.62mmhg (SD 4.95) at 6 months. The sponge-based group's mean pre-operative IOP was 26.00 (SD 8.97), which reduced to 14.49mmhg (SD 6.26) at 6 months. There was no significant difference in the trend of IOP change over time between the two groups ($p=0.055$). Both groups demonstrated a significant decrease in the mean number of AGMs post-operatively ($p=0.001$ for both). Bleb morphology was studied by comparing each component, which did not show any statistically significant difference. While postoperative suturolysis was done in 13.6% patients in the sponge group and 3.5% patients in the injectable group, this was not statistically significant.

Conclusions: Injectable MMC is as effective as the conventional sponge-based application in reducing IOP. The injectable method of administering MMC offers a safe and equally effective alternative to the

traditional sponge application in trabeculectomy, with a comparable safety profile.

Innovative Use of Ahmed ClearPath in ICE Syndrome–Related Glaucoma with Sulcus Tube Placement: A Case Report

First Author: Rida AZEEM

Co-Author(s): Afshan ALI, Muhammad Kaunain Razzak GOGHARI, Umair QIDWAI

Purpose: To report a unique case of secondary glaucoma due to iridocorneal endothelial (ICE) syndrome managed successfully with the Ahmed ClearPath (ACP) glaucoma drainage device, highlighting the novel use of sulcus tube placement via combined cataract surgery.

Methods: A 30-year-old woman presented with acute onset of right eye pain and vision loss. Examination revealed intraocular pressure (IOP) of 50 mmHg, corneal edema, iris nodules, corectopia, and pseudopolycoria—findings suggestive of the Cogan-Reese variant of ICE syndrome. Initial medical therapy provided transient relief. Despite maximal medical treatment, IOP remained uncontrolled at 42 mmHg.

Results: The patient underwent combined clear lens extraction and implantation of an ACP device with sulcus tube placement. The rationale for cataract extraction was to avoid anterior chamber tube placement, which in ICE syndrome carries a higher risk of endothelial decompensation due to shallow chamber and abnormal anatomy. Postoperatively, IOP decreased to 28 mmHg at 1 month and stabilized at 18 mmHg at 3 months, with improved visual acuity to 6/6. No intraoperative or postoperative complications occurred.

Conclusions: This is one of the first reported cases outside the United States using Ahmed ClearPath in ICE-related glaucoma. The case demonstrates successful short-term IOP control using ACP in a challenging ICE morphology, highlighting the importance of early surgical intervention and tube placement strategy. Given the high failure rate of trabeculectomy and the progressive angle closure in ICE syndrome, the ACP provides a promising alternative. More studies are needed to evaluate long-term efficacy of ACP in ICE and other secondary glaucoma.

Panel No.: GLA-0431

Inter-Grader Reliability of Portable Diagnostic Devices for Monitoring Stable Glaucoma

First Author: Lynn QUEK

Co-Author(s): Maria Cecilia Domingo AQUINO, Victor KOH, Jun Ying LEE, Weihan TONG

Purpose: To determine the inter-grader reliability of ophthalmologists of varying experience in interpreting results from portable diagnostic devices for assessing disease stability and treatment requirements in patients with stable glaucoma.

Methods: A prospective pilot study was conducted at a Singapore tertiary ophthalmology outpatient clinic, where patients with stable glaucoma, ranging from mild to severe, were recruited for monitoring. Visual acuity, visual field, and intraocular pressure were assessed using portable devices. The device results were independently reviewed by two ophthalmologists: a general ophthalmologist (undergoing first year of glaucoma fellowship) and a senior ophthalmologist (>10 years after fellowship training). Each grader classified disease status as stable or unstable and indicated whether medication changes were required. Inter-grader agreement was calculated, with subgroup analyses by disease severity.

Results: Seventy patients were enrolled (mean age 67.8 ± 8.1 years; 23 mild, 24 moderate, 23 severe glaucoma). For disease stability classification, overall inter-grader agreement was 74.3% (95% CI, 63.0–83.1%). By severity, concordance was highest in mild cases at 82.6% (95% CI, 67.1–98.1%), compared with 70.8% (95% CI, 52.6–89.0%) in moderate and 69.6% (95% CI, 50.8–88.4%) in severe disease. For medication change decisions, overall agreement was 80.0% (95% CI, 69.2–87.7%). Subgroup analyses showed concordance of 78.3% (95% CI, 58.1–90.3%) in mild, 83.3% (95% CI, 64.1–93.3%) in moderate, and 78.3% (95% CI, 58.1–90.3%) in severe glaucoma.

Conclusions: In this pilot study, glaucoma-trained ophthalmologists demonstrated promising inter-grader reliability in assessing disease stability and treatment needs using portable diagnostic devices, supporting the utility of portable devices for reliable monitoring of stable glaucoma in outpatient settings.

Intermediate Outcome of Preserflo MicroShunt in the Treatment of Open Angle Glaucoma in a Chinese Population – a Retrospective Interventional Study

First Author: Anthony Chuk-him LAI

Co-Author(s): Poemen Pui Man CHAN

Purpose: To evaluate the safety and efficacy of Preserflo MicroShunt in the management of open-angle glaucoma in a Chinese population.

Methods: Records of consecutive glaucoma patients with MicroShunt implantation at Hong Kong Eye Hospital from May 2023 to May 2024 were retrospectively reviewed. Patients of Chinese ethnicity with open-angle glaucoma were recruited. The MicroShunt was implanted in an ab externo fashion over the superotemporal or superonasal quadrant as a standalone procedure or combined with phacoemulsification, augmented with adjunctive mitomycin C (0.4mg/ml).

Results: Twenty-seven eyes of 26 patients were implanted with the MicroShunt, of which 22 cases (81.5%) were done as a standalone procedure, and 5 cases (18.5%) were combined with phacoemulsification. The mean follow-up period was 18.89 ± 5.81 months. The mean intraocular pressure (IOP) decreased from 22.33 ± 6.73 mmHg preoperatively to 16.11 ± 5.38 mmHg at the final follow-up ($p < 0.001$, paired t-test). The mean number of medications decreased from 3.93 ± 1.04 preoperatively to 1.48 ± 1.60 at the final follow-up ($p < 0.001$, paired t-test). There were no significant intraoperative complications noted. For post-operative interventions, 10 cases (37.0%) required needling, 5 cases (18.5%) required bleb revision, and 3 cases (11.1%) eventually required trabeculectomy.

Conclusions: Preserflo MicroShunt is a safe and effective treatment of open angle glaucoma in the Chinese population.

Investigating Developmental Glaucoma in a Series of Clinical Cases

First Author: Vandana ARORA

Purpose: Developmental glaucomas are a group of disorders characterized by improper development of the eye's aqueous outflow system, typically manifesting in infancy or childhood. They include primary congenital glaucoma and secondary glaucomas associated with ocular or systemic developmental anomalies. This case series aims to highlight the importance of recognizing adolescent presentations of developmental glaucoma and initiating timely diagnosis and management.

Methods: Three adolescent patients with elevated intraocular pressure (IOP) were evaluated for developmental glaucoma. A detailed systemic and family history was obtained. Ocular examination included IOP measurement using Goldmann applanation tonometry, central corneal thickness assessment, gonioscopy, specular microscopy, and fundus examination. Each case was assessed for associated ocular or systemic developmental anomalies.

Results: Case 1 was 18-year-old female with right eye posterior embryotoxon, peripheral anterior synechiae, and 0.7 cup-disc ratio, along with dento-facial anomalies and positive family history—diagnosed as Axenfeld-Rieger syndrome. Case 2, 18-year-old male, had corneal decompensation, flat iris insertion, IOP of 30 mmHg, 0.6 cup-disc ratio, and high polymegathism—diagnosed as Chandler syndrome. Case 3 16-year-old female, showed Haab's striae, megalocornea, anterior iris insertion, and corneal scarring diagnosed as mesodermal dysgenesis. Cases 1 and 2 underwent successful antiglaucoma surgery; Case 3 was managed medically.

Conclusions: Adolescent presentations of developmental glaucoma are uncommon but clinically significant. Accurate and early diagnosis, guided by characteristic ocular and systemic findings, is crucial for prompt intervention. Tailored management strategies—surgical or medical can help preserve vision and reduce long-term morbidity in such cases.

Investigation of 4E-BP1 as a Crucial Regulator of Collagen Synthesis in Human Trabecular Meshwork Fibrosis

First Author: Zuimeng LIU

Co-Author(s): Pin WANG, Binrong WU, Shaodan ZHANG

Purpose: This study aims to investigate the role of 4E-BP1 as a pivotal regulator of collagen synthesis in trabecular meshwork (TM) fibrosis and assess the efficacy of interventions targeting 4E-BP1 in this process.

Methods: Firstly, human trabecular meshwork cell (HTMC) injury models were utilized to induce dexamethasone (DEX), TGF- β 1, and oxidative damage (H₂O₂). The expressions of extracellular matrix (ECM) and fibrosis-related proteins such as fibronectin, α -SMA, and collagen I, alongside factors associated with the mTORC1 and mTORC2 pathways, namely 4E-BP1 and eIF4E, were assessed through immunofluorescence (IF) and Western Blot (WB) analysis. Secondly, various inhibitors of the 4E-BP1 pathway (such as AZD8055, CZ415, TORIN1, and Rapamycin), along with small interfering RNA (siRNA), were employed to investigate the significant involvement of 4E-BP1 in the development of TM fibrosis. Finally, the impact

of inhibitors targeting the phosphorylation of 4E-BP1 on TM fibrosis in DEX-induced mouse models with elevated intraocular pressure (IOP) was assessed, along with their efficacy in reducing IOP.

Results: Indicated a notable increase in the expression and phosphorylation of 4E-BP1 during TM fibrosis induced by various stressors. Inhibitors of 4E-BP1 phosphorylation demonstrated notable anti-fibrotic effects on diverse models of TM fibrosis. In Vivo, these inhibitors effectively mitigated DEX-induced TM fibrosis in mice and led to a significant reduction in IOP.

Conclusions: 4E-BP1 emerges as a pivotal regulator of TM fibrosis, and its inhibition represents a promising therapeutic strategy for managing glaucoma.

Investigation on the Current Status of Basic Knowledge About Glaucoma Among Primary-Level Ophthalmologists

First Author: Yuanyuan **ZHANG**

Co-Author(s): Ping **GE**, Yuan **HE**, Yan **LIU**, Qingqing **MU**

Purpose: As the leading irreversible blinding eye disease worldwide, early screening and intervention for glaucoma are critical to reducing vision loss. Primary-level ophthalmologists' limited knowledge, poor screening capacity, and scarce resources cause high misdiagnosis/missed diagnosis. This study evaluated their glaucoma knowledge in Shaanxi, explored cognitive factors, and provided evidence for improving primary ophthalmic care.

Methods: Cross-sectional survey with cluster random sampling of primary/secondary hospital ophthalmologists in Shaanxi. A validated questionnaire (KMO=0.837, Cronbach's $\alpha > 0.7$) covered 4 dimensions. 299 valid online responses were analyzed via SPSS 25.0.

Results: This study assessed glaucoma knowledge of primary ophthalmologists in Shaanxi, analyzing proficiency and cognitive differences. Among participants, secondary hospital doctors were the most (65.66%), tertiary next (24.49%), primary least (7.58%); 49.24% had >16 years of experience. Tertiary hospitals had advanced equipment, primary (especially private clinics) lacked it. Tertiary scored highest (32.94 ± 3.21), secondary lowest (31.76 ± 3.45).

Conclusions: Shaanxi's primary ophthalmologists have basic glaucoma knowledge but gaps in advanced diagnostic techniques. Continuing education and optimized equipment allocation are needed to enhance competence and reduce glaucoma-related blindness.

Large-Scale Multi-Trait GWAS and Retinal Flavoprotein Autofluorescence Imaging Implicate Mitochondrial Quality Control and Function in Glaucoma

First Author: Shisong **RONG**

Co-Author(s): Shihao **CHEN**, Chenfeng **GU**, Zhanhao **GU**, Qiuruo **JIANG**, Junfeng **LI**

Purpose: To test whether mitochondrial quality control and function contribute to glaucoma and related traits.

Methods: We performed multi-trait genome-wide association study (MTAG) analyses by integrating genetically correlated datasets from the UK Biobank, FinnGen, the GWAS Catalog, and curated literature. Findings were benchmarked against a meta-analysis of primary open-angle glaucoma (POAG; ~383,500 individuals). Within MTAG, gene-level associations for regulators of mitochondrial fission, fusion, and mitophagy were evaluated using MAGMA. To complement genomic analyses, we conducted retinal mitochondrial functional imaging in a hospital-based myopic cohort without retinal degenerations ($n = 446$; 892 eyes). Mitochondrial redox status was quantified by flavoprotein autofluorescence (FPF) assessed by OcuMet Beacon. Cup-to-disc ratio (CDR) was recorded, and its association with FPF tested using linear mixed-effects models with comprehensive covariate adjustment.

Results: Of 11 POAG-related GWAS datasets, four genetically correlated datasets were included in MTAG, yielding an effective sample size of ~560,000. MTAG results showed strong concordance with established POAG loci ($P < 0.05$; $R^2 > 0.95$). Among 30 mitochondrial dynamics genes, MFF and DNMT1L were significantly associated with POAG ($P < 0.005$), while fusion and mitophagy genes were not ($P > 0.05$). In the imaging cohort (mean age 25.8 ± 7.2 years), mean FPF was 17.8 ± 4.7 and mean CDR was 0.36 ± 0.11 . Larger CDR correlated with higher FPF at the optic disc ($P < 0.05$) but not at the macula ($P > 0.05$).

Conclusions: Genomic and imaging evidence supports a role for mitochondrial quality control and function—particularly fission pathways—in POAG. These findings nominate mitochondrial dynamics genes as potential targets for mechanistic studies and biomarker development in glaucoma.

Late-Detected Primary Congenital Glaucoma: Decision-Making and Salvage Therapy in a 7-Month-Old

First Author: Alma Pustika Kartikananda Retina

FIBULARIS

Co-Author(s): Evelyn KOMARATIH, Rozalina LOEBIS

Purpose: Primary congenital glaucoma (PCG), a rare disease occurring in 1:10,000-20,000 births with classic triads (photophobia, epiphora, and blepharospasm), presents diagnostic challenges leading to misdiagnosis and potentially irreversible damage.

Methods: A 7-month-old boy was referred to the General Hospital for the left eye enlargement and haziness for 6 months, with excessive tearing starting at 2 weeks old. Despite treatment from four ophthalmologists, his condition worsened. Visual acuity (VA) was 1.8 LogMAR in the right eye (RE) and no light perception in the left eye (LE). Examination revealed LE buphthalmos, megalocornea, and corneal edema, leading to a diagnosis of primary congenital glaucoma (PCG). Initial examination under anesthesia (EUA) showed LE intraocular pressure (IOP) of 50.4 mmHg and RE 17.3 mmHg. Due to the opaque cornea, cyclocryotherapy was performed on LE. Subsequent EUAs indicated fluctuating IOPs, necessitating further cyclocryotherapy with the last LE IOP 25.8 mmHg. Timolol was prescribed for both eyes and eyeglasses, improving VA in the RE to 0.3 LogMAR and enhancing cognitive and motor functions.

Results: Ophthalmologists must understand the PCG diagnosis algorithm to effectively diagnose, refer, and treat patients for better vision prognosis. Although angle surgery is the gold standard, cyclodestructive surgery can be used as a last resort. Early collaboration with pediatricians is essential to optimizing growth and development.

Conclusions: Accurate diagnosis is essential for early PCG management to prevent blindness. While proper treatment in delayed cases can optimize outcomes, as timely salvage surgery can preserve severely advanced cases with no light perception and enhance neuro-developmental milestones.

Lens or Barrier? Investigating the Paradox of Iris-Claw Lens-Induced Pupillary Block

First Author: Kemala OCTARINY

Co-Author(s): Elsa GUSTIANTY, R.Maula RIFADA, Indriyani RIFANDI, Sonie UMBARA

Purpose: To report the management of pupillary block following retropupillary iris-claw IOL implantation, highlighting the importance of early detection and

appropriate treatment when laser peripheral iridotomy (LPI) is insufficient.

Methods: A 62-year-old woman complained of ocular pain in the right eye for 1 month, which worsened 1 week ago. Symptoms included blurred vision, redness, and nausea. Visual acuity was hand movement, and intraocular pressure (IOP) was 56 mmHg. Examination revealed blepharospasm, ciliary injection, corneal edema, a shallow anterior chamber, a mid-dilated pupil with iris-claw enclavation at 5 and 11 o'clock, and a retropupillary iris-claw IOL. Posterior segment findings included a round optic disc, cup-to-disc ratio of 0.8-0.9 with optic disk cupping, and a flat retina. Anterior-segment OCT showed iris apposition with the corneoscleral wall, and ultrasound biomicroscopy revealed the dome-shaped optic of the IOL facing anteriorly. The patient was treated with ocular hypotensive agents and underwent trabeculectomy due to inadequate LPI.

Results: Following trabeculectomy, ocular pain resolved, corneal clarity improved, and the anterior chamber deepened with a functioning bleb. The IOP decreased to 21 mmHg and remained stable over a 3-month follow-up period.

Conclusions: Pupillary block after retropupillary iris-claw IOL implantation is a rare but serious complication. An iris-claw lens can paradoxically act as a barrier, obstructing aqueous humor flow and disrupting normal anterior chamber dynamics. Trabeculectomy may be needed when LPI is insufficient.

Long-Term Efficacy of Combined Phacoemulsification and Hydrus Microstent in Open-Angle Glaucoma Versus Combined-Mechanism/Primary Angle Closure Glaucoma

First Author: Kelly NGUYEN

Co-Author(s): Sunee CHANSANGPETCH, Andrew IWACH, Shan LIN, Eden NG, Ngoc NGUYEN, Sunita RADHAKRISHNAN

Purpose: Compare efficacy of combined Hydrus-cataract surgery in open angle glaucoma (OAG) to combined mechanism glaucoma (CMG) and primary angle closure glaucoma (PACG) over 36 months.

Methods: Retrospective review of OAG, CMG, or PACG eyes which underwent combined Hydrus-cataract surgery between Jul 2020-Dec 2021. Regression models were used to evaluate IOP, medication use, success rate (IOP $\leq$ 18 mmHg without medication) and proportion of medication-free eyes.

Results: CMG/PACG (n=39) group had significantly higher IOP reduction from baseline to 36-months than OAG (n=34) group (OAG, 15.03 $\pm$ 2.90 to 13.44 $\pm$ 3.85 mmHg, p=0.016; CMG/PACG, 15.62 $\pm$ 3.10 to 13.21 $\pm$ 2.61 mmHg, p=0.002) (p=0.021). Number of medications

was significantly reduced similarly in both groups (OAG, 2.44 ± 1.33 to 1.18 ± 1.40 , $p < 0.001$; CMG/PACG, 2.29 ± 1.27 to 0.87 ± 1.08 , $p < 0.001$) ($p = 0.882$). CMG/PACG had higher success rate (49% vs 29%) and more medication-free eyes (49% vs 35%) than OAG but these were not statistically significant ($p = 0.09$ and 0.25 , respectively).

Conclusions: This retrospective study supports long-term efficacy of combined Hydrus-cataract surgery for CMG/PACG and OAG.

Machine Learning With Aptamer-Based Plasma Proteomics for Detecting Oxidative-Stress-Linked Glaucoma

First Author: Takahiro **NINOMIYA**

Co-Author(s): Noriko **HIMORI**, Toru **NAKAZAWA**, Kota **SATO**, Airi **TAKAGI**, Satoru **TSUDA**

Purpose: To detect glaucoma that has progressed under the influence of oxidative stress using machine learning with aptamer-based plasma proteomics.

Methods: We analyzed 162 participants with primary open-angle glaucoma (POAG) (age 66.9 ± 6.8 years; visual-field mean deviation [MD] -13.1 ± 7.7 dB); one eye per participant was included (worse MD). Targets were defined by an and rule: visual-field damage (MD threshold as proxy for progression) and high derivatives of reactive oxygen metabolites (d-ROMs). We first trained a model at clinical cutoffs ($MD \leq -12$ dB; d-ROMs > 400 U.CARR), then scanned nearby thresholds (MD -14 to -12 ; d-ROMs 400-440) using five-fold out-of-fold logistic regression with elastic net feature selection ($k=166$) from 7,596 plasma protein measurements obtained with an aptamer-based platform (SomaScan). Final models (logistic, XGBoost, CatBoost) were compared by out-of-fold area under the receiver operating characteristic curve (AUC). Interpretation used Shapley additive explanations (SHAP).

Results: Clinical cutoffs yielded limited discrimination (logistic AUC 0.47; XGBoost 0.53). Including plausible pairs near the clinical range (MD -13.4 dB; d-ROMs 430) improved logistic AUC to 0.74. With these labels, XGBoost performed best (AUC 0.784), exceeding elastic net logistic (AUC 0.729-0.732). SHAP highlighted S100A8/A9 (calprotectin), Kelch-like protein 2, and thrombospondin-1, associated with oxidative stress biology.

Conclusions: Machine learning with aptamer-based proteomics improved detection when thresholds were adjusted near clinical cutoffs. These findings support oxidative stress involvement in glaucoma and highlight proteomics' potential for stratifying cases influenced by oxidative stress, warranting validation.

Macular Vascular Responses to Hyperoxia in Primary Open-angle Glaucoma: An Optical Coherence Tomography Angiography Study

First Author: Xintong **FAN**

Co-Author(s): Xiangmei **KONG**

Purpose: To explore macular vasoreactivity to hyperoxia in primary open-angle glaucoma (POAG) with optical coherence tomography angiography (OCTA).

Methods: With a prospective study design, we enrolled 45 patients (45 eyes) with POAG and 19 sex- and age-matched healthy controls (19 eyes). Macular vessel density (VD) was measured in the superficial capillary plexus (SCP) and deep capillary plexus (DCP) among all participants using OCTA before and after breathing 80% oxygen. The VD reduction, including absolute difference (value of baseline minus hyperoxia) and relative difference (the ratio between absolute difference and baseline value), was calculated and compared between the two groups. The factors influencing macular vasoreactivity were determined. Systemic blood flow characteristics before and after hyperoxia were also detected.

Results: Systemic hyperoxia significantly decreased macular SCP and DCP VD in healthy controls ($P < .001$, $P = .008$, respectively) and POAG patients (all $P < .001$). The VD reduction (between baseline and hyperoxia) was similar between the SCP and DCP in healthy controls ($P = .55$); however, in POAG patients, it was significantly lower in the SCP than in the DCP ($P = .007$). The VD changes in the SCP and DCP were significantly positively correlated with baseline VD in POAG patients (all $P < .001$), but there was no correlation in healthy subjects ($P = .50$, $P = .42$, respectively).

Conclusions: Macular microcirculation reacts to hyperoxia through decreasing SCP and DCP perfusion in healthy and POAG subjects. However, this vascular autoregulation was altered in POAG patients and was associated with baseline macular perfusion.

Abstract No.: 205564

Panel No.: GLA-0396

Managing Glaucoma With iStents as a Cataract and Refractive Surgeon in Australia

First Author: Kenneth **OOI**

Co-Author(s): Natasha **GOH**

Purpose: To measure the effectiveness of iStent inject W as a standalone (SA) procedure and combined with phacoemulsification (combined) as management of open-angle glaucoma (OAG) over 24 months (M24).

Methods: A longitudinal assessment was performed in patients with OAG implanted with iStent inject W as SA or combined from a private ophthalmology practice in Sydney. The primary endpoints were the changes

in mean intraocular pressure (IOP) and the number of glaucoma medications over time. Other endpoints included changes in the proportion of medication-free eyes, and average mean deviation (MD) and logMAR postoperatively at M24.

Results: Fifteen eyes from 11 patients and 15 eyes from 10 patients were analysed from the SA and combined groups respectively. The mean preoperative IOP was 14.7 ± 4.4 mmHg and 13.9 ± 4.5 mmHg for the SA and combined groups, respectively. The mean number of glaucoma medications preoperatively was 1.5 ± 0.7 for the SA group and 2.1 ± 1.1 for the combined group. At M24, the reductions in mean IOP were 2.1 mmHg (95%CI: -4.2, -0.1) for the SA group and 3.3 mmHg (95%CI: -6.0, -0.6) for the combined group. In terms of the mean number of glaucoma medications, the SA group exhibited reductions of 0.8 (95%CI: -1.7, 0.1), whereas the combined group had reductions of 2.7 (95%CI: -4.6, -0.8). 40% of SA eyes and 54% of combined eyes became medication-free postoperatively. No statistically significant improvement was observed in mean MD in both groups postoperatively. Mean logMAR values were improved in the combined group only.

Conclusions: iStent inject W, whether SA or combined, is a suitable surgical intervention in managing OAG and reducing medication burden.

Abstract No.: 206094

Panel No.: GLA-0411

Mid-term Outcomes of Trabeculectomy and Predictors of Surgical Success

First Author: Clarice SU

Co-Author(s): Thomas LAM, Audrey TANG

Purpose: To evaluate the two-year outcome and identify predictors of success for primary trabeculectomy in a heterogeneous glaucoma population at a tertiary referral center in Hong Kong

Methods: A retrospective chart review of 63 consecutive primary trabeculectomy cases was performed. The primary outcome measures were intraocular pressure (IOP), number of glaucoma medications, and surgical success, defined as complete (IOP ≤ 15 mmHg without medication) or qualified (IOP 15-18 mmHg on ≤ 3 medications).

Results: The cohort included diagnoses of primary open-angle glaucoma (57.1%), uveitic glaucoma (19.0%), and primary angle-closure glaucoma (9.5%). Trabeculectomy demonstrated significant efficacy, reducing mean IOP from 23.8 ± 6.7 mmHg preoperatively to 14.1 ± 3.8 mmHg at one year and 15.6 ± 6.1 mmHg at two years ($p < 0.003$). The mean number of medications was reduced from 4.0 to 0.7 at one and two years. The proportion of complete and qualified success was 81% at final follow-up. Five cases (7.9%) required further glaucoma surgery, including

cyclophotocoagulation, re-trabeculectomy and Paul glaucoma implant. In multilevel mixed-model logistic regression analysis, adjusting for inter-eye correlation, placement of the trabeculectomy in the superonasal quadrant (as opposed to the superior quadrant) was a significant predictor of surgical success ((odds ratio [OR], 4.26; 95% confidence interval [CI], 1.31-13.81). Other preoperative, intraoperative, and postoperative factors, including surgeon experience were not significant.

Conclusions: Trabeculectomy provides excellent IOP control and a high success rate in a complex, tertiary-level population. A potential novel finding is that the superonasal surgical location is a key predictor of surgical success, suggesting it may be a superior approach to the traditional superior location.

Abstract No.: 206538

Panel No.: GLA-0419

Midterm Outcomes of Phacotrabeculectomy Augmented With Mitomycin C in Patients With Advanced Glaucoma With Split Fixations

First Author: Shivam GUPTA

Co-Author(s): Devendra MAHESHWARI, Nimrita NAGDEV, Madhavi PILLAI

Purpose: To assess the surgical outcomes of phacotrabeculectomy in patients with advanced glaucoma with split fixations over 24 months.

Methods: This prospective observational study included patients with advanced glaucoma having split fixation undergoing combined phacoemulsification with Trabeculectomy. All patients were evaluated on postoperative days one, on day 15, one month, 3 months, 6 months, 12 months, and 24 months postoperatively. Baseline and follow-up visits were compared to assess significant differences in intraocular pressure (IOP), the number of antiglaucoma medications (AGM), and best-corrected visual acuity (BCVA). Other outcome measures included surgical success, complications, and interventions.

Results: 79 patients with advanced glaucoma were included. Mean IOP (mmHg) reduced from preoperative 19.59 ± 5.8 to 14.43 ± 5.8 ($p < 0.001$) at the end of 2 weeks and 14.04 ± 4.8 , 12.99 ± 4.8 , 12.35 ± 3.6 , 12.57 ± 4.2 , and 12.63 ± 4.3 at the end of one, 3, 6 months, 1 and 2 years ($p < 0.001$). The mean preoperative AGM was 1.76, which was reduced to 0.11 at 6 months and 0.22 at 2 years. Preoperatively, the BCVA was 0.60 log MAR (0.30 to 0.78), which improved to log MAR 0.18 (0 to 0.18) at 1 and 0 (0 to 0.18) 2 years postoperatively. BCVA at the third month and sixth month showed zero patients with a decline in visual acuity of ≤ 3 lines from pre-op vision. Most patients retained the same BCVA or experienced an improvement of 1 or more lines. No patients experienced the wipe-out phenomenon. Complete success was 70.9% and 64.6% using criteria

1 (IOP ≤ 18 mmHg and >5 mmHg or 30% reduction from baseline without AGM) and criteria 2 (IOP ≤ 15 mmHg and >5 mmHg or 40% reduction from baseline without AGM). Bleb needling was needed in 5 patients and 4 patients developed choroidal detachment, which resolved with conservative management.

Conclusions: Trabeculectomy has a beneficial effect in patients with severely compromised visual fields and intractable IOP. Sudden unexplained postoperative loss of vision in patients with end-stage glaucoma undergoing filtering surgery is, at most, a rare complication.

Abstract No.: 203239

Misdiagnosed Glaucoma Revealing a Suprasellar Meningioma Causing Compressive Optic Neuropathy

First Author: Tumenjargal **ERDENEBAATAR**

Co-Author(s): Sanjaadorj **GANSUKH**, Bayasgalan **PUREVDORI**

Purpose: To highlight the importance of differentiating glaucoma from compressive optic neuropathies by presenting a case of suprasellar meningioma initially misdiagnosed as glaucoma, emphasizing the role of neuro-ophthalmological evaluation in preventing delayed diagnosis and irreversible vision loss.

Methods: The patient underwent a comprehensive ophthalmic and neuro-ophthalmic evaluation, which included best-corrected visual acuity testing, slit-lamp examination, fundus evaluation, optical coherence tomography for structural assessment, and automated perimetry for functional analysis of the visual field. Standard laboratory investigations were performed to exclude endocrine dysfunction. Magnetic resonance imaging of the brain and orbits with contrast was subsequently conducted to identify possible compressive lesions affecting the optic pathways.

Results: Topical antiglaucoma therapy was discontinued. The patient was referred to neurosurgery, where the tumor was surgically resected. Histopathology confirmed a WHO grade I meningothelial meningioma. Postoperative recovery was uneventful. At one month and four months post-surgery, the patient's visual acuity improved to 6/6 bilaterally, with restoration of color vision and resolution of headaches. Follow-up visual field testing showed marked reduction of bitemporal defects.

Conclusions: Suprasellar meningiomas can masquerade as glaucoma in their early stages. This case emphasizes the importance of comprehensive evaluation for atypical glaucoma presentations. Early recognition and surgical management can lead to significant visual recovery and improved quality of life.

Mitochondria Transplantation Reduces Intraocular Pressure by Improving Mitochondrial Function and Remodeling Trabecular Meshwork

First Author: Xiaoling **WANG**

Co-Author(s): Yuanbo **LIANG**

Purpose: Mitochondria transplantation represents a promising therapeutic strategy for diseases characterized by mitochondrial dysfunction. Primary open-angle glaucoma (POAG) is characterized by trabecular meshwork's (TM) mitochondrial dysfunction, where mitochondrial impairment drives sustained intraocular pressure (IOP) elevation. Here, we describe a novel, effective approach that direct mitochondria transplantation to replenish mitochondrial quantity in TM cells.

Methods: Our study employed a comprehensive approach to investigate mitochondrial transplantation therapy, beginning with the isolation and characterization of healthy mitochondria from mouse liver. At the cellular level, we established an oxidative stress-induced trabecular meshwork (TM) cell injury model using H₂O₂, followed by therapeutic intervention with exogenous mitochondria. The treatment efficacy was systematically validated through confocal microscopy (mitochondrial uptake), flow cytometry (quantification), MTT (viability), ROS detection, and ATP measurement, complemented by mechanistic investigations via WB and proteomic analyses. These cellular findings were further confirmed in 3D TM cell cultures. In vivo, we developed a dexamethasone-induced ocular hypertensive mouse model and administered mitochondrial therapy via anterior chamber injection, subsequently evaluating therapeutic outcomes including intraocular pressure modulation, systemic safety (body weight), TM structural integrity, and mitochondrial functional recovery. This multi-level experimental design bridges fundamental mechanisms with translational potential in glaucoma treatment.

Results: This restoration included normalized cellular bioenergetics, attenuated oxidative stress, and enhanced TM cells viability. Consequently, mitochondria transplantation reinstated aqueous humor outflow capacity, remodeled TM tissues structure, and achieved IOP normalization. Mechanistically, supplemented mitochondria downregulated aberrantly elevated mitophagy-a key contributor to TM pathogenesis-thereby stabilizing cellular homeostasis.

Conclusions: Exogenous mitochondrial transplantation represents a potential therapeutic strategy for glaucoma

Abstract No.: 204469

Panel No.: GLA-0370

Morphology of Filtering Bleb After Ahmed Valve Glaucoma Surgery Using AS-OCT

First Author: Dinh Cang NGUYEN

Co-Author(s): Thi Thuy Tien PHAM, Thanh Nghiep TRANG

Purpose: To assess the morphology of filtering bleb after Ahmed valve glaucoma surgery using anterior segment optical coherence tomography (AS-OCT) and propose a classification system for bleb according to clinical and AS-OCT parameters.

Methods: A total of 48 patients who had received Ahmed valve implantation participated in this prospective study. Clinical morphology and AS-OCT parameters were measured post-operatively at 1 week, 1 month, 3 months and 6 months. The relationship between the bleb morphology and success of the surgery was evaluated. Success was defined as IOP < 21 mmHg with a maximum of 2 glaucoma medications.

Results: Photographic standards illustrating clinical bleb morphology characteristics were selected from the slit lamp images of blebs in the study. Bleb vascularity and color were significantly correlated with the hypertensive phase and surgery success ($p < 0.05$). Bleb analysis using AS-OCT revealed a significant reduction in bleb wall thickness and an increase in bleb wall reflectivity at 1 month, which was mostly associated with the hypertensive phase. There was a significant correlation between AS-OCT parameters (bleb wall thickness, bleb wall reflectivity, bleb height, microcyst) and surgery success ($p < 0.05$).

Conclusions: AS-OCT is an objective method for the assessment of bleb morphology. Clinical characteristics and AS-OCT parameters show potential as a tool to better understand, predict, and modify outcomes of Ahmed valve glaucoma surgery.

Abstract No.: 203758

Ocular Surface Changes in Primary Open-Angle Glaucoma on Anti-Glaucoma Medications Versus Treatment-Naïve Patients

First Author: Kavita BHATNAGAR

Purpose: To evaluate the effect of anti-glaucoma medications on the ocular surface using conjunctival impression cytology, AS-OCT, and conjunctival and corneal staining.

Methods: Prospective cohort study of 75 eyes of newly diagnosed patients and 77 eyes of POAG patients on anti-glaucoma medications. The follow-up period was 1 year. At each visit, Schirmer's test, TBUT, conjunctival and corneal staining, AS-OCT, and impression cytology were done.

Results: Mean values of lissamine green & rose bengal staining in newly diagnosed POAG patients and patients on anti-glaucoma medications were 0.05 ± 0.0228 , 0.23 ± 0.424 , 0.59 ± 0.526 , and 0.77 ± 0.602 , respectively (p -value < 0.05). Patients on anti-glaucoma medications for > 5 years showed pleomorphic changes and decreased goblet cell density (p -value < 0.05). Values of TMH, TMD, and TMA on AS-OCT showed statistically significant changes in patients on anti-glaucoma medications. Patients on more than 3 drops showed statistically significant ocular surface changes.

Conclusions: Long-term anti-glaucoma medication causes significant damage to the ocular surface.

Panel No.: GLA-0369

Ocular Surface Disease Management in Glaucoma Treatment

First Author: Dinh Cang NGUYEN

Co-Author(s): Thanh Nghiep TRANG

Purpose: To determine the pathophysiology of ocular surface inflammation (OSI) in glaucoma medical therapy and its effect on the treatment outcome. To propose new updates on the management of ocular surface disease (OSD) and innovation of glaucoma treatment.

Methods: We reviewed 3 clinical cases of glaucoma patients with OSD, which affects the treatment outcome. By that, we discussed pathophysiology on current literature of OSI caused by glaucoma medical therapy. The updates on management of OSD: preservative-free medications, OSI treatment were analysed.

Results: Case 1: A glaucoma patient with resolved OSD by switching from medical therapy to SLT treatment. Case 2: A patient with advanced glaucoma had improved ocular outcome by iStent implantation and preservative-free medication. Case 3: A patient with an Ahmed valve implantation had an overgrowth bleb resulting from severe OSI.

Conclusions: We proposed OSD to be a concurring diagnosis and monitoring factor of glaucoma. The inflammation affects the treatment outcome by reducing patient adherence, medication efficacy, and worsening post-operative wound healing. Preservative-free medication, MIGs, and addressing the underlying OSI were recommended recently by expert consensus.

Abstract No.: 205305**Panel No.: GLA-0384**

One-Year Outcomes of 5–0 Prolene Suture Gonioscopy-Assisted Transluminal Trabeculotomy in Juvenile Open-Angle Glaucoma

*First Author: Madhavi PILLAI**Co-Author(s): Shivam GUPTA, Devendra MAHESHWARI*

Purpose: To study the surgical outcomes of suture GATT in JOAG.

Methods: Prospective, non-randomised, interventional study. JOAG patients underwent GATT & followed up at 1 week, 1, 3, 6 months, and 1 year. Outcome measures were IOP, AGM, BCVA, Surgical success, and complications.

Results: Thirty eyes (26 patients) 11(mild-moderate-Group 1) 19-severe (Group 2) JOAG were included. Mean IOP reduced from 23.43 ± 9.65 to 13.27 ± 4.54 ($p=0.002$) in grp 1 & 23.26 ± 9.80 to 14.10 ± 8.32 at 1 year in grp 2. Mean AGM reduced from 2.89 ± 0.94 to 0.74 ± 0.81 & 3 ± 0.77 to 0.91 ± 1.30 ($p<0.001$) in group 1 & 2. Mean IOP reduction was 36.3% & 28.7% at 1 year. Complete success (IOP ≥ 6 & ≤ 21 mmHg & $\geq 20\%$ IOP reduction without AGM) was seen in 63.6% (30.0 – 84.5) & 73.7% (47.9 – 88.1) (Grp 1&2). 63.6% and 47.4% in each group remained medication free. Microhyphema (<1 mm) was the most common complication (6 patients), which resolved by the end of one week, with the need for AC wash in two cases.

Conclusions: GATT is a safe & efficacious procedure in JOAG, with good surgical success & IOP reduction.

Abstract No.: 205303**Panel No.: GLA-0387**

One-Year Outcomes of Standalone 5-0 Prolene Suture GATT in Advanced Open-Angle Glaucoma

*First Author: Madhavi PILLAI**Co-Author(s): Devendra MAHESHWARI, Nimrita NAGDEV*

Purpose: Surgical Outcomes of GATT in advanced POAG.

Methods: Prospective, interventional. Outcomes of GATT in advanced POAG. Fifty-one eyes of advanced POAG pts who underwent standalone GATT were included & followed for 2 weeks, 1, 3, 6, & 12 months. Outcome measures were changes in IOP, BCVA, AGM, Surgical success & complications. Complete success was defined as IOP ≤ 18 mmHg & 25% reduction without AGM.

Results: Baseline MD was $-19.18(10.06)$. Mean(SD) IOP decreased from 20.73 ± 8.98 to 14.59 ± 5.7 , 14.18 ± 5.2 , 15.24 ± 8.06 ($P<0.001$) at 3, 6, 12 mo. AGM reduced from 3.24 ± 0.8 to 1.08 ± 1.41 , 0.96 ± 1.3 , 1.0 ± 1.47 ($p<0.001$) at 3, 6, 12 months. The

percentage reduction in IOP was 16.8% at 1 year & 58.8% of pts remained medication-free. Cumulative probability of overall success was 54.9% 2 patients had IOP spikes, 2 patients had microhyphema, and 1 patient had macrohyphema requiring AC wash.

Conclusions: GATT is safe and effective, with good IOP reduction and medication burden in advanced open-angle glaucoma. GATT offers substantial pressure control with a reduced medication burden, underscoring its potential to serve as a standalone procedure in advanced POAG.

Abstract No.: 205581**Panel No.: GLA-0395**

Optic Disc Swelling in Acute Primary Angle Closure: Risk Factors and Longitudinal OCT Changes

First Author: Sung Uk BAEK

Purpose: To identify clinical risk factors associated with optic disc swelling (ODS) in acute primary angle-closure glaucoma (AACG) and to evaluate longitudinal structural changes in the retinal nerve fiber layer (RNFL) and ganglion cell-inner plexiform layer (GCIPL) using optical coherence tomography (OCT).

Methods: A prospective study was conducted on 102 eyes from AACG patients who underwent laser iridotomy (LI) and had at least years of follow-up. Patients were classified into ODS and control groups based on optic disc appearance and OCT findings. Risk factors were analyzed using multivariate logistic regression. RNFL and GCIPL thicknesses were measured at six time points post-LI. Thinning rates were calculated for short-term (1 week–6 months) and long-term (6 months–2 years) periods and compared between groups.

Results: ODS was identified in 42 eyes. Larger pupil diameter (odds ratio = 15.23) and longer symptom duration (odds ratio = 2.03) were independently associated with ODS. Mean IOP was consistently <16 mmHg in both groups at any time point, yet ODS eyes showed RNFL thickening followed by sustained thinning, whereas GCIPL thickness declined continuously. From 6 months to 2 years, RNFL thinning averaged $-2.86 \mu\text{m}/\text{year}$ in ODS vs. $-0.77 \mu\text{m}/\text{year}$ in controls; GCIPL thinning was -1.27 vs. $-0.69 \mu\text{m}/\text{year}$. Fellow eyes showed no differences in RNFL or GCIPL thinning rates between groups.

Conclusions: ODS in AACG is linked to delayed treatment and larger pupil size, suggesting more severe ischemic stress. ODS eyes exhibit sustained structural loss despite IOP control, highlighting the need for early intervention and tailored follow-up strategies.

Abstract No.: 205425

Optical Coherence Tomography Artifacts in Pathologic Myopia: Prevalence and Impact on Glaucoma Diagnosis

First Author: Yuzhou XIANG

Co-Author(s): Ying HAN, Jing HUANG, Jingjing HUANG, Nan LUO, Litong YE

Purpose: To investigate the prevalence of peripapillary retinal nerve fiber layer thickness (pRNFLT) and Bruch's membrane opening-minimum rim width (BMO-MRW) artifacts in pathologic myopia (PM) and the impact of artifacts on the diagnostic ability for open-angle glaucoma (OAG).

Methods: This cross-sectional study was conducted at Zhongshan Ophthalmic Center. PM eyes were divided into two groups based on OAG diagnosis. Artifacts of pRNFLT and BMO-MRW were classified, and their prevalences were compared. The diagnostic ability of pRNFLT and BMO-MRW for OAG was compared before and after the inclusion of eyes with artifacts.

Results: A total of 136 participants with PM were included, with a median age of 49 years and mean axial length of 28.03 mm. Seventy-four (54.4%) eyes were diagnosed as OAG. Seven and three types of pRNFLT and BMO-MRW artifacts were observed, respectively. Presence of pRNFLT artifacts was identified in 74.2% of eyes in PM group and 63.5% of eyes in PM with OAG (PMG) group, which was more prevalent than BMO-MRW artifacts (27.4% in PM group and 4.1% in PMG group, both $P < 0.001$). Before and after including eyes with artifacts, the AUC of global RNFLT decreased from 0.927 to 0.869, and the AUC of global BMO-MRW slightly decreased from 0.884 to 0.882.

Conclusions: Artifacts of pRNFLT were more complex and prevalent than those of BMO-MRW. In PM, the diagnostic ability of pRNFLT and BMO-MRW were comparable when artifacts were considered.

Panel No.: GLA-0380

Outcomes and Comparison of Trabeculectomy and Ahmed Glaucoma Valve Implant (AGV) in Eyes With In Situ Silicone Oil: A Retrospective Study

First Author: Smita PANDA

Co-Author(s): Parivadhini A, Baskaran M, Amritha P, Rathini DAVID

Purpose: To compare outcomes of trabeculectomy + Mitomycin -C and Ahmed glaucoma valve (AGV) implantation in eyes undergoing silicon oil insertion or in eyes with in situ silicone oil (SIO), without concurrent oil removal.

Methods: Records of patients with uncontrolled glaucoma and SIO undergoing trabeculectomy (Group

A) or AGV implantation (Group B) with ≥ 2 months' follow-up were retrospectively reviewed. Surgical success was defined as intraocular pressure (IOP) ≤ 21 mmHg $\pm$ antiglaucoma medications (AGMs).

Results: Thirty-two eyes of 32 patients were included (Group A: 21; Group B: 11). Mean age was 45.9 years in Group A, 42 years in Group B. Post-vitreotomy glaucoma was the most common etiology. At 2 months, mean IOP reduced from 30.7(13.5) to 22.0(10.7) mmHg in Group A ($p = 0.02$) and from 32.2(11.6) to 15.6(6.0) mmHg in Group B ($p = 0.003$). Mean AGMs decreased from 3.19(0.86) to 0.57(0.95) in Group A and from 3.72(0.8) to 1.27(0.7) in Group B ($p < 0.001$). At 6 months, mean IOP was 18.2(4.7) mmHg {1.5(1.5) AGMs} in Group A and 14.6(5.7) mmHg {1.53(1.2) AGMs} in Group B, with no significant intergroup difference. Surgical success at 2 months was 71.4% (Group A) and 90.9% (Group B). One-year cumulative success probability was 55% versus 71%, respectively. Five trabeculectomy eyes and 1 AGV eye required re-surgery. Silicone oil migration into the anterior chamber occurred in three AGV eyes.

Conclusions: Both procedures provided modestly effective IOP reduction in glaucomatous eyes with in situ SIO. AGV showed a higher trend of surgical success.

Outcomes of Ahmed Clear Path vs Aurolab Aqueous Drainage Implant in Refractory Glaucoma

First Author: Disha CHETANI

Co-Author(s): Sushmita KAUSHIK, Surinder Singh PANDAV, Srishti RAJ, Faisal THATTARUTHODY

Purpose: To compare the interim surgical outcomes of the Ahmed Clear Path (ACP) 250 mm² and Aurolab Aqueous Drainage Implant (AADI) 250 mm² in refractory glaucoma.

Methods: This prospective quasi-experimental trial included patients with uncontrolled intraocular pressure (IOP) despite maximally tolerated medical therapy or failed prior filtration surgery. Eyes were allocated to ACP or AADI based on affordability and patient preference. All procedures were performed by a single surgeon using standardized techniques with adjunctive Ripcord removal at 6–8 weeks. Primary endpoints were mean IOP and antiglaucoma medication (AGM) reduction at 3 months. Secondary outcomes included complete success (IOP 6–21 mmHg without AGMs), qualified success (IOP 6–21 mmHg with ≤ 2 AGMs), complications, and early postoperative interventions.

Results: Thirty-nine eyes (19 ACP, 20 AADI) were analysed. Baseline demographics and IOP were comparable. At 3 months, the mean IOP was 15.5 ± 3.5 mmHg in the ACP group and 13.9 ± 3.0 mmHg in the AADI group ($p = 0.19$). Mean AGM use was 1.6 ± 1.2

vs. 1.8 ± 0.9 , respectively ($p = 0.61$). Rates of complete and qualified success were similar between groups. One ACP eye developed endophthalmitis, while one AADI eye progressed to no perception of light due to hypotony-related complications.

Conclusions: Both ACP and AADI implants achieved significant IOP reduction, decreased medication burden, and demonstrated acceptable safety at 3 months. Outcomes were comparable between groups, supporting AADI-250 mm² as a cost-effective alternative to ACP in resource-limited settings. Device choice may thus be guided by availability, affordability, and surgeon preference.

Outcomes of High-Dose MMC(40µg) Augmented Bleb Needling After Failed/Failing Filtering Procedures

First Author: Shivam GUPTA

Co-Author(s): Devendra MAHESHWARI, Nimrita NAGDEV, Madhavi PILLAI

Purpose: Evaluate outcomes of bleb needling with high-dose (40µg) subconjunctival MMC after failing/failed filtering procedures

Methods: Prospective, interventional study. Pts who had raised IOP following filtering procedures, flat bleb, encapsulation, &/or requiring AGM were included. Outcome measures were AGM, IOP, BCVA, and success rate.

Results: Fifty-two eyes (52 pts) were included. Mean time to needling was 6.77 months & mean glaucoma duration was 2.92 years. IOP decreased from mean (SD) 25.56(6.78)mmHg to 13.65(4.58), 15.13(3.66), 15.42(4.23), 14.74(4.28) at 1,3,6,12 months ($p < .0001$) & AGM 2.02(0.96) to 0.17(0.47), 0.48(0.73), 0.85(0.94), 1.10(0.98) at 1,3,6,12 months ($p < .0001$). Complete success (IOP $>5 \leq 21$ mmHg without AGM) 95.8, 87.5 & 74.4% at 3,6,12 months. Overall success was 98.1, 94.2 & 88.3% at 3,6,12 months. No significant complication was noted. 3 patients required GDD implantation.

Conclusions: Bleb needling with high-dose MMC appears to be a viable option for salvaging failing/failed filtration without compromising safety.

Outcomes of Interventional Valve-Enhancing Trabeculotomy (iVenT) – a Novel TM Sparing MIGS

First Author: Devendra MAHESHWARI

Co-Author(s): Nimrita NAGDEV, Madhavi PILLAI

Purpose: Outcomes of phaco-iVenT in open-angle glaucoma.

Methods: A novel surgical technique, iVenT (Interventional valve-enhancing trabeculotomy), leverages motion-dependent outflow. It utilises a unique spatula to create a tiny vent in the anterior non-filtering part of the Trabecular meshwork. The key benefit of this technique is the unharmed Trabecular meshwork and minimal damage to the intracanalicular valve system. A total of 106 eyes (53 Phaco-Grp 1, 53 iVenT-phaco-Grp 2) were included & followed for 2 weeks, 1, 3, 6 & 12 months. A unique spatula is used to create a tiny vent in the anterior non-filtering TM, enhancing pulsatile outflow. Outcome measures were IOP, BCVA, AGM, surgical success, and complications. Surgical success was defined as IOP $\leq 21/\leq 18/\leq 15$ with $>20\%$, 25%, 30% reduction (Criteria 1,2,3).

Results: Mean IOP decreased from 24.0 ± 6.1 to 16.4 ± 3.7 , 18.04 ± 3.7 , 18.7 ± 3.6 with 19.1% redn in Group 1, and from 21.28 ± 4.2 to 13.2 ± 3.2 , 13.8 ± 3.2 , 13.7 ± 2.8 with 33.8% redn in Group 2 at 3,6,12mo, with significant differences between groups ($p < 0.001$). AGM changed from 1.35 ± 0.5 to 1.55 ± 0.7 ($p = .010$) & 1.7 ± 0.9 to 0.04 ± 0.19 in Grp 2 ($p < 0.001$). Cumulative probability of overall success in Grp1 was 60.4%, 41.5%, 17.9% & Grp2 77.4%, 69.8%, 54.7% ($p = 0.045, 0.002, < 0.001$) by Criteria 1, 2, 3. 4 pts (Group1) & 2 (Group2) had IOP spikes, micro hyphema (2-Grp 2). The conclusion is that iVenT with Phaco is safe & efficacious in OAG.

Conclusions: iVenT adds a unique and novel TM sparing procedure to the MIGS armamentarium. It leverages physiological mechanisms—specifically enhancing pulsatile aqueous outflow via inward and posterior displacement of the scleral spur while maintaining TM integrity.

Abstract No.: 206486

Panel No.: GLA-0421

Outcomes of Pars Plana Placement of Aurolab Aqueous Drainage Implant in Neovascular Glaucoma in Indian Eyes

First Author: Shivam GUPTA

Co-Author(s): Devendra MAHESHWARI, Nimrita NAGDEV, Madhavi PILLAI

Purpose: To study the outcomes of pars plana placement of Aurolab Aqueous Drainage Implant (AADI) in neovascular glaucoma (NVG).

Methods: The medical data of NVG patients (28 eyes) who underwent AADI implantation were retrospectively analyzed.

Results: Mean IOP reduced from preoperative 46.21 ± 8.6 mmHg to 32.07 ± 13.0 mmHg, 23.08 ± 12.8 mmHg, 21.00 ± 14.4 mmHg, and 22.67 ± 19.5 mmHg at 2 weeks, 6 weeks, 6 months, and 12 months, respectively. The mean number of AGM reduced from 3 preoperative to 2.42, 1.37, 1.55, and 1.65 at 2 weeks, 6 weeks, 6 months, and 12 months, respectively. The

BCVA was stabilized or improved in 54% of the eyes at 2 months, and in 66.6% of the eyes at the end of 12 months. Complete success was 50% and 37.5% (using criteria 1: IOP $\leq$ 18 mmHg or 30% reduction from the baseline without AGM, and criteria 2: IOP $\leq$ 15 mmHg or $\geq$ 5 mmHg or 40% reduction from baseline without AGM, respectively) after 12 months. Qualified success was seen in 83.3% and 72.2% (using criteria 1: IOP $\leq$ 18 mmHg or 30% reduction from the baseline with AGM, and criteria 2: IOP $\leq$ 15 mmHg or $\geq$ 5 mmHg or 40% reduction from baseline with AGM, respectively) of patients after 12 months.

Conclusions: This study demonstrates surgical success with the pars plana placement of the AADI in NVG in terms of IOP control and visual acuity.

Abstract No.: 202416

Panel No.: GLA-0343

Outcomes of Phacoemulsification Combined With Endoscopic Cyclophotocoagulation and iStent, in Open-Angle Glaucoma: A Meta-Analysis

First Author: Sheng Yang LIM

Co-Author(s): Bryan Chin Hou ANG, Bjorn Kaijun BETZLER, Angeline Rui Xi LAI, Nicole Xin Yi LEE, Krystal Valerie Qian Ying SOH

Purpose: This systematic review and meta-analysis (SRMA) evaluates the efficacy and safety of the combined Phacoemulsification-iStent-Endoscopic Cyclophotocoagulation (ICE) procedure in the management of open-angle glaucoma (OAG), which has been proposed to have synergistic effects for enhanced outcomes.

Methods: A literature search was performed on Embase, PubMed, and Cochrane Library from inception until 13 September 2024. All pilot, cohort, observational studies, and randomised controlled trials including subjects undergoing ICE for OAG were included. Meta-analysis of continuous outcomes was performed using the meta routine in R version 4.3.1.

Results: Four studies were included, with three studies (199 eyes) contributing to the meta-analysis. Results demonstrated statistically significant reductions in both mean IOP and anti-glaucoma medication (AGM) use at all timepoints up to 12 months post-operatively. The greatest effect was observed at 12 months, showing a mean IOP reduction of 5.28 mmHg (95%CI:1.93–8.63; $p < 0.05$) and a decrease of 0.77 AGMs (95%CI:0.50–1.04; $p < 0.05$). Safety outcomes were favourable, with the most common complication being transient IOP spikes ($< 5\%$), which resolved without significant sequelae.

Conclusions: The ICE procedure delivers sustained reductions in both mean IOP and medication burden for OAG patients, while maintaining an excellent safety profile, at least up to 12 months post-operatively.

The favourable outcomes may be attributed to the complementary mechanisms of both iStent implantation and ECP, the conjunctival-sparing nature of the procedure and preservation of the physiological aqueous outflow pathway.

Abstract No.: 205677

Panel No.: GLA-0398

Outcomes of the Paul Glaucoma Implant vs the Ahmed ClearPath Implant: A Systematic Review

First Author: Umair QIDWAI

Co-Author(s): Mariam ZEHRA, Muhammad Faisal Fahim, Shahmeer Hamid, Thiri Nyan Coe

Purpose: To systematically compare the clinical outcomes of two modern non-valved glaucoma drainage devices—the Paul Glaucoma Implant (PGI) and Ahmed ClearPath (ACP)—in patients with refractory glaucoma.

Methods: A systematic review was conducted according to PRISMA guidelines and registered with the Open Science Framework. Searches of PubMed, Scopus, Google Scholar, and Cochrane Library were performed up to January 2025, using terms related to PGI, ACP, and glaucoma drainage devices. Studies were included if they reported intraocular pressure (IOP) outcomes, success rates, or complication profiles for PGI or ACP. Data were extracted on patient demographics, surgical techniques, IOP and medication changes, complications, and follow-up durations. Methodological quality was assessed using the AXIS tool.

Results: Twenty-one studies (16 PGI, 5 ACP) met inclusion criteria. Both implants significantly reduced IOP from a preoperative mean of ~ 29 – 30 mmHg to ~ 12 – 14 mmHg at 12–24 months (~ 50 – 60% reduction). PGI recipients had a higher likelihood of achieving medication-free success (55–60%) compared to ACP (~ 40 – 45%). Complication rates were low and comparable, with transient hypotony ($\sim 10\%$), hyphema (slightly higher in ACP), and tube-related issues being rare ($< 3\%$). The PGI was more widely studied in pediatric and complex glaucomas, while ACP data were predominantly adult-based. Postoperative flow modulation (e.g., ripcord removal) was more commonly reported in PGI studies.

Conclusions: Both PGI and ACP are effective and safe for managing refractory glaucoma, offering significant IOP reduction with low complication rates. The PGI demonstrates broader applicability across age groups and a greater likelihood of medication independence, while the ACP offers comparable outcomes in adult populations. Further head-to-head trials and longer-term studies are needed to clarify their relative advantages.

Abstract No.: 206026**Panel No.: GLA-0409****Overlapping Phakomatoses With Secondary Glaucoma: A Rare Presentation***First Author: Rajat Mohan SRIVASTAVA**Co-Author(s): Siddharth AGRAWAL, Farheen ANSARI, Aradhna MISRA*

Purpose: To showcase an interesting and rare case of an adolescent male presenting to us with advanced glaucoma, along with overlapping clinical features of Sturge Weber and Klippel-Trenaunay Syndromes.

Methods: Descriptive case report. We describe the clinico-radiological profile and management of a patient with secondary glaucoma having overlapping clinical features of Sturge Weber Syndrome (SWS) and Klippel-Trenaunay Syndrome (KTS).

Results: A teenager with a history of seizures, presented with bilateral facial port-wine stain with hypertrophy of the left side of the face associated with ipsilateral advanced glaucomatous neuropathy. The port-wine stain was also present over the left side of the neck, shoulder, chest, and upper back. Additionally, the right lower limb had prominent dilated and tortuous veins with soft tissue hypertrophy of the limb. Patient was diagnosed with bilateral (L>R) Secondary Glaucoma with coexisting SWS & KTS. The intra-ocular pressures (IOP) remained uncontrolled even on maximal therapy in the left eye, which was subsequently managed with Mitomycin-C augmented trabeculectomy. At the 1-year follow-up, intraocular pressure is controlled with two antiglaucoma medications in each eye.

Conclusions: Multiple co-existing phakomatosis is rare but should be suspected, especially in the presence of bilateral extensive facial port-wine stain with underlying tissue hypertrophy. A primary trabeculectomy is a good option in managing advanced glaucoma in such cases.

Abstract No.: 203585**Panel No.: GLA-0361****Pattern of RNFL Damage in Early- and Late-Stage Primary Open-Angle Glaucoma Using the Disc Damage Likelihood Scale and Optical Coherence Tomography***First Author: Noor UL AIN**Co-Author(s): Tayyaba GUL MALIK*

Purpose: To determine patterns of the peripapillary retinal nerve fiber layer (RNFL) damage in early- and late-stage glaucoma based on the Disc Damage Likelihood Scale (DDLS).

Methods: This cross-sectional, multi-center study involved 267 eyes of 135 patients aged 18 years or older with suspected or diagnosed glaucoma. Exclusion criteria were high refractive errors, media opacities, trauma history, and systemic conditions

affecting the optic disc. After a comprehensive ocular examination, the DDLS was used for glaucoma staging. Disease severity was classified into three zones: green, orange, and red. RNFL thickness was measured in four quadrants using optical coherence tomography. Patterns of RNFL damage were analyzed, especially in terms of the ISNT (inferior>superior>nasal>temporal) rule, and compared between the three groups.

Results: The male-to-female ratio was 1.59:1 and the mean age was 45.12±15.76 years. There were statistically significant differences among the groups for average, inferior, superior, and temporal RNFL thickness ($p<0.00001$). However, the difference in nasal RNFL was insignificant. The ISNT rule was the commonest pattern in the study participants (64.4%) and progressive loss of pattern was observed with increased disease severity.

Conclusions: This study revealed an association between disease severity and RNFL thinning in the inferior, superior, and temporal quadrants, while nasal RNFL showed no significant association with disease severity. The ISNT rule was more frequently observed in the early stages and diminished with advanced glaucoma. These results highlight RNFL thinning based on the DDLS as an important marker for glaucoma monitoring

Abstract No.: 205127**Panel No.: GLA-0377****Portability, Precision, and Patient Experience: A Systematic Review Comparing Virtual Reality Perimetry to the Humphrey Gold Standard for Expanding Global Glaucoma Accessibility***First Author: Tiara DZULKARNAIN**Co-Author(s): Ardiella YUNARD*

Purpose: Glaucoma is projected to affect 112 million people by 2040, highlighting the urgent need for precise and accessible diagnostic tools. Visual field (VF) testing is indispensable for diagnosis and monitoring. The Humphrey Field Analyzer (HFA) is the current gold standard, but its bulk, cost, and immobility restrict accessibility, particularly in low-resource settings. HFA testing is also lengthy and fatiguing, reducing patient compliance. This systematic review compared the performance of virtual reality perimetry (VRP) with HFA across key outcomes.

Methods: A total of 20 studies directly comparing VRP with HFA were reviewed, involving adults with diagnosed or suspected glaucoma and healthy participants. The primary outcome was diagnostic accuracy, while secondary outcomes included test-retest reliability, patient acceptability, test duration, and feasibility. Owing to study heterogeneity, results were synthesized narratively.

Results: VRP demonstrated strong diagnostic precision with good agreement to HFA across global indices. Multiple studies reported high correlations. VRP consistently offered superior patient experience, with greater comfort, shorter fatigue, and reduced anxiety compared to HFA. Devices were lightweight, portable, and feasible for bedside, at-home, or community clinic use, offering critical flexibility to improve access in underserved and resource-limited regions.

Conclusions: VRP stands out as a highly promising alternative to HFA for VF testing, pairing solid diagnostic accuracy with portability and patient-friendly design. Though still complementary at this stage, VRP's unique potential to bring glaucoma monitoring directly into underserved communities makes it a powerful step toward more accessible, patient-centered eye care, awaiting validation in larger, long-term studies.

Postoperative Complications of iStent Inject Combined With Phacoemulsification in Asian Eyes With Glaucoma: Findings From a Systematic Review and Meta-Analysis

First Author: Masaru INATANI

Co-Author(s): Poemen CHAN, Wungrak CHOI, Alice CHU, Ashley REHN, Vivien Cherng-hui YIP

Purpose: To estimate the incidence rates of postoperative complications following implantation of iStent inject/iStent inject W combined with phacoemulsification in Asian eyes with glaucoma.

Methods: We systematically searched MEDLINE, Embase, Cochrane Library, and Web of Science through July 2025 for observational, interventional, and economic studies of iStent inject®, iStent inject® W, or iStent infinite® implanted either as a combined or standalone procedure in Asian patients with glaucoma, with ≥6 months of follow-up. Extracted outcomes included pre- and postoperative mean intraocular pressure, mean number of glaucoma medications, proportion of eyes meeting success criteria, frequency of complications and reinterventions, and economic results. This abstract reports pooled safety findings.

Results: Eighteen studies, including one cost-effectiveness analysis, contributed data from 1,140 eyes that all had combined procedures (60% implanted with iStent inject W), representing 1,162 eye-years of follow-up. The pooled incidence rate of postoperative complications was 14.4 events per 100 eye-years (95% CI, 10.4-20.1; $I^2=70.9\%$). Stent obstruction was the most frequent complication (6.2 events per 100 eye-years; 95% CI, 3.4-11.3; $I^2=51.6\%$). Of 153 postoperative complication events, 43% were considered mild/transient, and 31% stent-related. Additional glaucoma surgery was uncommon (1.6 events per 100 eye-years; 95% CI, 1.0-2.8; $I^2=0.0\%$).

Conclusions: In Asian eyes with glaucoma, combined iStent inject/iStent inject W had manageable postoperative adverse events with minimal failures. This systematic literature review supports the safety value proposition of iStent technologies.

Postoperative Outcomes of Microhook Trabeculotomy Using the Matsushita TMH Device

First Author: Rumi KAWASHIMA

Co-Author(s): Takahiro FUJINO, Kenji MATSUSHITA, Kohji NISHIDA, Tomoyuki OKAZAKI, Shinichi USUI

Purpose: To evaluate 3-year outcomes of microhook trabeculotomy (μ LOT) performed with the Matsushita-Tanito microhook trabeculotomy device (Matsushita TMH device) developed by our group.

Methods: Retrospective cohort study. Additional intraocular pressure (IOP)–lowering therapy was permitted as clinically indicated and recorded. Surgical “failure” was defined as a composite of (Definition 1) loss of light perception or IOP ≥ 22 mmHg on two consecutive visits ≥ 1 month after surgery, and (Definition 2) loss of light perception or IOP ≥ 17 mmHg on two consecutive visits ≥ 1 month after surgery. Changes in IOP and topical medication score over 3 years were analyzed using Dunnett’s test.

Results: Baseline diagnoses were primary open-angle glaucoma (POAG) in 17.0% and secondary glaucoma (SG) in 83.0%. Over 3 years, both IOP and topical medication scores decreased significantly ($p<0.01$). Kaplan–Meier survival at 1, 2, and 3 years was 62.3%, 52.8%, and 47.2% by Definition 1, and 40.8%, 35.0%, and 31.1% by Definition 2. Additionally, IOP-lowering therapy was required in 25 eyes (47.2%). Early postoperative events included hyphema in 14 eyes (26.4%), vitreous hemorrhage in 3 eyes (5.7%), and transient IOP elevation within 2 weeks in 28 eyes (52.8%).

Conclusions: μ LOT using the Matsushita TMH device achieved sustained reductions in IOP and medication burden over 3 years with an acceptable safety profile. Three-year survival ranged from 31.1% to 47.2% depending on the failure definition employed.

Abstract No.: 206955

Postoperative Outcomes of PreserFlo MicroShunt Surgery

First Author: Shinichi USUI

Co-Author(s): Yuto HASEGAWA, Rumi KAWASHIMA, Kenji MATSUSHITA, Kohji NISHIDA, Tomoyuki OKAZAKI

Purpose: To evaluate postoperative outcomes of PreserFlo MicroShunt (PMS) surgery.

Methods: We retrospectively analyzed 249 eyes that underwent initial PMS surgery at the University of Osaka Hospital between March 2023 and March 2025, with at least one month of follow-up. Parameters included intraocular pressure (IOP), medication score up to 24 months, glaucoma subtype, combined cataract surgery, stent placements. The surgical success rate was evaluated using Kaplan–Meier survival curves.

Results: Mean age was 70.2 ± 12.5 years. Diagnoses included primary open-angle glaucoma (POAG, 72%), exfoliation glaucoma (XFG, 16%), and secondary glaucoma (SG, 12%). Phakic eyes accounted for 38%, pseudophakic 60%, with 13% undergoing combined cataract surgery. Nylon stents were placed in 28% of cases and removed at 16.0 ± 14.5 days postoperatively. IOP and medication scores decreased significantly from baseline (21.1 ± 7.7 mmHg, 4.12 ± 1.25) to 1 month (11.1 ± 4.7 mmHg, 0.04 ± 0.28), and remained reduced through 24 months. The surgical success rate was lower for combined procedures involving lens reconstruction compared to standalone surgeries. Among glaucoma subtypes, eyes with XFG tended to have lower success rates than those with POAG. Additionally, eyes with stent implantation demonstrated better control of early postoperative hypotony and showed reduced incidence of shallow anterior chamber and choroidal detachment.

Conclusions: PMS is an effective surgical option; however, glaucoma subtype and combined cataract surgery may influence postoperative intraocular pressure. Furthermore, stent implantation helps suppress early postoperative hypotony and reduces the risk of associated complications.

Primary Ovarian Failure and the Risk of Glaucoma: Evidence From a Large Real-World Cohort

First Author: Chien-yun TSAI

Purpose: To investigate the association between primary ovarian failure (POF) and the subsequent risk of primary open-angle glaucoma (POAG) and ocular hypertension (OHT).

Methods: We conducted a retrospective cohort study using the TriNetX Global Research Network. Female patients aged ≥ 18 years with a diagnosis of POF (ICD-10-CM E28.3) were included as the exposure cohort. Controls were women with gynecological examinations but without POF, matched 1:1 by propensity scores for demographics and comorbidities. Patients with prior glaucoma, anti-glaucoma medication use, or other retinal disorders before the index date were excluded. Outcomes were incident POAG and OHT. Kaplan–Meier survival analysis and Cox proportional hazards regression were performed.

Results: A total of 31,783 women with POF were matched to 31,783 controls. Women with POF exhibited a significantly higher risk of POAG (HR: 1.71, 95% CI: 1.31–2.25). Likewise, the risk of OHT was also increased in the POF group (HR: 1.77, 95% CI: 1.36–2.32).

Conclusions: Primary ovarian failure was associated with a significantly higher risk of POAG and a trend toward increased risk of OHT. These findings suggest that estrogen deficiency and related hormonal dysregulation in women with POF may contribute to glaucoma susceptibility, highlighting the importance of regular ophthalmic surveillance in this population.

Profile of Secondary Glaucoma and Ocular Hypertension Following Retina Procedures Referred to the Glaucoma Clinic in a Tertiary Institution in the Philippines

First Author: Lee Tomas TAN

Co-Author(s): Nilo Vincent FLORCRUZ, Cesar PEREZ

Purpose: To provide valuable insights into the epidemiology, risk factors, and management of secondary glaucoma and ocular hypertension following retina procedures in the Filipino population, ultimately improving patient care and outcomes.

Methods: The study will be an epidemiologic study involving patients of the Section of Glaucoma in a tertiary hospital in the Philippines. The charts of glaucoma patients managed at out patient clinic from January 2022 to December 2024 will be reviewed. All charts to be review are electronic medical records.

Results: Among the 95 patients referred to the glaucoma clinic for secondary glaucoma or ocular hypertension, the majority were diagnosed with secondary open-angle glaucoma. The mean age of the cohort was 49. The most common underlying retinal diagnosis preceding glaucoma was rhegmatogenous retinal detachment. Only a minority required glaucoma surgery, with 64.21% not undergoing any surgical intervention. The most common procedure was implantation of a glaucoma drainage device.

Conclusions: Secondary open-angle glaucoma was the most common diagnosis among patients referred after retina procedures, followed by angle closure glaucoma and ocular hypertension. Patients were generally middle-aged, with significant visual impairment at the time of referral and advanced optic nerve damage as reflected in high cup-to-disc ratios. Most referrals occurred late, often more than a year after the initial retina intervention and were primarily due to uncontrolled IOP. Despite these measures, a large proportion of patients presented with poor baseline visual acuity, underscoring the advanced stage of

disease at referral and the complexity of managing secondary glaucoma in this setting

Quantitative Assessment of Retinal Parameters and Differential Diagnosis in Highly Myopic Glaucoma Using Deep Learning

First Author: Xiaohong CHEN

Co-Author(s): Zhidong LI, Lin LV, Yingting ZHU, Yehong ZHUO

Purpose: Despite the increasing incidence of highly myopic glaucoma (HMG) and its severe impairment to vision, the diagnostic parameters for early detection are lacking owing to atypical retinal deformation. Therefore, we aimed to assess retinal parameters quantitatively for discovering early signs and diagnostic markers.

Methods: This retrospective cross-sectional study recruited 256 color fundus photographs from 176 patients at Zhongshan Ophthalmic Center. Using a deep-learning-based algorithm, the retinal optic disc parameters, retinal vessel caliber, and the fundus tessellated density (FTD) were separately analyzed. FTD was quantified as the average exposed choroid area per unit area on fundus photographs. The tessellated fundus (Category 1) was defined based on the META-analysis for Pathologic Myopia classification system. Correlation analyses were performed to evaluate the parameters in association with axial length (AL) and visual field mean deviation (VFMD). Multivariate linear and logistic regression models were used to evaluate the differences between groups. Diagnostic efficacy was analyzed using the area under the curve (AUC).

Results: In the HMG fundus photographs, longer AL was correlated with increased vertical-disc diameter ($\beta = 0.002$) and inferior neuroretinal-rim widths (NRW, $\beta = 0.004$), while lower VFMD was associated with larger vertical cup diameter ($\beta = -0.008$) and vertical cup-disc ratio (VCDR, $\beta = -14.427$) but narrower superior NRW ($\beta = 0.019$, all $P < 0.05$). Compared to highly myopic (HM) eyes, a VCDR ≥ 0.48 (AUC, 0.88) had a 23.71-fold risk of being HMG. Besides, the retinal calibers including arteriolar diameter (AD), venular diameter (VD), vessel density and fractal dimension (FD) were negatively correlated with AL in HMG ($-0.485 \leq r \leq -0.260$, all $p \leq 0.05$). Negative VD-VCDR ($r = -0.304$, $p = 0.018$) and positive arterio-to-venule ratio (AVR)-VCDR correlations ($r = 0.312$, $p = 0.015$) were found in the HMG eyes. Moreover, in the tessellated fundus, the HMG eyes had lower global (0.20 ± 0.12 versus 0.36 ± 0.09) and macular FTD (0.25 ± 0.14 vs. 0.40 ± 0.09) but larger disc FTD (0.24 ± 0.11 vs. 0.19 ± 0.07) than HM eyes (all $P < 0.001$). A macular region nasal/temporal FTD ratio > 0.96 (AUC = 0.909) was 15.7 times more indicative of HMG than HM.

Conclusions: Our findings highlight alterations in retinal parameters in the pathogenesis of HMG. A comprehensive analysis of these data acquired by deep learning-based algorithms could potentially assist differential diagnosis of HMG in clinical practice.

Quirk of Fate - Catastrophic Bilateral Ocular Trauma Following a Game of Tug of War

First Author: Shalini SHALINI

Co-Author(s): Salwa KAIDAKATH, Meena MENON

Purpose: To report an unusual case of bilateral ophthalmic injury following a game of tug of war and its successful management.

Methods: A 17-year-old boy presented to our Glaucoma clinic for a second opinion, with diminution of vision in both eyes (OS>OD) and elevated intraocular pressure (IOP) in OS following injury with a rope while playing "tug of war". Comprehensive examination and investigations revealed Retinal Dialysis in OD, while Irido-dialysis with traumatic cataract, with angle recession glaucoma, with vitreous hemorrhage in OS. The patient was initially managed medically and then treated surgically in a stepwise approach. He underwent Scleral buckle with cryotherapy in OD, Phaco-Trabeculectomy along with irido-dialysis repair in OS.

Results: With prompt and active intervention, good IOP control was achieved, and the patient's vision was well-preserved.

Conclusions: "Tug of war", seemingly innocuous, is a popular game played by all age groups and socio-economic segments. The physical exertion demanded by the game, compounded by the competitive fervor it ignites, poses a significant risk of injury. This case emphasizes the need for heightened awareness and stringent safety measures to prevent any harm.

Rare Bilateral Iridocorneal Endothelial Syndrome: A Case Report

First Author: Lorenz Jacob MANGAHAS

Co-Author(s): Ian Ben BATCAGAN

Purpose: Iridocorneal Endothelial (ICE) Syndrome is a rare, progressive disorder of the corneal endothelium, usually unilateral and classified into three variants: Essential Iris Atrophy, Chandler's Syndrome, and Cogan-Reese Syndrome. This report describes an unusual bilateral manifestation of ICE syndrome complicated by cataract and secondary glaucoma.

Methods: A 65-year-old female with a 10-month history of recurrent eye pain, redness, and progressive visual loss was evaluated. Comprehensive assessment

included slit-lamp biomicroscopy, gonioscopy, specular microscopy, anterior segment OCT, and B-scan ultrasonography. Management involved topical Timolol for intraocular pressure control in the right eye and cataract extraction in the left eye.

Results: On presentation, the right eye was blind with an intraocular pressure (IOP) of 50 mmHg, while the left eye had hand movements vision with IOP of 12 mmHg. Both eyes presented corneal edema, extensive peripheral anterior synechiae, and iris atrophy. Specular microscopy revealed endothelial polymegathism and pleomorphism. Postoperatively, the left eye achieved functional vision of 6/30 at two months, with minimal Descemet membrane folds and stable IOP without any medications. The right eye remained blind, and IOP was controlled with one topical antiglaucoma medication.

Conclusions: This case underscores the diagnostic and management challenges of bilateral ICE syndrome. Although typically unilateral, bilateral involvement can occur and requires a high index of suspicion. Cataract surgery in ICE patients must be approached cautiously due to endothelial compromise, shallow anterior chambers, and iris abnormalities. Careful preoperative planning, individualized surgical strategies, and vigilant follow-up are essential to preserve vision and minimize complications.

Re-surgery Rates Across the Glaucoma Spectrum

First Author: Mona KHURANA

Co-Author(s): Machanagari AISHWARYA, Mani BASKARAN, Ronnie GEORGE

Purpose: To determine the rate, reasons, and risk factors of re-surgery following glaucoma surgery (GS).

Methods: Retrospective case control study. Patients who had undergone re-surgery within 2 years of GS (trabeculectomy, glaucoma drainage device-GDD with or without cataract surgery) were included (January 2011- December 2021). Demographics, clinical features, management, re-surgery type, and reason for re-surgery were noted. Age, surgery, and surgeon-matched controls (1:1) who had not undergone re-surgery were included to assess risk factors for re-surgery.

Results: Of the 14,008 primary GS, 350 eyes underwent re-surgeries within 2 years of primary glaucoma surgery. The overall re-surgery rate was 2.49%. The highest re-surgery rate was 3.39% (year 2020). Re-surgery rate was 3.74% in the trabeculectomy subgroup, 1.63% in the phacotrabeculectomy subgroup, 2.57% in the GDD subgroup, and 21.28% in the phacotrabeculectomy combined with vitreoretinal procedures. The mean number of re-surgeries per eye was 1.25 ± 0.5 . Bleb failure was the most common cause

of resurgery in the trabeculectomy group, and tube exposure in the GDD group. Lower visual acuity (Odds Ratio (OR) 1.47, confidence interval (CI) 1.03 - 2.11, $p=0.034$), highest recorded preoperative IOP (OR 1.02, CI 1.004 - 1.04; $p=0.014$), uveitic glaucoma (OR 2.78, CI 1.3 - 5.96; $p=0.008$), previous intraocular surgery (odds ratio: 1.57, CI 1.20 - 2.05; $p=0.001$) were associated with an increased odds of re-surgery.

Conclusions: Overall re-surgery rates following GS were low and comparable with other studies. Eyes with uveitic glaucoma, higher preoperative IOP and lower visual acuity prior to GS had a higher odds of resurgery and may need close follow up or modification of surgical technique.

Abstract No.: 206603

Real World Clinical Results of 360/High Protocol Selective Laser Trabeculoplasty (SLT) Using Tango Reflex Neo in Patients With Primary Open-Angle Glaucoma and Ocular Hypertension in Northern Thailand

First Author: Damrong WIWATWONGWANA

Co-Author(s): Wichaya SANGPANICH, Atchareeya WIWATWONGWANA

Purpose: To evaluate the efficacy and safety of 360/high protocol SLT performed with the Tango Reflex Neo equipment in patients with primary open-angle glaucoma and ocular hypertension. Both in naïve patients and in patients who would like to change the medication from eyedrops to laser due to poor compliance in the real world.

Methods: Patients with a diagnosis of open-angle glaucoma and uncontrolled IOP under medical treatment and/or patients with an initial diagnosis of ocular hypertension and primary open-angle glaucoma who had not previously received any form of treatment (first line) were included. SLT was performed with Tango Reflex Neo in 360° using the 360/high protocol and adapting the fluence of the treatment to the pigmentation of the angle of everyone. Baseline IOP and post-procedure values at 1, 3, and 6 months were recorded, as well as the presence of complications or adverse events.

Results: Treated patients showed a significant reduction in IOP from baseline to subsequent controls. The success rate, defined as $\geq 20\%$ reduction in IOP without additional medication, was 75%. Adverse events were mild and transient, mainly mild inflammation and self-limiting eye discomfort.

Conclusions: 360/high protocol SLT with Tango Reflex Neo is a safe and effective therapeutic option for IOP control in ocular hypertension and open-angle glaucoma, with results comparable to or superior to previous reports with other SLT systems. Its

safety profile reinforces its role as an alternative or complement to medical treatment.

Reduction of Lipid Droplets Alleviates Optic Nerve Inflammation and Enhances CNTF-Induced Axon Regeneration in Optic Nerve Crush

First Author: Xiaowei FAN

Co-Author(s): Ningli WANG, Shen WU, Jingxue ZHANG

Purpose: To explore the location of lipid droplets (LDs) in retina and optic nerve, and the effect of inhibiting LDs biogenesis on survival and function of retinal ganglion cells (RGCs) from optic nerve crush mice.

Methods: The right optic nerve was crushed for 5 seconds. Eyeball and optic nerve frozen sections were co-immunofluorescence stained by LDs and Tuj1, IBA1 and GFAP. Mice daily received oral gavage of DGAT1 inhibitor A-922500 to suppress LDs biogenesis beginning one day before crush. The retinal RBPMs positive cells, and IBA1+ cells and GFAP- area in optic nerve were calculated in 1week after injury. Post 2 weeks after injury, the CTB-labeled regenerated axons were compared among group receiving A-922500 monotherapy, group receiving intravitreal injection of AAV2-CNTF monotherapy and group combining A-922500 with AAV2-CNTF. Flash visual evoke potential (FVEP) was applied to evaluate the visual function.

Results: LDs were observed within Tuj1-positive cells in retina, whereas in IBA1-positive cells within GFAP-negative regions in optic nerve following injury. A-922500 markedly reduced LDs numbers and efficiently diminished microglia in lesion site without altering the GFAP-negative area in optic nerve. Neither RGCs survival nor FVEP responses were significantly affected by A-922500 therapy. No discernible CTB-labelled regenerating axons were detected after A-922500 treatment alone. However, combined intervention resulted in better axon regeneration than AAV2-CNTF monotherapy.

Conclusions: After optic nerve crush, LDs appeared within RGCs soma in retina and microglia in optic nerve injury site. Reduction of LDs did not independently preserve RGCs survival and function, but attenuated inflammation and enhanced CNTF-induced axon regeneration.

Regulation of Lactate Flux in Optic Nerve Head Astrocytes: The Roles of Insulin, dbcAMP and Monocarboxylate Transporters

First Author: Kenji MATSUSHITA

Co-Author(s): Weiran HUAN, Rumi KAWASHIMA, Kohji NISHIDA, Andrew J. QUANTOC, Shinichi USUI, Yuichi YASUKURA

Purpose: To investigate regulations in lactate flux in Optic Nerve Head (ONH) astrocytes.

Methods: Lactate sensor (laconic) was transfected into primary cultured ONH astrocytes, after which insulin and dibutyl cyclic adenosine monophosphate (dbcAMP) were used to regulate the expression of the lactate importing-related proteins, Aquaporin 9 (AQP9), Monocarboxylate Transporter 1 (MCT1) and Monocarboxylate Transporter 2 (MCT2). Lactate flux changes were assessed as fluorescence rate alterations upon exposure to lactate and pyruvate solutions. Furthermore, the influence of AQP9 on lactate uptake and release was analyzed after inhibiting MCT function.

Results: ONH astrocytes displayed pronounced fluorescence ratio changes when exposed to lactate gradient solutions. Insulin and dbcAMP had opposite effects on AQP9 expression, with insulin downregulating AQP9 ($p=0.0023$) and dbcAMP upregulating it ($p=0.0012$). MCT1 (fold-change, insulin-treated 1.417 ± 1.001 , dbcAMP-treated 1.843 ± 1.354) and MCT2 (fold-change, insulin-treated 1.020 ± 0.316 , dbcAMP-treated 1.104 ± 0.454) showed slight fluctuations but no significant statistical differences. Lactate inflow and outflow remained balanced, however, this balance was disturbed once the functions of MCT1 and MCT2 were inhibited. Laconic monitoring revealed that insulin pretreatment reduced lactate influx into the cells ($p=0.0256$). dbcAMP pretreatment, on the other hand, enhanced both lactate influx ($p=0.0008$) and efflux ($p=0.0089$). Inhibition of MCT1 and MCT2 functions significantly reduced lactate flux, but astrocytes pretreated with dbcAMP showed a marked improvement in both lactate influx ($p < 0.0001$) and efflux ($p < 0.0001$) even after inhibition.

Conclusions: ONH astrocytes respond to some metabolic-influencing chemicals, altering the expression of AQP9 and affecting their lactate flux. Specifically, insulin treatment reduced lactate flux, whereas dbcAMP increased it.

Panel No.: GLA-0329

Retinal Nerve Fiber Layer (RNFL) Thickness Before and After Trabeculectomy in Primary Open-Angle Glaucoma

*First Author: Shams **NOMAN***

Purpose: To assess the RNFL thickness in primary open-angle glaucoma (POAG) before and one month after trabeculectomy using optical coherence tomography

Methods: Patients aged 40-60 years with POAG comprised the study patients. 20 eyes of 16 patients were selected for the study group. The study duration was one year. A complete clinical evaluation was conducted, including intraocular pressure (IOP) measurement before and one month after surgery. Optical coherence tomography (OCT) RNFL was performed preoperatively and postoperatively in the ophthalmology department. Statistical analysis of the results was conducted using computer-based software, SPSS 22.

Results: Regarding retinal nerve fiber layer (RNFL) thickness, the superior RNFL thickness was 75.2 ± 23.7 preoperatively and 81.6 ± 25.29 postoperatively. The mean overall RNFL thickness was 60.65 ± 10.34 preoperatively and 63.85 ± 12.74 postoperatively. A significant (<0.05) increase was observed in superior and mean RNFL thickness postoperatively compared to the preoperative period. But in other quadrants, there were changes in RNFL thickness, but the changes weren't statistically significant (>0.05).

Conclusions: This study assessed RNFL thickness changes before and after trabeculectomy in primary open-angle glaucoma. A significant reduction in IOP was observed postoperatively. Superior and mean RNFL thickness increased notably, while inferior, nasal, and temporal regions showed mild changes.

Abstract No.: 201126

Scleral Thinning Following MicroPulse Cyclophotocoagulation (MPCPC)

*First Author: Yin Yung Alison **CHAN***

*Co-Author(s): Chee Yung Clement **THAM**, Mandy Oi-man **WONG***

Purpose: Micropulse cyclophotocoagulation (MPCPC) is a glaucoma laser treatment that has gained popularity over the past decade. It has generally demonstrated a favorable safety profile, with commonly reported complications being persistent anterior chamber inflammation, loss of best-corrected visual acuity, cystoid macular edema and hypotony, while scleral thinning remains a rare occurrence. We present 4 cases who developed scleral thinning following MPCPC at Hong Kong Eye Hospital. We aim to highlight this infrequent complication, which may impact or limit future treatment options.

Methods: Retrospective case series of patients who exhibited scleral thinning after MPCPC at Hong Kong Eye Hospital between January 2019 and July 2025. Demographic and treatment-related data is collected, including: MPCPC settings, pre-operative and post-operative visual acuity and IOP, complications specifically scleral thinning – onset, location, extent, presence of progression and need for treatment.

Results: A total of 4 eyes of 4 subjects demonstrated scleral thinning following MPCPC. This includes 2 paediatric patients, a 40-year-old with uveitic glaucoma, and a 60-year-old with steroid-induced glaucoma. Notably, none had pre-existing scleral thinning or identifiable secondary causes. The procedures were uneventful, with parameters well within the normal range. In all cases the thinning was non-progressive and required no treatment.

Conclusions: MPCPC continues to be a valuable treatment option owing to its favorable safety profile, low invasiveness, repeatability, and feasibility as an office procedure. Albeit rare, it is worthwhile to be vigilant and monitor for any post-operative scleral thinning, as it may impact future glaucoma interventions.

Sequential Serous Choroidal Detachment in Subjects Undergoing Bilateral Trabeculectomy

*First Author: Maryam **YADGARI***

*Co-Author(s): Sara **KAVOUSNEZHAD**, Nader **NASSIRI**, Kourosh **SHEIBANI***

Purpose: This study aims to assess the incidence of serous choroidal detachment (SCD) in the second eye of patients undergoing bilateral trabeculectomy (BT) and evaluate its impact on the clinical outcomes and failure rate of trabeculectomy in the second-operated eyes.

Methods: This retrospective case-control study analyzed 90 eyes of 45 patients who underwent BT. Surgical success was defined as maintaining intraocular pressure (IOP) between 5 and 21 mmHg, requiring no additional glaucoma surgery, and exhibiting a visual acuity of at least light perception. Relevant patient data, such as age, glaucoma type, systemic diseases, preoperative and postoperative IOP, and complications, were extracted from medical records.

Results: The mean age of patients was 59.8 ± 11.1 years. The five-year cumulative probability of success in the first- and second-operated eyes was 61.0% and 67.6%, respectively (log rank = 0.085, $P = 0.77$). Among the participants, 28.9% experienced SCD, and 76.9% of those who had SCD in the first-operated eye developed the same condition in the second eye as well ($P < 0.001$). In the first-operated eyes, the five-year

cumulative probability of survival was 71.7% without SCD and 35.0% with SCD (log rank = 2.59, $P = 0.107$).

Conclusions: The occurrence of SCD in the first eye following trabeculectomy may indicate a predisposition to its development in the second eye during BT. Furthermore, the surgical success rate of the second-operated eye is comparable to the outcomes of the first eye undergoing BT.

Should Glaucoma Surgical Devices Be the First Surgical Option for Refractory Uveitic Glaucoma on Maximally Tolerated Drugs? A Systematic Review

First Author: Ulifna **SIFYANA**

Co-Author(s): Aurilia **AFIA**, Desy **KUSUMANINGRUM**, Rina La Distia **NORA**, Ikhwanuliman **PUTERA**, Maria **WIBAWA**

Purpose: This review summarises the existing body of evidence comparing the efficacy and safety of implant versus non-implant surgical procedures in refractory uveitic glaucoma (UG). UG, if inadequately managed, can cause irreversible vision loss due to progressive optic nerve damage. Managing glaucoma in the context of uveitis is challenging, as elevated intraocular pressure (IOP) may arise either from corticosteroid therapy or from trabeculitis, which requires effective anti-inflammatory treatment. When IOP remains uncontrolled despite maximally tolerated medical therapy, surgical interventions are considered. These can be broadly classified into implant-based procedures, such as glaucoma drainage devices (GDD), and non-implant procedures, including trabeculectomy and sclerectomy.

Methods: A systematic search was performed in PubMed, ScienceDirect, EBSCOhost, Cochrane Library, and SpringerLink databases using predefined keywords to identify clinical trials and observational studies. Outcomes related to efficacy and safety, including complications, were summarised. The study protocol was registered with the International Prospective Register of Systematic Reviews (PROSPERO: CRD420251023969).

Results: Out of 195 screened articles, six studies were selected following abstract and full-text review. Implant-based procedures demonstrated comparable IOP reduction to non-implant procedures in refractory UG patients in five of the six studies. Complete or qualified success was more frequently achieved with implant-based procedures. In long-term follow-up, implant-based procedures showed a higher success rate, defined as sustained IOP reduction to target levels (<21 mmHg or $\geq 20\%$ from baseline), fewer reoperations, greater reduction in antiglaucoma medications, and improved surgical survival over ≥ 24 months compared to non-implant surgeries.

Conclusions: Both implant and non-implant surgeries effectively manage refractory uveitis glaucoma, with implant surgeries demonstrating better long-term pressure control with fewer bleb-dependent failures. Individualized surgical decision-making remains essential. Cost-effectiveness analyses and well-designed prospective studies are required.

Study on the Relationship Between Disease Cognition Level, Anxiety, Depression, and Self-Management Behavior in Glaucoma Patients

First Author: Yan **LIU**

Co-Author(s): Ping **GE**, Yuan **HE**, Qingqing **MU**, Yuanyuan **ZHANG**

Purpose: To assess glaucoma patients' disease cognition, anxiety, depression, and self-management, analyze their correlations, and provide a basis for targeted interventions to improve prognosis and quality of life.

Methods: Cross-sectional study: Tertiary hospital ophthalmology glaucoma patients recruited via convenience sampling (inclusion/exclusion criteria). Data were collected using five instruments: the General Information Questionnaire, the Glaucoma Awareness and Knowledge Questionnaire (GAKQ), the SAS, the SDS, and the Glaucoma Self-Management Behavior Questionnaire (GSMQ). All questionnaire responses are being analyzed with SPSS software.

Results: The glaucoma patient group had relatively low overall cognition scores (15.70 ± 6.052 , moderate-to-low level, significant individual differences), 37.5% anxiety incidence, and 27.5% depression incidence. Their self-management behavior scores were relatively high (57.85 ± 5.419) with smaller individual differences. Cognition scores had a significant positive correlation with self-management behavior ($r=0.372$, $p=0.018 < 0.05$) but no significant correlation with anxiety ($r=-0.212$, $p=0.190$) or depression ($r=-0.137$, $p=0.401$). Anxiety and depression had a highly significant positive correlation ($r=0.796$, $p < 0.001$). Anxiety showed no significant negative correlation with self-management behavior ($r=-0.259$, $p=0.106$), while depression did ($r=-0.373$, $p=0.018 < 0.05$).

Conclusions: Glaucoma patients with higher disease cognition show better self-management behavior. Anxiety and depression are closely related, and those with depressive symptoms have poorer self-management behavior. This suggests enhancing disease cognition and alleviating anxiety-depression symptoms in glaucoma patient management can help improve their self-management capabilities, thereby boosting prognosis and quality of life.

Abstract No.: 203235**Panel No.: GLA-0354**

The Clinical Significance of Pressure-to-Cornea Index in Primary Open Angle Glaucoma, Normal Tension Glaucoma, Ocular Hypertension and Normal Individuals: A Comparative Analysis in Eastern India

*First Author: Shraddha SHATAPARBA**Co-Author(s): Madhusmita Behera BEHERA, Santosh Kumar MAHAPATRA, Raj VAISHAL KENIA*

Purpose: This study aims to evaluate the Pressure-to-Cornea Index (PCI) as a predictive and diagnostic marker in glaucoma by analyzing its association with disease severity in POAG, OHT, NTG, and normal individuals. PCI was calculated using intraocular pressure and central corneal thickness, and its correlation with clinical staging, visual field loss, and optic nerve changes was assessed. Demographic influences such as age and sex were also analyzed. PCI values were compared with benchmarks established by Iliev et al. to validate their utility in early detection and risk assessment, especially where traditional IOP measurements may be misleading.

Methods: A longitudinal, non-randomized, observational design consisting of 80 eyes was employed at a tertiary eye hospital in Eastern India. The IOP (using GAT), CCT, and Visual Fields were estimated across all the groups and followed up after 6 months to see if PCI was a reasonable marker.

Results: Glaucoma diagnosis varied significantly with age ($p < 0.001$); POAG was most common in older groups, while normals dominated ≤ 40 years. NTG was male-predominant (90%, $p = 0.009$). POAG and NTG had poorer BCVA ($p = 0.019$) and thinner CCT (0.15 mm), while OHT showed thicker corneas (0.20 mm, $p = 0.003$). Mean IOP was highest in OHT (27.00 mmHg) and lowest in NTG (15.65 mmHg) ($p < 0.001$). PCI was significantly elevated in POAG (156.17) and OHT (135.77) ($p < 0.001$), correlating strongly with IOP in NTG ($r = 0.892$) and POAG ($r = 0.644$). Visual field defects were present in 95% of POAG and NTG ($p < 0.001$). At 6 months, PCI remained highest in POAG (134.95 ± 25.21), followed by OHT (117.26 ± 26.33), with lower values in NTG (105.30 ± 17.58) and normals (107.34 ± 16.02). The differences were statistically significant ($p < 0.001$), mirroring baseline trends. This stability across time supports PCI's potential as a reliable predictor for glaucoma severity and progression.

Conclusions: A strong positive correlation was found between IOP and PCI in POAG and NTG and strong negative correlation between PCI and CCT indicating that thinner corneas are associated with high PCI. In normal eyes, the IOP-PCI relationship remains significant, while in OHT, CCT appears to be the dominant correlating factor with PCI. These findings support the relevance of PCI as a useful structural

parameter that reflects both pressure-related and corneal biomechanical changes in glaucoma diagnostics and monitoring. In Eastern India with very less glaucoma screening and follow up in glaucoma, PCI becomes a composite structural and functional marker of disease progression.

Abstract No.: 203766**Panel No.: GLA-0363**

The Effectiveness of Micropulse Laser in Refractory and Neovascular Glaucoma

*First Author: Chansathya KHIEU**Co-Author(s): Sreyneang SIM*

Purpose: This study aims to report on the effectiveness of laser surgical procedures for end-stage glaucoma patients using a micropulse laser. The objective is to measure post-operative intraocular pressure >12 weeks post laser, the amount of anti-glaucoma eye drop used, and patient comfort.

Methods: Using micropulse transscleral cyclophotocoagulation for a patient with refractive glaucoma and neovascular glaucoma, in a sweeping motion. Standard laser power setting was used, including 2000mW, 80 seconds, and 31.3% duty cycle for one hemisphere (180 degrees). Postoperative anti-inflammatory eye drops were given, and IOP was measured at week 1, week 3, week 6, and week 12. Initial anti-glaucoma drops were kept until week 3. IOP, anti-glaucoma medication, and patient comfort were documented.

Results: Neovascular glaucoma has shown the most unpredictable IOP control post laser treatment, with fluctuation of IOP up until week 6. IOP dropped in most cases; however, at least one to two anti-glaucoma eye drops are still needed. Patient comfort was reported to be better than cyclocryocoagulation (CCC), but hypotony and rebleeding can also be seen.

Conclusions: Micropulse laser is an effective treatment for patients with refractory or end-stage glaucoma. However, results can be unpredictable, and patient selection should be advised. Noticeably, anti-glaucoma medication cannot be stopped post-laser treatment.

Abstract No.: 205901**Panel No.: GLA-0404**

The Efficacy of Thermal Pulsation and Intense Pulsed Light on Dry Eye and Intraocular Pressure in Glaucoma Patients With Meibomian Gland Dysfunction

*First Author: Shui King TSOI**Co-Author(s): Poemen Pm CHAN, Vanissa Ws CHOW, Thomas Ch LAM, Clement Cy THAM*

Purpose: This study aims to evaluate the clinical efficacy of a thermal pulsation procedure (LipiFlow) and intense pulsed light (IPL) treatments on dry eye

parameters and glaucoma disease control reflected by intraocular pressure (IOP).

Methods: Retrospective review of 9 glaucomatous patients with MGD who underwent either LipiFlow or IPL in a local eye hospital between July 2022 and December 2024. Changes in symptomatology (OSDI and SPEED scores), corneal staining, conjunctival hyperemia, tear break-up time, lipid layer thickness, Schirmer's test, meibum quality, meibomian gland expressibility, and dropout were analyzed before and after treatment. IOP was also analyzed before (mean of 2 measurements) and after the procedure.

Results: We included 17 eyes of 9 patients (mean age 63.47 years), with 4 patients (8 eyes) receiving a single LipiFlow and 5 patients (9 eyes) receiving 3-4 IPL sessions. They had been treated with an average of 2.5 no. of IOP-lowering eyedrops for a mean of 6.71 years. Statistically significant improvements were demonstrated in OSDI scores and meibum quality (graded by clinicians from clear to cloudy to toothpaste-like) ($p=0.026$ and $p=0.020$, respectively, Wilcoxon signed rank test). Mean change in OSDI was -21.33 ± 9.90 . $\frac{2}{3}$ eyes had meibomian quality improvement post-procedure. Mean baseline and post-procedure 3-month IOP were 16.38 mmHg and 15.31 mmHg ($p=0.041$, paired t-test). The mean % IOP reduction was 6.57%.

Conclusions: IPL and LipidFlow are effective in improving MGD symptoms and meibum quality in glaucomatous patients. A slight but significant IOP reduction was observed 3-months post-procedure. However, further studies with larger sample sizes are warranted.

The Metabolites Mediate the Effect of Immune Cells on Glaucoma: A Mendelian Randomization Study

First Author: Ma XIN

Co-Author(s): Zuo CHENGGUO, Luo NACHUAN

Purpose: To certify the causal relationship between circulating immune cells and glaucoma as well as quantify the role of blood metabolites as potential mediators.

Methods: A bidirectional Mendelian randomization (MR) analysis of circulating immune cells and glaucoma was performed with genome-wide association studies (GWAS). Moreover, two-step MR analysis was employed to quantify the proportion of the effect of blood metabolites mediating circulating immune cells on glaucoma. Genetic proxies of immunophenotypes and glaucoma were obtained from IEU OpenGWAS, while circulating metabolites were sourced from GWAS Catalog. These cross-sectional designs do not report a

duration of follow-up. Data analysis was performed in February 2024.

Results: MR analysis revealed a causal relationship between 33 immune cell traits and glaucoma. Further analysis identified a causal relationship between 10 blood metabolites and glaucoma. Generally, 9 specific blood metabolites mediated the effects of 8 immune cell phenotypes on glaucoma. The Aspartate-to-citrate ratio contributed to the effect of CD24+CD27+%lymphocytes on glaucoma, while N-acetyltaurine mediated the effect of Naive CD4+AC and SSC-A on HLA-DR+ CD8br on glaucoma. 5-acetylamin-6-amino-3-methyluracil facilitated the impact of CD64 on CD14-CD16+ monocytes and CD3 on EM CD4+ on glaucoma. 4-hydroxyhippurate contributed to the effect of Naive-mature B cell%B cell on glaucoma, while cortolone glucuronide and 2-hydroxy-4-(methylthio) butanoic acid (HMTBA) mediated the effect of Activated & resting Treg %CD4+ on glaucoma. Additionally, 1-palmitoyl-2-arachidonoyl-GPE, HMTBA and Adenosine 5'-diphosphate (ADP) to mannose ratio partially explained the effect of CD3 on EM CD4+ on glaucoma.

Conclusions: Immune cells contribute to the pathogenesis of glaucoma, partly through the influence of blood metabolites.

The Qidwai Quilt Pull-Over Patch-Graft (Q-POP) Technique: A Novel Method for Repairing Glaucoma Tube Exposure in Conjunctival Adhesions

First Author: Umair QIDWAI

Purpose: To describe a novel surgical technique—Qidwai Quilt Pull-Over Patch graft (Q-POP)—for managing glaucoma drainage device (GDD) tube exposure in high-risk patients with conjunctival scarring and mechanical stress from severe nystagmus.

Methods: A preventive revision was performed in a monocular 45-year-old male with aphakia, silicone oil tamponade, prior retinal surgeries, and secondary glaucoma. The conjunctiva over the drainage tube showed progressive thinning with posterior graft migration. The Q-POP technique was employed, involving hydrodissection, subconjunctival tunnel creation, and pullover delivery of a scleral graft without limbal peritomy.

Results: Postoperatively, the drainage tube remained well covered, conjunctival integrity was maintained, and intraocular pressure was well controlled during follow-up.

Conclusions: The Q-POP technique provides a safe, minimally invasive alternative to traditional patch graft approaches, particularly in eyes with limited conjunctival mobility and high surgical risk.

Abstract No.: 206148**Panel No.: GLA-0414****Trickling Down of Blood – Care Approaches in 2 Case Scenarios***First Author: Salwa KAIDAKATH**Co-Author(s): Shalini, Minija CK, Meena GOPINATH MENON, Divyansh MISHRA*

Purpose: To discuss care strategies in two uncommon presentations of anterior segment hemorrhage and to highlight individualized management strategies that resulted in favourable outcomes.

Methods: Case 1: A 72-year-old on systemic anticoagulants presented with a sudden onset of diminution of vision 1 year post-trabeculectomy. Examination revealed an evident trickling of blood into the anterior chamber secondary to a loose conjunctival suture superonasally. Following the loose suture removal, bleeding ceased, and visual acuity returned to baseline. Case 2: A 54-year-old diabetic presented with a sudden onset of diminution of vision and increased intraocular pressure. Clinical suspicion of iris microhemangioma was confirmed by iris fluorescein angiography, which demonstrated a linear streak of hyperfluorescence at 10 o'clock near the pupillary margin and additional hyperfluorescence in the mid-iris at 11–12 o'clock. The lesion was successfully treated with focal photocoagulation, leading to resolution of the vascular abnormality and stabilization of vision.

Results: With appropriate management, both cases of anterior segment bleeding resolved and vision stabilized.

Conclusions: Careful observation and utilization of appropriate diagnostic methods, along with timely and individualized interventions, are essential for optimal patient care and visual preservation.

Abstract No.: 205300**Panel No.: GLA-0386****Two-Year Comparative Outcomes of Gatt Combined With Phacoemulsification in Primary Open Glaucoma Versus Primary Angle-Closure Glaucoma***First Author: Madhavi PILLAI**Co-Author(s): Devendra MAHESHWARI, Nimrita NAGDEV*

Purpose: To compare the two-year outcomes of Gonioscopy assisted transluminal trabeculotomy combined with phacoemulsification in primary open angle glaucoma versus primary angle closure glaucoma.

Methods: In this prospective comparative, non-randomised study design, 121 consecutive eyes (61 POAG and 60 PACG) underwent 5-0 prolene suture GATT-Phaco and followed for 2 weeks, 1, 3, 6, 12, and 24 months. Outcome measures were Intraocular pressure (IOP), antiglaucoma medications (AGM), best corrected

visual acuity (BCVA), surgical success, complications, and interventions. Surgical success was defined as IOP $\leq 21/\leq 18/\leq 15$ with $>20\%$, 25% , 30% reduction from baseline (Criteria 1, 2 & 3).

Results: Mean IOP decreased from 21.15 ± 3.7 to 13.20 ± 3.5 , 13.20 ± 3.2 , 13.96 ± 3.4 mmHg in POAG (33% IOP reduction) and from 21.88 ± 6.4 to 12.72 ± 3.0 , 13.37 ± 3.6 , 13.27 ± 3.9 mmHg in PACG (33.8% IOP reduction) at 6, 12, 24 months respectively ($p=0.511$). AGM reduced from 1.64 ± 0.84 to 0.38 ± 0.59 in POAG (67.9% meds free) and from 1.95 ± 0.95 to 0.53 ± 0.79 in PACG (61.8% meds free) at 24 months ($p=0.21$). Complete success rates were 65.6%, 62.3%, and 49.2% in POAG and 56.7%, 55%, and 43.3% in PACG for Criteria 1, 2, and 3, respectively. Qualified success rates were 19.7%, 14.8%, and 11.5% in POAG and 26.7%, 21.7%, and 15% in PACG. 14 eyes had macrohyphema, and 10 eyes had IOP spikes. One patient with PACG had one clock hour of iridodialysis. 6 eyes underwent anterior chamber wash for non-resolving hyphema.

Conclusions: GATT combined with phacoemulsification is efficacious with similar surgical outcomes in both POAG and PACG, with a favourable safety profile. The results of this study reinforce that angle-closure does not preclude the use of GATT, expanding the role of MIGS in PACG management as well.

Abstract No.: 205297**Panel No.: GLA-0378****Two-Year Comparative Outcomes of Phacoemulsification With Microhook Trabeculotomy Versus Standalone Phacoemulsification in Open Angle Glaucoma – a Randomised Controlled Trial***First Author: Devendra MAHESHWARI**Co-Author(s): Nimrita NAGDEV, Madhavi PILLAI*

Purpose: To evaluate the 24-month safety and efficacy of phacoemulsification combined with ab interno Tanito microhook trabeculotomy (microLOT) compared with phacoemulsification alone in patients with open-angle glaucoma (OAG) and cataract.

Methods: Prospective, randomized, interventional clinical trial. 114 eyes of 114 patients with mild-to-moderate OAG and visually significant cataract were randomized to phaco-microLOT ($n=57$) or phacoemulsification alone ($n=57$). Outcome measures included intraocular pressure (IOP), antiglaucoma medication (AGM) burden, best-corrected visual acuity (BCVA), surgical success, and complications, assessed through 24 months. Success was defined as a combination of at least 20%, 25%, or 30% reduction in IOP and an absolute IOP of less than 21, 18, or 15 mm Hg, respectively (Criteria 1, 2, and 3).

Results: At 24 months, 99 patients out of the original cohort of 114 patients were analyzed (Group 1 = 50;

Group 2= 49). The mean IOP decreased from 26.5 ± 5.2 to 15.2 ± 4.9 mmHg in the phaco-microLOT group and from 25.3 ± 3.1 to 18.2 ± 2.8 mmHg in the phaco-alone group ($P < 0.001$). The percentage IOP reduction was significantly greater in Group 1 (42.6% vs 28.1%, $P = 0.004$). In Group 1, the mean (standard deviation [SD]) AGM used preoperatively was 0.6 (0.9), which significantly decreased to 0.2 (0.4) at 24 months, whereas in Group 2, it marginally increased from 1.4 (0.6) to 1.5 (0.9). Overall success (Complete + qualified) in Group 1 using Criteria 1, 2, and 3 was 83.3%, 72.9% and 43.8% while in Group 2 was 57.8%, 40% and 20% respectively. The risk of failure in Group 2 was 2.87 times higher. No additional complications were observed, and no interventions were required between 12 and 24 months of follow-up.

Conclusions: Phaco-microLOT achieved sustained IOP and medication reduction at 24 months, with a favorable safety profile and superiority over phacoemulsification alone. These results underscore the long-term role of microLOT as a cost-effective MIGS procedure for OAG.

Abstract No.: 203804

Panel No.: GLA-0364

Two-Year Outcome of Phacogoniotomy for Advanced Primary Angle-Closure Glaucoma With Cataracts: A Multicentre Study

First Author: Bin XIE

Co-Author(s): Yunhe SONG, Xiulan ZHANG

Purpose: To report the 2-year effective and safety profile of integrated phacoemulsification with intraocular lens implantation (PEI), goniosynechialysis (GSL) and 120° goniotomy (GT) in advanced primary angle-closure glaucoma (PACG) and cataracts.

Methods: A total of 201 eyes of 196 patients who received combined PEI+GSL+ GT were assessed at baseline and re-evaluated at days 1, 7, and at 1, 3, 6, 12 and 24 months post-surgery. The intraocular pressure (IOP), the number of topical hypotensive medications, surgical complications, and achievements of surgery success were also evaluated.

Results: All participants were followed up for a 2-year period. The average IOP declined from 33.0 ± 10.7 mm Hg to 13.6 ± 2.9 mm Hg, and the number of topical hypotensive medication decreased from an average of 2.4 types to 0.4 at month 24. For the safety profile, the major complications were hyphema ($n=14$, 7.0%), IOP spike ($n=9$, 4.9%) and transit corneal oedema ($n=23$, 11.4%). The complete success was achieved in 72.6% of the eyes (146 out of 201), and the qualified success rate was 91.5% (184 out of 201). Only one eye required tube shunt surgery while no one developed severe vision-threatening complications. The best-corrected visual acuity increased from 0.80 ± 1.08 to 0.54 ± 0.78 LogMAR.

Conclusions: PEI+GSL+GT is shown to be effective and safe in treating advanced PACG with cataract over a 2-year follow-up period. The combined surgery may be considered as an alternative for patients with advanced PACG.

Abstract No.: 205938

Panel No.: GLA-0405

Two-Year Outcomes of Gonioscopy-Assisted Transluminal Trabeculotomy in Eyes With Primary-Open Angle Glaucoma and Pseudo-Exfoliation Glaucoma

First Author: Nimrita NAGDEV

Co-Author(s): Devendra MAHESHWARI, Madhavi PILLAI

Purpose: Efficacy of gonioscopy-assisted transluminal trabeculotomy in primary open-angle glaucoma and pseudo-exfoliation glaucoma.

Methods: A prospective, interventional, and comparative study included 74 primary open-angle glaucoma (group 1) and 76 pseudo-exfoliation glaucoma (group 2) patients. Combined gonioscopy-assisted transluminal trabeculotomy with phacoemulsification was performed in both groups. Baseline characteristics like Intraocular pressure (IOP), best corrected visual acuity (BCVA), and anti-glaucoma medications (AGMs) were compared. Data were collected at 2 weeks, 1 month, 3, 6, 12, and 24 months. Surgical success was defined as IOP ≤ 21 / ≤ 18 / ≤ 15 mmHg with $> 20\%$ / 25% / 30% reduction from baseline, respectively (Criteria 1, 2, and 3). Complications, secondary interventions, and surgical risk factors were also analyzed.

Results: The mean (SD) IOP (mmHg) decreased from 21.26 ± 3.69 to 14.09 ± 3.42 and from 27.46 ± 6.57 to 13.17 ± 2.57 in groups 1 and 2, respectively, at the end of 24 months. ($p=0.117$). AGM reduced from 1.69 ± 0.84 to 0.38 ± 0.57 and 1.88 ± 0.75 to 0.11 ± 0.44 in groups 1 and 2, respectively, at 24 months. ($p=0.002$). Success rate 85.1%, 76.8% and 58 % by criteria 1, 2, and 3 in group 1, respectively. In group 2, it was 98.6%, 95.8% and 87.6%. Micro hyphemas were seen in 34 patients (20 in group 1, 14 in group 2), macro hyphemas in 10 patients (6 in group 1, 4 in group 2), and 19 patients had IOP spikes (8 in group 1, 11 in group 2). 6 patients required AC wash (4 in group 1, 2 in group 2).

Conclusions: At 24 months, gonioscopy-assisted transluminal trabeculotomy reduced IOP and AGM in POAG and PXF-G, with greater success in PXF-G.

Abstract No.: 200355**Panel No.: GLA-0312****Ultrasound Cycloplasty: Dynamic Efficacy and Long-Term Safety in Glaucoma Patients from Northwest China***First Author: Ping GE**Co-Author(s): Yuan HE*

Purpose: This study aims to comprehensively analyze the dynamic efficacy of UCP in treating various types of glaucoma in Northwest China, and to explore the changes in efficacy at different follow-up time points as well as its long-term safety.

Methods: We enrolled 24 patients (30 eyes) with complete clinical data. Sociodemographic characteristics and ophthalmic examination data were collected. All patients underwent UCP treatment and were followed up at various time points postoperatively. Follow-up assessments consisted of IOP measurements, IOP reduction from baseline, surgical success rate, 24-hour IOP fluctuation, pain score improvement, and complications.

Results: The overall IOP in all patients significantly decreased after UCP compared to preoperative levels ($P < 0.01$). UCP demonstrated significant long-term IOP-lowering effects in patients with various types of glaucoma, with a 59.91% reduction at 1 year postoperatively. The efficacy was particularly notable in patients with primary angle-closure glaucoma, achieving a surgical success rate of 96.67% at 1 year. Preoperative baseline IOP showed a positive correlation with IOP reduction at 1 year postoperatively ($r_s = 0.641$, $P < 0.01$), indicating that higher baseline IOP was associated with greater IOP reduction. 4. UCP significantly improved IOP fluctuation, with the mean 24-hour IOP fluctuation decreasing from 10.6 preoperatively to 5.3 postoperatively ($P = 0.001$). 5. UCP exhibited excellent safety, with significant reductions in pain scores ($P < 0.05$) and no severe complications such as hypotony or macular edema observed during follow-up.

Conclusions: UCP demonstrates significant long-term and dynamic efficacy and high safety in patients from Northwest China.

Abstract No.: 203487**Panel No.: GLA-0359****Unmasking the Ghost: A Rare Case of Ghost-Cell Glaucoma***First Author: Yulinda Arty LAKSMITA**Co-Author(s): Mario Marbungaran HUTAPEA, Devina Bunga MAWARNI, Virna Dwi OKTARIANA, Florentina PRISICILIA*

Purpose: To show the diagnostic challenges of ghost cell glaucoma (GCG), a rare secondary glaucoma that can mimic other ocular pathologies, thus prone to being misdiagnosed and mistreated.

Methods: A case report. A 50-year-old man with a whitish appearance on the left eye (LE), as well as moderate pain and persistent eye redness for 2 weeks. These occurred about 10 days after a core vitrectomy. His LE vision had been blurred for 5 months prior due to vitreous hemorrhage and tractional retinal detachment resulting from diabetes mellitus. Ophthalmology examination showed light perception visual acuity of the LE. The intraocular pressure (IOP) was 15 mmHg (on timolol and oral acetazolamide). Anterior chamber (AC) depth was von Herrick grade 2, filled with prominent AC cells and 4.7 mm in height, tan-colored hypopyon. Ocular ultrasound showed a dense vitreous haziness.

Results: The presence of a prominent hypopyon, vitreous opacity, and a history of recent intraocular procedure led to the diagnosis of possible postoperative endophthalmitis. AC clearance, re-vitrectomy, and antibiotic intravitreal injection were then performed. Surprisingly, aqueous and vitreous gram, KOH stains, and cultures showed no microorganisms, but instead showed Heinz bodies, degenerating erythrocytes, a typical finding in ghost-cell glaucoma. The diagnosis of ghost-cell glaucoma was confirmed, then management was focused on IOP control, cycloplegia, and surgical clearance of erythrocyte debris.

Conclusions: Although rare, GCG may follow vitreous hemorrhage and vitreoretinal surgery. With rising vitrectomy rates, clinicians may encounter it more often. Early recognition helps avoid misdiagnosis as uveitis or infection and enables timely, targeted treatment.

Abstract No.: 205282**Panel No.: GLA-0383****Visual Field Abnormalities in High Myopia With or Without Pathologic Changes and Open-Angle Glaucoma***First Author: Jing HUANG**Co-Author(s): Ying HAN, Jingjing HUANG, Jost B JONAS, Ajay KOLLI, Nan LUO*

Purpose: To develop a perimetric classification system for highly myopic eyes with or without pathologic changes and open-angle glaucoma (OAG), and to identify factors associated with OAG in these eyes.

Methods: In this hospital-based, cross-sectional study, participants with high myopia were consecutively enrolled and underwent visual field testing as well as detailed ocular examination. A modified perimetric classification system was proposed based on a previous literature review. And using this modified system, the prevalence of perimetric defect subtypes was determined by the presence of pathologic high myopia (PHM) and OAG.

Results: A total of 601 participants (906 eyes) were included in this study. Both non-PHM and PHM eyes

with OAG were more likely to have a nasal step, combined superonasal and inferonasal defects, and altitudinal defects compared to those without OAG ($P<0.05$ for each), while partial arcuate defects, arcuate defects, vertical step and central defect were associated with OAG only in non-PHM ($P<0.05$ for each), but not in PHM eyes. Older age, male sex, absence of peripapillary hyperreflective ovoid mass-like structures, and presence of glaucoma-related perimetric defects were associated with a higher risk of OAG in non-PHM eyes, while only older age and presence of glaucoma-related perimetric defects were associated with a higher risk of OAG in PHM eyes.

Conclusions: Glaucoma-similar perimetric defects can occur in highly myopic eyes without OAG, especially in those with pathologic changes. The overlap of myopic and glaucoma-similar perimetric defects should be taken into account in clinical routine.

Panel No.: GLA-0428

Visual Outcomes Following PreserFlo MicroShunt Surgery With or Without Nylon Stent Placement

First Author: Yuto **HASEGAWA**

Co-Author(s): Rumi **KAWASHIMA**, Kenji **MATSUSHITA**, Kohji **NISHIDA**, Tomoyuki **OKAZAKI**, Shinichi **USUI**

Purpose: To evaluate postoperative visual acuity following PreserFlo MicroShunt (PMS) surgery with or without nylon stent placement.

Methods: We retrospectively analyzed 114 eyes that underwent initial standalone PMS surgery at the University of Osaka Hospital between March 2023 and March 2025. Eyes were categorized into non-stent (NS, $n=79$) and stent (S, $n=35$) groups. Parameters assessed included pre- and postoperative LogMAR visual acuity, intraocular pressure (IOP), central four-point threshold values from Humphrey visual field (SITA 24-2 or 30-2), and axial length.

Results: No significant differences were found between groups in age ($p=0.51$), central threshold ($p=0.48$), or axial length ($p=0.30$). IOP was significantly lower in the NS group within 2 days (7.0 ± 2.6 vs. 11.1 ± 3.6 mmHg, and at 1 week (7.1 ± 2.7 vs. 11.3 ± 2.5 mmHg, $p<0.0001$), but not at 1 month ($p=0.42$). Visual acuity change was significantly smaller in the S group (0.04 ± 0.12 vs. 0.12 ± 0.16 LogMAR, $p=0.02$). In the NS group, eyes with ≥ 2 -step visual decline had significantly higher IOP (pre-op: $p=0.04$; 1 month: $p=0.01$) and lower pre-op acuity ($p=0.015$) and superior/inferior central thresholds ($p=0.04$ each).

Conclusions: Stent placement may mitigate early postoperative hypotony and help preserve visual acuity. Preoperative visual function and IOP dynamics appear to influence postoperative visual outcomes.

Panel No.: GLA-0355

Visual Reality Training Improves Visual Field Defects in Patients With Glaucoma

First Author: Fen **NIE**

Purpose: To investigate whether virtual reality (VR)-based visual perception training can improve the visual field of patients with glaucoma.

Methods: Patients with open-angle glaucoma who visited the Glaucoma Clinic of Changsha Aier Eye Hospital from July 2024 to March 2025 were recruited. A visual perception examination system was used to conduct binocular visual perception tests, and personalized training plans were developed based on the interocular relative threshold criteria of the patients. The patients completed 3 months of binocular visual perception training at home using a VR headset, with two 20-minute sessions per day. Before training and at the 3rd month after training, the patients' BCVA, IOP, RNFL thickness, ganglion cell thickness, and visual field were examined.

Results: A total of 8 patients completed the study. Before training, none of the 8 patients had fine stereoscopic vision; 4 had gross stereoscopic vision, and 4 had no gross stereoscopic vision. After training, all patients showed improvement in stereoscopic vision. The patients were aged 23-61 years, including 3 males and 5 females. There were no significant differences in BCVA, IOP, RNFL thickness in all directions, or ganglion cell thickness before and after training ($P>0.05$). After training, the visual field index (VFI) ($72.17\pm25.69\%$ vs. $67.75\pm26.88\%$, $P=0.001$) and mean deviation (MD) (-9.07 ± 8.56 dB vs. -11.08 ± 8.41 dB, $P<0.001$) were significantly improved compared with those before training.

Conclusions: VR-based visual perception training can improve the visual function (stereoscopic vision) and visual field of glaucoma patients. Further studies with larger sample sizes are necessary to evaluate the value of this novel therapeutic approach.

Wound Closure Techniques in Trabeculectomy: Impact on Postoperative Wound Leak and Hypotony

First Author: Audrey **TANG**

Co-Author(s): Poemen **CHAN**, Thomas **LAM**, Clarice **SU**

Purpose: To evaluate the incidence and clinical course of wound leak and hypotony following trabeculectomy and to compare the effect of two conjunctival closure techniques—wing sutures versus combined purse-string with horizontal mattress sutures—along with tenon repositioning, on these complications.

Methods: A retrospective chart review was performed for consecutive trabeculectomy cases at a single tertiary eye center.

Results: Among 63 trabeculectomy cases, the overall wound leak rate was 33.3% (21/63). Leaks presented at a mean of 5.0 ± 5.3 days postoperatively and persisted for an average of $11.5 \text{ days} \pm 10.3 \text{ days}$. Conservative management with a bandage contact lens was successful in 85.7% (18/21) of cases, while 14.3% (3/21) required surgical repair. The combined purse-string with horizontal mattress suture technique demonstrated a significantly lower leak rate (19.2%, 5/26) compared to wing sutures alone (43.2%, 16/37; $p = 0.040$). Multilevel mixed-effects logistic regression, adjusting for inter-eye correlation, confirmed the protective effect of the purse-string technique ($p = 0.047$) against wound leak. Tenon repositioning showed a non-significant trend toward reduced leakage ($p = 0.185$). Hypotony occurred in 34.9% of cases (22/63), with a mean onset of 4.09 days and resolution after 9.3 days. Conservative management was effective in 13 cases, whereas 9 required anterior chamber reformulation (mean 2.22 reforms per eye). No significant difference in hypotony rates was observed among closure techniques, and no other factors were significantly associated with hypotony.

Conclusions: Wound leak and hypotony are common complications after trabeculectomy. Using purse-string and horizontal mattress suture, along with tenon reposition, provides a higher rate of watertight closure and reduces complication rate.

Panel No.: GLA-0327

"Incidence of and Risk Factors for Steroid-Induced Ocular Hypertension Following Cataract Surgery in 150 Patients Without Glaucoma: A Prospective Study"

First Author: Virabot SOK

Co-Author(s): Sothea AIM, Kossama CHUKMOL, Piseth KONG, Leng UN

Purpose: This study aims to report the incidence of and risk factors for steroid-induced ocular hypertension in patients without glaucoma after cataract surgery.

Methods: This one-year hospital-based prospective observational study observes the changes in postoperative intraocular pressure in 150 non-glaucomatous patients who underwent phacoemulsification or small manual incision cataract surgeries for the incidence of steroid-induced ocular hypertension (defined as intraocular pressure (IOP) higher than 21 mmHg) after using topical prednisolone 1% or dexamethasone 0.1% for 1 month. In addition, risk factors were analyzed.

Results: Among 150 patients, 7 patients (4.67%) showed increased intraocular pressure during our

study, among whom the younger age group (in their 40s or under) and choice of steroid use (dexamethasone 0.1%) were found to be risk factors. However, all of our steroid-induced ocular hypertension patients had their intraocular pressure notably returned to within normal limits ($<21 \text{ mmHg}$) after 2 weeks of steroid cessation.

Conclusions: This study shows that topical steroids could be safely used by cataract surgeons postoperatively in non-glaucomatous patients with regard to steroid-induced ocular hypertension, as the risk is relatively low (4.67%) and the patients' intraocular pressure will return to normal limits upon cessation of steroid. Although some precautions should be taken with patients in their 40s or under and with a choice of steroid, dexamethasone.

Intraocular Inflammation, Uveitis and Scleritis

Abstract No.: 202996

Panel No.: IUS-0460

A Case of Red Eye With Pain and Headache

First Author: Yujie YAN

Co-Author(s): Yi CHEN, Honglei HAN, Mengyu HAN, Xiaoming SHU

Purpose: To report a case of scleritis with atypical relapsing polychondritis.

Methods: Case report.

Results: A 66-year-old female was admitted to the hospital with intermittent eye redness with pain and headache in both eyes for over a month. She had high IOP up to 30mmHg and was treated eye drops. BCVA was 0.6 in both eyes, IOP (mmHg) was 21.3 in the right eye and 25.3 in the left eye. Bilateral conjunctiva and sclera congestion were obviously seen. She had 3+++ mutton-like kps and 1+ flare in the anterior chamber. Vitreous was clear and fundus was almost normal. B-ultrasound indicated thickening of the eye walls with typical "T-sign". No significant leakage and vessel staining was found in FA+ICG except optic disc staining in late stage. OCT indicated choroidal folds. CRP and ESR were significantly increased. Aqueous humor test showed a significant increase in inflammatory factors. PET-CT indicated increased local metabolism in the upper and posterior wall of the left nasopharynx, left nasal tip, bilateral auricles, epiglottis, and thyroid cartilage suggesting the possibility of multiple cartilage inflammations; Pathological examination of the cartilage and subcutaneous tissue of the right auricle suggested lymphocyte infiltration in the cartilage, skin, and subcutaneous fibrous tissue. Scleritis with recurrent polychondritis was diagnosed. Methylprednisolone and cyclophosphamide were administered intravenously. Symptoms were relieved,

conjunctival and scleral congestion were reduced, and ESR and CRP were decreased.

Conclusions: Etiological diagnosis of scleritis is important in clinical practice. Relapsing polychondritis should be considered for scleritis with negative etiological laboratory tests.

Abstract No.: 203719

A Conundrum of Cladosporium Endophthalmitis

First Author: Lisa SUNNY

Co-Author(s): Rajshree EZHILAN, Vedhanayaki RAJESH, Radhika THUNDIKANDY

Purpose: To report an unusual case of Cladosporium endophthalmitis.

Methods: A 54-year-old man presented to the uvea clinic with a 1-month history of blurred vision in the right eye. He had complaints of redness previously, which was relieved with topical steroids and cycloplegics. At presentation, he was on topical and oral steroids. He mentioned noticing a white meniscus in the eye, which had recently increased in height. He worked in the veterinary department and had a doubtful history of trauma to eye with goat tail a month back. Best corrected visual acuity was 1/60, with 4+cells in anterior chamber(AC); thick endoexudates with few blackish pigments settled in AC inferiorly; at nasal pupillary and lens margin and at 1 o'clock position. Fundus had grade 2 vitreous cells and haze, and a few exudates in the vitreous. A diagnosis of endophthalmitis was made. Oral and topical steroids were stopped, and the patient was started on topical and oral broad-spectrum antibiotics. Pars plana vitrectomy and lensectomy were done with intravitreal vancomycin, ceftazidime, and voriconazole injection. Remnant exudates behind the iris were removed with a cutter. Culture of aqueous and vitreous grew Cladosporium fungus, which prompted 2 repeat voriconazole injections and initiation of oral itraconazole 200 mg bd.

Results: Post 3 months of itraconazole, patient has 6/9 BCVA, with complete resolution of exudates and is planned for secondary IOL implantation.

Conclusions: A high index of suspicion should be kept for fungal etiology in case of atypical presentations. This, when managed appropriately, can provide an excellent visual outcome.

Abstract No.: 210364

Panel No.: IUS-0486

A Nanotechnology-Based Dexamethasone Delivery System for Treatment of Anterior Uveitis

First Author: Jiabei XIONG

Co-Author(s): Jiayin CAI, Jian LI, Nasha QIU, Yangla XIE, Yijia ZHANG

Purpose: To develop a novel dexamethasone-loaded nanoparticle(DEX-NP) system to overcome the limitations of conventional eye drops, including poor ocular bioavailability and off-target effects, for anterior uveitis treatment.

Methods: DEX-NPs were synthesized using an optimized nano-preparation technique and systematically characterized. The biocompatibility, cellular uptake, and transport behavior of the system were assessed in human corneal epithelial cells. The therapeutic efficacy and safety were further investigated in an animal model of endotoxin-induced anterior uveitis, comparing the DEX-NPs to commercial dexamethasone eye drops.

Results: The optimized DEX-NPs demonstrated desirable physicochemical properties and excellent biocompatibility. In vitro, DEX-NPs significantly enhanced drug permeability across the corneal epithelium barrier. In the uveitis animal model, DEX-NPs achieved superior control of intraocular inflammation compared to conventional eye drops, with no signs of ocular toxicity.

Conclusions: This study demonstrates that the nanotechnology-based dexamethasone delivery system, as a non-invasive therapeutic strategy, holds considerable potential for improving efficacy and safety in the treatment of anterior uveitis, with significant potential for clinical translation.

Panel No.: IUS-0458

A Rare Case of Retinochoroiditis in a Patient Co-Infected With Syphilis, Tuberculosis, and Human Immunodeficiency Virus (HIV) in Rural Papua

First Author: Janice Eloise TAN

Co-Author(s): Evander Samuel BANUA ROUW, Dian I PAPENTE, Nathaniel Farrel TAN, Nyssa Alexandra TEDJONEGORO

Purpose: A 29-year-old man presented with sudden vision loss in the right eye. He was diagnosed with pulmonary tuberculosis 8 months ago and received antitubercular therapy. BCVA OD was 1/300 and BCVA OS was 20/20. Anterior segment had cell & flare. Fundoscopy OD revealed vitritis, papillitis, circinate hard exudates, soft exudates, chorioretinitis, peripapillary hemorrhage, and retinal vasculitis with dilatation. Retinal vasculitis, dilatation, and scattered

soft exudates found in OS. ELISA for HIV, rapid plasma reagin, and treponema pallidum hemagglutination test were positive. CD4 count was 278 cells/ μ L. A chest x-ray found active pulmonary tuberculosis. Treatment was with antisyphilis, antituberculosis, and antiretrovirals. Coinfection syphilis and tuberculosis in patients with newly diagnosed HIV is rare. Screening HIV-positive individuals for multiple co-infections is an appropriate measure.

Methods: This is a rare case report of a patient with retinochoroiditis coinfecting with syphilis, tuberculosis, and HIV. The patient was reviewed for clinical history, clinical examination, and prompt treatment.

Results: Antiretroviral therapy was deferred because of presence of multiple co-infections, the potential risk of immune reconstitution, good CD4 count, and oral corticosteroids were administered. At one month follow-up, BCVA OD improved to 20/40. Found a quiet anterior chamber, improvement in retinal abnormalities. Subsequently, antiretroviral therapy was given.

Conclusions: Intraocular inflammation caused by syphilis, tuberculosis, and HIV in the same eye is rarely reported. This case illustrates the increased susceptibility of HIV-infected patients to multiple opportunistic infections. Systematic and multidisciplinary management approach is essential to effectively control inflammation and recovery of visual acuity.

A Retrospective Study to Describe Clinical Features and Multimodal Imaging Features of Ocular Parasitosis in a Tertiary Care Ophthalmic Centre in South India

First Author: Eliza ANTHONY

Co-Author(s): Prabu BASKARAN, Anand RAJENDRAN, Mulla SHAIBAAN

Purpose: To study clinical features and multimodal imaging features of ocular parasitosis in a tertiary care ophthalmic centre in south India.

Methods: It's a retrospective study of patients diagnosed with ocular parasitosis, who presented to our outpatient clinic, over eight years (2017-2025). Complete analysis of demographic and clinical features was done. Detailed history taking, ocular examination, colour fundus photography, spectral domain optical coherence tomography (SDOCT), fluorescein angiography (FFA), indocyanine angiography (ICG) and B-scan ultrasonography was done to describe the multimodal features. Necessary blood work was performed.

Results: Among the 257 cases of ocular parasitosis, 187 cases were of ocular toxoplasma with age range of 4-73 years (mean age of 39.5 years), 31 cases of Diffuse

Unilateral Subacute Neuroretinitis (DUSN) having age range of 11-71 years (mean age of 29.35 years), 37 cases of toxocara in age group of 4-65 years (mean age of 26.1 years) and two cases of Gnathostomiasis. No gender predilection was noted in the toxocara and DUSN group, whereas in the toxoplasmosis group male gender was predominant. Appropriate blood work and multimodal imaging was done in each case and correlations were made to plan management options.

Conclusions: Our study demonstrates various clinical features of ocular parasitosis and the multimodal imaging features, which can aid in prompt and definitive diagnosis and management.

Panel No.: IUS-0457

A Vision of Vasculitis: Ocular Ischemia in Takayasu Arteritis

First Author: Sabrina Adabelle TIU

Co-Author(s): Timothy TANG LEE SAY

Purpose: To present a case of Takayasu retinopathy (TR), emphasizing the importance of early ophthalmic evaluation, laboratory work-up, and multidisciplinary management in patients diagnosed with or suspected to have Takayasu arteritis (TAK).

Methods: This study was conducted as a retrospective chart review of a single patient with TAK. Clinical data included visual acuity, slit-lamp biomicroscopy, gonioscopy, and fundus examination. Ancillary testing consisted of fluorescein angiography, indocyanine green angiography, and computed tomography angiography. Laboratory evaluation included inflammatory markers and infectious screening. Management strategies and short-term ocular outcomes were documented.

Results: A 21-year-old Filipino female presented with a two-year history of bilateral progressive vision loss. At baseline, visual acuity was hand movement in both eyes. Examination revealed iris and angle neovascularization with diffuse retinal ischemia, and angiography confirmed widespread retinal nonperfusion. Systemic evaluation demonstrated diminished upper limb pulses, asymmetric blood pressure, elevated inflammatory markers, and diffuse arterial wall thickening with branch vessel stenosis on CT angiography. Laboratory work-up was positive for purified protein derivative (PPD) and QuantiFERON-TB Gold. A diagnosis of TAK was established. The patient was started on immunosuppressants, and both eyes received intravitreal anti-VEGF injections with panretinal photocoagulation. One week after completing ocular treatment, vision improved to counting fingers at 5 feet in the left eye and remained hand movement in the right eye.

Conclusions: Ocular manifestations may precede systemic features in TAK. Early ophthalmic recognition, supported by laboratory and imaging findings, is

essential for timely multidisciplinary intervention to preserve vision and manage systemic disease.

Acute Anterior Uveitis Secondary to Hyperglycemic Crisis: A Case Report

First Author: Isela Angela VELASCO

Co-Author(s): Paul Gilbert APILADO, Francis Ezra LAXAMANA, Ronnie MANAYSAY, Giancarlo Miguel SANTOS

Purpose: To report a rare case of acute anterior uveitis with hypopyon associated with markedly elevated glycemic levels.

Methods: A 55-year-old male with poorly controlled Type 2 Diabetes Mellitus (HbA1c 15.73%) presented with a three day onset of unilateral hypopyon, eye redness, ocular discomfort, blurring of vision, and photophobia. Initial workup focused on infectious and autoimmune etiologies, which were ruled out through comprehensive laboratory tests and imaging.

Results: Of particular significance was the immediate resolution of the hypopyon the following day after prompt correction of the hyperglycemic crisis, even before starting topical corticosteroids or antibiotics. After ten days of topical corticosteroids and cycloplegics, along with good glycemic control, there was improvement in ocular symptoms and no recurrence on follow-up.

Conclusions: This case reinforces the potential role of hyperglycemia as a precipitating factor in intraocular inflammation. It underscores the importance of considering uncontrolled diabetes as a rare trigger of uveitis, particularly when infectious and autoimmune causes are excluded.

Adalimumab Reprograms M1 Macrophages to Promote CD4+ T Cell Apoptosis and Attenuate Th1/Th17 Responses in Behçet's Disease and Vogt-Koyanagi-Harada Syndrome

First Author: Yunyun ZHU

Purpose: To investigate the effects and mechanisms of adalimumab on monocyte-derived macrophage polarization and CD4+ T cell responses in patients with Behçet's disease (BD) and Vogt-Koyanagi-Harada (VKH) syndrome.

Methods: Macrophages were differentiated from CD14+ monocytes isolated from 30 patients with active BD disease and 32 patients with VKH syndrome. The effects of adalimumab on M1 macrophage polarization and cytokine production were assessed by flow cytometry and ELISA. Coculture experiments

of adalimumab-treated or untreated patient macrophages with CD4+ T cells from healthy donors were performed to evaluate T cell apoptosis and Th1/Th17 differentiation. Integrated transcriptomic and proteomic analyses were conducted on adalimumab-treated M1 macrophages from BD and VKH patients.

Results: Pro-inflammatory M1 macrophage polarization was significantly increased in BD and VKH. Adalimumab treatment reversed the M1-polarized phenotype and markedly reduced the expression of TNF- α , IL-1 β , IL-6, and IL-12 (all $P < 0.05$). Adalimumab-conditioned M1 macrophages promoted CD4+ T cell apoptosis and inhibited Th1/Th17 differentiation, while adalimumab itself had no direct effect on T cells. Multi-omics analysis revealed disease-specific mechanisms: significant downregulation of metallothionein members (MT1H, MT1G, MT1A, MT1F, MT1E, MT1X, and MT2A) was specific to BD, while suppression of SAA1, SLC39A8, SLC1A3, and TNFAIP2 characterized VKH.

Conclusions: Adalimumab exerts its therapeutic effects by inhibiting pro-inflammatory M1 macrophage polarization, which subsequently promotes CD4+ T cell apoptosis and attenuates Th1/Th17 immune responses. Disease-specific targets, particularly metallothioneins in BD, were identified, providing novel insights for precision immunotherapy in uveitis.

Airborne Fine Particulate Matter (PM2.5) Damages the Inner Blood-Retinal Barrier by Inducing Inflammation and Ferroptosis in Retinal Vascular Endothelial Cells

First Author: Yuzhou GU

Co-Author(s): Qiuli FU, Ke YAO

Purpose: Epidemiological studies suggest a potential link between major atmospheric pollutants like fine particulate matter (PM2.5) and retinal diseases such as retinal artery occlusion, including changes in retinal layer thickness and vascular caliber. This study aims to explore the impact and molecular mechanisms of atmospheric pollutant exposure on the retina using animal and cell models.

Methods: In vivo experiments utilized rat models exposed to PM2.5 suspension via eye drops. Inner blood-retinal barrier (iBRB) function was assessed using OCTA and Evans blue extravasation assays. In vitro experiments employed a model of human retinal microvascular endothelial cells (HRMECs) exposed to PM2.5. Cell viability, proliferation, migration, along with markers of inflammation and ferroptosis were evaluated.

Results: We observed iBRB damage in PM2.5-exposed animals, manifested as retinal vascular dilation, increased leakage, and retinal edema.

Concurrently, increased adhesion of leukocytes to vessels and elevated expression of inflammation-related proteins indicated that PM2.5 induces retinal vascular endothelial cell damage by triggering inflammatory responses. To investigate the specific injury mechanisms, we found that PM2.5 induced time- and concentration-dependent damage in HRMECs, inhibiting their viability, proliferation, and migration, while inducing inflammation and apoptosis. Ferroptosis was also triggered by PM2.5 exposure in HRMECs. Notably, the ferroptosis inhibitor Ferrostatin-1 significantly alleviated PM2.5-induced cytotoxicity.

Conclusions: This study is the first to investigate the effects of PM2.5 on the retina in vivo, revealing the critical role of inflammation and ferroptosis in PM2.5-induced iBRB injury. These novel findings further provide new perspectives for the prevention and treatment of PM2.5-related fundus pathologies.

Anterior Non-Necrotizing Scleritis With Semilunar Keratopathy- Morphological Patterns, Treatment Outcomes and Resolution

First Author: Vishal JADHAV

Co-Author(s): Anup KELGAONKAR, Mitali MANGOLI

Purpose: Non-necrotizing anterior scleritis has been linked to multiple etiologies. In literature, a semilunar sign is defined as keratopathy affecting the posterior corneal stroma and is usually associated with anterior scleritis. We report a cohort of such patients to determine their clinical presentation and management course.

Methods: A prospective, interventional, multicenter study included 14 patients (18 eyes) clinically diagnosed with anterior scleritis and semilunar sign. The descriptive findings and inclusion of cases were done by a single observer.

Results: Mean age was 40.92 years. 10 were unilateral, 4 were bilateral. All patients denied prior history of tuberculosis, except one. Mean number of semilunar lesions was 2.1. All patients had active anterior non necrotizing scleritis, with temporal (5) and superior quadrants (4) commonly involved. All semilunar lesions involved posterior stroma with granular (12), tigroid (2) and homogenous (2) as morphological patterns. 2 cases had ANA positive, while 5 had Mantoux positive. All cases were started on topical steroids and cyclosporine 0.1%, while 4 cases required systemic immunosuppressive therapy. 5 cases showed resolution of lesions and scleritis at mean treatment period of 3 months.

Conclusions: Anterior scleritis associated with semilunar lesions, although demonstrate slow resolution, but show response to topical steroids and immunosuppressives.

Abstract No.: 202199

Anterior Non-Necrotizing Scleritis in Ophthalmia Nodosa: Clinical Features and Healing Patterns

First Author: Vishal JADHAV

Co-Author(s): Kasturi CHAVAN, Anup KELGAONKAR

Purpose: Caterpillar hair setae-induced ophthalmic manifestations exhibit a seasonal pattern and have a wide spectrum of manifestations. We describe these morphological patterns at presentation and post-treatment.

Methods: Retrospective case series of cases presenting with ophthalmia nodosa associated scleritis.

Results: We analysed retrospectively 22 patients with a mean age of 40.5 years (+/-12.50 years). We observed a mean of 29.53 days' delay between presentation as scleritis and exposure to caterpillar setae. Inferonasal scleral quadrant was most common (n=13), followed by inferotemporal (n=9). Diagnostic feature was identification of corneal setae (n=22); common location being posterior corneal stroma (n=17). The healing pattern was non-necrotising (n=22) with the development of conjunctival brown pigmentation (n=16) in the area of scleritis. Pigmentation was either unifocal (n=10) or multifocal (n=6). The most common pattern of pigmentation noted was linear (n=14). Vitreous setae were seen in four eyes. Management of scleritis- 1. topical steroids & oral NSAIDs (n=20); 2. Oral steroids (baseline one eye, consecutively two eyes). Corneal removal of caterpillar hair was done in 5 patients. Recurrence was noted in the form of scleritis (n=5), keratitis (n=1), vitritis (n=1), and anterior chamber inflammation (n=1) requiring additional extension of treatment, including pars plana vitrectomy (n=1).

Conclusions: Caterpillar hair setae can cause anterior scleritis, which had a healing pattern of non-necrotising with localised conjunctival pigmentation. The scleritis resolved with oral NSAIDs, topical steroids and rarely needed oral steroids. It recurred in about one-fifth of the cases.

Panel No.: IUS-0483

Atypical Management of Presumed Tubercular Choroiditis With Isoniazid

First Author: Syecha Tsania ALAYDRUS

Co-Author(s): Halida WIBAWATY, Gagan Vihari Izzan YULIANTO

Purpose: To report a case of presumed tubercular choroiditis with multiple large choroidal tuberculomas that improved with isoniazid and corticosteroid therapy.

Methods: A 73-year-old woman presented with long-standing blurred vision mainly in the right eye. Initial

examination revealed UCVA 1/300 and 0.4, grade 2 cataracts in both eyes, and vitreous opacities. Fundus photography of the right eye showed multiple, yellowish elevated choroidal lesions, which collectively occupied approximately one-quarter to one-third of the imaged fundus. Laboratory evaluation showed elevated ESR, but Mantoux testing and systemic evaluation for tuberculosis were negative. The patient denied a history of tuberculosis and currently had no systemic TB symptoms. Based on these findings, a diagnosis of presumed tubercular choroiditis was made. The patient was started on oral isoniazid monotherapy combined with oral and topical corticosteroids.

Results: After two weeks of isoniazid therapy, visual acuity improved from UCVA 1/300 to 2/60. By four weeks, UCVA further improved to 0.5 in the right eye, accompanied by regression of the choroidal lesions.

Conclusions: This case demonstrates clinical improvement of presumed tubercular choroiditis with isoniazid monotherapy plus corticosteroids, suggesting a potential therapeutic role despite current recommendations for multidrug anti-tubercular therapy.

Balanced Medication Use in Patients With Systemic Lupus Erythematosus Fungal Endophthalmitis

First Author: Zhongyang YAN

Co-Author(s): Xin JIN, Lifei WANG, Kaixuan ZHAO

Purpose: Endogenous fungal endophthalmitis (EFE) is a blinding eye disease caused by hematogenous spread and is easily misdiagnosed as retinal vascular disease or noninfectious uveitis. This article reports the diagnosis and treatment of *Candida albicans* EFE secondary to SLE and vaginitis, exploring the risk of misdiagnosis and individualized management strategies.

Methods: A 33-year-old female SLE patient with vaginitis and nephrolithiasis was admitted to the hospital with blurred vision in her left eye. After differential diagnosis, EFE was confirmed and treated with intravitreal voriconazole and vitrectomy, combined with systemic oral fluconazole.

Results: There is a conflict between the underlying SLE disease and EFE: immunosuppression creates conditions for fungal entry into the bloodstream, but lupus control requires maintenance of immunosuppression, and antifungal treatment requires immune restoration. Compared to patients with common fungal endophthalmitis, our team adopted a prolonged antifungal therapy strategy, extending oral fluconazole therapy to 16 weeks after ocular treatment, which significantly improved the patient's vision, infection, and retinal condition.

Conclusions: Intravitreal injection of 100 µg voriconazole can reach a bactericidal concentration of 200 times the MIC90, and long-term regular systemic medication is recommended. Clinically, we should be alert to EFE manifestations. Even if the anterior segment symptoms are mild and the vitreous humor test is negative, infection cannot be ruled out. Antifungal treatment should be balanced with hormone therapy, and individualized treatment should be emphasized.

Abstract No.: 210368

Panel No.: IUS-0488

Bartonella-Associated Optic Retinitis: A Case Report of Treatment With Ranibizumab Plus Compound Sulfamethoxazole

First Author: Qihang LI

Co-Author(s): Jian LI

Purpose: To describe the clinical features, diagnosis, and treatment outcomes of Bartonella-associated optic retinitis (related to Cat Scratch Disease, CSD) and provide references for clinical differential diagnosis.

Methods: A retrospective analysis of a single case was conducted, integrating ophthalmic specialist examinations, multimodal imaging (OCT, FFA), laboratory tests, and etiological detection, with 13 weeks of follow-up data recorded.

Results: A 43-year-old male with hypertension and asymptomatic hepatitis B virus (HBV) carrier state (Xiaoyangsan) had blurred vision in the right eye for 2 days. He was misdiagnosed as optic neuritis locally, with ineffective hormone therapy. After transfer, his right eye visual acuity was 0.5, with optic disc edema (accompanied by hemorrhage), macular edema, and star-shaped exudation. The right eye's average retinal nerve fiber layer (RNFL) thickness was 146 µm (left eye: 97µm), and macular ILM-RPE thickness was 426 µm (left eye: 253µm). Further history showed he long-term kept unvaccinated stray cats. Serum Bartonella indirect immunofluorescence assay (IFA) titer was 1:256 (indicating recent infection). Post-diagnosis, he received 3 intravitreal Ranibizumab injections plus oral compound sulfamethoxazole tablets (twice daily for 8 weeks). After 13 weeks of follow-up, his right eye visual acuity improved to 1.0, RNFL thickness decreased to 102 µm, and edema and exudation completely resolved.

Conclusions: Inquiry about cat contact history, serum IFA detection, and multimodal imaging can confirm this disease, and Ranibizumab combined with compound sulfamethoxazole is an effective treatment.

Abstract No.: 201511**Panel No.: IUS-0447**

Biopsy-Proven Herpes B Virus Infection With Ocular Involvement in a Living Patient Following Monkey Bite

*First Author: Wilson Chung Fai CHAN**Co-Author(s): Rose Pui San CHAN, Eva Wai Nam WONG*

Purpose: Herpes B Virus infection is a rare zoonotic disease acquired via contact with macaques. Human infection of the virus typically leads to encephalitis and myelitis, which may result in permanent neurological sequelae or death. Ocular involvement of Herpes B virus is rarely reported in literature. We report the first vitreous biopsy proven Herpes B virus related panuveitis and chorioretinitis in an adult with severe neurological involvement.

Methods: Retrospective review of medical record was performed to extract the essential clinical history and management.

Results: A 37-year-old man with good past health developed severe Herpes B Virus infection after bitten by a monkey in Hong Kong. He presented with severe meningoencephalitis with bilateral ocular involvement. Diagnosis was delayed as the collateral history of monkey bite was obtained 10 days after admission. Ocular manifestations included anterior uveitis, vitritis, vasculitis and multifocal necrotizing haemorrhagic chorioretinitis with optic nerve involvement. Left eye vitreous biopsy PCR was positive for Herpes B Virus. Treatment included systemic and intravitreal ganciclovir injections, leading to gradual improvement of ocular disease. On his final eye review, retinitis had resolved bilaterally. Both eye showed optic atrophy, chorioretinal atrophy and residual vitritis. However patient had poor systemic recovery, resulting in death after two months.

Conclusions: This is the first reported vitreous biopsy-proven intraocular Herpes B Virus infection in a living patient. Systemic infection led to devastating outcome due to delay in diagnosis and severe neurological involvement, emphasizing the need of prompt diagnosis and treatment to prevent blindness and mortality.

Abstract No.: 206864**Panel No.: IUS-0482**

Clinical Profile and Long-Term Prognosis of Pediatric Uveitis at One Medical Institute in Beijing

*First Author: Liu YANG**Co-Author(s): Zonghui MA*

Purpose: To analyze the clinical characteristics and the prognosis of pediatric uveitis in a single eye center in Beijing.

Methods: This is a retrospective study. The children who were diagnosed with uveitis at the onset, aged no

more than 16 years old, were included. The patients underwent routine visual acuity, slit-lamp microscopy, ophthalmoscopy, and relevant laboratory tests. The clinical data of patients' onset age, unilateral or bilateral eye involved, recurrence, inflammation site, etiology, treatment modality, complications, and other clinical data were collected. The multifactorial regression analysis model was established to comprehensively analyze the factors affecting the prognosis of uveitis in children.

Results: A total of 198 pediatric uveitis patients were included in the study, with a mean age of 11.6 ± 3.1 years (range :2-16), and a slight female predominance (55.2%). A high proportion of patients presented with an insidious onset (52.5%) and bilateral involvement (64.1%). The most common type was pan-uveitis (43.9%), the most frequent cause was Juvenile Idiopathic Arthritis (13.6%), and the most common complications were concomitant cataracts (17.2%) and secondary ocular hypertension/glaucoma (13.1%). Key factors influencing visual prognosis include early standardized treatment, recurrence frequency, and ocular complications

Conclusions: Pediatric uveitis presents greater diagnostic and therapeutic challenges than adult uveitis due to insidious onset, atypical symptoms, relapsing course, and resistance to conventional management. Early diagnosis, individual-based, and more aggressive treatment are crucial. During management, efforts should focus on minimizing the risk of vision-threatening complications from uncontrolled ocular inflammation, preventing lifelong burdens of vision loss and medication side effects on affected children and their families.

Clinical Profile of Sympathetic Ophthalmia in a Tertiary Eye Care Centre in Eastern India

*First Author: Amitabh KUMAR**Co-Author(s): Jyotirmay BISWAS*

Purpose: To study the clinical profile of 43 patients with Sympathetic Ophthalmia (SO) in a tertiary eye care centre in Eastern India

Methods: Retrospective observational case series of 43 patients between January 2009 and December 2023. Data was compiled based on a detailed history, a thorough ophthalmological examination, relevant investigations, treatment and visual outcome

Results: Out of the 43 patients, 33 were males (76.74%) with a mean age of 34.60 years. The commonest cause was an open globe injury (34.9%). 11 patients (25.5%) developed SO post intraocular surgery. 2 patients had already undergone evisceration at the time of presentation. Mean duration between trauma or surgery and the onset of symptoms in the sympathising

eye was 77.3 months. Commonest symptom was diminution of vision(100%). Commonest anterior segment sign was granulomatous uveitis (88.3%). 88.3% had vitreous cells,53.5% had disc oedema and exudative retinal detachment each. 76.7% of patients were treated with intravenous steroids. Commonest steroid sparing agent used was azathioprine (81.4%). Average follow-up period was 40 months. Commonest complications were glaucoma (25.6%) and cataract (16.3%). Pre-treatment vision in the sympathising eye (LogMAR) was 1.03+/-1.02 which improved to 0.56+/-0.99 post treatment. 48.8% patients had no recurrence whereas 34.8% had one,9.3% had 2 and 2.3 % had 3 or more recurrences

Conclusions: Sympathetic Ophthalmia is a potentially visually devastating condition affecting people in their most productive years. It needs an early diagnosis and adequate treatment in view of recurrences

Collateral Damage: A Case Report on Sympathetic Ophthalmia in a 35-Year-Old Female Filipino Patient

First Author: Pia Jejame **MAMARIL**

Co-Author(s): Angelique **ANG**, *Janice* **FERRER-BERNARDO**

Purpose: Sympathetic ophthalmia is a rare autoimmune ocular inflammatory, with an incidence of approximately 0.03 per 100,000 persons per year. This case report details the progression, diagnosis, and management of SO, specifically analyzing the sequential blurring of vision in the fellow eye.

Methods: A 35-year-old Filipino female initially presented with a one- month history of bilateral sequential progressive painless blurring in the left eye, following a prior traumatic injury on the right eye. Initial ophthalmic examination revealed poor light projection and an intraocular pressure of 8 mmHg in OD, along with a supraorbital scar, enophthalmos, and Grade I traumatic hyphema. Visual acuity in OS was counting fingers, best corrected to 20/200, with granulomatous keratic precipitates, an IOP of 12 mmHg and optic nerve swelling. Despite multiple consultations and an initial impression of non-penetrating globe injury with intraocular hemorrhage on OD and optic disc edema on OS, further diagnostic workup- including an orbital MRI with contrast- led to the final diagnosis of a ruptured right globe, and Sympathetic Ophthalmia in OS.

Results: Early enucleation of the injured OD was performed, a measure known to improve the visual prognosis of the fellow eye. Also, following treatment with high-dose intravenous steroids and immunosuppressive therapy, vision in OS improved to 20/20.

Conclusions: The incidence of SO following traumatic eye injury is approximately 0.19%. Management requires prompt hospitalization, administration of high-dose corticosteroids, and Immunosuppressive therapy, which are key to improving visual outcomes in affected patients.

Complement Mediated Innate Immunity in Tubercular Serpiginous-Like Choroiditis: Initial Insights From a Targeted Genetic Study

First Author: Reema **BANSAL**

Co-Author(s): Payal **BAJAJ**, *Prateek* **BHATIA**, *Vishali* **GUPTA**, *Basavaraj* **TIGARI**

Purpose: Complement system is a key part of innate immunity, involved in inflammation. Complement proteins are expressed by retinal pigment epithelial cells. Dysregulation of this pathway is linked to diseases like AMD, diabetic retinopathy, and uveitis. However, its role in tubercular uveitis is unclear. This study investigates complement factor variations in patients with tubercular Serpiginous-like Choroiditis (TB-SLC).

Methods: Participants included: Group A (30 TB-SLC patients), Group B (30 TB-associated uveitis without SLC), and Group C (90 healthy controls). Genomic DNA was extracted from peripheral blood. A custom amplicon-based next-generation sequencing (NGS) panel targeting 25 complement-related genes was employed to detect single nucleotide variants (SNVs), insertions/deletions (INDELs), and copy number variations (CNVs). Variants were annotated and mapped to different complement pathways.

Results: Distinct variant patterns were observed. Group A had more CNVs (n=11) than SNVs/INDELs (n=5), involving C3, C5, and CFH. Group B showed more SNVs/INDELs (n=13) than CNVs (n=5), affecting CFHR1/2/4, CFB, CFI, and others. Controls had five SNVs/INDELs and no CNVs. Group A variants mostly affected complement proteins, while Group B showed a balanced protein-regulator distribution. Pathway analysis revealed predominant involvement of alternative pathway in Groups A and B.

Conclusions: This first-of-its-kind study in TB-SLC highlights the potential role of complement pathway variants, in disease susceptibility and phenotype. This opens future directions for prospective validation, and in vitro animal or cell line functional studies before exploring anti-complement therapy for TB-SLC.

Abstract No.: 210035**Panel No.: IUS-0485**

Core Fucosylation Modulates T Cell Proliferation and Differentiation in Autoimmune Uveitis

First Author: Peng XUENING

Purpose: Autoimmune uveitis (AU) is a severe disorder causing poor vision and blindness. Immune checkpoint inhibitor-associated uveitis (ICIU) accounts for 1% of ocular immune-related adverse events (irAEs). Core fucosylation—catalyzed by FUT8—represents a specialized N-glycosylation mechanism that has been reported to modulate several autoimmune diseases. However, the pathogenic mechanisms of FUT8 in AU as well as ICIU are still unknown.

Methods: In this paper, single-cell RNA sequencing of the retina and cervical draining lymph nodes (CDLNs) in experimental autoimmune uveitis (EAU) mice was conducted to identify the N-glycosylation level and upregulation of the core fucosylation-related gene FUT8.

Results: In results, our data indicated that the FUT8 inhibitor effectively alleviated inflammatory infiltration and reversed pathological alterations of EAU via suppression of core fucosylation. The imbalance of T effector (Teff) cells/T regulator (Treg) cells was rescued in CDLNs, spleen and retina in the EAU model. On the other hand, in tumor-bearing EAU mice and immune checkpoint inhibitor-associated uveitis (ICIU) models, FUT8 inhibitor demonstrated dual anti-tumor and anti-inflammatory effects. Tumor volume and weight in both B16 + EAU and B16 + EAU + anti-PD-1 (ICIU) models were significantly reduced by the FUT8 inhibitor. Though EAU inflammation level was exacerbated with anti-PD-1 treatment, our data suggested that the FUT8 inhibitor effectively restored the abnormal Teff/Treg ratio and alleviated EAU symptoms. Furthermore, combination therapy with FUT8 inhibitor and anti-PD-1 enhanced CD8⁺ T cell-mediated cytotoxicity while reducing CD8⁺ T cell exhaustion. Additionally, the FUT8 inhibitor promoted tumor cell apoptosis in vitro.

Conclusions: Collectively, these results elucidate the immunomodulatory mechanisms of the FUT8 inhibitor, highlighting its potential as a novel therapeutic strategy for AU and ICIU.

Diagnosis and Management in a Case of Ampiginous Chorioretinitis

*First Author: Chynna Pearl Tana BACCAY**Co-Author(s): Albert John BROMEIO*

Purpose: Ampiginous chorioretinitis (AC) is a rare inflammatory chorioretinopathy involving the retinal pigment epithelium (RPE) in a severe variant with features overlapping of acute posterior multifocal

placoid pigment epitheliopathy (APMPEE) and serpiginous choroiditis (SC). The lesions tend to recur in crops over time, leading to a wave of active chorioretinitis lesions and atrophy in healed areas. We report the clinical findings, diagnostic features, and management of a case of relentless placoid chorioretinitis (RPC).

Methods: Case Report

Results: A 33 year old male presented with blurring of vision OU. Best corrected visual acuity (BCVA) was 20/63 OD and 20/32 OS. Examination showed multifocal placoid hyper- and hypopigmented lesions on the retina associated with vitritis. Fluorescein angiography (FA) showed early hypofluorescence with late hyperfluorescence of active lesions and transmission defects in old lesions. OCT revealed RPE discontinuity and outer retinal loss with areas of hypertransmission defects and focal areas of RPE bumps. Fundus autofluorescence (FAF) showed mixed areas of hyperautofluorescent hypoautofluorescent areas. Systemic work-up was unremarkable. The patient was diagnosed with AC OU and started on course of oral prednisone as well as methotrexate. Over a follow-up period of 1 year, active lesions eventually became atrophic with no appearance of new lesions.

Conclusions: AC is a rare but vision-threatening inflammatory condition requiring early diagnosis and prompt initiation of immunosuppressive treatment. Multimodal imaging greatly aids in the diagnosis. Long-term follow-up is essential for effective management and improved visual outcome

Abstract No.: 201391**Panel No.: IUS-0446**

Distinct Glycoprotein B Genotypes in Cytomegalovirus Ocular Infection and Their Potential Impact on Antigen Presentation

*First Author: Tantri LESTARI**Co-Author(s): Hiroko MIYADERA, Yasuo MORI, Mariko SHIRANE, Koh-hei SONODA, Nobuyo YAWATA*

Purpose: Human cytomegalovirus (CMV) establishes latent infection and is typically asymptomatic in immunocompetent hosts. Nevertheless, CMV ocular infection can occur in the absence of immunodeficiency. UL55 encoding glycoprotein B (gB) is essential for viral entry and serves as a major immune target for antibody-mediated immunity. UL55 is highly polymorphic and classified into five genotypes (gB1-gB5). This study investigated the distribution of UL55 genotypes in CMV infection and their impact on antigen presentation.

Methods: Intraocular fluid and blood samples were obtained from 62 patients with CMV ocular infection or CMV viremia. UL55 polymorphic regions were sequenced, and genotype frequencies were determined using multiplex polymerase chain reaction.

gB genotype-specific peptides were identified and assessed in silico for binding affinity to HLA class II molecules. Predicted high-affinity peptides underwent peptide–HLA class II complex expression assays to evaluate binding efficiency.

Results: UL55 genotype distribution differed significantly between the eye and blood. In blood samples, gB2 predominated (41%), whereas in ocular fluid, gB3 (43%) and gB1 (37%) were most frequent, with gB2 found in only 17%. A peptide spanning residues 190–204, shared by gB3 and gB1 but distinct in gB2 was predicted to have altered HLA class II binding affinity. Expression assays confirmed that the gB1/gB3-derived peptide exhibited significantly lower peptide–HLA class II complex expression compared with the gB2-derived peptide.

Conclusions: gB1 and gB3 dominated UL55 genotypes in ocular fluids from patients with CMV infection. These genotypes may facilitate intraocular expansion of CMV through reduced peptide presentation on HLA class II molecules.

Efficacy and Safety of Pulsed Intravenous and Daily Oral Corticosteroids in Non-Infectious Intermediate and Posterior Uveitis: A Systematic Review

First Author: Ayu **NAWANG WULAN**

Co-Author(s): Teofilus **ABDIEL**, Elizar **ASRIYANI AKIB**

Purpose: Intermediate and posterior non-infectious uveitis account for 5–15% of visual impairment. Corticosteroids remain first-line, but the relative efficacy of pulsed intravenous (IV) versus daily oral therapy is uncertain. This review evaluates efficacy and safety.

Methods: Following PRISMA guidelines, PubMed, Cochrane Library, and ScienceDirect were searched (2005–2025). Nine studies including (638 patients; three randomized controlled trials, six observational) were analyzed. Risk of bias was assessed using the Newcastle–Ottawa Scale for observational or Cochrane Risk of Bias tool for RCTs. Study selection and data extraction were performed independently by two reviewers, with discrepancies resolved through consensus or adjudication by a third author.

Results: Most included studies involved Vogt–Koyanagi–Harada (VKH) and Behçet’s representative forms of uveitis. In VKH, comparative studies found no significant difference in final visual outcomes between IV and oral corticosteroids. Other VKH series reported the majority achieving good vision at follow-up. In Behçet’s disease, IV pulse improved vision compared with placebo. Recurrence in VKH ranged 15–25%, with IV showing fewer relapses. Despite aggressive treatment, many progressed to chronic–

recurrent disease. Complications included cataract and glaucoma, both lower with IV in some cohorts. Sunset glow fundus also appeared less frequent with IV. Adjunct therapy with IV pulse was non-inferior to prednisolone–cyclosporine for recurrence prevention and lowered cataract risk.

Conclusions: IV pulse and oral corticosteroids provide comparable visual improvement. IV may lower cataract, glaucoma, relapses, and sunset glow fundus in VKH, long-term safety requires further study.

Efficacy of Oral Methotrexate in Adolescents With Refractory Vernal Keratoconjunctivitis: A Case Series

First Author: Gaganvihari Izzan **YULIANTO**

Co-Author(s): Syecha Tsania **ALAYDRUS**, Halida **WIBAWATY**

Purpose: To evaluate the efficacy of low-dose oral methotrexate as an adjunct therapy in adolescents with refractory vernal keratoconjunctivitis (VKC).

Methods: Three boys aged 13–15 years presented with severe vernal keratoconjunctivitis (VKC). All patients exhibited symptoms of itching, excessive tearing, redness, and blurred vision. Slit-lamp examination revealed multiple giant papillae on the palpebral conjunctiva in all cases, with two patients developing corneal ulcers and one showing conjunctivalization of the cornea, suggestive of limbal stem cell deficiency (LSCD). Initial treatment with conventional therapies resulted in minimal improvement. Subsequently, oral methotrexate (5 mg/week) was added, leading to significant symptom relief within two weeks, stabilization of corneal involvement, and reduced dependence on corticosteroids, with no major adverse effects observed during follow-up.

Results: All three patients demonstrated significant symptomatic relief within two weeks of initiating oral methotrexate. Improvement included reduction in itching, tearing, and redness, along with stabilization of corneal involvement. The need for prolonged corticosteroid therapy decreased, and no major systemic adverse effects were observed during follow-up.

Conclusions: Low-dose oral methotrexate demonstrated efficacy as an adjunctive treatment in refractory VKC, providing symptom control, reducing steroid dependence, and stabilizing corneal complications, including LSCD. This therapy may represent a safe and effective option for adolescents with severe disease unresponsive to conventional management.

Endogenous Endophthalmitis in Diabetes: Breaking the Vicious Cycle With Aggressive Management and Ultra-Wide-Field Imaging

First Author: Yura PRADIPTAMA

Co-Author(s): Valerie GRACIA, Yelsi KHAIRANI, Rina La Distia NORA, Kiara NURMATHIAS

Purpose: To highlight the importance of aggressive management and ultra-wide-field fundus (UWFF) imaging in diagnosing and controlling endogenous endophthalmitis in uncontrolled diabetes.

Methods: A 54-year-old female with uncontrolled diabetes initially developed right endogenous endophthalmitis and underwent vitrectomy, with *Escherichia coli* isolated from the vitreous. She was discharged but was later readmitted for diabetic ketoacidosis and an intravenous site infection. During this admission, she developed new visual complaints in the left eye. UWFF imaging revealed posterior lesions consistent with endogenous endophthalmitis, despite minimal anterior signs. The patient was hospitalized, given systemic antibiotics, and underwent right eye evisceration. Blood and ocular cultures again confirmed *E. coli*. Evisceration revealed extensive pus trapped behind silicone oil, not apparent on anterior examination. The left eye was initially treated with broad-spectrum antimicrobials, then switched to intravitreal meropenem once cultures confirmed *E. coli*. Aggressive approach then was taken for the left eye that have visual acuity 1/300 to the vitrectomy for the patient. 1 week after the surgery patient visual acuity improved to 0.5/60 and planned for cataract extraction.

Results: The right eye was lost to infection, but aggressive systemic, intravitreal therapy, and ultimately the vitrectomy stabilized the left eye with visual acuity improving to 1/60 after cataract surgery. UWFF imaging guided repeated injections and objectively evaluate infection control.

Conclusions: Endogenous endophthalmitis in diabetes requires early aggressive management rather than conservative globe preservation. Breaking the vicious cycle of uncontrolled infection and hyperglycemia is essential. UWFF imaging is a powerful tool for early diagnosis, detecting hidden lesions, and monitoring therapeutic response.

Epidemic Retinitis With Extensive Retrobulbar Optic Neuritis in the Winter of 2023–24

First Author: Ronnie Abhishek TALLURI

Co-Author(s): Soumyava BASU, Anup KELGAONKAR

Purpose: To understand the extent of optic nerve involvement contributing to vision loss in retinitis post-

febrile illness and use of systemic corticosteroids in the treatment of epidemic retinitis.

Methods: We retrospectively reviewed all patients diagnosed with post-fever retinitis in the electronic medical records from October 2023 to February 2024 in a tertiary eye care facility. The study was approved by the Institutional Review Board (IRB) and adhered to the guidelines of the Declaration of Helsinki. Cases with documentation of best corrected visual acuity (BCVA) for near, intraocular pressure, slit lamp examination, and fundus evaluation, including investigations, were considered for inclusion.

Results: Eight patients (10 eyes) were included in the study. Bilateral presentation was in two (n=2, 28.5%) patients. Five patients (n=5, 62.5%) were male. Mean best corrected visual acuity (BCVA) in log MAR for distance was 0.896 and 0.65 for near. Symptomatic fever with skin rashes was seen in three cases (n=3, 42.8%). The etiology was Typhoid (n=2, 25%), Typhus (n=4, 50%), and Herpes viruses (n=2, 25%). Magnetic resonance imaging (MRI) showed optic nerve involvement in three (n=3, 37.5%) and a normal study in two (n=2, 28.5%). Doxycycline was given as empirical treatment in all patients except for two who had herpetic dermatitis and fever, who were treated with Valacyclovir. IV methylprednisolone was given to 4 patients (n=4, 50%) at baseline. Oral steroids were used in all cases. The mean BCVA for distance improved to 0.178 and for near to 0.21.

Conclusions: Disproportionate vision loss compared to fundus evaluation should raise the suspicion of optic nerve involvement necessitating the use of pulse steroids in the management of epidemic retinitis with extensive vision loss.

Abstract No.: 203609
Panel No.: IUS-0462

Famciclovir to the Rescue in a Case of Paediatric Acute Retinal Necrosis

First Author: Lisa SUNNY

Co-Author(s): Vedhanayaki RAJESH, Rathinam SIVAKUMAR, Radhika THUNDIKANDY

Purpose: To report a case of Paediatric Acute Retinal Necrosis (ARN), with poor response to Valacyclovir, treated successfully with oral Famciclovir

Methods: 9 year old child presented to the Uvea clinic with complaints of blurred vision in left eye (LE) for 2 weeks. Child had been treated outside as viral posterior uveitis and was on oral Valacyclovir 1 gram (g) thrice a day (tds), along with oral steroids for the past 1 week. She had history of bilateral parotitis 9 months back. Mumps was ruled out. She also had exposure to a chicken pox patient 1 week before onset of symptoms, but did not develop any viral exanthem. On examination, Right eye (RE) was within normal limits. LE had a best corrected visual acuity (BCVA)

of 6/24 p with 4+ cells in anterior chamber, grade 1 vitreous haze, 3+ cells, hyperaemic disc, multiple yellowish retinitis patches with haemorrhages and vessel sheathing in the periphery, nasally encroaching the optic disc with a serous retinal detachment. Patient was given 3 days of intravenous acyclovir 10 mg/kg tds, along with oral steroids, but with poor response. She was then switched over to oral Famciclovir 500 mg tds and underwent LE vitrectomy, biopsy, intravitreal gancyclovir with silicone oil injection. Vitreous biopsy was positive for Herpes Simplex Virus.

Results: 3 weeks post op, BCVA was 6/18, with complete resolution of retinitis. Famciclovir was continued with tapering oral steroids and child asked to review in 1 month.

Conclusions: Famciclovir can be considered as an alternative in cases of paediatric ARN with inadequate response to Valacyclovir.

Abstract No.: 206301

From Darkness to Light: Tubercular Neuroretinitis Unmasked in a Young Dialysis Patient With IgA Nephropathy

First Author: Sameera V V

Purpose: To present a rare and diagnostically challenging case of bilateral sudden vision loss in a young lady on dialysis with IgA nephropathy, initially mimicking central serous retinopathy (CSR) and later evolving into tubercular neuroretinitis with exudative retinal detachment.

Methods: A 28-year-old female on chronic dialysis for IgA nephropathy presented with sudden bilateral vision loss to counting fingers. Initial fundus findings suggested CSR. Extensive investigations, including infectious, inflammatory, and vascular work-up, were performed. The exudative retinal detachment did not resolve despite high-dose corticosteroids. Vision did not improve, and exudates appeared, creating a diagnostic dilemma. Radiological workups and sputum evaluation were done later.

Results: Empirical anti-tuberculosis therapy (ATT) was initiated based on clinical suspicion and risk factors. The patient exhibited gradual improvement, ultimately achieving complete visual recovery to 6/6 in both eyes. This case highlights the atypical presentation of tubercular neuroretinitis and the potential for full visual restoration with timely, targeted therapy.

Conclusions: Neuroretinitis can mimic CSR and progress to sight-threatening complications such as exudative retinal detachment, particularly in immunocompromised patients. Maintaining a high index of suspicion for infectious etiologies and initiating appropriate therapy can lead to excellent visual outcomes, underscoring the importance of vigilance in atypical retinal presentations.

Abstract No.: 204259

From Stiffness to Sight: "A Case Series on Rheumatoid Arthritis and Eye"

First Author: Prem SAI.T

Co-Author(s): Roshita GARGAIN, Krithika M, Padma REKA

Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disorder affecting joints, but can also involve the extra-articular manifestations, including eyes, cardiac, skin, pulmonary, renal & skeletal.

Methods: This case series examines eight RA patients, highlighting dry eyes as the most common symptom, along with other rare conditions being secondary to RA management. Ocular evaluations included visual acuity, intraocular pressure, and tests for dry eye.

Results: Results showed that 7 females and 1 male were diagnosed to have dry eyes, episcleritis, scleromalacia, posterior scleritis, PUK, steroid-induced cataract, and HCQ-induced maculopathy.

Conclusions: This study emphasizes the importance of regular ophthalmic evaluations in RA patients for early detection and management of ocular complications, ultimately improving health outcomes and quality of life.

Abstract No.: 205137

Panel No.: IUS-0473

Intraocular Abscess Caused by Fusicolla – a Plant Fungus

First Author: Radhika THUNDIKANDY

Co-Author(s): Lisa SUNNY

Purpose: To report a case of intraocular abscess in a female patient caused by Fusicolla quarantina.

Methods: A 32-year-old healthy female presented with pain in her right eye. She denied trauma or a foreign body fall. She worked with coconut fiber and was exposed to air blast in the factory. Best-corrected visual acuity was 6/6, N6, in both eyes, with normal intraocular pressures. Anterior segment right eye showed cells, streak hypopyon with dense yellow exudates in the anterior vitreous temporally. The left eye was normal. She underwent core vitrectomy with intravitreal vancomycin, ceftazidime, and voriconazole. There was no growth in the vitreous on culture. She was continued on topical and systemic antibiotics. The exudates continued to increase. Ultrasound bio-microscopy showed a hyper-echoic lesion in the inferotemporal quadrant with localized thickening of the sclera, ciliary body, and iris. She underwent repeat pars plana vitrectomy with lensectomy for the complicated cataract. The polymerase chain reaction was reported positive for pan fungus. Gene sequencing showed Fusicolla quarantina as the causative organism. During vitrectomy, a small piece of the lesion was

biopsied, and pathology reported Geimsa stain-positive round bodies suggestive of spores. Patient was treated with intravitreal voriconazole, topical, and systemic antifungals.

Results: After antifungal treatment the lesion resolved well.

Conclusions: This is the first report of fusicolla causing intraocular abscess. This fungus is found to grow on the bark and fruit of palm. This is significant because our patient was exposed to coconut fibres and is likely that fibres could have pierced the sclera.

Panel No.: IUS-0453

Intravitreal Triamcinolone Acetonide (IVTA) Alone as a Treatment Modality for Post-Fever Retinitis

First Author: Vishal JADHAV

Co-Author(s): Anup KELGAONKAR

Purpose: Post fever retinitis (PFR) is a terminology used to describe immune mediated uveitic entity seen post febrile episode. It shows distinctive morphological characteristics and is usually managed using systemic steroids with antibiotics, with good visual outcomes at end of treatment. However Intravitreal Triamcinolone Acetonide (IVTA) is a choice less opted for treatment. We describe clinical profile, imaging characteristics, visual outcomes, and resolution patterns in 36 eyes (25 cases) of PFR treated with intravitreal triamcinolone acetonide alone.

Methods: Single centre, retrospective analysis of patients diagnosed with PFR

Results: We report 36 eyes of 25 cases with mean-age 41.5 years (10 unilateral, 13 bilateral). 23 cases were males, while 2 were females. Retinitis lesions were either multifocal (n=24) or unifocal (n=12). All the retinitis lesions healed with variable retinal thinning. Patterns of resolution noted were centripetal and/or breadcrumb like. Best corrected visual acuity-Baseline 0.86 logMAR, Last visit 0.50 logMAR (P<0.05). There was statistically significant visual improvement after injection at 3 month follow up. Mean resolution time of lesions- 13.25 weeks. Raised IOP was found in 2 eyes, whereas none developed any Cataract/ Endophthalmitis during the course of treatment

Conclusions: We observed overall favourable visual outcomes and anatomical outcomes after IVTA, with resolution of lesions in cases of PFR. IVTA in PFR was a safe alternative in our case series, negating the need of oral steroids/ antibiotics and decreasing side effects of periocular depot steroids. Also, no treatment failures were noted

Panel No.: IUS-0479

Management of Vogt-Koyanagi-Harada Syndrome in Pregnancy

First Author: John Joseph DAYRIT

Co-Author(s): Albert BROMEO, Nikki Regis DE MESA

Purpose: Vogt-Koyanagi-Harada (VKH) syndrome is a rare, bilateral, granulomatous panuveitis that can threaten vision usually accompanied by auditory, neurologic and integumentary manifestations. The disease is usually treated by early aggressive high dose systemic corticosteroids. However, management during pregnancy requires balancing maternal and fetal safety. We describe the clinical course and treatment outcome of a case of VKH during pregnancy.

Methods: Case Report

Results: A 25 year old G2P1 pregnant patient presented at 13 weeks of gestation with a three month history of fever, myalgia, headache, and tinnitus followed by two months of bilateral blurring of vision, redness, and photophobia. On examination, best corrected visual acuity (BCVA) was 20/160 on the right eye and 20/100 on the left eye. Examination showed anterior chamber cells with flare, posterior synechiae, vitritis, disc hyperemia, and multifocal serous retinal detachment. The patient was diagnosed with VKH. She was started on topical prednisolone and underwent posterior sub-Tenon triamcinolone injection on both eyes, and started on low dose prednisone at 10 mg daily under the guidance of an obstetrician. There was complete resolution of serous retinal detachment and decrease in macular thickening and leakage at 1 month follow-up. BCVA recovered to 20/20 on both eyes and quiescence was maintained during the course of pregnancy with no significant maternal or fetal adverse events.

Conclusions: The course of VKH may vary during pregnancy and needs close monitoring and follow-up. Treatment protocols may vary from nonpregnant patients and requires multidisciplinary collaboration.

Panel No.: IUS-0477

Metastatic Breast Adenocarcinoma Manifestation Mimicking Unilateral Vogt-Koyanagi-Harada Disease

First Author: Kampang SRIVIYA

Co-Author(s): Taniya BHOOPAT

Purpose: Case report for early recognition of a rare disease that presented with an uncommon manifestation.

Methods: Acquisition and analysis of the data of the case report.

Results: Vogt-Koyanagi-Harada (VKH) disease is a rare inflammatory disorder challenging diagnosis in clinical

practice. This case report highlights a 43-year-old previously healthy Thai woman who presented with unilateral VKH-like disease as the initial manifestation of metastatic breast carcinoma. Clinical findings included serous retinal detachment with multiple pinpoint leakages in fundus fluorescein angiography and diffuse choroidal thickening, suggestive of VKH; however, the unilateral presentation was atypical. Following corticosteroid treatment, her vision deteriorated, leading to further imaging that revealed irregular enhancing masses, ultimately confirmed as metastatic adenocarcinoma of breast origin. This case underscores the importance of considering malignancy in the differential diagnosis of atypical uveitis and illustrates that failure to respond to corticosteroids should raise suspicion for masquerade syndromes, highlighting the need for early oncologic intervention to improve patient outcomes.

Conclusions: In summary, this case exemplifies how systemic malignancies can masquerade as atypical presentations of uveitis and emphasizes the importance of an interdisciplinary approach involving oncologists, ophthalmologists, and pathologists to ensure comprehensive patient care. A thorough investigation is essential to avoid misdiagnosis and inappropriate management. As breast cancer survival rates continue to improve due to advancements in systemic therapies, awareness of ocular metastases must also increase among healthcare professionals. Timely recognition of such cases can lead to early treatment interventions that significantly impact patient prognosis and quality of life.

Ocular Ischemic Pathologies as Early Indicators of Antiphospholipid Antibody Syndrome: A Southeast Asian Case Series

*First Author: Bryan Vincent **MESINA***

*Co-Author(s): Teresita **CASTILLO**, Gino Nicolo **GUANZON**, Jonathan Paul **LACANILAO**, Faye **LEVINA***

Purpose: To describe the ocular manifestations of antiphospholipid antibody syndrome (APS) among Filipino patients and highlight its role as a cause of ocular ischemic disease.

Methods: We conducted a retrospective case series of seven patients with criteria-defined APS who presented with ocular ischemic pathologies at a tertiary referral center in the Philippines. Demographic, clinical, laboratory, and treatment data were reviewed.

Results: The cohort included six females and one male (6:1 ratio) with a median age of symptom onset of 26 years. All patients demonstrated ocular findings consistent with arterial thrombosis, including ischemic optic neuropathy, retinal vessel occlusion, vascular sclerosis, vasculitis, retinal and vitreous hemorrhage, and vitritis. One patient (14.3%) presented with

central retinal vein occlusion. Obstetric complications were noted in two patients (28.6%). Persistent lupus anticoagulant positivity was observed in all patients, most commonly via dilute Russell viper venom test (85.7%). Reported ocular sequelae included glaucoma (42.9%), fibroproliferative membranes with tractional retinal detachment (28.6%), subretinal fibrosis (14.3%), and macular edema (14.3%). Medical management via anticoagulant therapy was coordinated with rheumatology and immunology, while four patients (57.1%) required surgical intervention including panretinal photocoagulation, pars plana vitrectomy, glaucoma drainage device implantation, and intravitreal anti-VEGF injections. Final visual outcomes ranged from 6/7.5 to no light perception.

Conclusions: APS is an important but underrecognized cause of ocular ischemic events. Early recognition and prompt systemic evaluation are essential to reduce vision loss and systemic morbidity. Larger studies are warranted to better characterize and document APS-associated ocular disease in Filipino patients.

Ocular Kaposi's Sarcoma as a Sentinel of Disseminated Disease in HIV

*First Author: Christy **MAGDALENA***

*Co-Author(s): Fadima Fitri **LARASATI**, Rina La Distia **NORA**, Pura Riza **PRATAMA**, Nathania **SUTANDI***

Purpose: To describe a rare case of where ocular Kaposi's sarcoma served as the first clinical indicator of disseminated disease in an HIV-positive patient, highlighting diagnostic and management challenges.

Methods: Case report.

Results: A 42-year-old male with poorly controlled HIV presented with one month of progressive bilateral periorbital edema and violaceous conjunctival nodules. During the week prior to admission, he developed fever, nasal obstruction, and discharge. He had initially been diagnosed with dacryoadenitis and bacterial rhinosinusitis, but symptoms persisted despite treatment. Examination revealed bilateral violaceous conjunctival nodules with chemosis, as well as cutaneous nodules on the chest, axillae, and neck. Nasoendoscopy identified a nodular mass in the nasopharynx. Laboratory tests showed severe anemia and leukopenia, consistent with autoimmune hemolytic anemia (AIHA), with CD4 count was 69 cells/ μ L and HIV RNA viral load was 203 copies/mL. Histopathology and immunohistochemistry confirmed Kaposi's sarcoma in conjunctiva, skin, and nasopharynx. Coexisting autoimmune hemolytic anemia and recurrent infections further complicated management. Despite antiretroviral adjustment, corticosteroids, transfusions, and intravenous antibiotics, the patient deteriorated and died of refractory septic shock secondary to hospital-acquired pneumonia.

Conclusions: This case underscores that ocular Kaposi's sarcoma may represent a sentinel sign of disseminated disease in profoundly immunosuppressed patients. Early recognition by ophthalmologists is crucial, as ocular findings may precede or coincide with systemic involvement. Management requires careful multidisciplinary coordination to balance immune reconstitution, immunosuppression for autoimmune comorbidities, and infection control.

Ocular Leprosy: Socioeconomic Aspects, Clinico-Surgical Features, Visual Outcomes and Associated Visual Impairment in the Last Decade

First Author: Vishal JADHAV

Co-Author(s): Soumyava BASU, Anup KELGAONKAR

Purpose: To determine the socioeconomic impact, demographic profile, and clinical features, varied surgical interventions, visual outcomes, and World Health Organisation (WHO) defined visual impairment associated with ocular leprosy in the last decade.

Methods: Retrospective, single-center study. Demographic details, ocular and systemic treatment, socioeconomic aspects, clinico-surgical features, and vision loss (pre- and post-treatment) of 29 patients (43 eyes) were analysed. Patients presenting as a known case of leprosy or diagnosed as having leprosy based on ocular features were included.

Results: Twenty-nine patients were recruited, 2 of whom were diagnosed with leprosy after ocular manifestation: Non-granulomatous anterior uveitis (NGAU) (n=12), nodular scleritis (n=6), necrotizing scleritis (n=1), and adnexal features (5) were the commonest. The mean age of patients was 56.2 years. Baseline and final follow-up best corrected visual acuity were 1.06 and 1.04 logMAR, respectively. Diagnosed lepromatous leprosy were 4, borderline lepromatous were 2 and 2 were multibacillary. 17 cases were economically underprivileged, while only 3 were economically privileged. 13 recruited cases required non surgical treatment, while 16 required surgical intervention including posterior subtenon injection (5), scleral derroofing (1), corneal scraping/ Tissue adhesive with bandage contact lens (2), vitreous biopsy (2), EDTA chelation (1), cataract surgery (2), DCT (1), descemetopexy (2), Anti- VEGF injections (1) and pars plana vitrectomy (2). Recurrences were accounted as NGAU-5, infectious scleritis-2, and staphyloma formation (1). WHO based visual impairment included economic (5), social (2), and legally (3) blind categories.

Conclusions: Lepromatous blindness is on the rise, with multiple cases requiring surgical intervention.

Ocular Tuberculosis: From Diagnostic Confusion to Clinical Conclusion – a Case Series

First Author: Ferdi KURNIAWAN

Co-Author(s): Siti CHADIJAH, Eka FALINTINA WATI

Purpose: To report a case series of ocular tuberculosis presenting as a primary active infection, and to highlight the diagnostic challenges as well as the clinical reasoning process that led to the final diagnosis and management.

Methods: This retrospective case series was conducted between March 2024 and July 2025. Six eyes from five patients with atypical ocular inflammation mimicking other uveitic entities were diagnosed with ocular tuberculosis. Clinical data, ancillary investigations (including chest imaging, tuberculin skin test or interferon-gamma release assays, and ocular imaging), treatment regimens, and outcomes were analyzed.

Results: There were four females (80%) and one male (20%) aged 34–47 years. All cases presented with recurrent anterior uveitis and vitritis. Bilateral exudative retinal detachment was observed in one case (33.3%), while others presented with papillitis (66.6%) and cystoid macular edema (16.6%), with no pathognomonic signs of ocular tuberculosis. Ancillary testing for other infectious causes, such as syphilis and toxoplasmosis, was initially performed and yielded negative results. Further work-up, however, revealed supportive evidence of tuberculosis infection. Anti-tuberculosis therapy, with or without adjunctive systemic corticosteroid treatment, resulted in significant clinical improvement and complete resolution of ocular inflammation in all cases.

Conclusions: Ocular tuberculosis remains a diagnostic dilemma due to its variable presentations and lack of pathognomonic signs. This case series underscores the importance of high clinical suspicion, comprehensive systemic evaluation, and timely initiation of anti-tuberculosis therapy to achieve favorable visual outcomes.

Panel No.: IUS-0465

Overlapping Clinical Characteristics of Vogt-Koyanagi-Harada (VKH) Disease and Multifocal Central Serous Chorioretinopathy (CSC): A Case Report

First Author: Nikki Colleen ONGTO

Co-Author(s): Jessica Marie ABANO, Francis Ezra LAXAMANA, Lorenzo MANIPON, Roberto UY

Purpose: This case aims to raise awareness among ophthalmology providers about the potential for confusion between these two posterior segment conditions, which can present with serous retinal

detachments. It emphasizes the importance of recognizing key clinical and imaging distinctions to enhance diagnostic accuracy, deliver appropriate treatment, and improve outcomes. It aims to provide an overview of emerging therapeutics, introducing the potential of immunosuppression with Methotrexate in equivocal or chronic cases of CSR.

Methods: The patient presented with progressive blurred vision in the left eye. Fundoscopic and angiographic findings raised concern for Posterior Uveitis (VKH). However, the patient was eventually reclassified as CSCR due to lack of response with high-dose oral corticosteroids, prior history of CSCR in the fellow eye, absence of systemic VKH features, and multimodal imaging findings leaning towards CSCR. Treatment was shifted from high-dose corticosteroids to low-dose Methotrexate, resulting in marked visual improvement and resolution of clinical findings.

Results: While Methotrexate is not traditionally a first-line treatment for CSCR, this case emphasizes that its immunomodulatory and steroid-suppressing properties offer a therapeutic advantage in a diagnostically ambiguous setting.

Conclusions: VKH and CSCR are two distinct chorioretinal disorders but may present with overlapping clinical and imaging features. Misdiagnosis can lead to inappropriate treatment and blindness since the therapeutic approaches to these two conditions are divergent, steroids treat VKH but worsen CSCR. The emerging use of Methotrexate offers potential benefits in ambiguous clinical scenarios since it is a treatment option for both VKH and chronic CSCR, with benefits particularly related to its steroid-sparing effects.

Abstract No.: 202310

Panel No.: IUS-0455

PEACOCX Study: A Phase 1 Evaluation of TRX103, an Engineered Tr1 Cell Therapy for Uveitis

First Author: Jia-horung HUNG

Co-Author(s): Amir AKHAVANREZAYAT, Frances Andrea ANOVER, Gunjan Anil AWATRAMANI, Ryan BJORDAHL, David CHANTHAN, Dalia EL FEKY, Jingli GUO, Hareem KHAN, Marco LONDEI, Viktoriya MEGRABOVA, Quan Dong NGUYEN, Janine POWERS, Mohammad Bagher RAJABI, Aim-on SAENGSRINAVIN, Ngoc Trong Tuong THAN, Zheng Xian THNG, Gunay ULUDAG, Negin YAVARI

Purpose: Despite advancements in novel biologics and drug delivery methods, many patients with noninfectious uveitis (NIU) remain refractory to treatment, and long-term remission remains elusive. Adoptive T cell therapy offers a new therapeutic modality for NIU, and TRX103, an engineered type 1 regulatory T (Tr1) cell product, represents a pioneering cell-based approach to NIU treatment. It aims to

modulate pathogenic inflammatory responses and induce durable immune tolerance.

Methods: The PEACOCX trial is a Phase 1, open-label, first-in-human clinical study evaluating the safety, tolerability, and preliminary efficacy of TRX103 in patients with active NIU. TRX103 will be administered as a single intravenous infusion. Pharmacokinetics and pharmacodynamics, both intraocular and in patient peripheral blood, will be monitored for 48 weeks. Clinical endpoints including best-corrected visual acuity and vitreous haze, will be evaluated.

Results: TRX103 is an allogeneic, off-the-shelf product generated by engineering CD4+ T cells with a lentiviral vector encoding for human IL-10. In preclinical in vitro studies, TRX103 secreted high levels of IL-10, suppressed the proliferation of CD4+ and CD8+ T cells, and reduced the production of inflammatory IL-1 β and TNF α cytokines by myeloid cells. TRX103 expressed multiple chemokine receptors, facilitating homing to the site of inflammation. Additionally, TRX103 had low immunogenic capacity, supporting extended persistence in vivo.

Conclusions: The PEACOCX trial represents a significant step toward developing Treg cell therapies for uveitis, aiming to offer a durable, targeted, and steroid-sparing treatment strategy.

Pattern of Uveitis in Pregnant Females

First Author: Eiman DESSOUKI

Purpose: To explore the referral pattern of uveitis in a cohort of pregnant females, the most prevalent causative diseases, and the effect of treatments.

Methods: Retrospective medical records review of all pregnant women with uveitis visiting a tertiary uveitis facility during a 12-year period.

Results: About two-thirds of all pregnant patients presented during the second trimester of pregnancy. Anterior uveitis was the major anatomical category depicted, affecting 57% of all referred patients. Herpetic uveitis, followed by toxoplasmosis and systemic lupus erythematosus, were the most prevalent causative diseases identified, respectively.

Conclusions: Infective uveitis followed by systemic lupus erythematosus, representing an antibody-mediated autoimmune disease, was the leading cause of uveitis among our 604 pregnant patients seeking care in a tertiary uveitis hospital over a period of 12 years.

Quantitative Assessment of Fluorescein Angiography Leakage via Deep Learning in Pediatric Uveitis: Correlation With Clinical Parameters

First Author: Yu JIN

Co-Author(s): Yuhan CHANG, Xumei DU, Nanhao GONG, Jianguo HUANG, Yuqin WANG, Jin YAO, Changlin ZHAO, Weifang ZHU, Xuefei ZHU

Purpose: Develop a deep learning algorithm for automated segmentation of retinal vascular and macular edema leakage in fluorescein angiography (FA) of pediatric uveitis.

Methods: The model was trained, validated, and applied to 28 independent pediatric cases to correlate leakage area with clinical metrics and determine clinically significant change thresholds.

Results: In five-fold cross-validation on 2,459 internal images (155 patients), the best mean Dice was 0.7241 (retinal leakage) and 0.7273 (macular leakage). On external data, the best mean Dice reached 0.7015 and 0.5918, respectively. In the cohort of 28 pediatric uveitis patients, vitreous cells (VC) and central macular thickness (CMT) were the most consistent parameters associated with retinal leakage across multiple analyses. After multiple comparison correction, both VC and CMT remained significantly associated with total and posterior-pole leakage areas at all timepoints. For macular edema leakage, CMT and best corrected visual acuity (BCVA) showed consistent associations, while VC was significant only at follow-up. whereas other examined variables showed no consistent association after correction for multiple comparisons. ROC analysis identified a -54.8% relative change in total visible retinal leakage area as the optimal cutoff, indicating quiescent inflammation.

Conclusions: The deep learning model reliably segments leakage in pediatric uveitis FA, showing multicenter generalizability. Quantitative angiographic parameters correlate with clinical metrics, suggesting potential utility for informing disease management strategies.

Rapid Plasma Reagin Tests of Serum, Cerebrospinal Fluid, and Aqueous Humor of Patients With Ocular Syphilis and AIDS

First Author: Yingjie WANG

Co-Author(s): Yong TAO

Purpose: The diagnosis of ocular syphilis in patients with acquired immunodeficiency syndrome (AIDS) remains challenging. This study aimed to evaluate the potential utility of aqueous humor (AH) RPR testing as an adjunctive diagnostic tool for assessing clinical

manifestations and visual function in AIDS-associated ocular syphilis.

Methods: We conducted a retrospective observational cohort study of 31 patients (42 eyes) with ocular syphilis and AIDS treated at Beijing You'an Hospital between 2022 and 2025, based on comprehensive ophthalmic and systemic evaluations.

Results: In patients with concurrent syphilis and AIDS, pre-treatment higher AH RPR reactivity level was associated with higher vitreous haze grades (OR = 4.10, 95% CI: 1.62–10.38, $p = 0.003$). Pre-treatment serum, CSF, and AH RPR titers individually predicted macular chorioretinal involvement (AUC 0.76–0.85) and optic nerve involvement (AUC 0.62–0.78). Combining all three markers improved prediction for macular chorioretinal involvement (AUC 0.88) and for optic nerve involvement (AUC 0.79). RPR titers in serum, CSF, and AH were all significantly correlated with both pre- and post-treatment best-corrected visual acuity, indicating that higher titers were associated with worse visual function.

Conclusions: AH RPR can serve as a valuable adjunct for diagnosing ocular syphilis, as it indicates intraocular disease activity and informs treatment recommendations for the condition.

Recurrent Methamphetamine-Associated Posterior Scleritis: A Case Report

First Author: Randolph DOBSON

Co-Author(s): Jonathan LAM

Purpose: To describe posterior scleritis associated with methamphetamine use, emphasizing diagnostic challenges, treatment response, and recurrence.

Methods: Retrospective case report.

Results: A 52-year-old woman presented with a two-month history of progressive left eye vision loss, acutely worsening with central scotoma, pain, and photophobia. Posterior scleritis was diagnosed on clinical and imaging findings, including B-scan ultrasound demonstrating scleral thickening with a T-sign. Optical coherence tomography, fundus angiography, and magnetic resonance imaging supported the diagnosis. Systemic workup for autoimmune and infectious causes was negative. She was treated with intravenous methylprednisolone followed by high-dose oral corticosteroids, with marked improvement during admission and methamphetamine abstinence. After discharge, she relapsed with bilateral involvement following methamphetamine use but again responded to systemic steroids. She has remained abstinent and recurrence-free since.

Conclusions: Posterior scleritis is rare and diagnostically challenging due to nonspecific symptoms. This case

underscores the value of early recognition, multimodal imaging, and timely immunosuppression to preserve vision. The recurrence temporally associated with methamphetamine use suggests a causative role, potentially mediated through sympathomimetic vasoconstriction, vascular injury, or direct toxic effects.

Sympathetic Ophthalmia: A Rare but Serious Complication of Penetrating Ocular Trauma – a Case Report

First Author: Muhammad Fachri Ridha **HERLAN**

Co-Author(s): Ovi **SOPIA**

Purpose: Sympathetic ophthalmia (SO) is a rare but potentially blinding bilateral granulomatous panuveitis triggered by ocular trauma or surgery. Delayed diagnosis can cause severe visual impairment. This case highlights the importance of timely recognition, multimodal imaging, and aggressive immunosuppressive therapy to preserve vision.

Methods: A 41-year-old woman developed SO after penetrating trauma to the fellow eye. A comprehensive approach, including history-taking, perimetry, and multimodal imaging such as funduscopy, ultrasonography (B-scan), and optical coherence tomography (OCT) of the optic disc and macula was performed. The patient was monitored for three months.

Results: The patient presented with profound visual impairment, severe anterior chamber inflammation, vitritis, and later finding of choroidal depigmentation. High-dose intravenous methylprednisolone was given, followed by oral prednisone and azathioprine. Perimetry showed generalized visual field depression. B-scan ultrasound revealed exudative retinal detachment in the right eye, which resolved after one month of treatment. Optic disc OCT showed retinal nerve fiber layer thickening, which decreased with treatment. Early corticosteroid and immunosuppressant therapy improved vision from light perception to 6/12. Imaging confirmed the resolution of vitritis, reduced optic disc edema, and retinal stabilization, demonstrating the role of early and intensive therapy in controlling inflammation and improving prognosis.

Conclusions: This case highlights the value of multimodal imaging and a prompt, aggressive treatment approach with corticosteroids and immunosuppressants. Increased awareness, early diagnosis, and standardized management can improve the prognosis of this rare but serious condition.

Panel No.: IUS-0472

Taming the Unknown – Vitrectomy for Exudative Retinal Detachment

First Author: Saarang **HANSRAJ**

Purpose: To report a case where pars plana vitrectomy in a patient with exudative retinal detachment helped diagnose and treat tuberculoid panuveitis

Methods: A 17-year-old man presented with sudden, painful, and progressive loss of vision in his right eye for 2 months, with acuity of PL PR inaccurate. His other eye was phthisical, with no vision for 7 years. There was no history of ocular trauma or ocular procedures for any of the eyes, with no systemic comorbidities. The right eye had 4+ AC cells, 4+ vitritis, with view of the retina. Ultrasound showed a retinal detachment. A diagnosis of exudative retinal detachment was made. Systemic investigations were ordered and a vitreous biopsy taken, with injection of intraocular antibiotics. Two days later, when the retinal detachment appeared to worsen on ultrasound, a pars plana vitrectomy with silicone oil injection was performed. This allowed retina to attach and view clearly, allowing multiple modal imaging. A diagnosis of ocular tuberculosis was made due to the presence of large choroidal granulomas as well as a history of positive tuberculosis contact and calcified lymph nodes on CT thorax. Patient was given IV methyl prednisolone and started on anti-tubercular therapy, oral corticosteroids, and methotrexate.

Results: Two months after the surgery patient is maintained on ATT and immunosuppression, with ambulatory vision of 1/60.

Conclusions: Pars plana vitrectomy may be beneficial in very selected cases of exudative retinal detachment. It allows for visualization, imaging and treatment. Ocular tuberculosis may present with severe panuveitis in certain cases, requiring intense immunosuppression.

Abstract No.: 200511

Panel No.: IUS-0441

Tattoo-Associated Uveitis

First Author: Xuchuan **WANG**

Purpose: This paper elaborates on the clinical features of tattoo associated uveitis by presenting a well-documented case, analyzes the pathogenesis of this disease based on the tattoo history, and describes the treatment process.

Methods: The patient's eye examination: Best Corrected Visual Acuity (BCVA): Right eye 20/100, Left eye 20/200. Intraocular pressure (IOP) in both eyes: 19mmHg (1mmHg = 0.133kPa). Slit-lamp examination: Conjunctival injection in both eyes; Keratic precipitates (KP) posterior to the cornea; Scattered gray-white nodules visible on the iris surface; Posterior synechiae of the iris. B-scan ultrasonography of the eyes showed:

Vitreous opacity in both eyes; Papilledema. Chest CT scan and the enhanced scan indicated that sarcoidosis was ruled out. The patient had no history of ocular surgery or trauma and no signs of hearing loss. Serum tests for C-reactive protein, rheumatoid factor, erythrocyte sedimentation rate, and autoantibodies were all negative. Ocular fluid analysis excluded viral infections, fungal infections, and lymphoma but indicated active intraocular inflammation. Hematological examination of the serum revealed a significant number of lymphocytes and neutrophils with lobulated nuclei, some of which contained blue homogeneous material within their cytoplasm. Additionally, multiple tattoos were noted on the patient's body, with discoloration, stiffness, redness, unevenness, and slight skin damage on the left upper arm where a tattoo had been removed by laser six months prior. Five days after the laser removal, the patient developed decreased vision, eye redness, and photophobia in both eyes.

Results: The patient's condition improved after local and systemic treatment with corticosteroids. Follow-up one month after discharge showed stable condition.

Conclusions: Both tattooing and laser tattoo removal can cause uveitis.

Panel No.: IUS-0444

The Association Between Diabetes Mellitus and Idiopathic Anterior Uveitis in Thai Patients

*First Author: Panida **SRISAT***

*Co-Author(s): Plern **SUTRA***

Purpose: To determine the association between diabetes mellitus (DM) and idiopathic anterior uveitis (AU).

Methods: Retrospective, cross-sectional study of patients with AU and DM. Logistic regression analysis was used to evaluate the association of DM and idiopathic AU.

Results: Among the 196 AU patients assessed, 112 (57.1%) had idiopathic AU, and 53 (47.3%) had a diagnosis of DM. A statistically significant association was found between DM and idiopathic AU ($p=0.015$). Idiopathic AU was associated with a 2.6-fold increased risk compared to AU without DM (adjusted OR = 2.640, 95% CI: 1.207–5.776). Furthermore, poorly controlled DM was significantly associated with idiopathic AU ($p<0.05$). A 1% increase in HbA1c levels correlated with a 56.3% increased risk of idiopathic AU (adjusted OR = 1.563, 95% CI: 1.197–2.041, $p=0.001$). Patients with preexisting DM also have a demonstrated a 79.7% higher risk compared to those without preexisting DM (adjusted OR = 1.797, 95% CI: 1.067–3.029, p -value = 0.028).

Conclusions: Elevated blood glucose and HbA1c levels are significantly associated with idiopathic anterior uveitis. We recommend that blood glucose and HbA1c levels should be routinely incorporated into the diagnostic workup for patients presenting with acute uveitis.

Abstract No.: 203721

Panel No.: IUS-0463

The Myriad Presentations of the Master Masquerader

*First Author: Lisa **SUNNY***

*Co-Author(s): Rajshree **EZHILAN**, Jonathan **MALCOLM CHAVAN**, Vedhanayaki **RAJESH***

Purpose: To report 4 varied presentations of Ocular syphilis.

Methods: Patient 1- 27-year-old male with 3 3-week history of right eye (RE) blurred vision, Best corrected visual acuity (BCVA) of 1/60 with vitritis, 5 DD necrotising retinitis temporal to macula, vasculitis, and superficial retinal precipitates. Lab investigations -positive VDRL, TPHA, and HIV. Patient 2 - 32-year-old man with left eye(LE) panuveitis. BCVA was 5/60 with circumcorneal congestion, 2+cells in the anterior chamber, an iris roseola at 2 o'clock, posterior synecchia, 2+vitreous cells, haze, and a nasal retinitis patch with haemorrhages and vasculitis. He also had healing vesicular lesions at the angle of the mouth. Lab testing was positive for HIV, VDRL, and TPHA. He was empirically started on oral valacyclovir and referred to the antiretroviral treatment centre. Patient 3 was a 34-year-old male with posterior uveitis, BCVA 1/60, on treatment elsewhere with oral steroids for the past 1 month. A placoid lesion was noted at the posterior pole with disc edema. OCT showed a sawtooth appearance of the outer retina. He was positive for VDRL and TPHA. Patient 4- 26-year-old male, with 1 1-week history of blurred vision. Background retina revealed pigment mottling, and OCT -sawtooth appearance. He was both VDRL and TPHA positive.

Results: Patients 1 and 4 reviewed with us post-treatment for syphilis and showed excellent clinical and visual outcomes with resolution of retinitis. Patient 1 was treated with antiretroviral therapy and benzathine penicillin, and patient 4 with oral doxycycline.

Conclusions: A high index of suspicion should be kept for ocular syphilis, as it can have varied manifestations.

Unveiling the Diagnostic Power of Metagenomic Sequencing in Ocular Infections: Evidence From Systematic Review and Meta-Analysis

*First Author: Florentina **FEBRINA***

*Co-Author(s): Azzahra **JELITA**, Rina La Distia **NORA**, Ikhwanuliman **PUTERA**, Fitri Setyani **ROKIM**, Made **SUSIYANTI***

Purpose: To evaluate the diagnostic value of mNGS for ocular infections, while highlighting the advantages, limitations, and future directions for the clinical application of mNGS in ocular cases

Methods: Literature search from electronic databases of PubMed/MEDLINE, Embase, Web of Science, and Scopus were done within the past decade, with general search term of «mNGS» and «ocular infection». Eligible original studies assessing the diagnostic utility of mNGS for ocular infections were evaluated according to predefined criteria. Meta analyses were conducted to evaluate overall diagnostic performance. Methodological quality was assessed using QUADAS-2.

Results: Sixteen studies (923 specimens) were included for analysis. Pooled sensitivity and specificity of mNGS for ocular infections were 84% (95% confidence interval (CI) 81-87%, I² 78.5%) and 62% (95% CI 57-67%, I² 83.7%), respectively. Bacteria were the most frequently detected (10/16 studies), followed by virus (10/16), fungi (8/16), and parasite (3/16). A diverse range of pathogens at the genus and species level were identified. Sub-group analysis was done based on ocular sample type and reference standard used. SROC analysis showed good overall diagnostic performance of mNGS with an AUC of 0.872 (SE=0.022).

Conclusions: mNGS shown to be valuable in identifying pathogens especially those undetectable through conventional methods, although it requires careful interpretation. It showed promising diagnostic performance in detecting different types of ocular infections, especially for ocular surface specimens. Further larger research on its application for ocular diagnostic that implement a well-defined protocol which address its drawbacks would be needed to enhance its applicability.

Abstract No.: 207426

Panel No.: IUS-0484

Uveitis in Flux: A Case of Perpetual Surprises and Incomplete Resolution

*First Author: Raj Shri **HIRAWAT***

Purpose: To describe an unusual case of recurrent, self-resolving panuveitis with presumed tubercular etiology.

Methods: A 51-year-old female with spastic paresis underwent detailed clinical evaluation and a

comprehensive uveitis work-up after presenting with left-eye blurring (6/60).

Results: Initial findings showed bilateral healed choroiditis and active retinochoroiditis in the left eye. Despite an initial course of oral steroids—discontinued due to intolerance—each new ill-defined lesion resolved spontaneously without therapy. A higher-centre opinion recommended observation. During long-term follow-up, recurrent episodes continued to resolve on their own. The patient later underwent cataract surgery and achieved a final visual acuity of 6/9.

Conclusions: The case serves as a reminder of the challenges and unexpected resolutions that can occur in medical practice. This case was not about indecision but about adaptation in the face of uncertainty. “Every step taken was guided by the patient’s evolving clinical picture and evidence at hand.” Sometimes, seemingly unrelated symptoms (like the «shadowing») can be due to a simple issue (cataract) rather than a complex underlying condition. “The management balanced caution with compassion — avoiding overtreatment while still addressing possible vision-threatening conditions.” “Referral and multidisciplinary collaboration were pursued at the right juncture, ensuring patient safety.”

Abstract No.: 202082

Visual Outcomes of Bridging Sub-Tenon’s Triamcinolone Acetonide With Adalimumab in Refractory Uveitic Macula Edema: A Retrospective Case Series

*First Author: Yaru **ZOU***

*Co-Author(s): Koju **KAMOI**, Kyoko **OHNO-MATSUI**, Mingming **YANG**, Jing **ZHANG**, Yuan **ZONG***

Purpose: To assess the efficacy of adalimumab (ADA) for refractory noninfectious Uveitic Macular Edema (UME) and to compare outcomes between ADA with sub-Tenon’s triamcinolone acetonide (STTA) bridging and ADA alone.

Methods: This retrospective study included 14 patients (18 eyes) with refractory noninfectious UME treated between January 2018 and 2024. Patients were divided into two groups: ADA monotherapy (without STTA) and ADA with STTA bridging therapy (20 mg of STTA administered within 4 weeks before initiating ADA, then discontinued). ADA was initiated with an 80-mg subcutaneous loading dose, followed by 40 mg every 2 weeks for 12 months. The primary outcome measures included central foveal thickness (CFT), best-corrected visual acuity (BCVA/Snellen), and intraocular pressure (IOP) at baseline, 1, 3, 6, and 12 months.

Results: The median age of 14 patients was 29 years (interquartile range, 23.5–53.25 years), and 10 patients (71.5%) were female. At 12 months, mean

CFT decreased from 416.33 μm to 245.50 μm ($P < 0.001$). The STTA-bridging group achieved greater CFT reduction than ADA monotherapy (119.60 μm vs. 92.25 μm ; $P < 0.001$ vs. $P = 0.013$). Mean BCVA improved from 0.41Log MAR (20/50) to 0.30 LogMAR (20/40) with STTA bridging ($P < 0.001$), while ADA monotherapy showed no significant change. A majority of eyes (13/18, 72.7%) showed improvement, with a sustained remission rate of 52.4% (11/18 eyes). IOP remained stable in all groups.

Conclusions: Our study highlights the potential short-term benefits of STTA bridging to ADA, providing both anatomical and functional improvements.

Myopia

0.01% Atropine for Myopia Prevention in Pre-Myopia (AMPP Study)

First Author: Meinan HE

Co-Author(s): Bei DU, Ruihua WEI

Purpose: This study aimed to evaluate the efficacy and safety of 0.01% atropine eye drops in preventing myopia in children with pre-myopia.

Methods: In this randomised controlled trial (ChiCTR2200055482), children aged 5-12 years with cycloplegic spherical equivalent (SE) between +0.75D and -0.50D were randomised 1:1 to receive either 0.01% atropine (0.01% atropine once nightly) or placebo (once nightly). The primary endpoint was the change in SE after 12 months.

Results: Sixty-four subjects (48.4% female) completed the 12-month follow-up (32 per group, mean age, 7.47 ± 1.72 vs. 7.84 ± 1.32 years). After 12 months, the change in SE was significantly smaller in the 0.01% atropine group than in the placebo group ($-0.23 \pm 0.50\text{D}$ vs. $-0.49 \pm 0.42\text{D}$; $p=0.030$), representing a 53% reduction in myopia progression. No significant intergroup difference was observed in axial length (AL) change ($+0.26 \pm 0.16\text{mm}$ vs. $+0.32 \pm 0.15\text{mm}$; $p=0.134$), corresponding to a 19% reduction in AL elongation. The 0.01% atropine group exhibited significantly larger pupil diameters at all time points (all $p < 0.05$), while safety parameters (e.g., amplitude of accommodation, tear film stability, intraocular pressure) remained comparable between the groups (all $p > 0.05$).

Conclusions: In 5-12-year-old pre-myopic children, nightly administration of 0.01% atropine eye drops for 1 year was found to delay myopic shift compared with placebo, and no persistent adverse events were observed. Additionally, the atropine group exhibited less axial elongation than the control group, though this difference was not statistically significant.

A Bibliometric Analysis of Pharmacological Interventions for Myopia Control: A 30-Year Review (1994-2024)

First Author: Yufeng HAN

Co-Author(s): Xiaotong LI, Wei ZHANG

Purpose: Myopia has emerged as a global epidemic, with its prevalence rapidly increasing among children and adolescents. In recent years, pharmacological treatments, particularly those involving atropine, have gained significant attention as a potential strategy for myopia control. This bibliometric analysis aims to provide a comprehensive overview of the research landscape and trends in pharmacological interventions for myopia over the past three decades (1994-2024).

Methods: We collected literature from the Web of Science Core Collection database, and analyzed it using VOSviewer and CiteSpace.

Results: The study included 848 papers published between 1994 and 2024. China had the most publications, while Singapore had the highest average number of citations. Fudan University led in publications, while the National University of Singapore had the highest average citations. The most cited journal is "Investigative Ophthalmology and Visual Science", while "Ophthalmology" has the highest average number of citations. The top cited references primarily focused on atropine for myopia, followed by those on dopamine. Burst analysis revealed that emerging trends in the field included the terms "pharmacological concentration", "childhood myopia", "efficacy", "axis length" and "prevention".

Conclusions: This bibliometric analysis reveals the milestone research trajectory of atropine treatment for myopia and identifies current research hotspots and future development directions in the field of myopia pharmacological treatment. This study is expected to be significant for researchers, helping them understand this field better.

A Modified Aniseikonia Measurement Method Based on Peripheral Fusion Lock

First Author: Xin TAN

Co-Author(s): Hongxi WANG

Purpose: Aniseikonia, often overlooked, can cause asthenopia, distorted vision, and headache. Traditional dichoptic tests are susceptible to fusion interference and central fixation instability, causing measurement errors. This study proposes a modified method based on peripheral fusion locking and compares its performance with the traditional method.

Methods: Participants aged 23–26 years without anisometropia were recruited. Size lenses (1%, 3%, 5%) over the non-dominant eye induced aniseikonia. In the traditional dichoptic test, participants judged when red and green stimuli appeared equal. The modified method spaced the stimuli and added four peripheral dot locks to stabilize fusion. Throughout testing, dominant-eye stimulus size varied randomly in 0.5% steps while non-dominant eye remained constant. Horizontal and vertical aniseikonia were measured. Pearson correlation assessed the relationship between measured and induced magnification, while linear regression evaluated the fit to theoretical values. Fusion instability or misalignment incidence was recorded.

Results: All 23 participants completed the study. The traditional method showed positive correlations for horizontal and vertical measures ($r = 0.799, 0.649$; slopes 0.630, 0.500; $R^2=0.638, 0.421$). The modified method showed stronger correlations ($r = 0.872$ and 0.749), slopes nearer theoretical values (0.728, 0.644), and higher R^2 (0.761 and 0.561) (all $P < 0.001$). Fusion instability occurred in 17.4% of participants using the modified method, significantly lower than 47.8% with traditional method ($P = 0.028$).

Conclusions: The modified method reduced fusion interference and improved fixation stability. Regression slopes and consistency suggest peripheral fusion locks enhance measurement accuracy.

A Stitch in Time Saves Sight: Early Intervention in Congenital Glaucoma With Sturge-Weber Syndrome

First Author: Prasanna Vekatesh RAMESH

Purpose: To report the outcomes and challenges of performing a combined trabeculotomy-trabeculectomy on a 15-day-old infant diagnosed with congenital glaucoma and Sturge-Weber syndrome.

Methods: The patient presented with left-eye (OS) buphthalmos, congenital glaucoma, and a hazy cornea, along with port-wine stains indicative of Sturge-Weber syndrome. Preoperative measurements revealed an increased axial length (AL) of 19.23 mm in the OS, with vertical and horizontal corneal diameters of 12 mm and 13 mm, respectively, and an intraocular pressure (IOP) of 20 mmHg. In comparison, the right eye (OD) showed an AL of 17.70 mm, vertical and horizontal diameters of 10 mm and 9 mm, and an IOP of 12 mmHg. Under challenging anesthesia, a combined trabeculotomy-trabeculectomy was performed on the OS. The surgical procedure was demanding due to the infant's thin sclera, requiring precise flap creation and suturing techniques.

Results: At two months, corneal edema had resolved, and the patient showed improved light response. And Sturge-Weber skin lesions also showed a reduction. By four months, patching of the non-operated eye was started, aiding binocular visual recovery. At six months, the operated eye demonstrated normalized measurements with an axial length of 20.75 mm, corneal diameters of 11.5×10.5 mm, and an IOP of 10 mmHg, comparable to the fellow eye.

Conclusions: This case demonstrates that combined trabeculotomy-trabeculectomy can effectively manage congenital glaucoma in infants with Sturge-Weber syndrome, achieving improved vision and ocular outcomes through careful surgical technique and follow-up.

Accelerated Hyperopic Shift in Peripheral Refraction During Myopia Onset: Evidence From 3-Year Longitudinal Observation

First Author: Runtong MA

Co-Author(s): Yin HU, Zhouyue LI, Mengyi WANG, Xiao YANG, Feng ZHAO

Purpose: To investigate 3-year dynamic changes in relative peripheral refraction (RPR) and their association with axial elongation and myopia progression stages in children.

Methods: A longitudinal observational cohort study (2020–2023) of 1,008 children (mean age 9.28 ± 0.59 years; 50.0% female) from Guangzhou, China. Annual assessments included cycloplegic autorefractometry, axial length (AL) measurement, and multispectral refractive topography. RPR was calculated across eccentricities (0° – 53°) and quadrants; total RPR (TRPR) represented the mean of all regions. Analysis was stratified by baseline refractive status (myopia: $SER \leq -0.50$ D, pre-myopia: -0.50 D $< SER \leq +0.75$ D, non-myopia: $SER > +0.75$ D) and 3-year outcomes (remained non-myopia, myopia onset, established myopia).

Results: Longitudinal hyperopic RPR shifts were most pronounced in peripheral retina ($>30^\circ$). In pre-myopia, baseline peripheral RPR differences ($>30^\circ$) predicted myopia onset 2 years pre-onset. Significant differences in ΔAL were observed: myopia onset (+0.91 mm), established myopia (+0.81 mm), remained non-myopia (+0.45 mm) ($p < 0.001$). However, $\Delta TRPR$ is more pronounced in onset group (0.21D) and remain non-myopia group (0.16D), but not in established myopia (0.06D). $\Delta TRPR$ correlated with ΔAL only in the onset group ($r = 0.317, p < 0.001$), not in established myopia ($r = -0.022, p = 0.789$).

Conclusions: RPR is a critical reflection for myopia progression, especially during myopia onset. The defocus shifts may reflect morphological changes in posterior eyeball but not simple axial elongation,

highlighting the stage-specific interpretation of RPR in clinical practice.

Accommodation and Peripheral Retinal Defocus in School-Age Myopic Children

First Author: Li JINYU

Co-Author(s): Vishal JHANJI, Ng TSZ KIN, Zhang RIPING, Zhang SIMIN

Purpose: To investigate the influences of accommodation on peripheral retinal defocus in school-age children with corrective glasses before and after cycloplegia.

Methods: In total, 69 children, aged 7-12 years, with spherical equivalent between +1.75 D and -9.75 D were recruited. Peripheral retinal defocus values (RDV) before and after cycloplegia were measured using multispectral refraction tomography (MRT), and compared among different severities of myopia. The correlation between retinal defocus and axial length was also evaluated. The parameters were measured in different circular areas (15°, 30°, 45°, and 53°), annular areas (15°-30°, 30°-45°, and 45°-53°), and quadrants (superior, inferior, temporal, and nasal). Data was obtained from the right eyes of all participants. An average of three values was used for analysis.

Results: Before cycloplegia, significant variations were identified in the inferior retinal quadrant across different severities of myopia and age groups. After cycloplegia, multiple retinal areas showed significant differences among different severities of myopia, while there were no differences in each area among different age groups. After cycloplegia, retinal defocus shifted significantly towards more hyperopic across all areas, except for the RDV-15o area. Superior retinal defocus was positively correlated with axial length before and after cycloplegia, whereas inferior retinal defocus was negatively correlated with axial length before cycloplegia.

Conclusions: This study revealed various distributions of defocus across different retinal areas in school-age children. Peripheral retinal defocus can be induced with cycloplegia. Alterations in accommodation can influence peripheral retinal defocus in school-age children.

Alterations of Circumpapillary Retinal Nerve Fiber Layer and Macular Ganglion Cell Complex in Eyes With Pathologic Myopia

First Author: Nan LUO

Co-Author(s): Ying HAN, Jingjing HUANG, Yuzhou XIANG

Purpose: To evaluate alterations of circumpapillary retinal nerve fiber layer (cpRNFL) thickness, circumpapillary vessel density (cpVD), and macular ganglion cell complex (mGCC) thickness in eyes with pathologic myopia.

Methods: This cross-sectional study included participants with myopia from the Zhongshan Ophthalmic Center. Eyes were grouped by non-pathologic mild-to-moderate, non-pathologic high myopia, and pathologic myopia. The cpRNFL thickness, cpVD, and mGCC thickness were compared among groups. Factors associated with these parameters were assessed using univariate and multivariate linear regression, adjusted for age, sex, axial length, central corneal thickness, and intraocular pressure.

Results: A total of 208 myopic eyes (one per participant) were analyzed: 61 non-pathologic mild-to-moderate myopic, 97 non-pathologic high myopic, and 50 pathologic myopic eyes. There were no differences in cpRNFL thickness, cpVD, or mGCC thickness between eyes with non-pathologic mild-to-moderate and high myopia. Pathologic myopic eyes showed thinner global, superior, and inferior cpRNFL thickness; lower cpVD in the globe and all quadrants; thinner mGCC thickness in the globe, inferior hemisphere, and 1-3 mm annular area (all $P < .05$). Thinner global cpRNFL thickness was associated with pathologic myopia ($\beta = -0.178$; $P = .028$). Lower global cpVD was associated with pathologic myopia ($\beta = -0.284$; $P < .001$) and smaller ratio of axial length to fovea-to-disc distance (AL-DFD) ($\beta = 0.134$; $P = .014$). Global mGCC thickness was not associated with pathologic myopia, but was associated with AL-DFD ratio ($\beta = 0.287$; $P < .001$) and rim area ($\beta = 0.169$; $P = .022$).

Conclusions: The changes in cpRNFL thickness, cpVD, and mGCC thickness associated with pathologic myopia should be considered when analyzing optic neuropathy in myopic eyes.

Alterations of Retinal Relative Peripheral Refraction in Myopic Children Following Orthokeratology

First Author: Mengdi LI

Co-Author(s): Lihua LI, Xiaoyan YANG, Bin ZHANG, Kailang ZHANG

Purpose: To quantify the changes in the spatial distribution of retinal relative peripheral refraction (RPR) in myopic children following orthokeratology treatment and explore its association with axial length growth (ALG).

Methods: This retrospective study included 100 eyes ($SE \leq -4.00$ D) from children aged 8 to 15 years. ALG was defined as axial length change from the baseline. RPR was calculated as peripheral minus central refraction and was first quantified in quadrants. RPR values, from center to periphery, were then organized into ten rings with 2.50 width each, and decomposed into Fourier components, F0 (spherical), F1 (asymmetry), F2 (astigmatism), and F3 (higher-order irregularity). Subjects were grouped by ALG (slow, moderate, fast) and the Fourier component changes in each group were identified.

Results: At baseline, hyperopic RPR was observed nasally (0.57 ± 0.67 D), inferiorly (0.65 ± 0.74 D), and temporally (0.77 ± 0.62 D), with mild myopia superiorly (-0.09 ± 0.61 D). Temporal RPR declined at 6 months (0.29 ± 1.13 D, $P < 0.01$) and became myopic at 12 months (-0.35 ± 0.94 D), as did inferior RPR (-0.04 ± 0.97 D, $P < 0.01$); nasal RPR remained hyperopic ($P > 0.05$). In the slow group (ALG: -0.10 ± 0.08 mm), F1 increased from 1 month (1.09 ± 0.60 D) to 12 months (1.20 ± 0.67 D, $P < 0.01$), with a myopic F0 shift at 12 months (-0.09 ± 0.69 D, $P < 0.01$). The medium group (0.06 ± 0.04 mm) showed a transient F1 increase at 1 month and F0 shift to plano (0.06 ± 0.59 D) at 12 months. The fast group (0.29 ± 0.93 mm) showed no significant changes in F0 or F1.

Conclusions: Orthokeratology induced time-dependent retinal refraction, mainly in the mid-peripheral and peripheral zones, with shifts toward myopia in the temporal and inferior regions. Increased peripheral asymmetry persisted in eyes with slower axial elongation, indicating it could be a potential marker of treatment effectiveness.

An Innovative Clinical Indicator for the Refractive Development of Children: The Volume Strain Value of Peripheral Retinal Wavefront Aberration

First Author: Lili SUN

Co-Author(s): Jinling YANG

Purpose: Study the correlation between the volume strain value of peripheral retinal wavefront aberration (ϵV) and other indicators of refractive development of children.

Methods: The enrolled children were 7 to 12 years old and the refractive status were emmetropia, myopia or hyperopia. Patients undergoing visits every two months after enrollment. The ϵV was respectively calculated by data from both i.Profiler and iTrace wavefront aberrometer.

Results: The data including emmetropia group (37 eyes), myopia group (13 eyes), hyperopia group (24 eyes). The results of linear regression analysis between axial length-to-corneal radius ratio (AL/CR ratio) and ϵV (by i.Profiler) show that: $R=0.883$ ($P=0.05$) in myopia group, $R=0.765$ ($P=0.05$) in hyperopia group, $R=0.102$ ($P=0.05$) in emmetropia group; spherical power Vs. ϵV (by i.Profiler): $R=0.917$ ($P=0.05$) in myopia group, $R=0.781$ ($P=0.05$) in hyperopia group, $R=0.154$ ($P=0.05$) in emmetropia group; AL/CR ratio Vs. ϵV (by iTrace): $R=0.595$ ($P=0.05$) in myopia group, $R=0.443$ ($P=0.05$) in hyperopia group, $R=0.029$ ($P=0.05$) in emmetropia group; spherical power Vs. ϵV (by iTrace): $R=0.731$ ($P=0.05$) in myopia group, $R=0.500$ ($P=0.05$) in hyperopia group, $R=0.185$ ($P=0.05$) in emmetropia group.

Conclusions: The volume strain value of peripheral retinal wavefront aberration is a promising indicator of refractive development of children.

Association Between Clinical Visual Function Parameters and CISS Scores in Visual Fatigue Assessment of School-Aged Children

First Author: Hanqing WANG

Co-Author(s): Yanglin JIANG, Lihua LI

Purpose: This study investigated to the association between clinical visual function parameters and the Convergence Insufficiency Symptom Survey (CISS) in assessing visual fatigue, aiming to establish a quantifiable detection framework for personalized intervention strategies.

Methods: A standardized experimental design was implemented with 32 school-aged children (7-16 years; 16 boys, 16 girls) with refractive errors ranging from -0.50 D to -5.00 D, corrected with spectacles. Visual fatigue was induced by 60 minutes of sustained near

work (continuous reading). Clinical parameters were collected before and after induction, including: (1) distance/near cover test; (2) near point of convergence; (3) distance/near phoria; (4) distance/near fusional ranges; (5) accommodative response; (6) monocular accommodative amplitude; and (7) accommodative facility. Subjective fatigue was evaluated using the CISS. Statistical analysis was performed using R (4.5.1), with Spearman's correlation coefficients.

Results: The mean age of participants was 10.25 ± 2.3 years. Near positive fusional vergence (Base-Out) showed significant negative correlations with post-induction CISS scores (blur: -0.355 , $p=0.046$; break: -0.418 , $p=0.017$; recovery: -0.399 , $p=0.024$). Lower near positive fusional capacity during sustained near-visual tasks was associated with higher subjective fatigue scores, whereas other visual function parameters showed only weak correlations.

Conclusions: The study validates the differential sensitivity of clinical visual function assessment in characterizing visual fatigue. Near positive fusional vergence emerged as a key factor and should be considered in future optometric clinics. Larger studies are warranted to validate these findings and refine predictive models. Enhancing near fusional ability via vision training may alleviate fatigue symptoms and contribute to myopia control in school-aged children.

Abstract No.: 203268

Panel No.: MYO-0520

Association Between Near Phoria and Axial Elongation in School-Aged Children: A Three-Year Cohort Study

First Author: Jing WANG

Co-Author(s): Yanglin JIANG, Xiaoyan YANG

Purpose: To investigate the association between axial elongation and near/distance phoria in school-aged children and evaluate the influence of binocular visual function on axial elongation.

Methods: A total of 983 first-grade students (500 boys, 483 girls) from three Tianjin primary schools were enrolled in October 2021. Baseline mean spherical equivalent was -0.22 ± 1.13 D, and mean axial length was 22.77 ± 0.76 mm. Annual ophthalmic examinations over three years, including visual acuity, autorefraction, Maddox rod testing for near phoria, and axial length measurement. Group-Based Trajectory Modeling (GBTM) classified axial growth into high-, medium-, and low-level groups.

Results: Over the three-year follow-up, near phoria was positively associated with axial elongation. Each one-unit increase in near phoria was associated with a 4% higher risk of high-level axial growth compared to the low-level group (OR = 1.04, $p = 0.008$). Similarly, each one-unit increase in near phoria was linked to a

3% increased risk in the medium-level versus low-level group (OR = 1.03, $p = 0.018$).

Conclusions: Near phoria is significantly associated with axial elongation in children. Both greater exophoria or esophoria may accelerate axial elongation, suggesting that abnormal binocular visual function contributes to myopia progression.

Abstract No.: 208649

Panel No.: MYO-0564

Association Between Peripapillary Retinal Nerve Fiber Layer Thickness and Age in Adults With High Myopia

First Author: Tsun Hei YIP

Co-Author(s): Kai Shun Christopher LEUNG, Zirong LIU, Xiujuan ZHANG

Purpose: Changes in peripapillary retinal nerve fiber layer (pRNFL) thickness has become an important diagnostic marker for glaucoma since the advent of Optical Coherence Tomography (OCT). Thus, understanding various risk factors is critical.

Methods: Participants aged ≥ 50 years old with spherical equivalent (SE) ≤ -5 D or axial length (AL) ≥ 22.5 mm were included in this study. Average and pRNFL thickness in four quadrants (superior, inferior, temporal, nasal) were measured by OCT. Pearson correlation coefficients (r) were calculated to investigate their correlation with age.

Results: Fifty-five high myopic right eyes from 55 Chinese were included, with mean ages 61.0 ± 7.83 years, mean SE -7.37 ± 2.50 D, mean intraocular pressure (IOP) 14.96 ± 3.40 mmHg, and 18 (32.73%) males. Statistically significant correlations were revealed between age and average pRNFL thickness ($r = -0.450$, $P = 0.0006$), pRNFL thickness in temporal region ($r = -0.285$, $P = 0.0351$), superior region ($r = -0.470$, $P = 0.0003$) and inferior region ($r = -0.449$, $P = 0.0006$). No significant association was evident between pRNFL thickness in nasal region and age ($r = -0.0894$, $P = 0.516$).

Conclusions: Age-related changes in pRNFL thickness may play a major role in the progression of myopic degeneration. Understanding this relationship emphasizes the need for regular monitoring of pRNFL as part of the comprehensive eye care in aging populations.

Abstract No.: 207052

Association of Body Mass Index and Demographic Differences With Simple Myopia in South Indian Children

First Author: Elackiya **MANIMARAN**

Co-Author(s): Sahithya **BHASKARAN**, *Kamatchi* **NAGU**, *Vijayalakshmi* **P**

Purpose: To evaluate the association between body mass index (BMI), urban-rural distribution, and simple myopia among South Indian children.

Methods: This is a retrospective hospital-based study which analysed electronic medical records (EMR) of children aged 6–15 years who attended a paediatric clinic between January 2020 and December 2024. Children were categorized as myopes or emmetropes (controls). BMI was calculated using the WHO age and sex specific growth charts. Urban–rural distribution data on children’s residence were obtained from the Local Government Directory, Government of India.

Results: A total of 10,960 children were included (myopia - 4,094 controls - 6,866). Mean age and sex distribution were similar across groups. Myopia was more prevalent among children residing in urban areas. Overweight and obesity were more common in the myopia group ($p < 0.001$). Multivariate regression showed that overweight (OR = 1.55, 95% CI: 1.35–1.77), obesity (OR = 1.98, 95% CI: 1.60–2.44), and urban residence (OR = 1.74, 95% CI: 1.59–1.90) were independently associated with higher odds of myopia.

Conclusions: Simple myopia in South Indian children was significantly associated with higher BMI and urban residency. Children with overweight and obesity had nearly double the odds of myopia compared to their normal weight peers. These findings imply that lifestyle, environmental and nutritional factors may be as critical as genetics in determining myopia risk in children.

Abstract No.: 208261

Panel No.: MYO-0554

Association of Retinal Microvasculature With Myopia Progression in Children: The Hong Kong Children Eye Study

First Author: Zixuan **LIN**

Co-Author(s): Lijia **CHEN**, *Carol Y.* **CHEUNG**, *Patrick* **IP**, *Ka Wai* **KAM**, *Kyoko* **OHNO-MATSUI**, *Chi Pui* **PANG**, *Fangyao* **TANG**, *Clement C.* **THAM**, *Jason C.* **YAM**, *Alvin L.* **YOUNG**, *Xiu Juan* **ZHANG**, *Yuzhou* **ZHANG**

Purpose: To investigate the associations between optical coherence tomography angiography (OCT-A) metrics and myopia progression in children.

Methods: This prospective, longitudinal cohort study recruited children ages 6 to 8 years for 2- to 6-year follow-ups. OCT-A captured macular images

from the superficial capillary plexus (SCP) and deep capillary plexus (DCP). Annual progression of spherical equivalent (SE) and axial length (AL) was calculated as (SE/AL at last visit – SE/AL at baseline)/follow-up duration. Multivariable linear regression analysis evaluated the associations of OCT-A metrics with SE/AL progression. Restricted cubic spline (RCS) analysis evaluated both linear and nonlinear associations. Holm–Bonferroni correction was applied to account for multiple comparisons.

Results: A total of 920 children were analyzed. Multivariable linear regression, adjusted for age, sex, baseline SE/AL, and other covariates, showed that baseline foveal avascular zone (FAZ) circularity was negatively associated with annual AL elongation ($\beta = -0.06$; 95% confidence interval [CI], -0.10 to -0.02 ; adjusted $P = 0.045$). Similarly, the baseline FAZ circularity was positively associated with annual SE progression ($\beta = 0.15$; 95% CI, 0.05 – 0.26 ; adjusted $P = 0.045$). No significant associations were found between OCT-A metrics in the DCP with annual AL/SE progression. Furthermore, RCS analysis demonstrated no significant nonlinear associations between OCT-A metrics and annual AL/SE progression (P for nonlinearity > 0.05).

Conclusions: Baseline FAZ circularity in the SCP was significantly associated with annual AL elongation and annual SE progression in children, suggesting its potential as an imaging biomarker for monitoring myopia progression.

Panel No.: MYO-0559

Behavioural Patterns and Thresholds Associated With Childhood Myopia in a Large-Scale School-Based Study in China

First Author: Jingjing **WANG**

Purpose: Childhood myopia is a growing public health concern worldwide, yet the behavioural determinants and their quantitative thresholds remain uncertain.

Methods: We investigate the associations between integrated lifestyle patterns and myopia among 12,763 school-aged children in Shanghai. Using machine learning and k-means clustering based on six daily activities—doing homework, reading, computer use, television watching, sleeping, and time outdoors—we identify six distinct behavioural patterns.

Results: Children characterised by reduced sleep and intensive nearwork (clusters 3, 4, and 6) show significantly higher risks of premyopia and myopia, longer axial length, and poorer uncorrected visual acuity compared with those in the balanced behaviour group. A grid search approach further defines optimal thresholds for reducing myopia risk: doing homework ≤ 1 h/day, reading ≤ 0.5 h/day, computer use ≤ 0.5 h/day, television watching ≤ 1 h/day, sleeping ≥ 10 h/day, and

outdoor activity ≥ 2 h/day. Contour analyses suggest a compensatory relationship between sleep and outdoor time, with each additional hour outdoors equivalent to 1.86 hours of sleep in lowering myopia risk.

Conclusions: Our findings provide evidence-based behavioural thresholds and highlight integrated lifestyle patterns as key determinants of myopia development in school-aged children.

Bilateral Marcus Gunn Jaw Winking Phenomenon With High Myopia- a Unique Observation

First Author: Nithya SRIDHARAN
Co-Author(s): Smrithi Sony Thampi

Purpose: To report a unique case of bilateral Marcus Gunn phenomenon jaw winking (MGJWP) with high myopia but without ptosis. To our knowledge, this is a new observation with regard to the refractive status in this syndrome.

Methods: This is a case of a 3-year-old girl who presented to the OPD with abnormal eyelid movements since birth. The mother observed these symptoms more prominently during mastication. She was a firstborn child out of a second-degree consanguineous marriage, with an unremarkable prenatal, perinatal, and postnatal history. Family history was negative for any ocular disease or abnormalities.

Results: On examination, the child had elevation of the eyelids on contralateral jaw thrust with no associated ptosis. The anterior segment examination was found to be within normal limits. Her versions were full with no limitations and orthotropic by Hirschberg testing. Cycloplegic refraction showed high myopia of -6.00DS in BE, with BCVA in BE 6/18 (Snellen's VA Chart). Fundus evaluation showed a myopic disc with no torsion and peripheral fields within normal limits. Using A-scan, axial lengths were measured to be 24.95 OD and 24.65 OS. The sensorimotor findings were normal, and all findings were unchanged on follow-up 6 months later. The child did not require any surgical intervention.

Conclusions: This is a unique case of bilateral MGJWP with high myopia in the absence of ptosis. To our knowledge, this is the first report linking abnormal refractive status with this rare phenomenon, warranting further investigation into potential developmental associations.

Childhood Myopia and Risk Factors: Findings From an Elementary School in a Remote Indonesian Island

First Author: Safirah KHAIRUNA
Co-Author(s): Abdullah RAHMAN

Purpose: To determine the prevalence of myopia and identify its associated risk factors among school-aged children attending an elementary school in Ternate, North Maluku, Indonesia. Ternate is a remote volcanic island in eastern Indonesia, geographically isolated from major urban centers and with relatively limited access to specialized health services, representing an underserved population.

Methods: A cross-sectional study was conducted among students aged 6–16 years at one elementary school in Ternate. Visual acuity testing was used for the screening and diagnosis of myopia. Sociodemographic information and potential risk factors were obtained through a structured 22-item questionnaire. Items covered demographic characteristics, parental background, screen exposure (television, smartphones, video games), reading duration, outdoor activity, extracurricular participation, and family history of myopia (parents or siblings). Data were taken from January to March 2025.

Results: A total of 217 children were included in this study, of whom 69 (31.8%) were diagnosed with myopia. Myopia was significantly more prevalent among females ($p = 0.041$). Presence of myopic siblings was strongly associated with myopia (OR 2.42; 95% CI 1.24–4.72; $p = 0.01$). Although not statistically significant, trends suggested a lower risk of myopia with reduced screen time, shorter reading duration, and increased outdoor activity.

Conclusions: Nearly one-third of children screened at this elementary school were affected by myopia. Female gender and sibling myopia were significant risk factors. Findings from this remote island school population provide valuable preliminary insights into childhood myopia, even in a remote island setting, emphasizing the importance of early school-based screening and family-oriented education in underserved regions in Indonesia.

Abstract No.: 208538

Clinical Study on the Effectiveness of Different Orthokeratology Lenses in Controlling Myopia Progression in Children and Adolescents

First Author: Qi ZHANG
Co-Author(s): Jianfeng ZHU

Purpose: To compare the efficacy and safety of different orthokeratology (OK) lens designs in

controlling axial elongation and myopia progression in children and adolescents with low myopia, and to identify potential predictive indicators for treatment response.

Methods: In this randomized, double-blind, controlled clinical trial, 80 participants aged ≥ 8 years with myopia ranging from -1.00 D to -3.00 D were enrolled. Subjects were randomly assigned to wear either standard design OK lenses (Control group) or specialty-designed OK lenses (Test group), the latter precision-customized by incorporating adjustments to the Base Curve (BC), Reverse Curve (RC), and Jessen Factor. Lenses were worn for approximately 8 hours per night over one year. Ophthalmic parameters were examined at 1, 3, 6, 9, and 12 months. Compliance and adverse events were monitored digitally.

Results: Axial measurements demonstrated a time-dependent treatment effect with precision-customized orthokeratology lenses. While initial differences at 1-3 months were not statistically significant ($p > 0.05$), the customized lens group showed markedly less axial growth from month 6 (0.040 vs 0.110 mm, $p = 0.002$), with the treatment effect strengthening through month 12 (0.071 vs 0.174 mm, $p < 0.001$). These findings establish the superior long-term efficacy of parameter customization in myopia control.

Conclusions: Different OK lens designs provide effective and individualized approaches for slowing myopia progression. Precision customization of key lens parameters offers a promising strategy, and monitoring of ocular parameters may help optimize personalized myopia control.

Comparative Efficacy Between Highly Aspherical Lenslets and Single Vision Lenses in Slowing Pediatric Myopia Progression: A Systematic Review and Meta-Analysis

First Author: Angelina Patricia **CHANDRA**
Co-Author(s): Ametysa **MIRANDA**, Tri **RAHAYU**,
Angelina Riadi Alim **SUPRAPTO**

Purpose: This systematic review and meta-analysis (PROSPERO-ID:CRD420251022299) of randomized controlled trials (RCTs) aim to investigate the efficacy of highly aspherical lenslets (HAL) compared to single vision lenses (SVL) in children aged 6–13 years old to control myopia progression.

Methods: Seven scientific databases were searched following PRISMA guidelines for studies published up to April 2025. Quality of studies was assessed using the Cochrane RoB Tool 2.0. A random-effects meta-analysis of standard mean differences (SMD) was calculated with STATA16. Subgroup analysis by 6 months and >12 months follow-up duration was calculated to assess study heterogeneity.

Results: The search yielded 8631 studies, in which 7 RCTs were selected ($n = 733$). Pooled SMD of SER and AL changes between the two groups were 0.39 (95% CI: -0.29 – 1.07 , $p = 0.26$) and -0.20 (95% CI: -0.40 – 0.01 , $p = 0.06$), respectively. However, sub-group analysis of studies with 6 months follow-up duration yielded a statistically significant difference in SER and AL SMD changes, being 0.17 (95% CI: 0 – 0.33 , $p = 0.04$) and -0.10 (95% CI: -0.15 – -0.06 , $p < 0.001$), respectively. However, studies with >12 months follow-up duration did not yield a significant change in SER 0.50 (95% CI: -0.54 – 1.55 , $p = 0.35$) and AL -0.23 (95% CI: -0.50 – 0.04 , $p = 0.10$). High heterogeneity between studies during overall and subgroup analysis (range $I^2 = 69.34$ – 99.97%) was identified. Despite the variability, the sensitivity analysis concluded the robustness of findings.

Conclusions: HAL was more effective compared to SVL in reducing both SER and AL in reducing myopia progression in children aged 6–13 years; however, this was not statistically significant. Subgroup analysis revealed a significant superiority of HAL over SVL at the 6-month follow-up, suggesting potential short-term efficacy. However, although the efficacy of HAL during >12 months was superior to SVL, it was not statistically significant. These findings highlight the need for more standardized, long-term RCTs to clarify the clinical efficacy of HAL in delaying pediatric myopia progression.

Comparing Clinical Outcomes of Software-Based and Trial Lens Orthokeratology Fitting in Pediatric Myopia: A Systematic Review and Meta-Analysis

First Author: Angelina Patricia **CHANDRA**
Co-Author(s): Ametysa **MIRANDA**, Tri **RAHAYU**,
Angelina **RIADI ALIM SUPRAPTO**

Purpose: To compare clinical outcomes of orthokeratology fitted with software-based fitting versus with trial lens fitting in pediatric myopia control strategies.

Methods: Six databases were searched with studies leading up to July 2025. This review had also been registered in PROSPERO (CRD420251121366). Studies were included if the population was pediatrics treated with orthokeratology fitted with either software or trials lens, report axial length (AL), spherical equivalent refraction (SER), corneal staining, and/or corneal endothelial density during 12 months follow-up. Quality of studies were assessed using Cochrane RoB Tool 2.0. A random-effects meta-analysis of standard mean differences (SMD) were calculated using STATA16.0.

Results: Initial search yielded 2,450 studies. After exclusion considering inclusion criteria, three randomized controlled trials (RCTs) were included

($n=404$). SMD of AL between software and trial lens fitting was statistically significant, -0.04 (95% CI: -0.07 – -0.00 , $p=0.05$, $I^2=0.02\%$). However, other clinical outcomes were not statistically significant, with SMD of SER and corneal endothelial density being 0.06 (95% CI: -0.10 – 0.23 , $p=0.21$, $I^2=37.53\%$) and -20.72 (95% CI: -74.90 – -33.47 , $p=0.56$, $I^2=0.00\%$), respectively. Software-fitting reduces odds of corneal staining, OR -0.64 (95% CI: -2.55 – 1.27 , $p=0.10$, $I^2=63.75\%$), although not statistically significant.

Conclusions: Software-based orthokeratology fitting significantly reduces axial length elongation in pediatric myopia after 12 months follow-up compared to trial lens fitting. Corneal staining as an adverse event was also significantly reduced with software-based fitting. These findings indicate better clinical outcomes when orthokeratology is fitted with software compared to a trial lens.

Comparing the Effects of High Order Aberration Diffusion (HOAD) Versus Defocus Incorporated Multiple Segment (DIMS) Spectacle Lenses on Myopia Control

First Author: Xiaoqin CHEN

Co-Author(s): Xingyi GUO, Lihua LI, Wenli LU

Purpose: To investigate the 12-month effectiveness of High Order Aberration Diffusion (HOAD) and Defocus Incorporated Multiple Segments (DIMS) spectacle lenses in myopic Chinese children.

Methods: A total of 138 Chinese children aged 8-13 years, with spherical equivalent refractive error (SER) -1.00 D to -6.00 D, were randomized to one of the three groups of EHOAD spectacle lenses with stronger higher-order aberrations modulation, HOAD spectacle lens with slightly higher-order aberrations modulation, and DIMS spectacle lens. Axial length (AL) and cycloplegic SER changes over 12 months were measured.

Results: A total of 129 participants completed the 12-month visit following 9 voluntary withdrawals after screening (4 in EHOAD, 3 in HOAD, and 2 in DIMS). The 12-month means for myopia progression were -0.20 (0.40) D, -0.30 (0.42) D, and -0.45 (0.34) D in the EHOAD, HOAD, and DIMS groups. The EHOAD and HOAD groups had less SER progression by a mean of 0.25 D (55%; $P = 0.002$) and 0.15 D (33%), respectively, than the DIMS group. The 12-month increase in AL was 0.10 (0.16) mm, 0.12 (0.18) mm, and 0.22 (0.13) mm in the EHOAD, HOAD, and DIMS groups. Compared with DIMS, the EHOAD and HOAD groups demonstrated significantly less axial elongation by a mean of 0.12 mm (55%; $P < 0.001$) and 0.10 mm (45%; $P < 0.001$).

Conclusions: Chinese children wearing spectacle lenses designed with HOAD had less myopia progression and

axial elongation than those wearing spectacle lenses designed with DIMS.

Control of Myopia Using Contrast Modulation Spectacle Lenses in a Chinese Population

First Author: Zhi CHEN

Purpose: Contrast modulation spectacle lenses (Diffusion Optics Technology™; DOT) are designed to slow myopia progression by reducing contrast signaling in the retina. The purpose of this study was to evaluate the myopia control efficacy of DOT spectacle lenses in a Chinese population.

Methods: The study (NCT05562622) is a 24-month, multicenter randomized (2:1 ratio), controlled clinical trial evaluating DOT spectacle lenses versus standard single vision control spectacle lenses in myopic children aged 6–13. A linear mixed-effects model for repeated measures was fitted to the data to evaluate the changes in axial length (AL) and cycloplegic spherical equivalent refraction (cSER).

Results: A total of 171 children completed the 18M visit (123 DOT; 48 Control). For DOT wearers, the least square (LS) means changes $\pm$ SE at 18M from baseline in AL was 0.17 ± 0.03 mm (95%CI: 0.12 to 0.22 , $p<0.0001$) and cSER was -0.20 ± 0.05 D (95%CI: -0.30 to -0.09 , $p=0.0004$). For the control group, AL was 0.51 ± 0.04 mm (95%CI: 0.44 to 0.58 , $p<0.0001$) and cSER was -0.89 ± 0.08 D (95%CI: -1.06 to -0.73 , $p<0.0001$). Adjusted means in AL elongation and cSER progression for DOT wearers was 0.34 mm (95%CI 0.25 to 0.42 , $p<0.0001$) and 0.70 D (95% CI 0.50 to 0.89 , $p<0.0001$) less than the control group, respectively.

Conclusions: Results from this ongoing trial demonstrate DOT spectacle lenses are effective at slowing axial elongation and myopia progression in Chinese children.

Correlation of Axial Elongation With Lens Thickness Changes in Pediatric Myopia Undergoing Orthokeratology

First Author: Huihu ZHENG

Co-Author(s): Xuehui ZHANG

Purpose: To investigate the correlation between the rate of axial elongation and changes in crystalline lens thickness in myopic children undergoing orthokeratology.

Methods: This retrospective study included 107 myopic children (aged 8–16 years) with spherical equivalent (SE) refraction ranging from -4.00 to -0.75 D who were fitted with orthokeratology lenses at Xi'an First Hospital between 2021 and 2024. All participants completed a

1-year follow-up. Axial length (AL), anterior chamber depth (ACD), crystalline lens thickness (CLT), and central corneal thickness (CCT) were measured before and after lens wear. The treatment zone area was calculated using custom MATLAB software. Statistical analysis was performed using paired t-tests and linear regression.

Results: After 12 months of lens wear, significant changes were observed, including axial elongation (AL), shallower anterior chamber depth (ACD), increased crystalline lens thickness (CLT), and reduced central corneal thickness (CCT) (all $P < 0.001$). Linear regression analysis revealed that slower axial elongation was associated with older baseline age, smaller treatment zone area, and greater increase of CLT (all $P < 0.001$). Additionally, greater increase of CLT was independently correlated with older age and smaller treatment zone area (both $P < 0.001$).

Conclusions: In myopic children undergoing orthokeratology, significant crystalline lens thickening was observed. Notably, older age, smaller treatment zone area, and greater lens thickening were associated with slower axial elongation.

Decadal Changes in Myopia Prevalence and Vision Impairment Among Children Aged 4–14 Years in Shanghai: Findings From the Shanghai Child and Adolescent Large-Scale Eye Study (SCALE)

First Author: Zikai **ZHANG**

Co-Author(s): Jun **CHEN**, Xiangui **HE**, Jingjing **WANG**, Xun **XU**, Haidong **ZOU**

Purpose: To report the prevalence of myopia, high myopia, and vision impairment among children aged 4–14 years in Shanghai based on the 2024 city-wide SCALE re-survey, using the same methodology as the 2013 baseline study.

Methods: A city-wide, school-based screening was conducted in 2024 in Shanghai. Distance visual acuity (unaided and presenting) was measured using the standard logarithmic “E” chart, and non-cycloplegic autorefractometry was performed with calibrated autorefractors. To minimize overestimation, refractive data were adjusted using the validated SCALE equation. Myopia and high myopia were defined as spherical equivalent ≤ -1.0 D and ≤ -5.0 D, respectively. Age-specific prevalence and 95% confidence intervals (CIs) were calculated and compared with the 2013 published data.

Results: Among 2,053,123 children in 2024, overall myopia prevalence was 20.9% and high myopia 1.8%. By school stage, myopia prevalence was 1.6% in preschoolers (ages 4–6), 19.8% in primary school students (ages 7–11), and 51.2% in junior middle school

students (ages 12–14). Compared with 2013, relative risks (RRs) declined most sharply in preschoolers ($RR = 0.17$) and least in adolescents ($RR = 0.79$). Vision impairment based on presenting VA (worse than 6/12) occurred in 6.7% of children, significantly lower than in 2013 (10.3%). District-level variation was evident, with higher prevalence in urban central districts and lower rates in suburban areas.

Conclusions: Myopia and high-myopia prevalence among Shanghai children declined substantially between 2013 and 2024, especially at early school ages. The improvement likely reflects strengthened public eye health initiatives, though high myopia in adolescents remains a significant concern requiring sustained preventive efforts.

Defining Critical Thresholds for Myopia Intervention in Paediatric Populations: A Review and Consensus-Based Approach

First Author: Meng **LU**

Co-Author(s): Jun **CHEN**, Xiangui **HE**, Xun **XU**

Purpose: The global rise in myopia poses a growing risk of irreversible vision loss. However, myopia control research faces major obstacles, including parental reluctance to enroll children in untreated control groups, limited industry willingness for head-to-head trials, and challenges in generalizing results across populations. These factors hinder the establishment of evidence-based intervention thresholds through traditional RCTs. This study aims to synthesize existing evidence to define the refractive change threshold for initiating effective pediatric myopia intervention.

Methods: A systematic literature review and Delphi expert consensus method were employed to analyze data from high-quality RCTs, real-world studies, and cohort studies. The analysis focused on identifying critical values of treatment response metrics, including annual axial length progression, spherical equivalent refraction (SER) changes, and other relevant ophthalmological parameters that demonstrate clinically meaningful intervention effects.

Results: Axial length progression ≤ 0.2 mm/year and SER progression ≤ 0.50 D/year were established as key indicators of treatment success. Additional ophthalmological parameters, including choroidal thickness changes and peripheral defocus metrics, were also recognized as valuable indicators for assessing intervention efficacy.

Conclusions: This study provides evidence-based efficacy thresholds for evaluating myopia control interventions in paediatric populations. The established metrics offer standardized parameters for assessing treatment response in both clinical practice and research settings. These findings facilitate more

objective evaluation of intervention outcomes and support personalized treatment approaches, ultimately contributing to improved myopia management strategies and prevention of vision-threatening complications.

Development of an Electricity-Free Highly Portable Manual Refractometer

First Author: Marina YAMAGUCHI

Co-Author(s): Toru NAKAZAWA, Makoto SUZUKI, Satoru TSUDA, Chiaki YAMAGUCHI, Katsuhiko YAMAGUCHI

Purpose: This study aimed to develop an electricity-free, highly portable manual refractometer (MR) and compare its performance with an autorefractometer (AR).

Methods: Forty phakic eyes (aged 20–80) were evenly divided into Groups A and B, with different optotypes used in each group. Agreement between MR- and AR-measured spherical equivalent refraction (SER), and the correlation between SER measured by each device and axial length (AL), were analyzed by Pearson's correlation (r_p) and Bland–Altman analysis (BAA). Optotype compatibility in the combined group was tested by Student's t-test and two one-sided tests (TOST; ± 1.00 D). In Group B, improvement in logMAR visual acuity (VA), defined as corrected minus uncorrected, was assessed by Spearman's correlation (r_s). MR-related adverse events were surveyed.

Results: MR-SER showed high reproducibility (A: $r_p = 0.96$; B: $r_p = 0.97$; A+B: $r_p = 0.96$; all $p < 0.001$). No significant difference was found between optotypes ($p = 0.956$), and equivalence was confirmed by TOST (90% Confidence Interval: -0.88 to 0.83). MR- and AR-SER correlated strongly ($r_p = 0.90$, $p < 0.001$) with minimal BAA bias (-0.12 D). AL negatively correlated with SER in both methods ($r_p = -0.65$, $p < 0.001$). Improvement in logMAR VA correlated strongly ($r_s = 0.95$, $p < 0.001$). No adverse events occurred.

Conclusions: MR performed comparably to AR. It is easy to use, optotype-compatible, cost-effective, and also suitable for underserved areas worldwide, with the potential to improve eye care accessibility and support the Sustainable Development Goals (SDGs).

Differential Three-Dimensional Posterior Pole Remodeling in Myopic Children: Comparing Repeated Low-Level Red-Light Therapy With Low-Dose Atropine

First Author: Ziwei ZHAO

Co-Author(s): Yanxian CHEN, Mingguang HE, Yue WU

Purpose: To compare longitudinal changes in three-dimensional macular morphology between repeated low-level red-light (RLRL) therapy and low-dose atropine (LDA) treatment in myopic children.

Methods: This secondary analysis of a randomized controlled trial included 50 myopic children (aged 7–15 years) randomized to receive either RLRL therapy (650 ± 10 nm) or 0.01% atropine eye drops. Spectral-domain optical coherence tomography was performed at baseline and 1, 3, 6, and 12 months. Custom software was used to perform distortion correction and quantify macular curvature (MC), macular outward scleral height (MOSH), and their respective asymmetry indices. Primary outcomes were 12-month changes in average regional macular curvature. Secondary outcomes included changes in MOSH, asymmetry indices, and retinal layer thicknesses. Linear mixed-effects models analyzed longitudinal changes.

Results: At 12 months, RLRL demonstrated significant macular flattening versus atropine across all regions (mean differences $\times 10^{-3}$): central (9.0; 95%CI: 4.4–13.6; $P < 0.01$), temporal (9.7; 6.7–12.8; $P < 0.001$), inferior (8.4; 5.2–11.6; $P < 0.001$), superior (7.0; 4.0–9.9; $P < 0.001$), and nasal (3.7; 0.8–6.7; $P < 0.05$). The inter-group difference was most pronounced centrally and decreased with eccentricity. MOSH decreased superiorly and increased inferiorly in the RLRL group at 12 months, while the LDA group showed minimal change. Both nasal-temporal and superior-inferior macular curvature asymmetry indices increased significantly more in the RLRL group ($P < 0.001$ and $P < 0.05$, respectively). No inter-group differences in retinal layer thicknesses were observed.

Conclusions: Myopic children treated with RLRL exhibited macular flattening and decreased inferior scleral height, indicating alterations in the three-dimensional ocular shape. These changes were more pronounced than those observed with low-dose atropine treatment, suggesting that RLRL therapy may achieve myopia control by increasing ocular blood flow and modulating scleral remodeling.

Panel No.: MYO-0556

Effect of Low-Concentration Atropine on Myopia Prevention in Pre-myopic Children: A Randomized Clinical Trial

First Author: Jingjing WANG

Co-Author(s): Guangzhuang JING

Purpose: This study aims to evaluate the efficacy of 0.01%, 0.02%, and 0.04% atropine eye drops for preventing myopia in pre-myopic children.

Methods: A 12-month randomized, double-blind, placebo-controlled trial was conducted at the Shanghai Eye Diseases Prevention and Treatment Center from March 2023 to June 2024. Children aged 6–9 years with cycloplegic SER between -0.05 and $+0.75$ D were enrolled. Exclusion criteria included ocular/systemic diseases, orthokeratology use, or prior myopia control treatments. Participants were randomized (1:1:1:1) to placebo or 0.01%, 0.02%, or 0.04% atropine eye drops, applied once daily to both eyes. The primary outcome was 12-month cumulative myopia incidence (SER ≤ -0.50 D). Secondary outcomes included changes in SER (right eye) and axial length (AL) measured by swept-source OCT.

Results: Of 428 randomized children, baseline characteristics were comparable across groups. The 12-month myopia incidence was 22.22% (0.04%), 26.14% (0.02%), 29.21% (0.01%), and 36.59% (control), showing a significant dose-response trend ($*P^*_{\text{trend}} = 0.048$). Mean SE progression at 12 months was -0.171 ± 0.390 D (0.04%), -0.315 ± 0.526 D (0.02%), -0.377 ± 0.502 D (0.01%), and -0.456 ± 0.452 D (control) ($*P^* = 0.004$). Post hoc analysis showed a smaller SE change with 0.04% atropine than control ($\Delta 0.28$ D; 95% CI, 0.15–0.42; $*P^* < 0.001$) or 0.01% atropine ($\Delta 0.21$ D; 95% CI, 0.07–0.34; $*P^* = 0.006$). Among children aged 8–9 years, myopia incidence was 26–28% with 0.02–0.04% atropine versus 60% in controls ($*P^* = 0.023$ –0.029). All concentrations reduced SE progression, with 0.04% showing the greatest effect.

Conclusions: Our findings provide evidence-based behavioural thresholds and highlight integrated lifestyle patterns as key determinants of myopia development in school-aged children.

Effects of Anatomical Correction on Structure-Function Associations in High Myopia Eyes With and Without Glaucoma

First Author: Li Xin Hannah WONG

Co-Author(s): Rachel S CHONG, Samantha LOR, Lee Ching PHANG, Damon WONG

Purpose: Overlapping features between glaucoma and high myopia (HM) make glaucoma diagnosis in HM eyes challenging. We investigate if anatomical adjustments

to the Drasdo model improve structure-function (SF) correlation in HM eyes with and without glaucoma.

Methods: 261 HM eyes, including 138 with HM and glaucoma (HM-G) and 123 with HM without glaucoma (HM-N), were enrolled in this study. The Drasdo model, with and without anatomical correction for magnification and disc-fovea angle, was applied to the standard SF map that measures ganglion cell-inner plexiform layer (GCIPL) thickness corresponding to focal visual field (VF) locations. SF correlation between GCIPL thickness and VF sensitivity was assessed using Spearman correlation (rs). Correlations were compared between corrected and uncorrected models across all HM eyes, and separately in HM-G and HM-N subgroups using Steiger's Z-test.

Results: Anatomical correction significantly improved SF association in almost all sectors in the combined HM group, except superior and superotemporally, with strongest correlations in inferior (rs=0.66 corrected vs 0.61 uncorrected, $p=0.005$) and inferotemporal sectors (rs=0.63 corrected vs 0.56 uncorrected, $p=0.001$). Anatomical adjustment improved SF correlation in all sectors of HM-G eyes except superiorly, with minimal effect in HM-N eyes. Notably, HM-G eyes displayed strong correlations throughout (rs ≥ 0.40) compared to HM-N eyes (rs < 0.20).

Conclusions: Implementing anatomical correction for myopia significantly improves SF associations in HM eyes, especially in HM-G eyes. Strong SF concordance in HM eyes may suggest glaucomatous changes, aiding early detection and intervention.

Panel No.: MYO-0542

Efficacy of Combined Surgery for Managing High Myopia with Exotropia in Children

First Author: Tong QIAO

Co-Author(s): Wangyi FANG, Zupeng LU, Kai XU, Haiyun YE

Purpose: To assess outcomes of combined posterior scleral reinforcement (PSR) and exotropia surgery in children with high myopia, evaluating axial length (AL) control, best-corrected visual acuity (BCVA), retinal vascular changes, and strabismus correction.

Methods: This retrospective study analyzed 62 children (124 eyes; mean age 9.19 years) treated at Shanghai Children's Hospital (2021–2024) with ≥ 6 -month follow-up. AL, spherical equivalent (SE), BCVA, exotropia angle and ETDRS-grid-based angio-OCT analysis of nine retinal zones were examined by standard ophthalmic assessments.

Results: Postoperatively, BCVA improved slightly and AL showed non-significant reduction. All grafts remained stable without complications. Exotropia angle decreased significantly ($p<0.05$). Contrast sensitivity (CST) improved at high spatial frequencies (12/18

cpd bilaterally; 6 cpd right eye). Foveal and superior parafoveal vessel density increased significantly in both superficial (SCP) and deep capillary plexuses (DCP) ($p < 0.05$). FAZ area decreased significantly in SCP/DCP (right SCP most pronounced). Perifoveal vessel density (300 μ m) improved significantly except in left DCP. No significant correlation existed between AL reduction and vascular improvements.

Conclusions: Our findings demonstrate that combined PSR and exotropia surgery effectively controls AL in pediatric high myopia while significantly improving retinal microcirculation. The angio-OCT detected vascular improvements appear more pronounced and immediate than AL changes, suggesting this modality may serve as a sensitive biomarker for monitoring myopia progression. Additionally, this combined approach successfully corrects ocular misalignment and enhances binocular visual function.

Exploration of Visual Perception Metrics As Indicators for Myopia Screening

First Author: Hongwei DENG

Purpose: The aim of this study is to assess and analyze the relationship between myopia screening and visual perception indicators and to explore the predictive utility of these indicators for myopia screening outcomes in children.

Methods: For 180 third-grade students aged 8-10 in Shenzhen, we conducted myopia screening and assessed ocular biometrics and visual perception. Group differences were analyzed using the Wilcoxon rank sum test. Subsequently, myopia prediction models were developed using the axial length/corneal radius ratio (AL/CR) and visual perception metrics, with their diagnostic efficacy evaluated by ROC curve analysis.

Results: Significant differences ($P < 0.05$) were found between the emmetropia and screening myopia groups for AL/CR (max), PEP-DL (max), and the 0.8mE and 1.5mE optotype parameters. Prediction models were subsequently developed using AL/CR (max) along with visual perception indicators. Model 1 was constructed exclusively on AL/CR (max), with an area under the ROC curve (AUC) of 0.779, a sensitivity of 0.605, specificity of 0.859. Meanwhile, Model 2 was solely based on visual perception indicators, resulting in an AUC of 0.709, with a sensitivity of 0.750, specificity of 0.594. Model 3 was a combination of both AL/CR (max) and visual perception indicators, which are PEP-DL (max) and E 0.8m, achieving an AUC of 0.794, with sensitivity of 0.590, specificity of 0.921.

Conclusions: The integration of visual perception indicators with AL/CR (max) substantially enhances the diagnostic capacity of myopia screening, thereby

enhancing both the precision and dependability of myopia screening initiatives conducted within schools.

From Concentric to Non-Geometric: A Paradigm Shift in Ortho-K Design to Overcome Challenging Corneas, Decentration, Under-Correction, and Axial Length Control

First Author: Maylee HUANG

Co-Author(s): Zoe WU, Yingli XU

Purpose: Myopia progression and axial elongation remain key challenges in pediatric eye care. Conventional concentric Ortho-K designs often struggle with decentration, under-correction, and limited axial control, particularly in eyes with challenging corneal shapes. This lecture introduces an innovative n-Points Ortho-K design based on point-to-point axis alignment, generating multidirectional suction forces and optimized fitting to address the limitations of concentric designs.

Methods: In a prospective cohort study, 172 subjects aged 9–18 years were recruited. Sixteen completed one-year follow-up with 374 eyes analyzed. The N-point design applied AI-derived 360° freeform fitting with an additional Best Fit Ring (BFR) forming a dual reverse curve. This configuration stabilized lens positioning and produced suction-like effects, enhancing peripheral myopic defocus and refractive reduction.

Results: Baseline axial length averaged 24.65 $\pm$ 0.87 mm. After 12 months, elongation was only 0.15 $\pm$ 0.22 mm, significantly lower than reported in conventional Ortho-K studies (0.16–0.22 mm) and far below untreated controls (0.36–0.39 mm). Uncorrected visual acuity improved to 1.00 $\pm$ 0.02 by 6 months and remained stable. Lens decentration was clinically insignificant, and no adverse corneal effects were observed. Importantly, under-correction cases seen with concentric designs achieved more effective reduction with the n-Points alignment.

Conclusions: By shifting from concentric to point-to-point axis alignment, the n-Points Ortho-K design overcomes challenges of corneal irregularity, lens decentration, and under-correction, while providing effective axial length control. This paradigm shift represents a new era in Ortho-K for myopia management.

Fundus Curvature as a Clinical Marker for Posterior Staphyloma Based on Widefield Optical Coherence Tomography

First Author: Nan LUO

Co-Author(s): Shida CHEN, Bingqian LIU

Purpose: To investigate the ability to quantify fundus curvature and detect posterior staphyloma using widefield optical coherence tomography (OCT).

Methods: This cross-sectional diagnostic evaluation included 205 highly myopic eyes of 205 participants. The Gaussian curvature map of the fundus was automatically calculated from two million scan points over an area of 24mm × 20mm, visualizing localized deformations in the posterior region. Two fovea-centered areas were designated as follows: the 6mm × 6mm was the macular region, and the 8mm × 16mm area was the posterior region. Macular mean curvature (MMC) and curvature deviation (MCD), posterior mean curvature (PMC) and curvature deviation (PCD), and maximum posterior curvature (MPC) were calculated. The relationship between curvature indices, ocular parameters, and myopic complications was investigated. The diagnostic ability of curvature indices for posterior staphyloma was evaluated.

Results: The mean (SD) age of 205 participants was 34.06 (12.74) years, with 107 being female (52.2%). Posterior staphyloma was found in 33 of 205 (16.1%) eyes. The curvature value map and curvature deviation map revealed detailed morphologic patterns of posterior staphyloma. Eyes with staphyloma had a steeper and more irregular fundus than eyes without staphyloma, with a larger MPC ($20.420 \times 10^{-3} \text{ mm}^{-2}$ vs. $10.925 \times 10^{-3} \text{ mm}^{-2}$, $P < 0.001$), PMC ($6.754 \times 10^{-3} \text{ mm}^{-2}$ vs. $5.352 \times 10^{-3} \text{ mm}^{-2}$, $P = 0.002$), MCD ($1.889 \times 10^{-3} \text{ mm}^{-2}$ vs. $1.078 \times 10^{-3} \text{ mm}^{-2}$, $P < 0.001$), and PCD ($3.894 \times 10^{-3} \text{ mm}^{-2}$ vs. $1.683 \times 10^{-3} \text{ mm}^{-2}$, $P < 0.001$). However, no difference in MMC was found between eyes with and without posterior staphyloma. Larger MPC, MCD, and PCD were associated with greater degrees of myopia, more severe myopic maculopathy, and worse best-corrected visual acuity (all $P < 0.05$). PCD demonstrated the ability to discriminate the presence of posterior staphyloma (area under the curve: 0.909 [95% CI, 0.854-0.963; $P < 0.001$]). The optimal cutoff value of PCD was $3.060 \times 10^{-3} \text{ mm}^{-2}$ (Youden's index = 0.725), with a specificity of 90.7% and a sensitivity of 81.8%.

Conclusions: Widefield OCT-based analysis of fundus curvature enhances detection and quantitative assessment of posterior staphyloma in high myopia.

Global Real-World Pilot Data on Treatment Compliance With Repeated Low-Level Red-Light (RLRL) Therapy for Myopia Control

First Author: Yuri AUNG

Co-Author(s): Lisa Zhuoting ZHU

Purpose: Treatment compliance with repeated low-level red-light (RLRL) therapy is important given its previously established dose-response relationship, where treatment compliance >75% was associated with a 76.8% efficacy in slowing axial length progression and 87.7% efficacy in slowing spherical equivalence progression. In this study, we therefore aim to evaluate real-world treatment compliance of RLRL in 7 countries outside of China.

Methods: De-identified patient data were extracted from the Eyerising International portal until 1 August 2025 from Japan (n=612), Australia (n=123), New Zealand (n=112), the United Kingdom (n=71), Vietnam (n=50), and Malaysia (n=44). All patients used the Eyerising RLRL device for 3 minutes, twice daily, 5 days per week. Compliance was defined as the proportion of prescribed sessions completed. Treatment drop-off was defined as ≥30 consecutive days of device non-use following at least one month of RLRL.

Results: A total of 1,012 patients were included, with an average of 80.7% treatment compliance. Japan contributed the largest cohort and the highest mean treatment compliance of 85.3%, with a median treatment duration of 221 days and 153 patients completing 12 months. Other countries with patients completing 12-18 months were Australia (compliance 71.6%, median 224 days), New Zealand (72.0%, 326 days), and the UK (64.9%, 430 days). Compliance was higher where RLRL had been introduced for <12 months in Vietnam (74.9%, 107 days) and Malaysia (80.0%, 107 days). Compliance was also slightly higher in patients who had been using RLRL for <12 months (81.6%) compared to 12 months or more (78.6%). Drop-off rates ranged from 2.8% to 12.7%.

Conclusions: This first multinational real-world analysis of RLRL adherence demonstrates generally high treatment compliance across diverse populations outside of China, sustained through 12-18 months in several countries.

High Myopia Prevalence in Special Educational Needs Children and Its Link With Earlier and Longer Exposure to Electronic Screens During the COVID-19 Pandemic

First Author: Cheuk Lam Cherlin LEE

Co-Author(s): Kendrick Co SHIH

Purpose: To determine myopia prevalence and electronic screen time of special educational needs (SEN) children, aged 6-8 years, during the ongoing COVID-19 pandemic.

Methods: Between July 1st and August 31st 2022, 46 SEN children and 53 controls, aged 6-8, were actively recruited into our cross-sectional study. Patients underwent best corrected visual acuity assessment (BCVA), subjective refraction and axial length assessment (IOL Master 700, Zeiss Group). Parental educational level, children's outdoor time and electronic screen use were collected by validated questionnaires.

Results: In SEN children, aged 6-8 years, 39.1% had myopia on presentation. Among myopic subjects, 33.3% had spherical error of less than -1.0D, 22.2% were between -1.0D and -1.9D, 11.1% were between -2.0D and -2.9D, 22.2% were between -3.0D and -3.9D, and 0.06% were -4.0D or more. Mean axial length was 23.7 (± 1.16) mm. Comparatively, controls had a myopia prevalence of 30.1%. For SEN children, 43.5% reported to be using electronic screens regularly before the age of 4 compared to 37.8% in controls. 58.7% of SEN children used electronic screens for 2 or more hours a day, and 65.2% used them at least 5 days a week. Comparatively, 49.1% of controls used electronic screens for 2 or more hours a day, and 58.4% used them at least 5 days a week. Parental education level and socioeconomic status were similar between groups.

Conclusions: Myopia prevalence and severity were significantly higher in SEN children than controls. This was associated with earlier and longer exposure to electronic screens in SEN children.

Higher Order Aberrations and Visual Quality After Refractive Surgeries for Adult Myopia: A Systematic Review and Network Meta-Analysis

First Author: Chen TINGTING

Co-Author(s): Wei CHI

Purpose: To compare higher-order aberrations (HOAs) and visual quality outcomes among different refractive surgical protocols for adult myopia.

Methods: This systematic review and network meta-analysis (NMA) searched PubMed, Embase, Web of Science, the Cochrane Library, and ClinicalTrials.gov for studies published up to 22 August 2025. Eligible studies included randomized controlled trials and cohort studies involving myopic patients undergoing corneal refractive surgery or phakic intraocular lens (ICL) implantation. Baseline and follow-up data for continuous indicators were extracted, and standardized mean differences (SMDs) with 95% confidence intervals (CIs) were calculated. Primary outcomes were total HOAs, spherical aberration, coma, and trefoil; secondary outcomes included vertical and horizontal coma and trefoil. Analyses were performed using R 4.5.0.

Results: Fifty studies (5141 eyes) were included. Compared with other interventions—SMILE, FS-LASIK, LASIK, PRK, LASEK, FLEX, and T-PRK—ICL showed significantly lower total HOAs (SMD range 0.61–0.80) and spherical aberration (SMD range 0.97–1.72; $P < 0.05$). ICL also significantly reduced coma aberrations (SMD range 0.31–0.87). SUCRA rankings placed ICL first in total HOAs (99.9%), spherical aberration (99.9%), coma (93.6%), trefoil (76.2%), horizontal coma (90.8%), and horizontal trefoil (97.5%), and second in vertical coma and vertical trefoil (69.2% each). No significant differences were observed among other interventions in spherical aberration or trefoil.

Conclusions: ICL implantation demonstrated superior performance in reducing HOAs compared with other refractive correction methods and appears to be the most effective option for patients requiring high visual quality.

Hyperopic Shifts of Second Baseline in Low-Concentration Atropine Random Control Trial

First Author: Zhehui LIU

Co-Author(s): Xiangui HE, Xun XU

Purpose: To explore the associated factors of hyperopic shifts at the second baseline in The Effect and Safety of Different Doses of Atropine on Myopic Progression of Highly Myopic Children: Multi-centered Randomized Clinical Trial.

Methods: Post hoc analysis. Children aged 6 to 12 years old with high myopia in Shanghai were enrolled as participants and double-blindly randomized to 0.01%, 0.04% and 0.10% atropine. Comprehensive and ocular parameters were collected at baseline, and cycloplegic spherical equivalent (SE) was mainly collected in the second baseline. A linear regression model was used to explore the association between the difference of SE from baseline to second baseline (hyperopic shifts) and the parameters collected.

Results: A total of 177 participants who completed baseline and second baseline examinations were included. The hyperopic shifts were exclusively associated with concentration group (coefficient: 0.102, 95%CI: 0.068 to 0.137, $p < 0.001$) and photopic pupil size (coefficient: -0.104, 95%CI: -0.161 to -0.046, $p = 0.001$).

Conclusions: Higher atropine concentration and smaller photopic pupil size are associated with a lower degree of hyperopic shifts. The definition of SE change needs uniformity, and a second baseline is recommended in trials involving 0.10% or higher concentration.

Intraocular Pressure Is a Promising Target for Myopia Control

First Author: Xiaoyi LIU

Co-Author(s): Jiaxuan JIANG, Kangjie KONG, Fei LI, Xiulan ZHANG

Purpose: To investigate the impact of different intraocular pressure (IOP)-lowering medications on reducing IOP, decelerating axial elongation, and influencing pressure-dependent scleral remodeling.

Methods: To explore the effects of reducing IOP to varying extents on myopia progression, three groups receiving distinct IOP-lowering medications (Brinzolamide, Latanoprost, and a combination of Brinzolamide and Latanoprost) were designed in a form-deprived myopic guinea pig model. Additionally, proteomics analyses were conducted to identify differentially expressed proteins in the sclera.

Results: Based on 24-hour and 4-week IOP monitoring, the group receiving both Brinzolamide and Latanoprost exhibited the greatest magnitude of IOP reduction and the most significant inhibition of axial length (AL) growth. Moreover, the administration of IOP-lowering medications increased choroidal thickness and induced alterations in the structure of scleral collagen fibrils. Notably, scleral proteomics revealed remodeling processes associated with key mechanisms, including proteolysis, fibrinolysis, and metal ion binding.

Conclusions: Our findings highlight that pressure-dependent scleral remodeling contributes to the deceleration of AL elongation. These results underscore the efficacy of IOP reduction in mitigating the progression of myopia, providing a promising alternative strategy for myopia management.

Investigating the Roles of Circadian Rhythm-Related Genes in Myopia Pathogenesis

First Author: Ying ZHANG

Purpose: This study employed summary data-based Mendelian randomization (SMR) to examine

associations between circadian rhythm-related gene expression and myopia risk using large-scale genomic datasets.

Methods: Circadian rhythm-related genes were retrieved from GeneCards database. Expression quantitative trait locus (eQTL) data from eQTLGen consortium ($N = 31,864$) and myopia data from UK Biobank GWAS ($N = 287,448$) were analyzed. Replication used autorefraction-measured mean spherical equivalent (MSE) data ($N = 95,619$). SMR assessed associations between gene expression and myopia risk. Significant cis-eQTLs were identified within $\pm 1,000\text{kb}$ genomic regions using $P < 5.0 \times 10^{-8}$. HEIDI test distinguished pleiotropy from linkage.

Results: Among 73 circadian rhythm genes tested, ten showed significant MSE associations. After false discovery rate correction and pleiotropy exclusion, four genes remained significant: MYBPC3, PSEN1, RORA, and PPARA. Higher MYBPC3 expression (odds ratio [OR] = 0.97, 95% confidence interval [CI] = 0.96-0.98, $PFDR = 0.002$) associated with decreased MSE, indicating increased myopia risk. Conversely, higher expression of PSEN1 (OR = 1.05, 95%CI = 1.02-1.07, $PFDR = 0.022$), RORA (OR = 1.13, 95%CI = 1.05-1.22, $PFDR = 0.023$), and PPARA (OR = 1.20, 95%CI = 1.07-1.33, $PFDR = 0.023$) associated with increased MSE, indicating lower myopia risk. The associations of MYBPC3 (OR = 0.90, 95% CI = 0.86-0.94, $PFDR < 0.001$) and PPARA (OR = 1.84, 95% CI = 1.30-2.60, $PFDR = 0.008$) were confirmed in the replication sample.

Conclusions: This study provides genetic evidence for causal relationships between circadian rhythm gene expression and myopia risk. Four identified genes substantiate that circadian dysregulation contributes to myopia pathogenesis, suggesting potential therapeutic targets for myopia prevention.

Keratoconus Masked As Myopia Progression: A Case Report

First Author: Nhi NGUYEN HUYNH YEN

Purpose: To report a pediatric keratoconus case masked as myopia progression.

Methods: This is a case report.

Results: A 10-year-old female presented for a routine eye examination. Her personal and family history were unremarkable. The prescription of her spectacle, which she had been wearing for one year was $-2.75/-1.25 \times 175$ in the right eye and $-2.50/-0.50 \times 175$ in the left eye. At the current visit, refraction showed $-4.25/-1.75 \times 175$ in the right eye and $-3.50/-1.25 \times 165$ in the left eye, with a best-corrected visual acuity of 9/10 in each eye. The marked increase in refractive error within just one year initially led to the impression of progressive myopia. Slit-lamp examination of both

anterior and posterior segments was unremarkable. However, keratometry revealed abnormally steep corneal curvatures: K1 48.19D and K2 49.87D in the right eye, and K1 48.86D and K2 50.18D in the left eye. Axial length measurements were within the normal range (22.71 mm in the right eye and 22.22 mm in the left eye), suggesting that the refractive changes could not be fully explained by axial elongation. Corneal tomography with Pentacam subsequently confirmed the diagnosis of progressive keratoconus and corneal cross-linking was indicated.

Conclusions: This case emphasizes that rapid refractive changes in children should not be attributed solely to myopia progression, particularly when the degree of refractive change is disproportionate to axial length. Corneal imaging is essential in such cases to enable early detection of keratoconus and timely treatment.

Abstract No.: 206325

LRP2 Is a Potential Molecular Target for Nonsyndromic Pathological Myopia

First Author: Francine BEHAR-COHEN

Co-Author(s): Olivier CASES, Lasse CEHOFSKI, Kimberley DELAUNAY, Kentaro KOJIMA, Renata KOZIRAKI, Emilie PICARD, Jose Maria RUIZ MORENO, Jorge RUIZ MEDRANO, Alicia TORRIGLIA

Purpose: High myopia (HM), particularly when complicated by posterior staphyloma (PS), is a major cause of irreversible vision loss. Genetic and environmental factors, including light exposure, are implicated, but underlying molecular mechanisms remain poorly understood. LRP2 (megalin), an endocytic receptor mutated in syndromic myopia, was investigated as a potential target in nonsyndromic HM with PS.

Methods: LRP2 levels were quantified in vitreous samples from HM patients with PS and emmetropic controls by proteomics and ELISA in independent Japanese and European cohorts. Post-mortem HM donor eyes with PS were analyzed by OCT, histology, and immunohistochemistry, and compared to Foxg1-Cre-Lrp2lox/lox mice. In human iPSC-derived RPE (iRPE), LRP2 was silenced by RNA interference followed by bulk RNA-seq and pathway analysis. The effects of light exposure (red, blue, white LEDs) and cortisol on LRP2 expression were evaluated by qPCR and immunocytochemistry.

Results: LRP2 levels were significantly decreased in the vitreous of HM+PS patients versus controls in both cohorts. Human HM eyes with PS displayed severe retinal thinning, Müller cell disorganization, and RPE morphological defects with reduced LRP2 expression, paralleling Foxg1-Cre-Lrp2lox/lox mice. In iRPE, LRP2 silencing downregulated genes involved in retinol metabolism, steroid signaling, and RPE polarity, while upregulating extracellular matrix and cytoskeletal

pathways. Light exposure transiently increased LRP2 expression (most strongly with red light), whereas cortisol reduced it.

Conclusions: LRP2 is decreased in vitreous, retina, and RPE of HM eyes with PS. Its regulation by light and cortisol suggests LRP2 as a molecular link between environmental and hormonal factors in nonsyndromic HM.

Learnings From Implementing a Myopia Control Clinic in a Public Health Setting

First Author: Zeinab FAKIH

Co-Author(s): Nellie DEEN, Rumeysa DOGER

Purpose: Myopia is a growing public health concern, with Australian prevalence projected to exceed 50% by 2050. In 2021, the Australian College of Optometry (ACO) established the first known public myopia control clinic in Victoria. This study examines the challenges, limitations, and outcomes of implementing such a clinic in a public health setting.

Methods: A retrospective review of case files from January 2021 to September 2025 was conducted, involving 1,258 myopic children seen at the ACO myopia control clinic. Data on referral pathways, treatment recommendations, and factors influencing treatment compliance were analysed. Additionally, clinicians involved in the clinic completed an online questionnaire to identify trends in treatment decisions and perceived barriers to care.

Results: Referrals primarily came from existing ACO Children's Clinic patients, external optometrists, and ophthalmologists. Treatment options included single-vision spectacles, ortho-keratology, soft contact lenses, atropine, peripheral defocus lenses, and Repeated Low-Level Red Light Therapy (RLRL). Low-dose atropine (0.05%) was the most commonly initiated treatment for progressive myopia. However, barriers to compliance included limited access to compounding pharmacies and frequent prescription renewals. Clinicians identified additional challenges, particularly for patients from lower socioeconomic backgrounds, including cost and the burden of follow-up appointments.

Conclusions: This study highlights real-world barriers to childhood myopia treatment in a public health context. Health literacy and socioeconomic factors significantly impact compliance with evidence-based treatments. Targeted management frameworks are essential for supporting children from disadvantaged backgrounds in accessing effective myopia care.

Lifelong Changes in the Choroidal Thickness, Refractive Status and Ocular Dimensions in C57BL/6J Mouse

First Author: Tang TAO

Co-Author(s): Ren CHI, Wang KAI, Zhao MINGWEI, Li YAN

Purpose: To investigate the changes in choroidal thickness (ChT), refractive status, and ocular dimensions in the mouse eye in vivo using updated techniques and instrumentation.

Methods: High-resolution swept-source optical coherence tomography (SS-OCT), eccentric infrared photoretinoscopy, and custom real-time OCT were used to analyze choroidal changes, refractive changes, and ocular growth in C57BL/6J mice from postnatal day (P) 21 to month 22.

Results: The ChT gradually increased with age, with the thickest region in the para-optic nerve head (ONH) and thinning outward, and the temporal ChT was globally thicker than the nasal ChT. Retinal thickness (RT) remained stable until 4 months and subsequently decreased. The average spherical equivalent refraction error (SER) was -4.81 ± 2.71 diopters (D) at P21, which developed into emmetropia by P32, reached a hyperopic peak ($+5.75 \pm 1.38$ D) at P82, and returned to $+0.66 \pm 1.86$ D at 22 months. Central corneal thickness, anterior chamber depth, lens thickness, and axial length (AL) increased continuously before 4 months but subsequently exhibited subtle changes. ChT was significantly correlated with the ocular parameters (except for RT) before the age of 4 months, but these correlations diminished after 4 months. Furthermore, for mice younger than 4 months, the difference in the ChT, especially the temporal ChT, between the two eyes contributed most to that of AL and SER.

Conclusions: Four months could be a watershed age in the growth of mouse eyes. Large-span temporal recordings of refraction, ocular dimensions, and choroidal changes provided references for the study of the physiological and pathological mechanisms responsible for myopia.

Longitudinal Chromatic Aberration Mediates Red Light's Choroidal Targeting Mechanism

First Author: Yanqing LI

Co-Author(s): Ye SHEN

Purpose: This study uses a biomimetic mouse eye model, human eye modeling and animal experiments to explore if longitudinal chromatic aberration (LCA) mediates 630 nm red light's choroidal targeting, aiding myopia therapy.

Methods: The form-deprivation myopia model was built with 2-week-old C57BL/6J mice. After 2 weeks, 630 nm red light exposure (275 lx) was applied (white light as control), with refraction and ocular parameters measured weekly. Based on the data above, a Zemax eye model was established to verify the focal point of red light and RMS wavefront aberration. After 2 weeks, ocular parameters, choroidal blood flow density and thickness were measured. Measurement of refractive development was performed on VIP::Ai14+/+ mice (retina-specific tdTomato expression).

Results: Red light inhibited myopia in a refraction-dependent manner ($R^2=0.4691$, $P<0.001$), inducing hyperopic shift, slower axial elongation, thicker choroid, and higher choroidal blood flow vs. the white light group. Zemax simulations showed a -3.5D focal shift for 630 nm vs. 555 nm light in mice (smaller in myopic eyes) and a 122.4 μm shift in the human eye model; red light also reduced myopic eyes' higher RMS wavefront aberration. A 20D positive lens-induced defocus eliminated ocular parameter differences between red and white light groups, while VIP::Ai14+/+ mice (red filter, no LCA) had no parameter differences vs. controls.

Conclusions: This study first clarifies LCA as the key mechanism for 630 nm red light's choroidal targeting. Future red light devices should account for individual LCA variations to achieve personalized precision therapy.

Morning Administration Is More Effective Than Evening Administration of 0.01% Atropine Eye Drops Combined With Orthokeratology for Myopia Control

First Author: Xuwei LI

Co-Author(s): Kai WANG

Purpose: To assess the varying myopia control outcomes between morning (QM) and evening (QN) application of 0.01% atropine drops in conjunction with orthokeratology (ortho-K) therapy in myopic children.

Methods: A total of 163 right eyes of myopic children were included, receiving either morning or evening 0.01% atropine combined with ortho-K, with 78 in the QM group. Age, gender, spherical equivalent refraction, axial length, e-value, average K-reading (Ave-K), and pupil diameter (PD) were all documented as baseline characteristics. Follow-up assessments at 1-, 3-, 6-, 9-, and 12-month visits were centered on alterations in treatment zone diameter (TZD), decentration, PD, and axial elongation. Parental refraction and children's behavioral factors were gathered through a questionnaire.

Results: At baseline, there were no significant differences in ocular characteristics between the two

groups. After one month, the QM group exhibited a significantly larger PD compared to the QN group (4.09 ± 0.67 mm vs. 3.84 ± 0.76 mm, $P = 0.03$), while measurements for TZD and decentration showed no significant variance. Over the course of 1 year, the QM group demonstrated significantly less axial elongation than the QN group (0.13 ± 0.19 mm vs. 0.21 ± 0.16 mm, $P < 0.05$). Regression analysis revealed that the timing of atropine administration, age, PD, and reading and writing posture were significant predictors of axial elongation over the 12-month period.

Conclusions: Morning administration of 0.01% atropine eye drops combined with ortho-K shows greater efficacy in axial elongation.

Myopia Control Effect Repeated Low-Level Red-Light Therapy in Australian Children: A Multi-Ethnic Randomized Controlled Trial

First Author: Nellie **DEEN**

Co-Author(s): Yuri **AUNG**, Rumeysa **DOGER**, Zeinab **FAKIH**

Purpose: This study assessed the efficacy and safety of repeated low-level red-light (RLRL) therapy for controlling myopia progression in multi-ethnic school-aged children in Australia.

Methods: Thirty-four children aged 8–13 years with myopia (cycloplegic spherical equivalent [SE] -0.50 to -5.00 D), astigmatism ≤ 2.50 D, anisometropia ≤ 1.50 D, and monocular best-corrected visual acuity (BCVA) 20/20 or better were enrolled from Australian College of Optometry clinics and randomly assigned to RLRL or single-vision spectacles (SVS). RLRL therapy was administered 3 minutes, twice daily, 5 days a week. The SVS group continued routine activities. Assessments were performed at baseline and 1, 3, 6, and 12 months. Treatment efficacy was analysed using a longitudinal-mixed model. Safety was monitored through questionnaires, BCVA, optical coherence tomography (OCT), and dilated fundus examinations.

Results: Seventeen children were included in each group. At 12 months, axial elongation was -0.03 mm (95% CI, -0.05 to -0.01) and SE progression 0.09 D (95% CI, 0.04 to 0.14) for RLRL, compared with 0.12 mm (95% CI, 0.10 to 0.14) and -0.21 D (95% CI, -0.31 to -0.12) for SVS. Between-group differences were 0.15 mm (95% CI, 0.10 to 0.20 mm) for axial elongation and -0.31 D (95% CI, -0.51 to -0.12 D) for SE progression. No severe adverse events, BCVA loss, or OCT-detected damage occurred. One child withdrew due to mild headache at 3 months.

Conclusions: RLRL therapy is a promising, well-tolerated option for myopia control, with no functional or structural damage observed. Larger studies are required to confirm efficacy and long-term safety.

Myopia Control Efficacy of Defocus Incorporated Multiple Segments Triple Enhanced Design Spectacle Lenses

First Author: Dennis Yan-yin **TSE**

Co-Author(s): Rachel Ka Man **CHUN**, Ying **HON**, Carly Siu Yin **LAM**, Tsz Wing **LEUNG**, Chi Ho **TO**

Purpose: To Evaluate the Myopia Control Efficacy of Defocus Incorporated Multiple Segments Triple Enhanced Design (DIMS TED) Spectacle Lenses in 4 to 12 Years Old Myopic Children.

Methods: Two hundred and two Chinese children aged 4 to 12 years with myopia ≤ -0.75 diopters (D) in both eyes, and with documented evidence of myopia progression ≥ 0.50 D per year or axial length growth ≥ 0.27 mm per year in at least one eye for 7 to 12 years old, or with myopia ≤ -1.75 D in at least one eye for 4-6 years old, were enrolled in a double-masked, placebo-controlled, randomized controlled clinical trial. Participants were randomized and age-stratified into three arms (DIMS TED, DIMS, and single-vision (SV)) in an equal ratio. Cycloplegic spherical equivalent autorefraction (SER) and axial length (AL) were measured at 6-month intervals.

Results: A total of 199 subjects completed the 6-month visit ($n=68$, 66 , and 65 for DIMS TED, DIMS, and SV, respectively). Subjects in the DIMS TED and DIMS arms exhibited significantly less progression in SER and AL compared with the SV: changes in SER (D) adjusted mean (SE) — DIMS TED: 0.13 (0.04); DIMS, -0.10 (0.04); SV, -0.26 (0.05); changes in AL (mm) adjusted mean (SE) — DIMS TED, 0.01 (0.01); DIMS, 0.11 (0.01); SV, 0.18 (0.01).

Conclusions: The DIMS TED spectacle lenses demonstrated strong efficacy in controlling myopia progression and axial elongation in children over 6 months

Abstract No.: 206117

Myopia Control With Low-Dose Atropine in Children (MYLAC) Study: Safety of 0.02% and 0.04% Doses

First Author: Shifei **WEI**

Co-Author(s): Wenzai **AN**, Shi-ming **LI**, Yunyun **SUN**, Ningli **WANG**

Purpose: To evaluate the safety of myopia control with low-dose atropine in children.

Methods: In this randomized controlled multicenter trial (CTR20212468), children aged 6-12 years with spherical equivalent (SE) from -1.00 D to -4.00 D and astigmatism ≤ 1.50 D were assigned to receive 0.02% atropine, 0.04% atropine, or placebo nightly in both eyes. Safety outcomes included pupil diameter,

accommodation amplitude, best-corrected distance visual acuity (BCDVA), intraocular pressure (IOP), tear break-up time (TBUT), and height.

Results: A total of 800 children were enrolled (300 in 0.04% atropine, 300 in 0.02% atropine, and 200 in a placebo). At 48 weeks, pupil diameter increased from baseline by 1.34 mm, 1.06 mm, and 0.04 mm ($p < 0.001$), and accommodation decreased by -1.56 D, -0.91 D, and -0.22 D (0.04% atropine vs placebo, $p = 0.006$; 0.02% atropine vs placebo, $p = 0.15$), respectively. Similar trends were observed at 96 weeks. All values returned to baseline levels at 24 weeks after discontinuation, with no significant differences among the three groups ($p > 0.05$). No significant intergroup differences were found in BCDVA, IOP, or TBUT at 48 or 96 weeks ($p > 0.05$). Height increased similarly across groups. No serious adverse events occurred. Photophobia is the most common adverse reaction and is concentration-dependent (15% in the 0.04% group; 10.1% in the 0.02% group).

Conclusions: Both 0.02% and 0.04% atropine demonstrated a favorable safety profile for myopia control in children.

Network Meta-Analysis of Pediatric Myopia Control in Asia: Methodological Framework and Baseline Progression Insights

First Author: David CHAMPION

Co-Author(s): Veni VENUSHA SAKTI, Thom DE MILLIANO

Purpose: Pediatric myopia is a major concern in Asia due to faster progression than global averages. This study aimed to evaluate the comparative efficacy of interventions for slowing myopia progression in East and Southeast Asian pediatric populations using network meta-analysis (NMA).

Methods: A systematic review of RCTs from Embase, Cochrane CENTRAL, MEDLINE, and supplementary sources identified interventions for pediatric myopia control. Eligible studies reported change from baseline in spherical equivalent refraction (SER) and axial length, and annual progression rate (APR) for NMA inclusion. A geographic subgroup analysis was performed to isolate evidence from East and Southeast Asian populations. Bayesian random-effects models were used to estimate relative treatment effects. Network meta-regression (NMR) was applied to assess the influence of prespecified effect modifiers, including age, baseline SER, and geographic region.

Results: Of 115 RCTs in the literature review, 96 were assessed. Sixty-six were conducted in East/Southeast Asia, with 42 forming the Asian evidence network. The network was well-connected via a common control node, enabling robust indirect comparisons. The mean

APR in control arms was approximately 0.89 D/year—substantially higher than in Western cohorts. NMR identified geography and baseline SER as borderline significant modifiers of treatment effect. The model demonstrated overall good fit and convergence.

Conclusions: This NMA, which indicates high APR in the Asian population, supports region-specific evidence to guide clinical and policy decisions, highlights the urgency of early interventions in myopia control, and provides a robust platform for evaluating low-dose atropine and other emerging pharmacological therapies.

OCT Choroidal Radiomic Parameters Associated With Visual Impairment and Identification of Pathological Myopia

First Author: Yixin LI

Co-Author(s): Guangqing LIN, Fan LU, Yilei SHAO, Ni WAN

Purpose: To analyze choroidal radiomic features from optical coherence tomography (OCT) in patients with high myopia and assess their association with visual acuity and diagnostic value for pathological myopia (PM).

Methods: A total of 237 myopic participants aged 18-50 years were enrolled. Utilizing the PyRadiomics platform and machine learning, we extracted and refined choroidal radiomic features from OCT images. The correlations of these features with best-corrected visual acuity (BCVA), age, spherical equivalent, and axial length were examined. A classifier developed from these features was evaluated for its efficacy in identifying PM via five-fold cross-validation, using the area under the curve (AUC), accuracy, recall, and F1-score as primary metrics. Its performance was benchmarked against a clinical parameter-based model.

Results: From 464 initial radiomic features, four choroidal intensity and shape features demonstrating significant correlation with axial length ($P < 0.001$) were ultimately identified. A smaller maximum diameter, higher coarseness, and greater perimeter-surface ratio were linked to poorer BCVA ($P < 0.05$). In the task of identifying PM, the radiomic features outperformed clinical parameters in both the internal test set (AUC = 0.970 vs. 0.938) and external validation set (AUC = 0.884 vs. 0.720). Integrating the radiomic features with risk factors further enhanced the classification performance (internal AUC = 0.990, external AUC = 0.912). SHAP analysis identified intensity features as the most decisive predictors of PM.

Conclusions: Choroidal OCT intensity and morphological features demonstrate strong correlations with axial elongation and visual

impairment, surpassing conventional clinical indicators in detecting pathological myopia, and show promise as objective biomarkers for monitoring high myopia progression.

Abstract No.: 206676

One-Month Changes in Choroidal Vascularity Index of Medium Vessel Layer in Myopic Children Wearing Orthokeratology Lenses: A Predictor for One-Year Changes in Axial Length

First Author: Junmeng **LI**

Co-Author(s): Pei **RONG**, Liu **YANG**

Purpose: To investigate the changes in the choroidal vascularity index (CVI) of choroid sublayers after orthokeratology (Ortho-K) treatment, the association between one-month CVI changes and one-year eye elongation, and the role of CVI responses in predicting the one-year control efficacy of Ortho-K treatment.

Methods: A prospective cohort study was conducted, including 257 myopic children aged 7-16 years. The subjects continuously wore Ortho-K lenses for 12 months. Vascular volume (CVV), stromal volume (CSV), choroidal volume (CV) and CVI of the choroid sublayers was assessed using optical coherence tomography images at baseline and 1-month follow-up. The total choroid layer (TCL) includes the large-vessel choroidal layer (LVCL) and the medium-vessel choroidal layer (MVCL). The round fundus area with a 6mm diameter was divided into 9 regions using the Early Treatment of Diabetic Retinopathy Study (ETDRS) grid.

Results: The 1-month CVI of TCL and MVCL in all ETDRS grid regions were significantly lower than the baseline CVI ($P \leq 0.036$), except for TCL_S36 ($P=0.070$). After 1-month Ortho-K treatment, both CSV and CV significantly increased in all choroidal sublayers compared to baseline data ($P \leq 0.027$), while CVV also showed significant increases in half of the ETDRS grid regions (14/27). After adjusting for age and gender, the baseline TCL_T13 CVI ($\beta=0.146$, $P=0.006$), and 1-month changes of MVCL_T36 CVI ($\beta=0.337$, $P<0.001$) and MVCL_N13 CVI ($\beta=0.174$, $P=0.002$), were independently associated with one-year axial length (AL) elongation during Ortho-K treatment. Based on 1-month changes in MVCL_T36 CVI and MVCL_N13 CVI, age, and sex, the prediction model demonstrated an area under the curve (AUC) of 0.905 (95% CI: 0.870 to 0.941) for distinguishing myopic children with slow or fast AL elongation.

Conclusions: One-month of Ortho-K induces differential CVI changes in choroidal sublayers. The early CVI reduction in MVCL suggests disproportionate vascular-structural alterations, holding promise for elucidating myopia control mechanisms and predicting future axial elongation.

Abstract No.: 203001

One-Year Myopia Control Efficacy of Hexagon Optimized Reticular Integration (HORI) Spectacle Lenses

First Author: Xingyi **GUO**

Co-Author(s): Xiaoqin **CHEN**, Junyi **HU**, Lihua **LI**, Ting **WANG**

Purpose: To investigate the 12-month effectiveness of hexagon optimized reticular integration (HORI) spectacle lenses in Chinese myopic children.

Methods: A prospective, single-aim study. A total of 38 Chinese children aged 8-13 years, with spherical equivalent refractive error (SER) of -0.50 D to -3.00 D, were enrolled in the HORI group. Patient records involving the use of single-vision lenses (SVL) were collected from the optometric center. Propensity score matching (PSM) was performed at a 1:1 ratio based on baseline characteristics, including age, gender, axial length (AL), and cycloplegic SER measurements. AL and cycloplegic SER changes over 12 months were measured.

Results: Thirty-seven participants completed the 12-month visit following 1 voluntary withdrawal after screening in the HORI group. The 12-month means for myopia progression were -0.36 (0.41) D and -0.74 (0.45) D in the HORI and SVL group. The HORI group had less SER progression by a mean of 0.38 D than the SVL group ($P < 0.001$). The 12-month increase in AL was 0.19 (0.16) mm and 0.34 (0.18) mm in the HORI and SVL group. Compared with SVL, the HORI group demonstrated significantly less axial elongation by a mean of 0.15 mm ($P < 0.001$).

Conclusions: Chinese children wearing spectacle lenses designed with HORI had less myopia progression and axial elongation than those wearing SVL.

Optometric Validation of the -0.50D Empirical Rule in Pediatric Myopia

First Author: Zhehui **LIU**

Co-Author(s): Xiangui **HE**, Xun **XU**

Purpose: To describe the relationship between uncorrected visual acuity (UCVA) and spherical equivalent (SE) and explore potential associated factors.

Methods: Cross-sectional study. Demographic and ophthalmologic data, including UCVA, cycloplegic refraction, intraocular pressure (IOP), and axial length (AL) from children and adolescents aged 3 to 19 in Shanghai, were analyzed. Kernel density estimate plot and histogram were used to describe the association between UCVA and SE. Linear regression was used to explore related factors.

Results: A total of 18,300 participants were included in the analysis. Significant vision loss was initially observed when SE decreased to -0.50D. Per 1.00 D reduction, logMAR UCVA worsened by 0.20, 0.09, and 0.03 in low, moderate, and high myopia, respectively. Over 50% participants maintained 0.1 logMAR VA or better within SE range from -0.50D to +3.00D. UCVA of 3- to 5-year-old children with non- or low myopia remained averaged 0.2 logMAR. UCVA was associated with SE (coefficient: -0.105, 95%CI: -0.108~-0.102, $P < 0.001$), AL (coefficient: -0.012, 95%CI: -0.018~-0.007, $P < 0.001$), non-dominant eye (coefficient: 0.014, 95%CI: 0.007~0.021, $P < 0.001$), IOP (coefficient: -0.003, 95%CI: -0.004~-0.002, $P < 0.001$), age (coefficient: -0.005, 95%CI: -0.007~-0.004, $P < 0.001$), female (coefficient: 0.011, 95%CI: 0.003~0.018, $P = 0.005$) and BMI (coefficient: 0.002, 95%CI: 0.001~0.004, $P < 0.001$). Only SE maintained statistically and clinically significance in stratification by myopic degree.

Conclusions: For myopia diagnosis, $SE \leq -0.5D$ represents a superior threshold compared to -0.25D, -0.75D, or $SE < -0.5D$. UCVA is not recommended to be the sole basis for judging the refractive development of children aged 3 to 5.

P2RY12-Mediated Retinal Microglial Ramification Drives Myopia Onset and Development in Mice

First Author: Pengfan CHEN

Co-Author(s): Jing JI, Longqian LIU, Xiangyi WEN

Purpose: The role of retinal microglia in myopia development remains unclear. We investigated whether microglia and their key purinergic receptor, P2RY12, respond to abnormal visual signals and drive myopia onset and progression.

Methods: Myopia was induced in postnatal mice via 4-week form deprivation (FD). We assessed refraction and axial length. Microglia were depleted using PLX5622, and P2RY12 was inhibited pharmacologically and via conditional knockout. Microglial morphology (branching, Sholl analysis) was quantified in flat-mounted retinas. Dopaminergic amacrine cells (DACs) were specifically stimulated using chemogenetics.

Results: Microglial depletion significantly suppressed FD-induced myopia (refractive shift: $-2.29 \pm 0.47 D$ vs. $-5.89 \pm 0.49 D$ in controls, $P < 0.0001$). Similarly, P2RY12 antagonism and genetic knockout inhibited myopia progression and reduced microglial ramification. Conversely, chemogenetic stimulation of DACs exacerbated myopia (refractive shift: $-8.26 \pm 0.81 D$, $P < 0.0001$) and induced complex microglial ramification, with increased total branch length ($1368.97 \pm 42.68 \mu m$ vs. $1195.27 \pm 52.99 \mu m$ in controls, $P = 0.0414$).

Conclusions: Retinal microglia and P2RY12-mediated ramification are critical mechanisms driving myopia onset and development. Our findings identify microglial morphology as a key cellular process responding to visual cues, positioning it as a potential novel therapeutic target for myopia control.

Prevalence and Machine Learning-Identified Risk Factors for Dry Eye Disease in Myopic Children: A Cross-Sectional Study

First Author: Bingqing LI

Co-Author(s): Fengju ZHANG

Purpose: To investigate the prevalence of dry eye disease (DED), characterize ocular surface features, and identify independent risk factors among myopic schoolchildren in northern China.

Methods: A cross-sectional study was conducted among 1,303 myopic children, who completed ocular surface examinations, including FBUT, Schirmer I test, and OSDI questionnaire. LipiView was used to assess lipid layer thickness (LLT) and partial blink rate (PBR). XGBoost and Random Forest were trained and evaluated on a test set to assess predictive performance. Model interpretability was explored using the SHapley Additive exPlanations (SHAP) method to identify key risk factors.

Results: The prevalence of objectively diagnosed DED was 31.2%. High myopia was significantly associated with higher OSDI scores, although objective DED prevalence did not significantly differ by myopia severity. The XGBoost model achieved an overall accuracy of 0.6858, with the Random Forest model performing similarly (accuracy 0.6935). The SHAP analysis revealed Ortho-K Lens Wear (0.1128) as the most influential risk factor, followed by FBUT $\leq 5s$ (0.0749) and Myopia Severity_Moderate (0.0533). A diagnostic score, calculated from the sum of SHAP values, showed a distinct difference between the non-dry eye group (mean -0.4217) and the dry eye group (mean -0.2323).

Conclusions: DED is prevalent among myopic children in northern China. Machine learning models can identify and rank complex risk factors, with Ortho-K lens wear emerging as the most significant predictor. The use of SHAP-based diagnostic scores provides a nuanced, continuous measure of dry eye risk, offering a valuable tool for targeted clinical management in this population.

Abstract No.: 202353**Panel No.: MYO-0507**

Prevalence and Severity of Pathologic Myopia Among Older Adults With High Myopia in Hong Kong: Hong Kong High Myopia Cohort

*First Author: Xiujuan ZHANG**Co-Author(s): Christopher K.s. LEUNG, Kendrick C. SHIH*

Purpose: To investigate the prevalence and severity of pathologic myopia (PM) among highly myopic adults in Hong Kong.

Methods: This cross-sectional, population-based study included participants aged 50 years and older who underwent comprehensive ophthalmic examinations in Hong Kong. High myopia was defined according to WHO criteria as spherical equivalent refraction (SER) ≤ -5.0 diopters or axial length (AL) ≥ 25.5 mm. Pathologic myopia was graded using the META-Analysis of Pathologic Myopia (META-PM) classification system based on colour fundus photography.

Results: Among 26,437 adults, 4,947 (18.7%) were high myopia. After them, 4,511 participants (7,819 eyes) were analyzed. The mean age was 61.2 ± 7.1 years, with 57.0% female. Mean AL was 26.50 ± 1.25 mm and mean best-corrected visual acuity (BCVA) was LogMAR 0.09 ± 0.21 . Using the META-PM classification, 2,053 eyes (26.3%) were Category 0, 3,634 eyes (46.5%) Category 1, 1,999 eyes Category 2, 101 eyes (1.3%) Category 3, and 32 eyes (0.41%) Category 4. Worse BCVA was significantly associated with higher META-PM grade ($B = 0.188$; 95% CI 0.135 to 0.241; $P < 0.001$) and a shorter distance between patchy atrophy and the macula ($B = -0.0003$; 95% CI -0.0005 to -0.00005; $P = 0.017$).

Conclusions: The prevalence of high myopia and pathologic myopia is high among older adults in Hong Kong. Higher META-PM grades and proximity of patchy atrophy to the macula are linked to worse visual acuity. These findings suggest the need for targeted, intensive follow-up in patients at higher risk of vision loss.

Abstract No.: 208227**Panel No.: MYO-0553**

Prevention Efficacy of Pre-myopia Using 0.01% Concentration Atropine Eye Drops Twice a Day

*First Author: Yinrui LI**Co-Author(s): Jie CHEN, Xiaoman LI, Jianing ZHANG*

Purpose: To evaluate the efficacy of the prevention of pre-myopia using 0.01% concentration of atropine eye drops twice a day.

Methods: A one-year randomized, placebo-controlled, clinical trial. A total of 160 pre-myopic children (cycloplegic sphere diopters: +0.75 D to -0.50D, astigmatism less than 1.50 D) aged 6 to 12 years were enrolled and randomly assigned to 4 groups: Twice a

day 0.01% atropine group (0.01%TD), 0.01% atropine per night and placebo per morning (0.01OD), 0.04% atropine per night and placebo per morning (0.04%OD), placebo twice a day (PTD). All the bottles were masked to the researchers and subjects.

Results: The mean spherical equivalent refraction (SER) change was -0.44 ± 0.55 D, -0.28 ± 0.41 D, -0.00 ± 0.46 D, and -0.69 ± 0.57 D in the 0.01% TD, 0.01% OD, 0.04%OD, and PTD groups, respectively (0.01%TD VS 0.01%OD, $P > 0.05$, 0.01%TD VS 0.04%OD, $P < 0.001$, 0.01% TD VS PTD, $P = 0.05$). The mean axial length increase was 0.30 ± 0.22 mm, 0.25 ± 0.19 mm, 0.18 ± 0.19 mm, and 0.42 ± 0.22 mm (0.01%TD VS 0.01%OD, $P > 0.05$, 0.01%TD VS 0.04%OD, $P = 0.016$, 0.01% TD VS PTD, $P = 0.023$).

Conclusions: Adopting 0.01% atropine eyedrops twice a day is efficient for myopia prevention in pre-myopia children. But using 0.01% atropine twice a day is not better than 0.01% or 0.04% once a day.

Abstract No.: 202006**Panel No.: MYO-0503**

Refractive Status and Ocular Biometry in Chinese Children Aged 3-15 Years: Before, During and After COVID-19 Lockdown

*First Author: Tao SHEN**Co-Author(s): Lin DING, Yafei MU, Yanli QIN, Bixia WEI, Wei WEI, Xiaoxiao ZHANG*

Purpose: To assess whether myopia development is affected differently by the COVID-19 lockdown among children of different ages.

Methods: This hospital-based retrospective study evaluated data from 4186 Chinese children aged 3-15. The comparative analysis of spherical equivalence (SE), axial length (AL), axial length-to-corneal radius (AL/CR) ratio, and refractive status distribution was stratified by age before, during, and after the lockdown.

Results: Comparison before and after the lockdown, the overall proportion of myopia increased from 57.8% to 65.0%, and the SE, AL, and AL/CR ratio increased by -0.267 diopters (D) ($P = 0.002$), 0.234 mm ($P < 0.001$), and 0.039 ($P < 0.001$), respectively. In preschool-aged children (aged 3-6), early myopic shifts of the refractive status and ocular biometry in 2020 were observed followed by remarkable regressions during and after the lockdown. In school-aged children (aged 7-15), myopic shifts of the refractive status and ocular biometry showed an increasing trend, which increased most rapidly in children aged 13-15 during the later period of the lockdown in 2022. In school-aged children (aged 7-15), the proportion of moderate and high myopia had nearly doubled in 2022 compared to the pre-pandemic level, followed by regression after the lockdown.

Conclusions: The COVID-19 lockdown had an earlier impact on myopia development in preschool-aged than in school-aged children.

Repeated Low-Energy Red Light Interventions to Control Myopia in Children and Adolescents: A Randomized Clinical Trial

First Author: Min TONG

Co-Author(s): Linlin DU, Xiangui HE, Xun XU, Bo ZHANG

Purpose: To evaluate the effects of repeated low-energy red light interventions on spherical equivalent (SE) and axial length (AL) in myopic children and adolescents.

Methods: A prospective randomized controlled trial was conducted. Eligible adolescent children aged 6-12 years were recruited as participants in July 2022 at the Shanghai Eye Diseases Prevention and Treatment Center, and were randomly divided into the trial group and the control group. The trial group received daily low-energy red light interventions, and the control group was treated with atropine. Follow-up visits were conducted at 3, 6, 9, and 12 months after enrollment, and information on optometric parameters such as SE and AL in both eyes of the participants was collected through questionnaires and ophthalmological examinations. The t-test was used to compare binocular SE and AL progression between the two groups at 3, 6, 9, and 12 months.

Results: A total of 104 participants were included (52 each in the trial and control groups), and there were no significant differences between the two populations in baseline characteristics ($P>0.05$). The 12-month binocular SE progression was -0.027 ± 0.539 D (right eye) and -0.125 ± 0.505 D (left eye) in the trial group and -0.761 ± 0.588 D and -0.641 ± 0.549 D in the control group, which was a significant difference between the two groups ($P<0.001$). The binocular AL progressions at 3, 6, 9, and 12 months were significantly slower in the trial group than in the control group (all $P<0.001$), with a 12-month binocular AL progression of 0.021 ± 0.203 mm and 0.036 ± 0.194 mm in the test group and 0.338 ± 0.235 mm and 0.315 ± 0.266 mm in the control group.

Conclusions: Low-energy red light therapy is an effective intervention for controlling myopia in adolescents and children, with high effectiveness in controlling SE and AL progression.

Seasonal Variation in the Effect of Controlling Myopia Progression Using Orthokeratology

First Author: Tang TAO

Co-Author(s): Wang KAI, Zhao MINGWEI, Li YAN

Purpose: To investigate seasonal variations in the effect of controlling myopia progression using orthokeratology (Ortho-K) in Chinese myopic children.

Methods: A total of 116 myopic children aged 7 to 12 years old who completed 1 year of Ortho-K treatment. Based on initial time wearing Ortho-K, subjects were classified as four groups: spring group (March-May), summer group (June-August), autumn group (September-November) and winter group (December-February). Axial length (AL) was measured every 3 months for 1 year by a partial coherence interferometer. Axial elongation over time and between groups was compared.

Results: The effect of myopia control using Ortho-K was influenced by seasonal variation. After adjusting study groups (type of Ortho-K), age, AL, spherical equivalent refractive error (SER) and ocular parameters at the baseline, the mean axial elongation over 1 year wearing Ortho-K was 0.33 ± 0.08 mm for the spring group, 0.30 ± 0.10 mm for the summer group, 0.21 ± 0.08 mm for autumn group, and 0.22 ± 0.09 mm for winter group ($p<0.001$). Statistically significantly higher mean axial elongation was observed in winter months than in summer (0.09 ± 0.06 mm vs. 0.05 ± 0.05 mm, $p<0.001$).

Conclusions: In general, axial elongation in myopic children receiving Ortho-K in the summer months was approximately 56% of that in winter. Initially, when wearing Ortho-K in the autumn/winter months, the effect of myopia control is better than in the spring/summer. Our results indicated that seasonal variation should be taken into account in studies related to Ortho-K.

Solving the Flat Cornea Challenge: Clinical Outcomes of a Novel NP Orthokeratology Lens

First Author: Maylee HUANG

Co-Author(s): Zoe WU, Xuyingli XU, Rui ZHANG

Purpose: To evaluate the clinical effectiveness and underlying mechanism of a newly designed NP orthokeratology lens in managing myopia for patients with flat corneal curvature.

Methods: A 13-year-old female with moderate myopia and flat corneal curvature was fitted with NP OK lenses (Optact, Taiwan) for overnight wear. Clinical follow-ups were performed at 1 week, 1 month, 3 months, 1 year, 2 years. Assessments included unaided visual acuity (UCVA), corneal topography, ocular health, and axial length.

Results: Conventional VST-design OK lenses showed poor fitting and limited adjustability. In contrast, NP OK lenses achieved excellent fluorescein patterns, UCVA of 1.0 after one week, and stable outcomes over two years. The NP design utilizes three synergistic forces: positive pressure from the base curve and negative pressure from the reverse curve, as well as the alignment region, which drive the redistribution

of central epithelial cells and the upward shift of peripheral fluid. This mechanism created a broader and flatter treatment zone, yielding greater myopia reduction and improved visual quality.

Conclusions: Orthokeratology lens fitting on relatively flat corneas commonly results in incomplete daytime vision correction, rapid corneal rebound, and inadequate control of axial length elongation. The NP orthokeratology lens offers a more predictable fit, stable vision, and effective myopia control, making it a valuable solution for challenging flat corneal profiles.

Spontaneous Suprachoroidal Haemorrhage in a High Myopia Patient With Rhegmatogenous Retinal Detachment

First Author: Fang CHAI

Co-Author(s): Xiquan ZHAO

Purpose: To report a case of spontaneous suprachoroidal haemorrhage in a high myopia patient with rhegmatogenous retinal detachment and successful treatment.

Methods: This is a case report of a 73-year-old female who presented with blurred vision in the left eye for fifty days. Her medical history included high myopia, but no systemic illness ever. B-ultrasound and fundus examination revealed retinal detachment with choroidal detachment. We performed combined phacoemulsification without intraocular lens implantation and vitrectomy with silicone oil injection.

Results: After phacoemulsification, 20G mixed with 23G vitrectomy cannulas were placed 3.5 mm from the limbus. The 20G cannula were left open, and the infusion line was placed in the anterior chamber through a clear corneal paracentesis with a bottle height of 40 mmHg. As soon as the infusion line was opened, a copious, thick flux of blood and occasional tiny clots flowed out of the 20G cannulas. As the blood flow continued, the choroidal detachment visibly recessed. A 1/5PD hole in the arch of the vascular arch below the macula was found, and full vitrectomy with silicone oil tamponade was performed. Undergo surgical treatment, retinal detachment and choroidal detachment were reduction. With silicone oil tamponade, the visual acuity was manual and 20/2000 (Snellen visual Acutles) on the one day and one month postoperation separately.

Conclusions: Spontaneous suprachoroidal haemorrhage is a rare but serious sight-threatening ocular condition. Appropriate operation time and thorough drainage of suprachoroidal haemorrhage during operation were the key to successful treatment.

Study of Binocular Vision Parameters and Peripheral Refraction in Children With Progressive Myopia on Low-Dose Atropine

First Author: Sowmya RAVEENDRA MURTHY

Co-Author(s): Shifa ANJUM, Kaushik MURALI

Purpose: To study the vergence, accommodation parameters in children on low-dose atropine and to note the correlation with duration of use. Also to note peripheral refraction in these children.

Methods: A prospective cross-sectional study was conducted between December 2023 and September 2024, including all children between 7 and 18 years of age on low-dose atropine for at least 3 months. Those on combination treatment were excluded. The following parameters were checked after informed consent: Detailed history of LDA usage, BCVA, phoria for distance and near, NFV, PFV, NPC, NPA, NRA, PRA, AA, and Cycloplegic refraction measured in the central, 15°, 20°, and 30 degrees in nasal and temporal meridians.

Results: We enrolled a total of 231 children within the specified study period. The mean age was 12 years (SD 2.97), with a total of 100 males and 131 females. The majority of the children had normal vergence and accommodation parameters. Mean values of Peripheral refraction show a hyperopic shift in both the nasal and temporal meridians, the shift being slightly more in the temporal meridian. There was no correlation of duration of LDA use with Vergence or accommodation parameters (chi-square test and showed no significant correlation. There was no significant correlation between peripheral refraction and NRA in our study group. A weak but significant negative correlation was found with peripheral refraction at nasal and temporal meridians and PRA, indicating a small inverse relationship in the right & left eyes (15° & 30 degrees).

Conclusions: Children on LDA showed mostly normal vergence & accommodation parameters with no correlation with duration of usage. And hyperopic peripheral refractions in nasal and temporal meridians

Targeting the ALKBH5-ERK1/2 Epitranscriptomic Axis: A Novel Therapeutic Strategy for Myopia Intervention

First Author: Jiru ZHU

Co-Author(s): Ye SHEN, Jianping TONG

Purpose: With global myopia prevalence reaching epidemic levels and treatment options remaining limited, this study investigates the pathogenic role of retinal epitranscriptomic regulation, specifically N6-methyladenosine (m6A) modification, and explores its therapeutic potential.

Methods: Peripheral blood m6A levels were measured in 38 myopic patients undergoing implantable collamer lens surgery. Murine form-deprivation myopia (FDM) models were employed to assess retinal m6A methylation and ALKBH5 expression. Mechanistic studies involved intravitreal injection of the ALKBH5 inhibitor DDO-2728 and the ERK1/2 activator Ro 67-7476. ALKBH5-knockout mice were also subjected to FDM. Outcomes included myopia progression (refraction, axial length), retinal thickness, inflammatory mediators (IL-6/8/10, MMP2, MCP-1, TGF- β 1), extracellular matrix regulation, and key signaling pathways (ERK1/2, Wnt/ β -catenin).

Results: Clinical analysis revealed significant inverse correlations between peripheral blood m6A levels and myopia severity (refraction: $r = 0.435$, $p < 0.01$; axial length: $r = -0.338$, $p < 0.05$). FDM mice exhibited retinal m6A hypomethylation and ALKBH5 upregulation. Pharmacological inhibition of ALKBH5 with DDO-2728 effectively attenuated myopia progression, mitigated retinal thinning, suppressed inflammatory responses, and modulated early extracellular matrix dysregulation. These effects were mediated through the specific suppression of ERK1/2 hyperphosphorylation, independent of the Wnt/ β -catenin pathway. The therapeutic benefits of DDO-2728 were completely abolished by co-administration of the ERK1/2 activator Ro 67-7476. Genetic ablation of ALKBH5 provided similar but weaker protection, suggesting compensatory mechanisms.

Conclusions: This study identifies the ALKBH5-ERK1/2 axis as a novel pathogenic driver and promising therapeutic target for myopia. The ALKBH5 inhibitor DDO-2728 demonstrates strong translational potential for controlling myopia progression.

Abstract No.: 210385

Taxonomic Structure and Diversity of the Ocular Surface Microbiota in Children With and Without Myopia: A 16S rRNA Sequencing Study

First Author: Gulnara REZBAEVA

Co-Author(s): Alexandr BABUSHKIN, Alexandra DANILOVA, Vasilisa DUDURICH, Olga ORENBURKINA, Karina SOGOMONIAN

Purpose: To investigate the taxonomic composition and diversity of the ocular surface microbiota in children with different degrees of myopia compared with children without clinically confirmed myopia, using 16S rRNA metagenomic sequencing.

Methods: A total of 29 children (58 eyes) with mild, moderate, or high myopia and 12 age-matched children without myopia (24 eyes) were examined. Biological samples were collected from the conjunctival surface. After quality filtration, samples with insufficient sequencing depth were excluded. Bacterial composition was analyzed at the genus level using 16S

rRNA sequencing. Alpha diversity (Chao1, Shannon) and beta diversity (Bray-Curtis NMDS) were assessed. Statistical comparisons were conducted to evaluate differences between groups and to explore the influence of myopia severity.

Results: A study of the microbiota of the ocular surface using 16S rRNA sequencing in children with myopia revealed an increase in alpha and beta diversity compared with the control group. There was a significant increase in the abundance of *Staphylococcus* sp., *Streptococcus* sp., *Corynebacterium* sp., *Cutibacterium* sp., *Pelomonas* sp. and *Bacteroides* sp. compared to the control. The control samples showed a limited but stable microbial profile with less variability. The overall structure of the microbiota in patients with myopia was characterized by a higher number of taxonomic units due to opportunistic flora, which indirectly indicates the presence of dysbiosis.

Conclusions: The microbiota of the ocular surface in children with myopia demonstrates increased diversity and taxonomic imbalance compared to healthy peers. The presence of dysbiosis correlates with the degree of myopia and may be a potential biomarker of disease progression. Further studies of microbiological and immune interactions in the eye can improve early diagnosis and individual prevention strategies.

The Dumbbells Pattern of Myopia Management Practice in Southeast Asia

First Author: Jong Mei KHEW

Co-Author(s): Mohd Zaki AWG ISA, Monica JONG, Philip MORGAN, Kah Ooi TAN

Purpose: This is a project initiated by the Asia Optometric Congress to understand the main intrinsic and extrinsic barriers in practicing myopia management amongst optometrists in Southeast Asia.

Methods: Optometrists from Malaysia, Singapore, Thailand, Vietnam, and the Philippines were recruited voluntarily through local professional associations. In-depth semi-structured live interviews up to 45 minutes were conducted with recruited optometrists, which were recorded and transcribed. A framework method was used for thematic analysis of the data.

Results: Fifty-seven optometrists with a mean age of 41.5 (± 12.1) years completed the interview. Thematic analysis revealed a dumbbell pattern with extrinsic barriers (treatment cost, accessibility, awareness of myopia management) on one end, and intrinsic barriers (limited scope of practice, lack of clinical guidelines, lack of co-management, time constraint) on the other end. The extents of these barriers vary from country to country. The main supports to narrow the gap are advocating public awareness and continuing education

to upskill clinical competencies to practice holistic myopia management more effectively.

Conclusions: This is the first in-depth qualitative study to explore the perspectives of optometrists in Malaysia, Singapore, Thailand, Vietnam, and the Philippines on practicing myopia management. It highlighted the challenges in addressing patients' understanding of myopia management and the urgency of acquiring the right clinical skill set to practice myopia management. There is a need to involve the stakeholders, including government and industry partners, for strategic advocacy for public awareness, and the need for professional development for practitioners to provide holistic myopia management practice.

The Effect of Pretreatment With Repeated Low-Level Red Laser-Light (RLRL) on Normal Refractive Development and Form-Deprivation Myopia in the Chick

First Author: Qianqian SONG

Co-Author(s): Mengtian KANG, John PHILLIPS, Wenjun XU, Zihang ZHANG

Purpose: There is significant clinical interest in using Repeated Low-level Red Laser-light (RLRL) treatment to delay childhood myopia development. We investigated pretreatment with RLRL on normal refractive development and form-deprivation myopia (FDM) in the Chick model to study mechanisms.

Methods: Three-day-old White Leghorn chicks (n=20) received monocular RLRL pretreatment (n=10: 650 nm, 2 mW, 3 minutes twice daily) or sham pretreatment (n=10) for 4 days. Ocular biometry (Lenstar) and refractions (retinoscopy) were then measured in all eyes. FDM, without further RLRL treatment, was then induced in the RLRL and sham pretreated eyes for three days, after which, refractions and ocular biometry measures were repeated. Outcomes are presented as interocular differences (treated eye minus fellow eye).

Results: Four days of RLRL pretreatment induced a hyperopic shift compared with the sham pretreatment ($+1.50 \pm 1.81D$ vs. $-0.02 \pm 0.60D$, $P=0.009$), accompanied by decreased vitreous chamber depth (VCD, $-0.10 \pm 0.07mm$ vs. $+0.02 \pm 0.03mm$, $P=0.001$), shorter axial length (AL, $-0.14 \pm 0.09mm$ vs. $+0.00 \pm 0.05mm$, $P<0.001$), and increased choroidal thickness ($+47.6 \pm 47.6\mu m$ vs. $+2.89 \pm 12.9\mu m$, $P=0.010$). FDM-induced AL elongation ($-0.04 \pm 0.05mm$ vs. $+0.07 \pm 0.07mm$, $P=0.002$) and VCD growth ($-0.02 \pm 0.06mm$ vs. $+0.05 \pm 0.07mm$, $P=0.042$) were lower in the RLRL pretreatment group compared to the sham pretreatment group, although no significant differences were observed in spherical equivalent refraction or choroidal thickness.

Conclusions: In chicks, RLRL pretreatment reduced normal eye growth, induced a hyperopic shift in refraction and protected against myopia development, potentially through increasing choroidal thickness. These findings confirm the value of the Chick model for investigating mechanisms underlying the therapeutic benefits of RLRL pretreatment in children.

The Impact of Visual Training on Myopia Progression in Myopic Children and Adolescents With Visual Impairment

First Author: Man CUI

Co-Author(s): Guanghao QIN, Xinyu TONG, Sile YU

Purpose: To investigate the effect of visual training (VT) on myopia progression in myopic children and adolescents with visual impairment (VI).

Methods: This retrospective cohort study included VT participants (63 patients) who received at least one month of VT and control participants (109 patients). All participants received single vision spectacle treatment, and were examined at baseline (T0), month 3 (T1), month 6 (T2), and month 12 (T3) for axial length (AL), spherical equivalent, and indicators of visual function test. The visual improvement rate (VIR) was calculated based on visual function test.

Results: The mean age of VT group was 8.84 ± 1.98 years (Male: 52.38%), and the control group was 8.94 ± 1.70 years (Male: 41.28%). The results showed that the changes in AL (ΔAL) in VT group at T1, T2, and T3 were significantly lower than that in the control group (T1: 0.05 ± 0.05 mm vs. 0.09 ± 0.04 mm, T2: 0.11 ± 0.07 mm vs. 0.19 ± 0.08 mm, T3: 0.2 ± 0.13 mm vs. 0.38 ± 0.12 mm, $P<0.001$). VIR in VT group at T2 and T3 was significantly higher than those in the control group (T2: 39.3% vs. 16.5%, T3: 61.4% vs. 18.2%, $P<0.001$).

Conclusions: VT not only can improve visual function, but also slow myopia progression in myopic children and adolescents with VI.

The Longitudinal Effect of Parental Myopia on Childhood Myopia Progression in Hong Kong: A Three-Year Study of 1093 Trios

First Author: Che Ching Chloe WAN

Co-Author(s): Yu Zhou ZHANG

Purpose: With an alarming onset of myopia among children aged 6 to 9 in Hong Kong, we aim to investigate the association between genetic factors and childhood myopia through the 3 year longitudinal study of trios to identify risk groups for early intervention.

Methods: This study involved 1,890 subjects from 1,093 family trios, each consisting of one child and both

parents. Strict cycloplegic autorefractive protocols were used for children. Thorough visual acuity examination has been performed on children and parental status to define results, rather than the typical approach of traditional studies that solely relies on questionnaire responses. Data on spherical equivalence, myopia incidence, axial length of the trios have been analysed. Children were classified into ten groups based on their parents' myopia levels. Regression analyses were utilized to assess the associations between these factors to monitor myopia progression within the critical age range.

Results: Parental myopia contributes to children having a more myopic baseline refractive error and longer axial length even before myopia onset. During a median follow-up of 3.45 years, 880 children developed myopia. 19.5% of participants are emmetropic with parents that are non-myopic, versus 43.4% of total myopia prevalence (OR = 1.17, 95% CI = 1.07–1.23, $P < 0.001$). Children with two highly myopic parents had a higher risk of 68.8% incidence (OR = 5.18, 95% CI = 1.15–23.43, $P = 0.03$). 74.5% of children's myopia progression is contributed by parental myopia, while 25.5% are mediated by extraneous factors. Children with at least one parent with 'High Myopia' compared to the baseline group show a 2.2-fold higher incidence.

Conclusions: Given the increasing prevalence of childhood myopia in post-covid Hong Kong, comprehensive public health strategies are critical to slow progression of myopia.

The Mediating Effect and Predictive Value of Choroidal Thickness Changes in the Prevention of Myopia by Repeated Low-Intensity Red Light Treatment

First Author: Zhuzhu LIU

Purpose: To evaluate the efficacy of repeated low-level red light (RLRL) in Chinese children with premyopia and investigate the mediating and predictive role of sub-foveal choroid thickness (SFCT).

Methods: In this multicenter, single-blind randomized trial, 175 children aged 7–12 years (104 RLRL, 71 controls) were followed for 12 months. Axial length (AL), cycloplegic spherical equivalent (SE), and OCT/OCTA were measured at baseline and follow-up. Sensitivity analysis was conducted in different SE and age groups. Interaction and mediation analysis were performed to determine if baseline SFCT was a moderator of SE/AL progression and if SFCT changes mediated SE/AL progression. Receiver operating characteristic (ROC) curves assessed the predictive value of early SFCT changes.

Results: After 12 months of RLRL, 29.8% showed hyperopic shift and 19.2% had AL reduction (>0.05

mm). Mean changes were 0.16 mm/year in AL and -0.12 D/year in SE. Children with insufficient hyperopic reserve or older age benefited more. Baseline SFCT showed no interaction with outcomes ($P > 0.05$). Mediation analysis revealed that choroidal thickening accounted for 24.5% of AL and 37.8% of SE control. Early SFCT change at 3 months significantly predicted AL outcomes, improving model accuracy.

Conclusions: RLRL effectively slowed myopia progression in premyopic children, with part of the effect mediated by choroidal thickening. Early SFCT response serves as a valuable biomarker for predicting long-term efficacy, supporting individualized myopia prevention strategies.

The Prevalence of Myopia Among Primary School Students From 2022 to 2024 in Liaoning Province, Northeast China

First Author: Yimeng

Co-Author(s): Wei HE, Xingru HE, Guanghao QIN, Sile YU

Purpose: To report the prevalence and trend of myopia among primary school students from 2022 to 2024 in Liaoning Province, Northeast China.

Methods: This cross-sectional study included 2,132,729 primary school students from Northeast China. Uncorrected distance visual acuity and non-cycloplegic autorefractive were measured. Screening myopia was defined as having both uncorrected visual acuity <5.0 and spherical equivalent refraction ≤ -0.50 D.

Results: In 2022, 481,209 students were included, with a mean age of 9.12 ± 1.72 years. The prevalence of myopia was 29.1%. In 2023, 742,782 students were included, with a mean age of 9.15 ± 1.76 years, and the prevalence of myopia was 29.0%. In 2024, 908,738 students were included, with a mean age of 9.25 ± 1.78 years, and the prevalence of myopia was 30.3%, predominantly mild myopia (59.30%). The prevalence was significantly lower in males (28.42%) than in females (32.23%) (OR = 0.81, $P < 0.05$). The prevalence of myopia increased progressively with grade level, rising from 10.01% in first grade to 48.00% in or sixth grade.

Conclusions: The overall prevalence of myopia among primary students in Northeast China is relatively high and shows an increasing trend year by year. Strengthening myopia prevention and control measures in lower grades is essential to delay the progression of myopia.

Abstract No.: 201011**Panel No.: MYO-0493****The Relationship Between Vitamin A and Myopia: A Population-Based Study***First Author: Yeo Jin LEE**Co-Author(s): Dong Hyun JEE*

Purpose: We sought to evaluate the relationship between blood vitamin A levels and myopia in adults aged ≥ 20 years in Korea.

Methods: We collected data of 15,899 participants aged ≥ 20 years from the Korean National Health and Nutrition Examination Survey. Participants underwent refraction tests to identify myopia and high myopia, and their blood pressure and obesity levels were measured. Blood tests were conducted to assess vitamin A, fasting blood glucose, triglyceride, and total cholesterol levels. Blood vitamin A levels were classified into quartiles.

Results: After adjusting for confounding variables like age, sex, income, education, hypertension, diabetes, and obesity, the odds ratio (OR) of blood vitamin A in the second quartile for myopia was 0.66, while the OR in the fourth quartile was 0.74 (P for trend < 0.001). Among women, the ORs for myopia in the second and third quartiles of blood vitamin A levels were 0.48 (95% confidence interval [CI], 0.35–0.66) and 0.67 (95% CI, 0.49–0.90), respectively (P for trend < 0.001). In men, the ORs for high myopia in the second, third, and fourth quartiles of blood vitamin A levels were 0.05 (95% CI, 0.004–0.58), 0.15 (95% CI, 0.024–0.91), and 0.05 (95% CI, 0.008–0.364), respectively (P for trend < 0.001).

Conclusions: An inverse relationship was observed between higher blood vitamin A levels and the prevalence of myopia. Notably, higher blood vitamin A levels were associated with a lower prevalence of high myopia in men and a lower prevalence of myopia in women.

Abstract No.: 201050**Panel No.: MYO-0495****Therapeutic Effect of Orthokeratology Combined With Unilateral 0.01% Atropine in Children With Unilateral Myopic Anisometropia***First Author: Xuehui ZHANG**Co-Author(s): Huihu ZHENG, Lin KANG*

Purpose: To investigate the therapeutic effect of orthokeratology combined with unilateral 0.01% atropine in children with unilateral myopic anisometropia.

Methods: This prospective study enrolled 47 children (aged 8–16 years) with unilateral myopia from Xi'an First Hospital between 2022 and 2024. The myopic eyes were treated with orthokeratology lenses, while

the non-myopic eyes received 0.01% atropine gel once nightly. A historical control group of 46 unilateral myopia children with matched baseline parameters, treated solely with orthokeratology, was included. Changes in axial length (AL) and interocular AL differences were analyzed. Statistical analyses included paired t-tests, independent samples t-tests, and linear regression.

Results: 1. Intergroup comparison: The intervention group showed significantly slower AL progression in non-myopic eyes compared to the control group ($0.45 \pm 0.25 \text{ mm/year}$ vs $0.13 \pm 0.12 \text{ mm/year}$, $P=0.003$), while no significant difference was observed in myopic eyes ($0.11 \pm 0.19 \text{ mm/year}$ vs $0.15 \pm 0.17 \text{ mm/year}$, $P=0.207$). 2. Intragroup comparison: In the intervention group, AL progression did not differ between two eyes ($P=0.335$). In controls, myopic eyes exhibited slower AL progression than non-myopic eyes ($P<0.001$). 3. Interocular AL difference: The intervention group showed no significant change in interocular AL difference ($0.92 \pm 0.57 \text{ mm}$ VS $0.94 \pm 0.57 \text{ mm}$, $P=0.117$), whereas the control group demonstrated a significant reduction ($0.99 \pm 0.56 \text{ mm}$ VS $0.66 \pm 0.53 \text{ mm}$, $P=0.001$).

Conclusions: Orthokeratology combined with unilateral 0.01% atropine effectively slows axial elongation in both eyes of children with unilateral myopia without altering interocular axial length differences.

Abstract No.: 206907**Panel No.: MYO-0546****Tilted Crystalline Lens in Children Across Different Refractive Statuses With Minimal Age-Related Changes***First Author: Ruozhen RUAN**Co-Author(s): Jian CAO, Mengyi WANG, Xiao YANG*

Purpose: To assess the morphological and tilt characteristics of the crystalline lens in children along different orientations and their correlations with age and spherical equivalent (SE).

Methods: This cross-sectional study encompassed 966 eyes of 493 children (5–15 years) with SE ranging from -6.00 to $+3.00$ diopters (D). The binocular crystalline lens biometric parameters in 16 orientations were measured using swept-source anterior segment optical coherence tomography. Parameters included the anterior radius of the lens (LAR), posterior radius of the lens (LPR), lens thickness, diameter, as well as lens tilt and decentration. Group comparisons were performed among no, low, and moderate myopic eyes.

Results: Lens tilt and decentration demonstrated semi-periodic variations ($R^2=0.984$ and 0.789 , respectively). The tilted lenses were predominantly oriented in the temporal and inferior directions, with corresponding lens decentration observed in the temporal quadrant. The emmetropic group exhibited a significantly more

curved crystalline lens, with higher LAR and LPR values compared to the low and moderate myopia groups (all $P < 0.001$). As myopia increased, lens tilt consistently increased across all refractive subgroups (all $P < 0.001$), whereas other parameters either reached a turning point at approximately -4.00 D or showed no linearity. Age-stratified polynomial analysis revealed that the positive correlation between lens tilt and SE remained strong within the SE range of -4.18 D to +3.00 D.

Conclusions: The lens tends to exhibit greater tilt toward the temporal and inferior regions in eyes with higher myopia across different age groups in children.

Panel No.: MYO-0518

Tracking Myopia Development Through Axial Length Progression: A Retrospective Longitudinal Study

First Author: Zhengyang TAO

Co-Author(s): Lifei CHEN, Hongwei DENG, Guorui HU, Zongyue LV, Jiao WANG, Zhixing XU

Purpose: This retrospective cohort study analyzed longitudinal ocular biometric data from repeated measurements in a school-based population to provide personalized myopia risk assessments.

Methods: The dataset was randomly partitioned into development and validation cohorts at a 2:1 ratio, with two-thirds of the data allocated for nomogram model construction and the remaining one-third reserved for validation. The axial length-to-corneal radius (AL/CR) ratio was defined as the AL divided by the mean CR value measured in 90° meridians and 180° meridians: $AL/CR = 2AL / (CR_{90^\circ} + CR_{180^\circ})$. The primary outcome is progressive myopia, defined as an annualized SE progression rate ≥ 0.75 DS/year over 1.5 years. The key predictor, first-visit AL progression, reflects 6-month axial elongation from baseline.

Results: The baseline subjects (N=1697) were divided into the training set (N=1132) and the validation set (N=565). The first-visit AL progression showed significant correlations with annualized SE progression ($r = -0.495$, $P < 0.001$). Multivariate Logistic regression analysis indicated AL/CR in baseline (OR= 70.414, 95%CI: 22.795-217.511, $p < 0.001$) and first-visit AL progression (OR= 12845.569, 95%CI: 2915.219-56602.490, $p < 0.001$) significantly contributed to the risk of progressive myopia. Accordingly, baseline AL/CR and first-visit AL progression were treated as the main factors to build the nomogram model. The model showed good predictive performance (AUC=0.785 in training set / 0.771 in validation set) with well-calibrated slopes (approaching 1) and clinically useful thresholds (0.20-0.80).

Conclusions: This study develops a personalized and clinically actionable prediction model for progressive myopia, grounded on factors at the first visit, AL

progression, and baseline AL/CR. The model offers a dynamic and reliable foundation for selecting effective myopia control measures in future stages.

Tumbling E or HOTV Optotypes for Pediatric Vision Screening: An Observational Study

First Author: Haotian WU

Co-Author(s): Jun CHEN, Xiangui HE, Kathryn ROSE, Yanjiao WANG, Xun XU

Purpose: To compare uncorrected visual acuity (UCVA) measured by HOTV and Tumbling E tests, and assess their efficiency in pediatric vision screening.

Methods: Children aged 3–15 years were randomly selected from the Shanghai arm of a national multicenter study. Each child underwent two UCVA tests using HOTV and Tumbling E logMAR charts, with random assignment to the HOTV-first or E-first group. All participants received cycloplegia and a comprehensive examination to identify amblyopia and refractive errors.

Results: A total of 1,053 children were included. To minimize fatigue effects, only initial UCVA results were compared. Overall, mean (SD) UCVA was 0.16 (0.24) with HOTV and 0.21 (0.21) with Tumbling E (95% CI, -0.07 to -0.02; $P < 0.001$). The difference decreased with age, exceeding 3 letters in children under 8 but remaining within 3 letters in older children. In those aged 3–<4 years, the average difference reached 1 logMAR line. Using AAPOS criteria, 16.94% of preschoolers were referred via HOTV, versus 31.15% via Tumbling E (mean difference, 14.21%; $\chi^2 = 14.88$; $P < 0.001$). Using Shanghai criteria, referral rates were 32.79% via HOTV and 54.10% via Tumbling E (mean difference, 21.31%; $\chi^2 = 24.48$; $P < 0.001$). Both charts showed good sensitivity for amblyopia, with comparable performance in detecting myopia, hyperopia, astigmatism, and anisometropia.

Conclusions: Children aged 3–8 years yielded better UCVA with the HOTV test compared to the Tumbling E test, while no such difference was observed in older children. Although both charts demonstrated comparable performance for amblyopia and refractive errors, the HOTV test identified fewer children requiring referral and enhanced screening efficiency.

Use of Low-Dose Atropine 0.025% for Childhood Myopia Control in Clinical Practice

First Author: Kaiwen **NG****Co-Author(s):** Chia Wei-lin, audrey, Aaron **GOH QI YANG**, Bryan **SIM XIANG RONG**, Hia Myint Htoon, Sri Yudah**Purpose:** Clinical audit of the efficacy of Atropine 0.025% eye drops.**Methods:** A total of 295 children (n=588 eyes) were separated into treatment naïve eyes (Group A, n=147 eyes), those progressing on 0.01% daily and started on 0.025% alone (Group B, n=287 eyes) or combined with optical treatment (Group C, n=66 eyes), and those on 0.01% twice daily converted to 0.025% once daily (Group D, n=89 eyes). Change in equivalent (SE) and axial length (AL) 6 months prior, and at 6, 12 and 24 months was recorded.**Results:** Group A children were younger (8.4 years) with lower myopia, while Group D were older (10.4 years) with higher myopia. Eyes in Groups A-C recorded significantly less myopia progression after starting Atropine 0.025% with mean SE/AL progression 6 months prior and after treatment changing from -0.97D/0.24mm, -0.46D/0.20mm and -0.64D/0.23mm to -0.14D/0.12mm, -0.07D/0.13mm, and -0.02D/0.09mm, $p < 0.001$, respectively. No change was noted in Group D (-0.22D/0.13mm to -0.14D/0.11mm, $p = 0.09$). Over the 2-year period, treatment was increased in 42%, 41%, 12% and 46% of eyes within Groups A-D, respectively. In the remaining eyes, the mean change over 2 years was not significantly different between groups, at -0.34D/0.22mm, -0.22D/0.24mm, -0.26D/0.25mm, and -0.22D/0.23mm, in Groups A-D, respectively. Multivariate analysis suggest that SE/AL change was associated with younger age, and greater progression in the 6 months prior.**Conclusions:** Atropine 0.025% was useful in slowing myopia in most children.

Abstract No.: 201483**Panel No.: NEU-0574**

A Case Report: Wernicke's Encephalopathy Presenting as Bilateral Optic Neuropathy in a Young Woman with Recurrent Acute Pancreatitis

First Author: Baigalmaa **DOOROV****Co-Author(s):** Dovchinjamts **DAGVADORJ****Purpose:** A 27-year-old female with recurrent acute pancreatitis and hepatitis was admitted with

persistent vomiting, diarrhea, dizziness, decreased vision, diplopia, and gait disturbances. She had no history of alcohol or tobacco use. On ophthalmologic examination, she demonstrated bilateral horizontal nystagmus, decreased visual acuity (right eye: 6/60; left eye: 6/12), optic disc edema in both eyes, and optic disc hemorrhage in the left eye.

Methods: A case report.**Results:** IV thiamine 100 mg/day x 3 days. IV methylprednisolone 1 g/day x 3 days, followed by oral steroids. Outcome: Vomiting resolved, nystagmus disappeared, completely resolved from ataxia. Visual acuity returned to 6/6 in both eyes by the 23rd day of admission. OCT-ONH and the visual field test results had normalized by the 39th day of admission.**Conclusions:** Wernicke's encephalopathy should be considered in any patient presenting with prolonged vomiting, malnutrition, or neurological signs—even in the absence of alcohol use. Early recognition and treatment with thiamine can lead to complete recovery and prevent permanent damage. Visual loss due to optic neuropathy in WE is rare but potentially reversible with timely intervention. This case emphasizes the importance of interdisciplinary collaboration and prompt treatment in suspected cases of WE.**Abstract No.: 206200**

A Case of Late-Onset Leber Hereditary Optic Neuropathy (LHON) in Association With m.11778G>A Mutation

First Author: Timothy P.H. **LIN****Co-Author(s):** Carmen K.M. **CHAN**, Matthew C.W. **LAM****Purpose:** We report a case of genetically confirmed LHON in an elderly female.**Methods:** Case report.**Results:** A 71-year-old Chinese woman with good past health presented with left eye subacute visual loss. At presentation, visual acuity was 0.6 in the right eye and hand movement in the left eye with left RAPD. Examination revealed temporal disc pallor in the left eye only and otherwise unremarkable. The OCT of the macula had no obvious abnormalities. Her blood pressure was elevated at 204/94 mmHg on presentation. There were no features of giant cell arteritis. Further blood tests and neuroimaging were unremarkable and not suggestive of optic neuritis or compressive optic neuropathy. In view of the presence of left optic atrophy and cardiovascular risk factors, the initial diagnosis was left optic atrophy secondary to prior vascular insults and aspirin was started. She further developed sequential visual loss in the right eye, with deterioration of right eye visual acuity to 5/60. She completed a trial of high dose intravenous methylprednisolone without significant clinical improvement. Further ophthalmic imaging with OCT of the retinal nerve fiber layer (RNFL) and ganglion

cell inner plexiform layer (GCIPL) revealed selective thinning of the GCIPL. A review of her family history revealed unexplained visual loss at young age among her 3 siblings. The working diagnosis was revised to LHON, which was confirmed with genetic testing. Idebenone was initiated whilst her steroid tapered.

Conclusions: A high clinical suspicion is critical in atypical presentation of mature onset LHON in the presence of positive family history.

Abstract No.: 205552

A Case of Prostate Cancer Dural Metastases Presenting With Bilateral Visual Deterioration

First Author: Ying ZHAO

Co-Author(s): Xiuli CHEN, Jiaxin MENG

Purpose: To analyze a case of prostate cancer dural metastases presenting with bilateral visual deterioration as the initial symptom, and explore its diagnosis and prognosis.

Methods: Retrospectively analyzed the clinical data of a 67-year-old male patient, including medical history, ophthalmic examination, laboratory tests, neuroimaging, pathological results, and follow-up records.

Results: The patient had 6-month vision loss, previously misdiagnosed as optic neuritis (steroids ineffective). Referral examination showed elevated ICP (330mmH₂O), dural thickening/enhancement, venous sinus stenosis, and markedly high PSA. Pathology confirmed prostate adenocarcinoma (Gleason 4+4=8). Diagnosed with prostate cancer, dural metastases, intracranial hypertension, and papilledema. Followed to 2025, vision declined (OD HM/20cm, OS 0.02) with worse metastases.

Conclusions: Unexplained papilledema in elderly males requires neuroimaging and PSA testing; multidisciplinary evaluation helps detect underlying prostate cancer and improve management.

Abstract No.: 202177

A Challenging Case of Bilateral Optic Neuropathy in Tuberculous Meningoencephalitis: Diagnostic and Therapeutic Dilemmas

First Author: Anya Dewi NASTITI

Co-Author(s): Sita Paramita AYUNINGTYAS, Michael HARTONO, Hindun ZAKIYAH

Purpose: To report a challenging case of bilateral optic neuropathy in tuberculous meningoencephalitis (TBME), highlighting diagnostic and therapeutic complexities.

Methods: This case report describes a 33-year-old woman with TBME presenting with progressively vision loss in both eyes. Following treatment, initial improvement in visual acuity was observed, however subsequent deterioration occurred several weeks later.

Results: A 33-year-old woman presented with complaints of blurred vision in both eyes. Three months prior, she was diagnosed with TBME. The patient received high-dose steroids, which reportedly improved her visual acuity. However, weeks later, the patient was unconscious and admitted to the ICU. MRI examination revealed multiple punctate lesions in both cerebellar hemispheres. The patient experienced worsening vision to hand movement in both eyes and papilledema was observed. Lumbar puncture was performed and the opening pressure was 25 mmHg. From the cerebrospinal fluid analysis confirmed tuberculous infection. Following the lumbar puncture, the patient's visual acuity improved to 6/30 in both eyes. Two weeks after the improvement, the patient presented again with decreased visual acuity, deteriorating to hand movement in both eyes. Ethambutol was discontinued, and the patient was administered intravenous dexamethasone and acetazolamide. A repeat lumbar puncture revealed persistent elevation of intracranial pressure and MRI showed no enhancement of the optic nerve.

Conclusions: The treatment of TBME and optic neuropathy poses significant challenges, necessitating a comprehensive diagnostic and multidisciplinary approach, often resulting in a poor visual prognosis.

Panel No.: NEU-0618

A Persistent Red Eye: An Alert of the Possibility of Carotid Cavernous Sinus Fistula

First Author: Miranti Laras AYU

Co-Author(s): Dianita Veulina GINTING, Antonia KARTIKA, Rusti Hanindya SARI, Prettylla YOLLAMANDA

Purpose: To report a case of carotid-cavernous sinus fistula (CCFs) initially misdiagnosed as scleritis in a patient presenting with chronic red eye at a tertiary hospital in Indonesia.

Methods: A case report of a 55-year-old woman with persistent redness, blurred vision, and intermittent ocular pain in the left eye (LE) for five months. Clinical history, ophthalmic examinations, and neuroimaging were reviewed.

Results: The patient had a history of hypertension with irregular treatment since 2022. She was previously diagnosed with scleritis and hypertensive retinopathy of the LE and had received medications without improvement. On presentation, best-corrected visual acuity (BCVA) of the LE was 0.4 pinhole 0.63, and intraocular pressure (IOP) was 30 mmHg despite ongoing antiglaucoma therapy. Examination revealed

a hyperemic corkscrew appearance of the conjunctival vessels and a grade II relative afferent pupillary defect (RAPD). Funduscopy showed mild tortuosity of retinal vessels. Computed Tomography (CT) of the orbit with contrast demonstrated dilation of the left superior ophthalmic vein (SOV), suggesting indirect low-flow CCFs. The patient was managed with external manual carotid compression, continued antiglaucoma therapy, oral citicoline, and was referred to neurosurgery for digital subtraction angiography (DSA). At 6-month follow-up, IOP was controlled at 14 mmHg with a single topical medication, the red eye had decreased significantly, and VA remained stable.

Conclusions: Indirect low-flow CCFs may mimic chronic ocular inflammation. Careful ophthalmic evaluation, recognition of clinical signs, and timely imaging are crucial to avoid misdiagnosis and irreversible vision loss.

Abstract No.: 202205

Panel No.: NEU-0584

A Rare Case of MOG-IgG-Associated Bilateral Optic Neuritis Concurrent With Psoriasis Vulgaris and Psoriatic Arthritis

First Author: Yu-ting **HSIAO**

Co-Author(s): Hsiu-mei **HUANG**, Jong-jer **LEE**

Purpose: To report a rare case of myelin oligodendrocyte glycoprotein-associated disease (MOGAD)-associated optic neuritis in an Asian patient with psoriasis vulgaris and psoriatic arthritis.

Methods: A 53-year-old female with psoriasis vulgaris and psoriatic arthritis presented with sudden onset of bilateral vision loss for one week, accompanied by retro-orbital pain that worsened with eye movements. Comprehensive ophthalmic and systemic evaluations were conducted, including fundus examination, optical coherence tomography (OCT), laboratory investigations, cerebrospinal fluid (CSF) analysis, and magnetic resonance imaging (MRI).

Results: Ocular examination revealed a best corrected visual acuity (BCVA) was 20/800 in her right eye and 20/400 in her left. The patient was unable to identify any Ishihara plates in either eye. Fundus examination showed mild bilateral disc edema with bulging discs, confirmed by OCT. CSF studies demonstrated normal intracranial pressure, with unremarkable cell cytology and biochemistry findings. Orbital MRI revealed bilateral swollen optic nerves with mild contrast enhancement. Serum anti-AQP4 antibody tested negative; however, a MOG-IgG cell-based assay was positive, with a titer of 1:10 (normal <1:10). Based on the clinical and investigative findings, a diagnosis of MOGAD-associated bilateral optic neuritis was established. She was treated with intravenous methylprednisolone 1g/day for three days, followed by a three-month oral prednisolone taper, resulting in near-complete visual recovery and no relapses.

Conclusions: Although rare, this case highlights the importance of recognizing MOGAD-associated optic neuritis in autoimmune patients. Prompt initiation of appropriate immunosuppressive therapy is crucial, as delayed or inadequate treatment may result in permanent vision loss.

Abstract No.: 204314

Panel No.: NEU-0603

A Window to the Mass: A Rare Presentation of Bilateral Neuroretinitis Unmasking a Silent Intracranial Tumor in an 18-year-old Filipino Female

First Author: Richard **VILLAMOR**

Co-Author(s): Janice **BERNARDO**

Purpose: To report a case of an 18-year-old female presenting with painless bilateral sequential blurring of vision in the left eye, then the right eye, in La Union, Philippines. The patient had symptoms of atypical optic neuritis, presenting with bilateral neuroretinitis. No neurologic deficits were elicited. No history of antecedent viral infection. Cat exposure was elicited.

Methods: Basic systemic work-up and imaging were done to determine the etiology.

Results: Optical Coherence Tomography (OCT) of the optic nerve and macula OU showed a generalized thickening of the optic nerve and intraretinal layer with hyperreflective exudate deposits and the presence of sub-Retinal Pigment Epithelium (RPE) edema. Serologic tests for Bartonella Henselae and Treponema pallidum were negative, and was also negative for Mycobacterium tuberculosis. The patient also tested negative for Anti-Nuclear Antibody (ANA). Cranial/Orbital Magnetic Resonance Imaging with contrast and fat suppressed images showed a lobulated, avidly enhancing, predominantly solid, extra-axial mass measuring approximately 7.7 x 4.9 x 6.3 cm (CC x W x AP) seen centered in the atrium/trigone of the left lateral ventricle. Radiologic primary consideration is a choroid plexus papilloma versus a choroid plexus carcinoma, which is a rare brain tumor, accounting for <1% of brain tumors, that arises from the choroid plexus. Patient was co-managed with Neurosurgery and Pediatric Oncology.

Conclusions: To the best of the researchers' literature review, this is the first documented true intracranial mass (tumors within the cranial vault) causing bilateral neuroretinitis.

Abstract No.: 208241

Panel No.: NEU-0637

Acute Vision Loss from Allergic Fungal Sinusitis: A Clinical Imposter

First Author: Divya CACULO

Co-Author(s): Disha AGARWAL

Purpose: This case emphasizes the necessity of suspecting compressive pathology—such as allergic fungal sinusitis—when optic neuritis manifestations diverge from typical presentations. Timely imaging, surgical decompression, & antifungal therapy can restore function and avert irreversible optic nerve damage.

Methods: A 26-year-old man presented with two weeks of acute, mild vision loss and ocular pain in the left eye, initially diagnosed as optic neuritis. Visual acuity was 6/6 bilaterally, color vision intact, but contrast sensitivity was reduced (1.35 log right, 1.05 log left), with trace left RAPD, mild disc hyperemia bilaterally, and scattered visual field scotomas (central in left eye). With the findings not correlating to each other, neuroimaging was advised, which revealed hyperdense soft tissue in the sphenothmoidal sinuses compressing the prechiasmatic optic nerves, consistent with allergic fungal sinusitis and secondary polyposis. Endonasal endoscopic resection confirmed septate, branching hyphae of *Aspergillus* and was followed by systemic antifungal therapy.

Results: Patient underwent a base of skull sinus surgery. One month post-surgery, visual acuity remained 6/6, contrast sensitivity improved (1.95 log right, 1.35 log left), disc appearance normalized, and most scotomas resolved, though a left central scotoma persisted.

Conclusions: Timely imaging, surgical decompression, & antifungal therapy can restore function and avert irreversible optic nerve damage.

Panel No.: NEU-0593

Altered Spontaneous Brain Activity and Correlated Clinical Characteristics in Adults With Esotropia and Exotropia

First Author: Guo XUERAN

Co-Author(s): Jing FU, Jie HAO

Purpose: Esotropia (ES) and exotropia (EX) are common forms of concomitant strabismus associated with distinct visual and neural adaptations. This study aimed to investigate cortical alterations in ES and EX patients through resting-state functional magnetic resonance imaging (rs-fMRI).

Methods: Rs-fMRI signals were collected from eighteen ES, fourteen EX, and sixteen age-, sex-, and handedness-matched controls (MC). The two-sample t-test and ANOVA test were used to investigate

statistical differences in the amplitude of low-frequency fluctuation (ALFF) values. Multiple linear regression analysis was conducted to examine brain regions influencing the occurrence of EX and ES. Correlation analysis validated their relationship with clinical characteristics.

Results: Compared to MCs, ES patients exhibited significantly higher ALFF values in the primary visual cortex and dorsal pathway; whereas EX patients presented decreased ALFF values in the occipital lobe, precentral gyrus (PreCG), and precuneus gyrus (PCUN). Notably, the right superior temporal gyrus (TPOsup) displayed opposite ALFF patterns in ES (decreased) and EX (increased) patients, and multivariate regression identified it as a predictor for both EX and ES ($p = 0.012$). Correlation analyses revealed that in EX patients, the deviation angle was positively associated with ALFF values in the right middle temporal gyrus (MTG) ($r = 0.57$, $p = 0.04$), and the binocular functions were positively correlated with ALFF in the right PreCG ($p < 0.05$). The loss of simultaneous perception was correlated with reduced ALFF in the left middle occipital gyrus (MOG, $p = 0.004$) and right superior occipital gyrus (SOG, $p = 0.004$) in EX patients. The ALFF value of the inferior frontal gyrus (IFG) was associated with the preserved distance and near stereopsis, both in the ES ($p = 0.018$) and EX ($p = 0.041$).

Conclusions: Our findings reveal opposite brain activity patterns in ES and EX patients, with the ALFF values within TPOsup emerging as a key biomarker for deviation direction. These results provide new insights into the neural mechanisms underlying the direction of eye deviation.

Abstract No.: 207248

Panel No.: NEU-0634

An Atypical Presentation of Myelin Oligodendrocyte Glycoprotein Antibody-Associated Disease (MOGAD) Relapse in a Pregnant Filipino

First Author: Angelo Jud CRUZ

Co-Author(s): Katrina FELICIANO, Buenjim MARIANO

Purpose: To report an atypical presentation of MOGAD relapse in a pregnant primigravid Filipino.

Methods: Case report.

Results: A 30-year-old female primigravid at 18 weeks of pregnancy was previously diagnosed with myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD), for which she initially received intravenous methylprednisolone and oral prednisolone with a gradual taper, resulting in improved vision. After discontinuing oral prednisone for 2 weeks, she experienced recurrence of right retroorbital eye pain, blurred vision, and poor color vision. Perimetry revealed a cluster of shallow to deep inferior visual field defects compared to prior testing. The patient was

then admitted and treated with IV methylprednisolone for 3 days, leading to improvement in eye pain, color vision, and visual acuity. Work-up for MOGAD relapse causes was unremarkable; with no active infection, no uterine contractions, and no fetal abnormalities on congenital scans. She was discharged on a tapering dose of oral prednisone. Repeat perimetry one month after discharge showed no significant visual field defects. Relapses of MOG antibody disease (MOGAD) during pregnancy are considered uncommon, with most relapses reported to occur within the first three months after delivery.

Conclusions: We report a rare case of a pregnant Filipino patient who experienced an intrapartum relapse of MOGAD without identifiable triggers. This case highlights an unusual presentation of MOGAD during pregnancy and contributes to the limited literature on disease activity in this period.

Association Between Chronic Headache and Sight-Threatening Ocular Diseases: A UK Biobank Study

First Author: Yujie **WANG**
Co-Author(s): Wenyi **HU**, Zhuoting **ZHU**

Purpose: To investigate the association between chronic headache and incident sight-threatening ocular diseases in a large population-based cohort.

Methods: This prospective cohort study included 489,953 UK Biobank participants who had complete data on headache status. Chronic headache was defined as self-reported headache lasting ≥ 3 months. Incident ocular diseases were ascertained through hospital inpatient records. Cox proportional hazards models were used to estimate adjusted hazard ratios (HRs) and 95% confidence intervals (CIs).

Results: Among 489,953 participants (mean age, 56.5 $\pm$ 8.1 years; 52.6% female), chronic headache was associated with 11% increased risks of age-related macular degeneration (HR: 1.11; 95% CI: 1.01–1.22), 27% for retinal vascular occlusion (HR: 1.27; 95% CI: 1.01–1.61), 14% for glaucoma (HR: 1.14; 95% CI: 1.05–1.25), 10% for cataract (HR: 1.10; 95% CI: 1.05–1.16), and 49% for optic nerve disorders (HR: 1.49; 95% CI: 1.17–1.91). No significant associations were observed for retinal detachment or diabetic retinopathy. Sensitivity analyses excluding events diagnosed within one year of baseline showed consistent results.

Conclusions: Chronic headache is associated with increased risks of age-related macular degeneration, retinal vascular occlusion, glaucoma, cataract, and optic nerve disorders, suggesting shared vascular or neurodegenerative mechanisms.

Abstract No.: 206522
Panel No.: NEU-0627

Beyond mTOR: Rapamycin-Induced α -Crystallin Expression as a Neuroprotective Mechanism in Diabetic Retinopathy

First Author: Yipin **WANG**
Co-Author(s): Thomas Chuen **LAM**, Wai-ching **LAM**, Edmond Man Hin **LEUNG**, Amy Cheuk Yin **LO**, Tsz Chung **NG**, Ka Cheung **TAM**

Purpose: Diabetic retinopathy (DR) is a leading cause of blindness. This study investigated the protective effects of long-term, low-dose rapamycin on retinal function in diabetic Ins2Akita mice, focusing on α -crystallin, a small heat-shock protein and a molecular chaperone primarily found in the lens that prevents protein aggregation and protects against cellular stress, as a key mechanistic target in DR.

Methods: Diabetic Akita mice received long-term, low-dose rapamycin. Retinal function was assessed by electroretinography (ERG). Global protein expression was analysed using mass spectrometry, with α -crystallin findings verified by Western blotting and localised via immunohistochemistry (IHC).

Results: Rapamycin treatment significantly preserved retinal function, improving ERG a- and b-wave amplitudes. Mass spectrometry revealed that diabetes induced a complex, age-dependent dysregulation of α -crystallin, with downregulation at 26 weeks and paradoxical upregulation at 36 weeks, highlighting its inherent neuroprotective role. Rapamycin administration corrected this instability, effectively restoring and maintaining α -crystallin levels at both time points. IHC localised this restored expression to Müller cells and the retinal pigment epithelium (RPE), and Western blotting verified the protein restoration.

Conclusions: Long-term, low-dose rapamycin protected retinal function by correcting the age-dependent dysregulation of α -crystallin. This neuroprotective effect is driven by stabilising α -crystallin levels in critical retinal support cells (Müller cells and RPE). Our findings highlight stabilising α -crystallin expression as a promising therapeutic strategy for mitigating DR.

Panel No.: NEU-0615

Bilateral Anti-Myelin Oligodendrocyte Glycoprotein (MOG) Antibody Positive Optic Neuritis in a Young Malay Male – a Case Report

First Author: Ker Yin **TOH**
Co-Author(s): Siddharth **SUBRAMANI**, Xiu Ling **TAN**

Purpose: To describe a case of bilateral anti-MOG optic neuritis in a 45-year-old Malay male successfully treated with steroids, with full visual recovery.

Methods: Retrospective case report.

Results: A 45-year-old Malay male, smoker with untreated type 2 diabetes mellitus of haemoglobin A1c of 6.4%, presented with a two-week history of bilateral blurring of vision, pain on eye movements, colour desaturation, inferior visual field loss, and intermittent occipital headache. Best corrected visual acuity (BCVA) was 6/20 in the right eye and 6/12 in the left eye. There was bilateral optic disc swelling, left relative afferent pupillary defect, and no diabetic retinopathy. Systemic workup was unremarkable except for positive anti-MOG antibodies. Magnetic resonance imaging (MRI) of the brain and orbits showed swelling and enhancement of the infraorbital segments of both optic nerves. Lumbar puncture revealed elevated opening pressure (25mmH2O) and positive anti-MOG antibodies, without oligoclonal bands. The patient received intravenous methylprednisolone 1g/day for 5 days, followed by tapering oral prednisolone for eight months. Treatment was complicated by right lower limb deep vein thrombosis, requiring anticoagulation. Despite transient worsening of visual fields, BCVA improved to 6/6 (right eye) and 6/7.5 (left eye), with complete resolution of disc swelling and colour vision recovery within three months with no recurrence.

Conclusions: Anti-MOG antibody positive optic neuritis, though rare in the Malay population, can mimic non-arteritic anterior ischaemic optic neuropathy, especially with vascular risk factors. Prompt recognition through careful history, targeted investigations, and timely immunosuppressive therapy is essential to ensure good visual outcomes.

Abstract No.: 204302

Panel No.: NEU-0601

Case Report: Nutritional and Toxic Optic Neuropathy in Autoimmune Disease

First Author: Diane Frances PERALTA

Co-Author(s): Marianne CARABEO

Purpose: Nutritional and toxic optic neuropathy are rare but vision-threatening complications. Autoimmune conditions leading to a dysregulated systemic state can trigger a pathophysiologic cascade of nutritional depletion and toxin accumulation.

Methods: This is a case of a 15 year-old female with Graves' disease admitted for impending thyroid storm, complicated by liver injury and severe malnutrition.

Results: She presented with sudden blurring of vision, weakness, and vomiting at the emergency room. Clinical examination showed light perception, exophthalmos, mild relative afferent pupillary defect, and yellow-orange disc. Diagnostics showed low levels of thyroid stimulating hormone, elevated thyroid hormones, liver enzymes, ammonia, and deranged electrolytes. The extraocular muscles were not enlarged on computed tomography scan. There was gradual improvement of visual acuity, maintained within 20/20-20/50 via near chart and intact color

vision during admission. However, blurring of vision recurred at 16th hospital day to hand movement with fair light projection accompanied by decreased color vision of 9/16. Patient's status eventually declined due to worsening hyperammonia. Further work-up showed increasing bilirubin and decreasing hemoglobin levels which is more consistent with autoimmune etiology of liver injury.

Conclusions: This case demonstrates the potential for optic nerve damage as an underrecognized complication of hemodynamic and metabolic derangements. The patient's dynamic vision changes can be attributed to toxic-metabolic insult from multifactorial causes of hypoxic state from liver injury, hyperthyroid state, and severe malnutrition, rather than compressive mechanism of dysthyroid optic neuropathy.

Abstract No.: 202684

Panel No.: NEU-0589

Clinical Characteristics and Visual Outcome of Optic Perineuritis in South India: A Single Center Experience

First Author: Padma Lakshmi

Co-Author(s): Olma Veena Noronha, S.Ambika

Purpose: Optic perineuritis is an inflammatory disorder primarily involving the optic nerve sheath. It could be idiopathic or secondary to underlying systemic / autoimmune diseases. Our aim is to describe the clinical features and outcomes of patients with optic perineuritis seen at a tertiary eye care center in South India.

Methods: Retrospective observational case series. We reviewed the medical records of all patients diagnosed with optic perineuritis. All patients were evaluated and managed at the Neuro-ophthalmology services and single referral neurologist during 2018-2024.

Results: 23 eyes of 20 patients were identified. Mean age was 51.7 ± 13.45 years (range: 25-70 years). 11 (55%) were males and 9 (45%) were females. 17 patients had unilateral involvement while 3 were bilateral. Mean visual acuity at presentation was 1.45 ± 1.76 log MAR. Painful vision drop was noted in 15 patients. Disc edema was seen in 19 eyes (82.6%), disc was normal in 2 eyes (8.69%), and pallor was seen in 2 eyes (8.69%). All patients underwent Magnetic Resonance Imaging of brain and orbit and perineural enhancement on MRI was seen in all of them. All patients were treated with intravenous steroids followed by oral steroid taper. 17 of the 23 eyes (73.91 %) recovered Snellen visual acuity of 20/40 or better. A statistically significant improvement between pre and post-treatment visual acuity was noted ($p=0.001$).

Conclusions: Optic perineuritis in our series has a favorable visual outcome. Disc edema and painful

vision drop were more common and anti-MOG antibody was noted in 55 % of patients.

Abstract No.: 206340

Panel No.: NEU-0624

Clinical Features, Diagnosis, and Treatment of Pediatric Idiopathic Intracranial Hypertension

First Author: Yu TIAN

Co-Author(s): Aoxiang WANG

Purpose: To analyze the clinical features, diagnosis, and treatment of pediatric idiopathic intracranial hypertension (IIH) to facilitate early recognition and intervention.

Methods: A retrospective analysis was conducted on 11 children diagnosed with IIH in our ophthalmology department from December 2022 to April 2025.

Results: The study included 11 children aged 10 months to 10 years, with 8 in the preschool group. The male-to-female ratio was 6:5, and none were obese. Potential triggers included viral infection (5 cases), trauma history (1 case), and growth hormone use (1 case). No headache was reported, but 2 cases presented with intermittent head pounding (lumbar opening pressure >400 mmH₂O). Non-projectile vomiting occurred in 3 cases, and visual impairment (diplopia or visual field defect) in 2 cases. All patients had papilledema (1 detected incidentally during routine fundus examination), and 8 had esotropia. Some infants exhibited irritability or poor appetite. Diagnosis was confirmed by elevated lumbar opening pressure (>200 mmH₂O) with normal cerebrospinal fluid composition. MRI ruled out secondary causes, with partial cases showing empty sella or optic nerve sheath distension. All patients received acetazolamide, discontinued within one month, with complete resolution of ocular alignment and papilledema. No recurrence was observed during follow-up exceeding 3 months.

Conclusions: Pediatric IIH in this cohort primarily presented with ocular signs, with rare headache complaints. Acetazolamide treatment yielded favorable short-term outcomes.

Abstract No.: 205539

Panel No.: NEU-0613

Clinical Profile and Outcomes of Patients with Sellar–Suprasellar Masses Referred to the Neuro-Ophthalmology Service of a Tertiary Hospital in the Philippines

First Author: Zadkiel VELASQUEZ

Co-Author(s): Karen REYES

Purpose: This study aims to present the number and diagnoses of patients seen by the Neuro-Ophthalmology Service from January to December 2024, describe key findings based on visual acuity,

visual fields, and OCT parameters (RNFL and GCL thickness), and correlate post-operative changes in visual acuity with baseline OCT and visual field results.

Methods: Charts of sellar-suprasellar mass patients referred to the Neuro-Ophthalmology Service from January to December 2024 were reviewed for demographics, diagnosis, interventions, and baseline and post-op visual acuity, visual fields, and OCT (RNFL and GCL) data.

Results: The average baseline mean deviation (MD) was -13.13 dB, improving to -8.26 dB post-op in 5 patients, with 4 showing visual field gains. Visual acuity improved in 6 patients but remained unchanged in 5. Baseline OCT was available in 13 patients. Average RNFL was 85.08 μ m, decreasing to 66.17 μ m post-op (6 eyes). VA improved in 6 eyes with RNFL >75 μ m and 3 with <75 μ m. GCL averaged 69.04 μ m at baseline and dropped to 59.83 μ m post-op. VA improved in 7 eyes with GCL 55–77 μ m and 1 with >77 μ m, while others showed no improvement.

Conclusions: Most patients showed improved visual acuity and visual fields post-operatively, though only a few had follow-up labs. OCT findings revealed RNFL thinning in most and GCL thinning in all cases. Many patients remain on the OR waitlist, with some experiencing vision decline while awaiting surgery.

Panel No.: NEU-0600

Coil the Weak, Embolize the Threat, Stent the Stream — The Interventional Radiology Way in Securing Sight and Preserving Life

First Author: P.sangavi SAMRITHA SELVI

Co-Author(s): Virna SHAH

Purpose: Interventional Radiology (IR) is transforming Neuro-Ophthalmic care by offering minimally invasive solutions for complex, vision-threatening neurovascular disorders. By navigating critical vessels, IR opens new therapeutic frontiers. This study evaluates the clinical outcomes of IR-guided interventions in vision-related neurovascular diseases and highlights the importance of multidisciplinary collaboration.

Methods: A retrospective study was conducted in the Neuro-ophthalmology clinic between August 1, 2024, and July 31, 2025. 31 patients were included in the study and were co-managed with the IR team. Among them, 14 patients presented with diplopia, 1 with headache, 1 with Visual field defects, 1 with defective vision due to Vitreous hemorrhage. Out of 16 patients with Diplopia, 6 patients had Third nerve palsy, 5 had Sixth nerve palsy and 2 with multiple cranial nerve palsies. All patients underwent neuroimaging and tailored endovascular intervention.

Results: The cohort (31 patients) comprised 14 intracranial aneurysms (45.1%), 14 carotid-cavernous fistulas (CCF) (45.1%), and 1 Idiopathic intracranial

hypertension (IIH), 1 Dural venous fistula (DVF) and 1 Arterio-venous fistula (AVF). Among Aneurysms (14): Saccular (42.8%), Giant (7.1%) and small/others (50%). Presentations were Terson's syndrome (14.3%), third nerve palsy (14.3%), sixth nerve palsy (21.4%), Visual field defects (14.3%) and Headache (7.1%). Diplopia improved in 21.4%. Among CCF (14): Multiple cranial nerve palsies (21.4%), third nerve palsy (28.6%), and sixth nerve palsy (14.3%). Diplopia improved in 28.6%. All underwent successful interventions with symptomatic relief.

Conclusions: Included a curated video series of three representative cases illustrates these outcomes. By combining advanced endovascular techniques with neuro-ophthalmic expertise, multidisciplinary care enables timely intervention, visual preservation, and improved outcomes-effectively bridging vision and vessels.

Panel No.: NEU-0631

Comparing the Effectiveness and Safety of Lumboperitoneal (LP) Shunts, Ventriculoperitoneal (VP) Shunts, and Optic Nerve Sheath Fenestration (ONSF) As Therapy of Idiopathic Intracranial Hypertension: A Systematic Review

First Author: Hindun ZAKIYAH

Co-Author(s): Salmarezka DEWIPUTRI

Purpose: Idiopathic intracranial hypertension (IIH) is defined as elevated cerebrospinal fluid (CSF) pressure without an identifiable cause, with a recurrence rate of 15–38%. It may lead to persistent headache and vision loss. While medications and lumbar puncture are first-line treatments, recurrent cases often require surgery. This review compares the outcomes of available surgical techniques for IIH.

Methods: This review was conducted in accordance with the 2020 PRISMA guidelines. Literature searches were performed in PubMed, Cochrane, and ClinicalKey using the keywords "LP shunt," "VP shunt," "ONSF," "IIH," "Pseudotumor Cerebri," and "Benign intracranial hypertension," including their synonyms. Eligible studies were critically appraised using the ROBINS-I tool for risk of bias assessment.

Results: This systematic review included 27 studies with 1,169 patients, predominantly female (84.75%). Most were retrospective cohorts, with follow-up ranging from 1 to 108 months. VP and LP shunts generally reduced postoperative headaches, though comparative results were inconsistent. All procedures improved visual outcomes, with ONSF showing more consistent visual acuity preservation. Shunting procedures achieved higher rates of papilledema resolution, but both LP and VP shunts carried risks of shunt failure and revision, with VP shunts showing slightly lower revision rates. ONSF had variable outcomes and

occasionally required repeat fenestration or additional CSF diversion.

Conclusions: ONSF, VP shunt, and LP shunt are all effective surgical options for IIH. VP shunts appear more durable than LP shunts, while ONSF provides superior visual outcomes but with variable long-term stability. Collaboration between neurosurgeon and neuroophthalmologist is important to make the best decision

Contralateral Optic Neuropathy Post-Unilateral Trauma: A Case of Sympathetic Optic Neuropathy

First Author: Yue FU

Co-Author(s): Yang HUI

Purpose: To describe a rare case of contralateral optic neuropathy presenting as painless vision loss and field defects six months after unilateral eye trauma, suggesting sympathetic optic neuropathy.

Methods: A 41-year-old male reported progressive right eye (OD) vision loss and field defects six months post-left eye (OS) trauma. OS, with no light perception, underwent reconstruction with foldable capsular vitreous body and silicone oil. OD was initially treated as idiopathic optic neuritis with corticosteroids, later suspected as sympathetic ophthalmitis. Assessments included visual acuity (BCVA), visual fields (VF), fundus photography, fluorescein angiography, optical coherence tomography (OCT), electroretinogram, visual evoked potentials (PVEP), and MRI. Laboratory tests excluded autoimmune and infectious causes.

Results: OD BCVA dropped from 1.0 to 0.01, with VF mean deviation worsening to -26.02 dB over nine months. Fundus showed OD disc atrophy; OCT revealed ganglion cell layer thinning; PVEP amplitudes initially decreased but improved post-therapy; MRI indicated bilateral optic tract demyelination (OD > OS). Treatment with methylprednisolone, cyclophosphamide, immunoglobulin, and neurotrophic agents stabilized OD function.

Conclusions: This case suggests sympathetic optic neuropathy as a delayed contralateral response to trauma. MRI-confined visual pathway demyelination and treatment response support the diagnosis. Early recognition and multimodal therapy may mitigate vision loss, emphasizing vigilance post-trauma.

Abstract No.: 201769**Panel No.: NEU-0579****Demyelinating Disease Presenting As Chronic Exotropia***First Author: Ghadeer ALARAYEDH**Co-Author(s): Reem NASER*

Purpose: To shine the light on uncommon causes of amblyopia and eye deviation, and less common presentations of demyelinating diseases in pediatric age.

Methods: The case presents a 9 year old boy not k/c/o any medical illness who was brought by his father complaining of left eye deviation since few years seeking squint correction. History, orthoptic work up, refraction and detailed eye examination did not align with the profound vision loss in the left eye. Multidisciplinary team was involved in the work up which included imagine, blood antibodies and CSF analysis to determine the diagnosis and start treatment.

Results: Investigations revealed underling demyelinating disease. He was started on Interferon beta-1a. Diganosis, prognosis, treatment and side effect were discussed with parents.

Conclusions: Periodic eye screening is essential in the pediatric age group. Knowledge of causes and limits of refractive error than can lead to amblyopia can alert to the presence of other causes. Demyelination disease in the pediatric age group is uncommon but causes sensory disability. early intervention of multidisciplinary team is crucial.

Abstract No.: 202208**Panel No.: NEU-0585****Differences of Retinal Microvascular Parameters in Patients With Acute Ischemic Stroke and Healthy Controls: An Age-Sex Matched Cross-Sectional Analysis***First Author: Varis RUAMVIBOONSUK**Co-Author(s): Ruttanabhorn CHONRAMAK, Parima HIRUNWIWATKUL, Supharat JARIYAKOSOL, Naruchorn KIIPAISALRATANA, Wasee TULVATANA*

Purpose: To investigate retinal microvascular changes in acute ischemic stroke patients using optical coherence tomography angiography (OCTA) compared with those without a history of stroke.

Methods: An age-sex-matched cross-sectional analytical study was conducted. Retinal microvascular features were collected and compared between acute ischemic stroke and those without a history of stroke. Features, such as superficial capillary plexus vessel density (SVD), deep capillary plexus vessel density (DVD), and the foveal avascular zone (FAZ) area, were obtained using Optovue RTVue. Only one eye was used in the analysis for each participant. A linear mixed

model was used to adjust the associated factors with the main outcomes.

Results: From 154 eyes of 77 cases and 77 controls, SVD and DVD were significantly lower in stroke patients compared with controls ($p=0.003$ and <0.001 , respectively). However, the FAZ area was not significantly different between the two groups. After adjusting for associated factors, including underlying diseases, fasting blood glucose, HbA1C, lipid profiles, and complete blood analysis, SVD and DVD were still significantly lower in stroke patients compared with controls ($p<0.001$ and <0.001 , respectively).

Conclusions: Retinal microvascular changes, detected on OCTA, were observed in patients with acute ischemic stroke even after adjusting with associated factors. Therefore, SVD and DVD might serve as biomarkers for acute ischemic stroke and emphasize the potential role of OCTA in these patients.

Abstract No.: 206152**Panel No.: NEU-0622****Disappearing Diplopia-Recurrent Sixth Nerve Palsy With Mysterious Recovery***First Author: Neethu PRADEEP*

Purpose: A 57-year-old female, with history of hypertension, presented with left sided headache and double vision for previous 1 week, which was more on looking to left. She had 5 similar episodes in the past. On examination, there was abduction restriction in left eye and horizontal diplopia suggestive of left lateral rectus palsy. No other focal signs were present.

Methods: Routine blood investigations, Vasculitis workup, Neurology opinion was done. MRI brain with MRA was performed and it showed a hypertrophied Left Anterior Inferior Cerebellar Artery(AICA) abutting Left 6th nerve near the root. Hence a diagnosis of RPON(Recurrent painful ophthalmoplegic neuropathy) previously known as ophthalmoplegic migraine, with probable neurovascular conflict as etiology was made.

Results: Patient was given a short tapering dose of oral prednisolone and analgesics. 2 weeks later head ache and diplopia had subsided with minimal residual abduction restriction.

Conclusions: Intermittent but spontaneously resolving diplopia as a presenting symptom should never be ignored. A neurovascular conflict causing inflammatory demyelination or compression of a single cranial nerve and resultant relapsing remitting painful ophthalmoplegic neuropathy is a rare condition and a final conclusion regarding etiology remains elusive.

Diverse Manifestations of Neurosyphilis – Our Experience of the Great Masquerader

First Author: Joyce MBEKEANI

Co-Author(s): Jessinta OSENI, Se Eun PARK, Moshe SZLECHTER, Joyce TANG, Lily YOUNG

Purpose: Syphilis cases have increased globally. We describe CSF-confirmed neurosyphilis cases.

Methods: Clinical presentations and investigations of patients with neurosyphilis were documented.

Results: Case 1: A 65-year-old African-American male presented with a left red, painful eye of 2 months' duration. Examination revealed visions of 20/30(R) and Hand motions(L), mild anterior uveitis (R), and severe hemorrhagic panuveitis with vitreous cells with cystoid macular edema (L). Positive investigations included CRP=14; ESR=108; RPR titers=1:1024. MRI was unremarkable. Lumbar puncture (LP) revealed CSF VDRL=1:4. Skin biopsy histopathology showed focal suppurative, granulomatous changes consistent with secondary syphilis. Topical and CDC-recommended systemic therapy were administered with good effect. Case 2: A 35-year-old Hispanic female was referred for mild headaches and optic disc edema. She had a one-month history of vaginal pruritus. Examination revealed bilateral normal Snellen (20/20) and color (11/11) vision. Anterior and posterior segments were normal except bilateral disc edema with OCT(RNFL) >421microns (R) and 184microns (L). Visual fields were full. MRI/MRV was unremarkable and LP opening pressure was 16cmH2O. Lacking evidence for IHH, investigations were expanded and revealed RPR titers = 1:256. CSF analysis revealed VDRL=1:1. Neurosyphilis in presumed primary syphilis was diagnosed. CDC-recommended systemic therapy was administered with a gradual reduction of disc edema. Visual functions remained intact.

Conclusions: Neurosyphilis may manifest in all stages of syphilis, have diverse manifestations, and be symptomatic or asymptomatic. Serologic and confirmatory CSF analysis are key to diagnosis, with implications for management to prevent neurologic and systemic sequelae.

Early OCT Biomarkers Predicting Visual Prognosis in Acute Syphilitic Posterior Placoid Chorioretinopathy

First Author: Angelina Patricia CHANDRA

Co-Author(s): Alia ARIANTI

Purpose: This systematic review aims to investigate optical coherence tomography (OCT) biomarkers during initial presentation as a predictor of visual acuity (VA)

in patients diagnosed with acute syphilitic posterior placoid chorioretinopathy (ASPPC).

Methods: Five databases were searched following PRISMA guidelines for studies published up to April 2025. Quality of studies were assessed using The Clinical Advances Through Research and Information Translation (CLARITY) tools for cohort and National Institutes of Health (NIH) tools for case series. Correlation analysis was conducted using Spearman's rank correlation to investigate correlation between final VA and the presence of three OCT biomarkers at initial presentation; ellipsoid zone (EZ) disruption, hyperreflective foci, and optic nerve involvement.

Results: The search yielded 499 studies, in which 4 retrospective cohorts and 5 case series were selected (n=192). Final VA showed a moderate inverse correlation with EZ disruption (Spearman's $\rho=-0.64, p=0.064$), suggesting a trend toward worse visual outcomes when EZ disruption was not present at initial presentation. No statistically significant associations were found for hyperreflective foci ($\rho=-0.18, p=0.638$) or optic nerve involvement ($\rho=+0.41, p=0.272$). Reported risk factors that may correlate with final VA include positive HIV test, smoking history, and intravenous (IV) drug use. All included patients received a regimen of IV penicillin with or without corticosteroid, with time to treatment ranging from 14 days to 12 months after initial complaint.

Conclusions: EZ disruption on OCT at initial presentation may be a meaningful predictor of visual prognosis in ASPPC, although further investigation in larger cohorts is needed to strengthen result significance and reduce confounding variables.

Elderly-Onset Bilateral Optic Neuritis: Therapeutic Challenges in Patients with Comorbid Conditions

First Author: Muhammad Khoirul HUDA

Co-Author(s): Amani Sakinah AUGIANI, Sita Paramita AYUNINGTYAS, Agnesstacia Vania LUMINTANG

Purpose: Optic neuritis in elderly with the presence of systemic comorbidities presents considerable diagnostic and therapeutic challenges. This report describes a case of bilateral optic neuritis following a presumed viral infection, complicated by multiple comorbidities, that achieved successful visual recovery.

Methods: A case report.

Results: A 63-year-old male presented with sudden vision loss in the left eye for 5 days and progressive blurring in the right eye for 1 day, following an upper respiratory infection. Past history included hypertension treated with amlodipine and peripheral neuropathy. On examination, visual acuity was no light perception in the left eye and 6/19 in the right, with a

positive relative afferent pupillary defect. Funduscopy showed bilateral hyperemic discs with indistinct margins, and Ishihara testing was 8/16 in the right eye. MRI revealed bilateral optic nerve hyperintensity with contrast enhancement, confirming optic neuritis. He received intravenous methylprednisolone (1 g/day for 5 days) followed by oral tapering. During hospitalization he was newly diagnosed with dyslipidemia and steroid-induced hyperglycemia. While on oral tapering, he developed chronic obstructive pulmonary disease exacerbation and community-acquired pneumonia requiring high-care unit admission and accelerated steroid tapering. Despite these complications, visual acuity improved to 6/6 in the left eye and 6/7.5 in the right with completely resolved visual field defect.

Conclusions: Bilateral optic neuritis in elderly patients with complex comorbidities can still yield excellent outcomes. Early recognition, timely corticosteroid therapy tailored to systemic risks, and coordinated multidisciplinary management are essential to optimize recovery.

Abstract No.: 200972

Panel No.: NEU-0571

Empty Sella Syndrome Secondary to Intracranial Hypertension From a Cortisol-Producing Adrenal Adenoma: A Case Report

First Author: Rishanne Meire ORTIZ

Co-Author(s): Jennifer Joy RAYOS

Purpose: There are only two reported cases of intracranial hypertension secondary to empty sella syndrome from a cortisol-producing adrenal adenoma. The purpose of this report is to add to the limited literature of secondary empty sella syndrome (adrenal adenoma) causing intracranial hypertension.

Methods: A 65-year-old man presented with persistent headache and vomiting accompanied with episodes of blurring of vision predominantly in the morning. A significant past medical history is the presence of adrenal adenoma. Bilateral papilledema was noted on physical examination.

Results: Cranial magnetic resonance imaging revealed an incident finding of empty sella with no other abnormalities. Laboratory work up were unremarkable except for elevated serum cortisol levels. The patient was managed with acetazolamide and intravenous high-dose corticosteroids to reduce intracranial pressure for visual improvement. Initiation of treatment leads to resolution of subjective complaints and visual improvement.

Conclusions: Cortisol-secreting adrenal adenoma causes degrees of elevated intracranial pressure and subsequent empty sella. Awareness of this disease entity is essential for timely diagnosis to give the appropriate management.

Abstract No.: 202063

Panel No.: NEU-0580

Evaluation of Quality of Life in Patients With Graves' Orbitopathy Before and After Therapy Using the Indonesian Version of the Graves' Orbitopathy Quality of Life Questionnaire: A Prospective Cohort Study

First Author: Salmarezka DEWIPUTRI

Co-Author(s): Sita Paramita AYUNINGTYAS, Ajeng Sekar KIRANA, Syntia NUSANTI, Muhammad SIDIK

Purpose: This study aims to assess changes in the quality of life of patients with Graves' Orbitopathy before and after therapy using the Indonesian version of the Graves' Orbitopathy-Specific Quality of Life Questionnaire (GO-QOL), as well as changes in clinical parameters.

Methods: A prospective cohort study was conducted at the ophthalmology clinic of a tertiary hospital in Indonesia from July 2023 to July 2025. Sixty newly diagnosed patients with Graves' Orbitopathy were recruited using consecutive sampling. Patients completed the Indonesian version of GO-QOL at their initial visit, with follow-up evaluation approximately one month after therapy. The questionnaire consists of two subscales: visual functioning (QOL-VF) and physical appearance (QOL-AP).

Results: The mean age of patients enrolled in the study was 40.91 ± 12.16 years, with 49 females (81.7%). Quality of life assessment using the GO-QOL questionnaire showed a significant improvement in QOL-AP ($p = 0.001$), while QOL-VF demonstrated a non-significant trend toward improvement ($p = 0.053$). The proportion of active GO decreased significantly after therapy ($p < 0.000$). Mean proptosis, measured by Hertel exophthalmometry, showed a statistically significant reduction ($p = 0.029$). Inflammatory signs demonstrated improvement, with reductions in conjunctival redness ($p = 0.016$) and inflammation of the caruncle or plica ($p = 0.021$).

Conclusions: Quality of life in patients with GO improved following therapy, particularly in physical appearance. This was accompanied by improvements in clinical parameters, including clinical activity, proptosis, and inflammatory signs.

Abstract No.: 206708

From A Silent Growth to a Diplopia: A Case of Abducens Nerve Palsy Due to Cerebellopontine Angle Tumor

First Author: Nathasya SUSILO

Co-Author(s): Dianita Veulina GINTING, Antonia Kartika INDRIATI, Rusti Hanindya SARI, Prettylya YOLLAMANDA

Purpose: To report a rare case of a cerebellopontine angle (CPA) tumor with abducens nerve (CN VI) involvement.

Methods: This is a case study reporting a 54-year-old male who came with double vision for the past five months.

Results: The diplopia was reported to improve when one eye was closed. Headache, tinnitus, and postural imbalance were also experienced. On examination, 15° right esotropia with an abnormal compensatory head turn to the right was demonstrated by the Hirschberg test. Limitation of right eye abduction was identified (−3), while movements of the fellow eye were found to be normal. Brun's nystagmus was observed. Additional cranial nerve evaluation revealed deficits of the right peripheral CN VII and CN VIII. Multiple cranial nerve palsies (CN VI, VII, VIII) on the right side were diagnosed, suspected to be secondary to a space-occupying lesion. Orbital and Head computed tomography (CT) with contrast revealed a cystic mass measuring approximately 2.61 × 2.21 × 3.03 cm in the right CPA.

Conclusions: Involvement of the abducens nerve is considered an uncommon but clinically important neuro-ophthalmologic manifestation of CPA tumors. It is emphasized that recognition of associated features, including Brun's nystagmus and multiple cranial nerve palsies, can facilitate early diagnosis. A favorable prognosis is more likely when timely detection and appropriate management are undertaken.

Panel No.: NEU-0617

From No Light Perception to Full Vision: Dramatic Recovery of Pediatric Optic Neuritis

First Author: Rahayu OKTALIANI

Co-Author(s): Dianita Veulina GINTING, Antonia Kartika INDRIATI, Rusti Hanindya SARI, Prettylla YOLLAMANDA

Purpose: Pediatric optic neuritis is a rare inflammatory optic neuropathy, often difficult to diagnose due to limited clinical cooperation and nonspecific presentations in children. Evidence-based treatment guidelines remain limited. We report an unusual case of pediatric optic neuritis presenting with profound vision loss that achieved complete recovery following prompt corticosteroid therapy.

Methods: Case report based on detailed review of electronic health records and essential ophthalmic and neuroimaging investigations.

Results: A 12-year-old girl presented with sudden blurred vision in the right eye, rapidly progressing to no light perception over four days, preceded by febrile illness. Ocular examination revealed a positive relative afferent pupillary defect, optic disc edema with hyperemia, and peripapillary hemorrhage. Magnetic Resonance Imaging demonstrated contrast enhancement of the right optic nerve, confirming acute optic neuritis. High-dose intravenous methylprednisolone was initiated, resulting in

progressive visual improvement and complete restoration of visual acuity within one month.

Conclusions: This case highlights that even severe pediatric optic neuritis with initial no light perception can achieve full visual recovery with timely and aggressive treatment. Early recognition and prompt corticosteroid therapy are crucial, and profound vision loss at onset should not preclude intensive intervention.

Genetically Coordinated Neuroanatomical Networks Underlying Anisometropia: Evidence From Mediation Mendelian Randomization and Colocalization

First Author: Wanyi SHU

Co-Author(s): Liang HU, Meng LIN

Purpose: To test whether brain morphology and connectivity causally contribute to anisometropia and to map the neuroanatomical networks and shared variants underlying this link.

Methods: We harmonized genome-wide association study (GWAS) summary statistics from UK Biobank neuroimaging and FinnGen R12 (H7_ANISOMETROPIA; 1,141 cases, 476,776 controls), plus complementary imaging resources. Two-sample Mendelian randomization (MR) (inverse-variance weighted (IVW) primary with MR-Egger, weighted median, MR-PRESSO, Cochran's Q, leave-one-out) tested effects from 3,935 magnetic resonance imaging (MRI) phenotypes and 2,212 sex-stratified brain traits. Mediation MR evaluated 26,333 white-matter (WM) connectivity metrics and 256 latent MRI-derived dimensions. Bayesian colocalization reported posterior probability for a shared causal variant (PP.H4).

Results: Initial MR signals appeared across cerebellar, hippocampal, thalamic, and cortical measures but none survived false-discovery-rate (FDR) correction. Network-aware mediation MR yielded five significant models ($P < 0.05$) where intermediates explained 54–69% of the total effect: (i, ii) right/left hippocampal-tail volumes acting via right-hemisphere somatomotor-amygdala WM connectivity (61–69% mediated); (iii–v) sex-stratified cerebellar cortex volumes acting via a T1-derived latent MRI dimension (54–60%). Colocalization supported shared variants for cerebellar volumes with latent MRI dimensions (PP.H4 0.91–1.00) and for right thalamic mediodorsal nucleus, magnocellular part (MDm) volume with inter-hemispheric control-network connectivity (PP.H4 = 0.84); hippocampal subfields with somatomotor-amygdala connectivity showed moderate evidence (PP.H4 = 0.51–0.53). Enrichment implicated axon guidance, myelination, and synaptic plasticity.

Conclusions: Anisometropia is embedded in genetically coordinated cerebellar-hippocampal-thalamocortical

circuits. Although single-trait MR effects are modest, convergent mediation and colocalization implicate specific WM pathways and latent structural dimensions as mechanistic bridges, nominating imaging-genetic biomarkers for early risk assessment and neuroplasticity-based adjuncts to optical correction.

Panel No.: NEU-0599

Hiding in Tandem: A Case Report on Atypical Optic Neuritis Secondary to Syphilis and HIV Co-infection

First Author: Allbvi Enric BASA

Co-Author(s): Miriam Louella FERMIN

Purpose: To present a case of infectious optic neuritis To discuss diagnosis, treatment, and prognosis of cases of syphilis and HIV related optic neuritis

Methods: This is a case report

Results: This is a case of 42-year-old Filipino male with progressive bilateral blurring of peripheral vision eventually involving his central vision as well, accompanied by color vision disturbances and headaches. Ocular exam revealed a visual acuity of 20/125 on the right and 20/60 on the left. Pupils were 3-4 mm sluggishly reactive to light with a grade 2 RAPD noted on the right. Ishihara testing showed 1/8 on the right and 3/8 on the left. Fundoscopy revealed indistinct disc margins bilaterally. Ancillary work up which included nontreponemal, treponemal, HIV antibody testing were all positive, with a CD4 count of 205. Patient was started on oral methylprednisolone 16mg/tab 3x daily with weekly tapering, as well as Aqueous Crystalline Penicillin G 4 million units IV every 4 hours for 14 days. He showed improvement of vision with a BCVA of 20/25 on the right eye and 20/20 on the left eye, as well as complete resolution of dyschromatopsia upon completion of antibiotic treatment for syphilis.

Conclusions: In cases of atypical optic neuritis, infectious causes should be suspected given the rise of HIV cases in the country. Ocular syphilis may be the first presentation of patients living with undiagnosed HIV infection. Early screening and treatment in these patients is not only sight saving, but may eventually be life saving.

Human Induced Pluripotent Stem Cell-Derived Extracellular Vesicles Promote Neuroprotection Effects in Rat Optic Nerve Crush Model

First Author: Yuezhu LU

Co-Author(s): Hua YAN, Yong ZHONG

Purpose: Optic neuropathies cause irreversible vision loss due to retinal ganglion cell (RGC) degeneration and axonal injury, with no effective treatments available. Human-induced pluripotent stem cell-derived extracellular vesicles (iPSC-EVs) have emerged as a promising cell-free therapeutic candidate. This study aimed to evaluate the neuroprotective and regenerative effects of iPSC-EVs in a rat optic nerve crush (ONC) model and investigate underlying mechanisms.

Methods: iPSC-EVs were isolated, characterized, and administered via intravitreal injection immediately after ONC. RGC survival and apoptosis were assessed by RBPMS immunostaining and TUNEL assay. Retinal morphology was examined with optical coherence tomography. Optic nerve regeneration and function were evaluated using cholera toxin subunit B anterograde labeling and flash visual evoked potentials (F-VEP). Transcriptomic alterations were analyzed by RNA sequencing, and PI3K/AKT pathway activation was confirmed by Western blot.

Results: Intravitreal iPSC-EVs significantly promoted RGC survival and reduced apoptosis compared to PBS-treated controls. OCT demonstrated preserved retinal nerve fiber layer and ganglion cell complex thickness, along with reduced optic nerve atrophy. Treated rats showed enhanced axonal regeneration and partial functional recovery in F-VEP recordings. RNA sequencing and protein analyses indicated that iPSC-EVs exert their neuroprotective effects through activation of the PI3K/AKT signaling pathway.

Conclusions: iPSC-EVs promote neuroprotection and regeneration in the ONC model by preserving RGCs, mitigating optic nerve damage, and enhancing functional recovery, likely via PI3K/AKT activation. These findings highlight iPSC-EVs as a promising therapeutic strategy for optic neuropathies.

Identification of RPE-Specific AAV Variants via Intravitreal Injection

First Author: Xiaolai ZHOU

Purpose: To identify an AAV variant that transduces retinal pigment epithelium (RPE) cells with high specificity and efficiency via intravitreal injection.

Methods: We conducted multiple rounds of in vivo screening in mice by intravitreal injection using a

randomized 9-mer library (with a diversity of $1.34E6$) inserted between positions 587–588 of the AAV2 capsid.

Results: We identified a novel AAV variant (AAV206) that transduces RPE cells with high specificity and efficiency, but with low retinal toxicity and immunogenicity when delivered via intravitreal injection. Moreover, we demonstrated that AAV206-based gene therapy achieves superior treatment outcomes compared to conventional AAV2 in a laser-induced wet AMD animal model.

Conclusions: Our findings suggest that the AAV206 vector represents a valuable tool for studying RPE biology and holds promise as an intravitreal delivery vector for treating RPE-related retinal degenerative diseases.

Panel No.: NEU-0610

Impact of Citicoline Treatment on Enhancing Visual Function in Stroke Patients

First Author: Silvia FRANSISCA

Co-Author(s): Bobby Ramses Erguna SITEPU, Delfi

Purpose: Visual disturbances are a common and often debilitating complication following stroke, significantly impairing patients' functional independence and quality of life. Among various neuroprotective agents, Citicoline (cytidine-5'-diphosphocholine) has demonstrated multifaceted mechanisms of action, including modulation of phospholipid metabolism, reduction of oxidative stress, and enhancement of dopaminergic and cholinergic neurotransmission. These properties suggest potential benefits in promoting visual recovery post-stroke.

Methods: This quasi-experimental study employed a pre- and post-intervention design involving 30 post-stroke patients who received 1000 mg of oral Citicoline daily for 30 consecutive days. Visual function was evaluated through standard ophthalmological assessments, including visual acuity (logMAR), visual field analysis using the Humphrey Field Analyzer, contrast sensitivity (Pelli-Robson chart), and color sensitivity test (Farnsworth Munsell D-15 test), both before and after treatment.

Results: Post-treatment analysis revealed no statistically significant improvement in visual acuity or visual field parameters ($p > 0.05$). However, contrast sensitivity showed a statistically significant enhancement following Citicoline administration ($p < 0.05$). No significant changes were observed in color vision outcomes ($p > 0.05$).

Conclusions: Oral Citicoline supplementation over a 30-day period appears to exert a beneficial effect specifically on contrast sensitivity in stroke patients with visual dysfunction, while its impact on visual acuity, visual fields, and color perception remains

inconclusive. Further research involving combinations with other neuroprotective agents, larger sample sizes, or longer intervention durations is needed to confirm these findings and to explore the potential benefits of Citicoline more comprehensively.

Importance of Pattern ERG As Adjunct to Visual Evoked Potential in Ethambutol Induced Optic Neuropathy

First Author: Deepika R

Co-Author(s): Maheshkumar, Rupa Anjana Moorthy

Purpose: Pattern VEP is a standard test in analyzing functional changes due to ethambutol-induced optic neuropathy (EON). Pattern ERG complements VEP by providing insights into retinal ganglion cell function. Our study evaluates the effectiveness of combining PERG with PVEP in Ethambutol induced Optic Neuropathy, thereby enhancing diagnostic accuracy.

Methods: A prospective study of 50 patients was done. Data analyzed include visual acuity, fields, color vision, fundus evaluation, neuroimaging and VEP (P100 amplitude and peak time) with PERG (N95/P50 ratio amplitude).

Results: The Mean duration of presentation was 6.23 months. On fundus examination, 72% of our patients had a normal disc, followed by Temporal pallor in 25%. In those patients with no obvious fundus abnormality, there was significant reduction in amplitude of N95/P50 ratio in 70% of eyes (PERG), reduction in amplitude of P100 in 50% of eyes and delayed peak time of P100 (VEP) in 22%.

Conclusions: Even in cases without obvious disc changes, PERG complements VEP by detection of RGC dysfunction making it highly sensitive.

Influenza Virus Type A-Induced Multiple Evanescent White Dot Syndrome

First Author: Yalin REN

Co-Author(s): Haiyan LIN

Purpose: This is the first case reported influenza virus type A causes multiple evanescent white dot syndrome all around the world.

Methods: Clinical observation. A scanning laser ophthalmoscope (SLO) color photo of the right eye presented multifocal grey-white dots in the retina. SLO red-free photo showed multifocal white dots and plaques in the retina. OCT scanned through a grey-white dot indicating a hyper-reflective lesion in the outer nuclear layer.

Results: Influenza virus can lead to some ocular diseases, including conjunctivitis, acute macular

neuroretinopathy (AMN), acute posterior multifocal placoid pigment epitheliopathy (APMPPE), serous macular detachment (SME), optic neuritis, acute anterior uveitis, and retinitis (submacular hemorrhage without neovascularization, macular edema with exudates, perifoveal edema with star-like pattern). This is the first case reported influenza virus type A causes multiple evanescent white dot syndrome.

Conclusions: The Influenza virus can cause MEWDS, which may decrease visual acuity but does not need to be treated.

Key Predictors of Final Visual Outcome in Patients With Traumatic Optic Neuropathy

First Author: Sabarinath A

Co-Author(s): Deepika R

Purpose: To analyze the key factors influencing the final visual outcome in a patient with Traumatic optic Neuropathy.

Methods: A Retrospective study of 51 patients with TON presented to our tertiary eye care centre between July 2022 and December 2022 was conducted. Data analyzed include demographics, mode of trauma, BCVA at the time of presentation, pupillary reflex, complete ocular examination, associated orbital and cranial bone fractures, associated intracranial injuries based on CT images, and treatment initiated based on time of presentation. BCVA was analyzed at follow-up visits and taken as the primary visual outcome.

Results: Out of 51 patients, 49 were males (96.1%) and 2 patients were females (3.9%). The most common modes of injury were RTA (82.4%), fall (13.9 %), and assault(3.9%). Of the 51 patients, 33 patients (64.7%) had orbital and cranial bone fractures, with the lateral wall of the orbit fracture being the most common. 13 patients had Intracranial injury (26.3 %) of which SDH being most common (9%). The median pre-treatment BCVA (Logmar 1.78) and post-treatment BCVA (Logmar 1.3) were compared, and the difference was found to be statistically significant($P<0.0001$).

Conclusions: There is a significant improvement in BCVA from baseline in patients treated with high-dose corticosteroids. Those who presented late with loss of consciousness or cranial fractures had a poorer outcome.

Linezolid-Associated Optic Neuropathy in Drug-Resistant Tuberculosis Patients in Indonesia

First Author: Andrea SILITONGA

Purpose: To describe reversible effect of optic neuropathy due to Linezolid-induced.

Methods: A case series of two patients. The first patient is 32 year old Indonesian female complained of rapid, painless diminution of vision in both eyes for 1 month. She was under medication for MDR TB for 17 months with linezolid 600mg, levofloxacin 250mg, cycloserine 250mg, bedaquiline 100mg, and clofazimine 100mg. Visual acuity of both eyes was counting finger close to face. The second patient is 49 years old Indonesian male, with visual acuity in both eyes of counting finger at 2 meters. He had consumed MDR-TB drugs including linezolid for 14 months. Both patients had hyperaemic optic disc with blurred edges. Optical Coherence Tomography (OCT) showed thickening of the retinal nerve fiber layer (RNFL) in both eyes. Visual field examination showed a local scotoma in both eyes.

Results: After stopping Linezolid treatment and follow up monthly for 3 months, there was remarkable visual acuity and visual field improvement. The female patient had best corrected visual acuity of 20/20 in month 3. The male patient's visual acuity improved to 20/200 in both eyes and full recovery of optic disc OCT and visual field. Optic neuropathy was encountered in 13.2% of patients receiving long-term linezolid (duration 5-14 months with dose 600mg). Linezolid is thought to affect the visual nerve by interfering with oxidative phosphorylation in the mitochondria. It is reversible and the majority of cases resolved within 1–3 months after drug discontinuation.

Conclusions: Physicians need to recognize linezolid neurotoxicity to avoid permanent visual loss.

Abstract No.: 201472

Panel No.: NEU-0575

Linezolid-Induced Toxic Optic Neuropathy in Two Patients With Drug-Resistant Tuberculosis

First Author: Alec Xavier BUKUHAN

Co-Author(s): Franz Marie CRUZ, Bryan Vincent MESINA

Purpose: To describe the clinical presentation and disease course of two Filipino patients with toxic optic neuropathy from linezolid given for drug-resistant tuberculosis.

Methods: This is a small case series.

Results: Case 1 is a Filipino female in her 30s with rifampicin-resistant pulmonary tuberculosis on

bedaquiline, pretomanid, linezolid and moxifloxacin (BPALM) regimen who developed bilateral painless blurring of vision with optic disc swelling. A comprehensive laboratory and neuroimaging work-up was unremarkable and a diagnosis of linezolid toxic optic neuropathy was made. Linezolid was immediately discontinued leading to improvement of visual acuity within one month. The second case is a 14-year-old Filipino female who presented bilateral decreased visual acuities, dyschromatopsia and mild disc swelling seven months after initiating TB medications containing linezolid. Toxic optic neuropathy was suspected, and linezolid was promptly discontinued. On follow-up one year later, visual acuity and color vision had normalized, but optic disc temporal pallor was noted. Ocular diagnostics showed bilateral thinning of the retinal nerve fiber layer and persistent mild central scotoma in both eyes.

Conclusions: Linezolid is a second-line agent used in the treatment drug-resistant tuberculosis, but it can rarely cause toxic optic neuropathy. A high index of suspicion and prompt discontinuation of the drug may lead to reversal of vision loss.

Long-Term Assessment of Optic Nerve Function in Thyroid Eye Disease Treated With Intensity-Modulated Radiotherapy: A Retrospective Case-Control Study With Multidimensional Evaluation

First Author: Yue FU

Co-Author(s): Yang HUI

Purpose: To evaluate the long-term effects of intensity-modulated radiotherapy (IMRT) on optic nerve function in patients with moderate-to-severe thyroid eye disease (TED), using a multidimensional assessment.

Methods: In this retrospective case-control study, 24 patients with TED (NOSPECS stage IV) were divided into an IMRT group (n=12; 20 Gy/10 fractions, optic nerve Dmax <15 Gy) and a control group (n=12; glucocorticoid therapy followed by orbital decompression). Patients were followed for a median of 9 years (range 2-14 years). Optic nerve function was assessed via best-corrected visual acuity (logMAR BCVA), visual field mean deviation (VF_MD), optical coherence tomography for retinal nerve fiber layer (RNFL) and ganglion cell layer (GCL) thickness, pattern visual evoked potentials (PVEP) amplitude and latency, and intraocular pressure (IOP). Multiple linear regression adjusted for confounders including age.

Results: No significant differences were found between groups in BCVA (P=0.478), VF_MD (P=0.378), mean RNFL (P=0.568), GCL thickness (P=0.979), or most PVEP parameters (P≥0.07). Inferior RNFL was thinner in the IMRT group (119.00±24.46 μm vs. 135.58±16.18 μm, P=0.063), and large-checkerboard latency showed a

prolongation trend (116.23±9.58 ms vs. 109.33±8.11 ms, P=0.07). IOP was significantly higher in the IMRT group (median 19.00 mmHg vs. 14.50 mmHg, P<0.001).

Conclusions: IMRT provides long-term safety for optic nerve function in TED without evidence of radiation-induced optic neuropathy. However, elevated IOP suggests the need for ongoing monitoring. These findings affirm IMRT as a safe, non-invasive treatment option for TED. (248 words)

Mixed-Mechanism Optic Neuropathy With Wernicke Encephalopathy Following Ileal Resection: A Rare Clinical Intersection

First Author: Robbie Alyssa MALIWAT

Co-Author(s): Marianne CARABEO

Purpose: To report a case of mixed-mechanism optic neuropathy following segmental jejuno-ileal and terminal ileum resection.

Methods: A 14-year-old female developed acute, bilateral, painless visual blurring, diplopia, and agitation after repeated small bowel resections with anastomosis for obstruction due to complicated appendectomy. She required prolonged parenteral feeding, multiple blood transfusions for anemia, and had recurrent severe vomiting. Initial visual acuity was 20/200 in the right eye and hand movement with poor light projection in the left, progressing to bilateral blindness within days. Clinical findings included horizontal gaze restriction, diplopia, sluggish pupils, and nystagmus, with otherwise normal anterior segments. Visual evoked response showed bilateral conduction delay. Fluorescein angiography revealed resolving Valsalva retinopathy but was otherwise unremarkable. Optical coherence tomography revealed global thinning of the ganglion cell layer and inner plexiform layer in both eyes. Neuroimaging was consistent with Wernicke encephalopathy. The patient was treated with intravenous Vitamin B complex followed by oral supplementation.

Results: Nine days after infusion, visual acuity recovered to 20/20 bilaterally, with marked reduction in diplopia and improved visual evoked potentials.

Conclusions: Acute bilateral visual loss in patients with poor nutrition, anemia requiring transfusions, and extensive bowel resection should raise suspicion for nutritional or hypoxic optic neuropathies. Early recognition and treatment are crucial for vision preservation and recovery.

Neuroprotective Effects of Lycium barbarum Glycopeptide in a Mouse Model of Neuromyelitis Optica Spectrum Disorders Associated Optic Neuritis

First Author: Shaoying **TAN**Co-Author(s): Henry Ho-lung **CHAN**, Xiayin **YANG**, Shiqi **YAO**

Purpose: To explore the neuroprotective effects of Lycium barbarum glycopeptide (LBGP) in a mouse model of Neuromyelitis Optica Spectrum Disorders Associated Optic Neuritis (NMOSD-ON).

Methods: C57BL/6 mice, aged 8 to 12 weeks, received intracranial injections of Anti-aquaporin-4 IgG (AQP4-IgG) coupled with human complement to induce NMOSD-ON. A week before this induction, the mice received Phosphate-buffered saline (PBS) as a control. The control group had intracranial injections of normal IgG with human complement, without additional treatment. In the LBGP group, all mice were administered LBGP (50 mg/kg) daily, commencing one week before AQP4-IgG and human complement induction. This treatment persisted for one-month post-induction. Evaluation metrics included Optical Coherence Tomography (OCT), Visual Evoked Potential (VEP), and Electroretinography (ERG), all measured at baseline and weeks 1, 2, and 4. Furthermore, we collected optic nerves and eyes for histological analysis of aquaporin-4 (AQP4) protein, astrocytes, myelin sheath, and retinal ganglion cells (RGCs) at weeks 1 and 4.

Results: Findings suggest that LBGP enhances the inflammatory microenvironment by decreasing tumor necrosis factor alpha (TNF α), interleukin-1beta (IL-1 β), and IL-6 levels. Moreover, LBGP mitigates microglial activation, protects astrocytes, and promotes recovery of the myelin sheath and RGCs. OCT, ERG, and VEP evaluations revealed both functional and structural improvements after LBGP treatment.

Conclusions: LBGP treatment effectively halted progressive neuronal degeneration post-initiation. It preserved RGC density and sustained visual pathway function in an NMOSD-ON mouse model, yielding results like those observed prior to model induction.

Neuroradiologic Evidence of Cerebrovascular Ischemia in Patients Presenting With Retinal Artery Occlusion

First Author: Joyce **MBEKEANI**Co-Author(s): Behram **KHAN**, Gregory **PARNES**, Jainam **SHAH**, Joyce **TANG**

Purpose: To determine neuroradiologic evidence of pre-existing cerebrovascular ischemia at presentation of retinal artery occlusion (RAO).

Methods: Patients with CRAO, BRAO and HHP (Hollenhorst plaques) were identified using ICD-10CM diagnostic codes. Types of RAO, demographic data, intercurrent medical problems, past CVA history and neuroradiologic findings were tabulated. Descriptive and analytical calculations were performed using SPSS (29.0.2.0), with significance set at $P < 0.05$.

Results: Thirty-nine patients (28 CRAO, 7 BRAO, 4 HHP) were identified. Mean (SD) age was 62.8 (12.6) years old. Males comprised 66.7%. Race distribution was 7.7% white, 51.3% black, and 41% other. 33.3% of the total were identified as Hispanic ethnicity. Intercurrent problems included obesity (46.2%), hypertension (87.2%), diabetes mellitus (59.0%) and hyperlipidemia (53.9%). 28.2% had past cardiovascular events, and 15.4% had past CVA. MRI was performed in 5 patients (12.8%), CT in 9 (23.1%), and both in 18 (46.2%). Overall, 66.7% had evidence of cerebrovascular ischemia at presentation, mostly microvascular (46.2%) and less commonly remote/prior occult infarcts (20.5%). Chi-square analysis showed associations between ischemia on MRI or CT and black race ($P = 0.010$) and obesity ($P = 0.015$). No associations were found between ischemia and age, sex, ethnicity, diabetes, hyperlipidemia, cardiac history, or prior CVA.

Conclusions: Most patients presenting with RAO had neuroradiologic evidence of cerebrovascular ischemia, most commonly microvascular. These results support prompt neuroimaging and comprehensive stroke evaluation for all RAO cases, alongside tailored interventions to address modifiable vascular risk factors. Significant associations with black race and obesity, in this population, highlight the need for targeted prevention strategies.

Abstract No.: 204316

Panel No.: NEU-0602

Nine Syndrome in a 52-Year-Old Filipino Female: A Rare Convergence of Ocular and Neurological Deficits

First Author: Richard **VILLAMOR**Co-Author(s): Janice **BERNARDO**

Purpose: To report a case of a 52-year-old Filipino female presenting with binocular horizontal diplopia in La Union, Philippines. The right eye showed adduction

deficit on the left lateral gaze and abducting nystagmus on the right lateral gaze. Whereas, the left eye showed an abduction deficit on the left lateral gaze. Patient also presented with facial asymmetry and right sided weakness. Pertinent history includes hypertension with no history of trauma and infection.

Methods: Basic systemic workup and imaging was done.

Results: Plain Cranial MRI showed T1W/T2W hyperintense signal in the left pontine area, midbrain, capsulo-ganglionic region, indicating acute to subacute hemorrhagic infarct. Confluent T2/FLAIR hyperintensities are also seen in the periventricular and subcortical white matter of both cerebral hemispheres. Patient was co-managed with Neurology team, given neuroprotectants and occlusion patch was given for symptomatic relief of diplopia.

Conclusions: Nine syndrome is a rare clinical entity characterized by the triad of one-and-a-half syndrome, ipsilateral facial nerve palsy, and contralateral hemiparesis or hemianesthesia, localizing the lesion to the dorsal paramedian pontine tegmentum. This condition remains exceedingly rare, citing just 14 documented cases in the literature review.

Abstract No.: 205418

Non-Arteritic Anterior Ischemic Optic Neuropathy and Cataract Surgery (Case Series)

First Author: Elena IOILEVA

Co-Author(s): Alexandra SAFONENKO, Arina ZASYPKINA

Purpose: The occurrence of nonarteritic anterior ischemic optic neuropathy (NAION) after cataract extraction varies from 0.01% to 0.1% according to published researches [1-8]. It has not yet been clearly identified, whether cataract surgery increases the risk of NAION. Whether it depends on the technique of the operation, the type of IOL, or anesthesia, it is still subject of discussion. The aim of the work is to study different cases of unilateral NAION during one year after cataract surgery.

Methods: Clinical cases of 5 patients aged 51 to 84 years (4 men, 1 woman) with unilateral NAION after phacoemulsification cataract surgery with intracapsular implantation within timeframes from 3 weeks to 1 year. The second eye of all patients has no history of NAION. An ophthalmological examination was performed, including OCT and OCT angiography (OCTA) using Solix and Cirrus HD-OCT 5000, ultrasound of the eyeball (Aviso, France). All patients had systemic vascular risk factors.

Results: All patients have decrease in visual acuity, defects in the visual field. The IOL is in a capsule bag, centered. The optic disk was swollen with

blurred boundaries. OCT and OCTA peripapillary area examination showed thickening of the retinal nerve fiber layer, decrease of capillary density in all patients, prominence of the optic disk was diagnosed by ultrasound scanning. Three of the five patients had cup-to-disk ratio <0.2 ; two patients had C/D Ratio = 0.26. The patients underwent conservative and physiotherapeutic treatment with enhanced visual functions

Conclusions: According to this dataset of clinical cases, certain anatomical characteristics of optic disc were identified in all patients. Timely performed treatment led to improved visual functions and improved quality of life for patients.

Abstract No.: 206366

Panel No.: NEU-0625

Nonarteritic Anterior Ischemic Optic Neuropathy in a 45-Year-Old Patient: Atypical Presentation and Fast Recovery

First Author: Cindy Prajna METTA

Co-Author(s): Bobby Ramses Erguna SITEPU

Purpose: To describe an atypical case of nonarteritic anterior ischemic optic neuropathy (NAION) in a relatively young patient, highlighting unusually rapid and complete visual recovery following early high-dose intravenous corticosteroid therapy.

Methods: A 45-year-old male presented with sudden, painless vision loss in the right eye upon awakening, preceded by two weeks of blurring and an inferior "curtain-like" field defect. Risk factors included untreated hypertension, hyperlipidemia, and smoking. Best-corrected visual acuity (BCVA) was 20/400 OD and 20/20 OS, with right relative afferent pupillary defect (RAPD), optic disc edema and peripapillary hemorrhage. Automated perimetry revealed an inferior altitudinal defect, and OCT showed diffuse optic disc edema with RNFL thickening. The patient was treated with intravenous methylprednisolone 1 g/day for 3 days, followed by a tapering oral regimen and systemic risk factor management.

Results: Vision improved progressively, reaching BCVA 20/20 by 2 weeks, accompanied by resolution of optic disc edema, normalization of color vision, and disappearance of RAPD.

Conclusions: This case illustrates an atypical, early-onset NAION with complete visual recovery following prompt corticosteroid therapy. While the role of steroids in NAION remains controversial, the dramatic functional and structural recovery in this patient suggests potential benefit in selected cases when administered early.

Abstract No.: 201778**Panel No.: NEU-0578****Optic Disc Edema After High-Altitude Exposure: A Case Report and Literature Review***First Author: Bo WAN**Co-Author(s): Yong ZHONG*

Purpose: To present a case of optic neuropathy associated with high-altitude exposure, highlighting the importance of recognizing and summarizing optic neuropathy related to altitude sickness.

Methods: We conducted the patient with visual acuity, fundoscopic examination, visual field testing, OCT, VEP, ERG, intracranial pressure and laboratory test for this case. Furthermore, a comprehensive review and synthesis of the relevant literature was conducted.

Results: Optometric assessment reveals the presence of high myopia in the patient. Fundoscopic examination revealed bilateral disc edema. Visual field testing demonstrated enlarged physiological blind spots in both eyes (OU). OCT indicated OD macular serous retinal (SRD) detachment and OU thickening of the optic nerve fibers. The patient reported no headaches but disclosed residence at high altitude for two months. A lumbar puncture revealed an intracranial pressure of 240 mmHg. The intracranial laboratory test results of optic neuritis and infection were negative. Albumin and immunoglobulin G levels elevated in cerebrospinal fluid (CSF) and he was treated with 4 weeks of oral acetazolamide and glycerol-sodium chloride solution. Follow-up examination at 4 weeks showed resolving OD SRD, improved OD BCVA, OU visual fields and intracranial pressure.

Conclusions: It is hypothesized that the high-altitude environment contributed to the elevation of intracranial pressure, subsequently leading to bilateral optic disc edema. Visual field examination and cerebrospinal fluid test are of great significance for diagnosis. Timely reducing intracranial pressure can achieve benefit for improving optic disc edema.

Abstract No.: 203979**Panel No.: NEU-0598****Optic Nerve Head Status Changes of Tuberculosis Patients Treated with Linezolid at Northern Mindanao Medical Center***First Author: Benedicto Juan Enrique AGUILAR**Co-Author(s): Mayjane Joan TUMULAK*

Purpose: To determine optic nerve head status changes of patients identified for linezolid treatment tuberculosis at Northern Mindanao Medical Center (NMMC) by comparing baseline and follow-up.

Methods: Prospective cohort study that compared optic nerve head status of outpatients who underwent linezolid treatment from baseline to patient's latest

follow-up after the initiation of treatment. The effects of patients' weight, medical history and comorbidities, body surface area, and duration from baseline to reassessment, were tested against the changes in visual acuity, color vision acuity, optic nerve head peripapillary retinal nerve fiber layer (PRNFL) thickness, and visual field results.

Results: Eight of nineteen patients participated in the study, with average duration from initiation of treatment being 16.25 weeks (SD = 9.38). No statistically significant change was noted in visual acuity and color visual acuity, optic nerve head PRNFL thickness on Optical Coherence Tomography (OCT), or visual field analysis results, even when considering duration of treatment, presence of comorbidities, or smoking history ($p = 0.05$). One patient developed non-arteritic anterior ischemic optic neuropathy (NAION) during the course of linezolid treatment, for which cautious continuation of linezolid treatment yielded progressive recovery and no recurrent deterioration of visual acuity.

Conclusions: No significant change in optic nerve head status was found among tuberculosis outpatients treated with linezolid at Northern Mindanao Medical Center, even when factoring in duration or patient weight, body surface area, or systemic or ophthalmologic comorbidities. Linezolid intake may have an effect on NAION and is worth further investigation.

Abstract No.: 202166**Panel No.: NEU-0583****Optic Neuritis Beyond the Typical Age: Rare Presentation and Successful Management in an Elderly Patient***First Author: Michael HARTONO**Co-Author(s): Sita Paramita AYUNINGTYAS, Anya Dewi NASTITI, Hindun ZAKIYAH*

Purpose: To report a rare case of optic neuritis in an elderly patient, highlighting diagnostic challenges, chronic pain, immunological evaluation, and visual recovery following corticosteroid therapy.

Methods: This case illustrates unilateral vision loss with persistent ocular pain in a 59-year-old woman.

Results: The patient presented with three months of chronic ocular pain and progressive vision loss in the left eye (hand movement). Fundus examination revealed optic disc swelling; magnetic resonance imaging demonstrated optic nerve enhancement along most of its length with orbital fat stranding, consistent with optic neuritis. Laboratory work-up including Infection screening and tumor marker (CEA and CA-125) were negative. Antinuclear antibody was positive at 1/100, while myelin oligodendrocyte glycoprotein (MOG, indirect immunofluorescence assay test) and aquaporin-4 (AQP4) antibodies were negative. She

was treated with intravenous methylprednisolone 1g/day for five days; then tapered orally. Pain resolved, and vision improved to 6/30 at discharge. At six weeks, visual acuity reached 6/7.5, color vision as well as contrast sensitivity were improved. Visual field mean deviation improved from -17.81 dB to -2.72 dB, and optic disc swelling resolved.

Conclusions: Optic neuritis in the elderly is rare and often atypical, necessitating thorough exclusion of infectious, infiltrative, and autoimmune causes. This case emphasizes the importance of recognizing chronic pain as a presenting feature and the value of a comprehensive diagnostic work-up. High-dose corticosteroid therapy resulted in marked visual and functional recovery, even in late-onset seronegative optic neuritis.

Abstract No.: 205816
Panel No.: NEU-0616

Orbital Apex Syndrome Secondary to Latent Tuberculosis Infection

First Author: Snehal GANATRA
Co-Author(s): Nirathya ANISHA, Virender SACHDEVA

Purpose: The study aimed to describe the clinical and radiological features of orbital apex syndrome (OAS) caused by latent tuberculosis infection (LTBI).

Methods: This is a retrospective study analysing medical records of patients with OAS at a tertiary eye care centre in southern India. Patients with OAS due to presumed LTBI were included based on clinical presentation, imaging findings, and exclusion of other potential causes.

Results: Patient profile: Eight patients (mean age 43.6 years, 50% male) were included. All had unilateral involvement. Symptoms: The primary symptom was ocular/peri-orbital pain accompanied by ipsilateral headache. Three had diplopia, and 4 presented with upper eyelid ptosis. Only 2 complained of vision loss. None had constitutional symptoms. Diagnostic tests: The tuberculin skin test was positive in 7 cases, borderline in 1 case, and a chest X-ray showed past infection in 3 cases. Visual acuity ranged from 20/20 to hand-motion. MRI revealed enhancement at the orbital apex in all, with cavernous sinus extension in 5 cases. Treatment and Outcome: Due to the diagnostic challenge, all were treated with high-dose corticosteroids under anti-tuberculous therapy. All achieved complete recovery of extraocular motility and diplopia. One of two patients with initial hand movements improved to 20/50 at the last follow-up.

Conclusions: Diagnosing LTBI at the orbital apex and cavernous sinus is difficult, as the lesion cannot be biopsied. Presuming LTBI after ruling out other causes can be a reasonable approach. Combination therapy with anti-tuberculous drugs and high-dose steroids

can lead to improvement in symptoms and visual outcomes.

Abstract No.: 202983
Panel No.: NEU-0594

Painful Ophthalmoplegia in Young Adults: Diagnostic Challenges and Complete Resolution of Tolosa-Hunt Syndrome After Prompt Corticosteroid Therapy

First Author: Mochamad Tito Aditya PRATAMA
Co-Author(s): Lukisiari AGUSTINI

Purpose: Tolosa-Hunt Syndrome (THS) is a rare inflammatory cause of unilateral painful ophthalmoplegia involving cavernous sinus or superior orbital fissure. This case highlights a young male with acute ophthalmoplegia and ptosis who showed rapid corticosteroid response, underscoring the importance of early diagnosis and treatment

Methods: A 26-year-old male presented with right eye pain, ptosis, and diplopia for five days. Examination revealed restricted right eye motility, mild proptosis, and ptosis. Magnetic resonance imaging (MRI) demonstrated a partially ill-defined lesion with regular borders, hyperintensity on T2-weighted imaging, and restricted diffusion in the right cavernous sinus, suggesting THS. Corticosteroid therapy initially produced marked improvement, though recurrence required dose adjustment. With tailored steroid therapy and tapering, the patient fully recovered visual acuity, ocular motility, diplopia, and proptosis by week 24, completing therapy successfully.

Results: Tolosa-Hunt Syndrome is a granulomatous inflammation of the cavernous sinus, often triggered by trauma, tumours, or aneurysms. It typically presents with unilateral retro-orbital pain and diplopia. Diagnosis is confirmed by MRI or biopsy. High-dose corticosteroids provide rapid pain relief, aiding diagnosis, while other diseases may take months to resolve. Patients demonstrating corticosteroid responsiveness typically require no additional therapy; immunosuppressive agents are reserved for recurrent or refractory disease, whereas steroid-unresponsive cases generally portend an unfavourable prognosis

Conclusions: Tolosa-Hunt Syndrome is a rare condition requiring a multidisciplinary approach for diagnosis, with corticosteroids as the main treatment. Timely diagnosis and management are crucial for optimal outcomes

Abstract No.: 202590

Panel No.: NEU-0587

Prevalence of Subretinal Fluid, Intraretinal Fluid, and Paracentral Acute Middle Maculopathy in Anterior Ischemic Optic Neuropathy

First Author: Akihiro **TSUTSUMINO**Co-Author(s): Eri **NAKANO**, Kenji **SUDA**, Satoshi **KASHII**, Akitaka **TSUJIKAWA**

Purpose: To determine the prevalence of subretinal fluid (SRF), intraretinal fluid (IRF), and paracentral acute middle maculopathy (PAMM) in arteritic anterior ischemic optic neuropathy (A-AION) and non-arteritic anterior ischemic optic neuropathy (NA-AION).

Methods: We retrospectively reviewed patients diagnosed with A-AION or NA-AION who underwent PLEX Elite 9000 (Carl Zeiss Meditec, Dublin, CA, USA) within 1 month of onset at Kyoto University Hospital between January 2018 and March 2025. The presence of SRF, IRF, and PAMM was assessed using 12×12 mm OCT scans centered on the optic disc.

Results: Five eyes of 5 patients (all female) had A-AION, and 26 eyes of 24 patients (14 male, 10 female) had NA-AION, with mean ages of 76.6 ± 2.2 and 63.2 ± 13.1 years, respectively. Peripapillary SRF was observed in 2 eyes (40%) with A-AION and 1 eye (3.8%) with NA-AION ($P = 0.06$). Macular SRF was observed in 0 eyes (0%) with A-AION and 1 eye (3.8%) with NA-AION ($P = 1.00$). Peripapillary IRF was present in 4 eyes (80%) with A-AION and 19 eyes (73.1%) with NA-AION ($P = 1.00$). Macular IRF was present in 0 eyes (0%) with A-AION and 1 eye (3.8%) with NA-AION ($P = 1.00$). PAMM occurred in 1 eye (20%) with A-AION and in none with NA-AION ($P = 0.16$).

Conclusions: The prevalence of SRF, IRF, and PAMM did not differ significantly between A-AION and NA-AION. Although not statistically significant, peripapillary SRF tended to be more frequent in A-AION.

Progressive Multifocal Leukoencephalopathy Manifesting As Homonymous Hemianopia in an AIDS Patient: A Case Report

First Author: Yue **FU**Co-Author(s): Yang **HUI**

Purpose: Progressive multifocal leukoencephalopathy (PML) is a rare demyelinating disease caused by JC polyomavirus (JCPyV) reactivation in immunocompromised individuals, often presenting with visual field defects. This case highlights PML as a cause of homonymous hemianopia in an AIDS patient, emphasizing the diagnostic challenges and therapeutic approaches.

Methods: A 36-year-old male with a 14-month history of painless bilateral vision loss, right homonymous hemianopia, and left-sided headache was evaluated. He had an 11-year history of hypertension and was recently diagnosed with HIV (CD4 count indicative of severe immunosuppression). Initial cerebrospinal fluid (CSF) analysis showed elevated cytomegalovirus (CMV) DNA and positive *Aspergillus fumigatus*, but antiretroviral therapy (ART), anti-CMV, anti-Toxoplasma, and antifungal treatments yielded no improvement. Ophthalmic examination revealed best-corrected visual acuity of 0.5 OD and 0.4 OS, normal fundus, and no relative afferent pupillary defect. Brain MRI demonstrated T2 hyperintensities in the left optic radiation and occipital lobe without enhancement, involving U-fibers. Further CSF next-generation sequencing (NGS) confirmed JCPyV positivity.

Results: The patient was diagnosed with PML secondary to AIDS. Treatment with ART, antivirals, and immune checkpoint inhibition using pembrolizumab led to visual field improvement, as evidenced by serial perimetry showing reduced hemianopia at 8 and 14 months post-onset.

Conclusions: PML should be considered in AIDS patients with homonymous hemianopia and non-enhancing white matter lesions on MRI. CSF NGS is crucial for early JCPyV detection. Immune reconstitution with pembrolizumab may enhance outcomes, though vigilance for PML-immune reconstitution inflammatory syndrome is essential. This case underscores the value of multidisciplinary management in immunocompromised visual impairment.

Protecting Retinal Neurons in Ischemic Retinopathy via Ferroptosis Inhibition – the Role of Alpha-Melanocyte Stimulating Hormone

First Author: Lu **XIANG**Co-Author(s): Amy Cheuk Yin **LO**, Andrew W. **TAYLOR**

Purpose: Retinal ischemia/reperfusion (RIR) injury is a leading cause of vision loss, occurring when blood flow is restored after vascular blockage. Ferroptosis, a regulated cell death involving iron-dependent lipid peroxidation, has been implicated in RIR injury. Alpha-melanocyte-stimulating hormone (α -MSH) exhibits antioxidant and anti-inflammatory properties, providing cellular protection. However, its role in RIR-induced ferroptosis remains unclear. This study investigates whether ferroptosis contributes to RIR injury and if α -MSH can exert neuroprotection via ferroptosis regulation.

Methods: In vitro, mouse 661w photoreceptor cells underwent oxygen-glucose deprivation/reperfusion (OGD/R). Ferroptosis markers (ACSL4, GPX4, xCT, iron,

MDA, GSH, and SOD) were analyzed using Western blot, immunocytochemistry, and assays. JC-1 staining assessed mitochondrial integrity. For in vivo studies, RIR was induced in C57BL/6J mice via middle cerebral artery occlusion (MCAO). Retinal function was evaluated by electroretinography (ERG). Ferroptosis-related proteins in retinal sections were examined via immunofluorescence and Western blot.

Results: In both in vitro and in vivo studies, OGD/R and RIR increased ACSL4 and decreased GPX4 and xCT expression. Besides, iron and MDA levels rose, GSH decreased, indicating ferroptosis. Notably, α -MSH treatment significantly reduced these changes in both models. Correspondingly, retinal function improved with α -MSH administration.

Conclusions: Ferroptosis mediates neuronal death and retinal dysfunction after ischemic injury. α -MSH provides neuroprotection by modulating ferroptosis pathways, highlighting its potential as a therapeutic agent for ischemic retinopathy.

Pupil Light Reflex as a Biomarker in Alzheimer's disease: A Systematic Review

First Author: Ying Hei LEE

Co-Author(s): Lok Man AU, Kelvin KI CHONG, Kenneth Kh LAI, Calvin Cp PANG, Clement Cy THAM, Yiu Man WONG

Purpose: This review aims to examine the relationship between pupil light reflex (PLR) parameters and AD, and how these non-invasive diagnostic tools can be a potential biomarker for early detection and assessment of AD.

Methods: The research scope includes case-control and cross-sectional studies using PubMed, Scite and Google Scholar search engines. The eligible criteria for articles inclusion are studies after 1990 investigating the effectiveness of using PLR parameters to diagnose AD.

Results: Using search terms, 1338 studies are identified and 19 studies (12 white light studies with 863 patients and 1202 healthy controls (HC) ; 7 chromatic stimulation studies with 202 AD patients and 160 HC) meet the inclusion criteria. There are some parameters highlighted in the studies with high diagnostic value. For white light stimuli, maximum constriction acceleration with perfect classification ability of AUC = 1.0, $p < 0.001$. For chromatic stimuli, contraction latency was most discriminative. Across all studies, for white light stimuli, 11 out of 12 studies and for chromatic stimuli 7 out of 7 studies agree there are significant differences between HC and AD patients.

Conclusions: The findings reinforce the potential of PLR parameters as biomarkers for AD. In general, diagnostic models showed discriminatory ability (AUROC range

0.74-0.81) when distinguishing patients with AD patients from HCs and other causes of dementia. Given their diagnostic accuracy, further research is essential to standardize PLR assessments and explore their utility in early AD diagnosis and disease monitoring.

Risk Factors and Clinical Findings in Hypoxic Ischemic Encephalopathy Among Children in North-East India

First Author: Damaris MAGDALENE

Co-Author(s): Phinri BLAH

Purpose: To investigate the association between Hypoxic ischemic encephalopathy and etiology, MRI findings, vision loss, perinatal causes, and gestational age.

Methods: This was a retrospective study of 40 children diagnosed with Hypoxic Ischemic encephalopathy in a tertiary eye care centre over a 1-year period. Basic demographic information was collected from the database. Categorical variables are expressed as the number of patients and the percentage of patients and compared across the groups using Pearson's Chi-Square test for Independence of Attributes/ Fisher's Exact Test as appropriate. Significance of the distributions is calculated using the Frequency Chi-Square Test. Continuous variables are expressed as Mean, Median, and Standard Deviation and compared across the groups using the Mann-Whitney U test/Kruskal-Wallis Test, as appropriate, since the data do not follow a normal distribution.

Results: Of the total 40 children, males were affected more commonly than females, and HIE was more common in children with low birth weight(1500-2499 gm) and lesser gestational age (32-36 weeks)at birth. 52.5% fell under the blindness category IV B, and Visual impairment correlated with abnormal findings on Fundoscopic examination. MRI Brain demonstrated the Cerebral cortex to be the most commonly affected part. Finally, hypoxia caused by neonatal birth asphyxia was found to be the most associated complication in children with Hypoxic Ischemic Encephalopathy.

Conclusions: Children with Low Birth weight, low gestational age at birth, and associated neonatal hypoxia are associated risk factors for HIE.

Panel No.: NEU-0596

Screening for Non-Arteritic Anterior Ischemic Optic Neuropathy (NAION): Can Atherosclerotic Cardiovascular Disease (ASCVD) Risk Scores Contribute?

First Author: Bobby Ramses Erguna SITEPU
Co-Author(s): Cindy Prajna METTA, Rifhani Atthaya PUTRI

Purpose: To evaluate atherosclerotic cardiovascular disease (ASCVD) risk scores in the screening of non-arteritic anterior ischemic optic neuropathy (NAION), considering its vascular etiology and the absence of definitive treatment.

Methods: An observational analytic cross-sectional study was conducted from March 2025 until sample completion. Thirty-seven subjects with cardiovascular risk were enrolled. ASCVD risk was assessed using the WHO cardiovascular risk prediction chart. Ophthalmic examinations included visual field testing, contrast sensitivity, color vision, cup-to-disc ratio, and crowding disc index. Data were analyzed using Mann–Whitney and Kruskal–Wallis tests.

Results: The majority of subjects were in the high ASCVD risk category (37.8%). Functional visual assessment revealed mild visual field defects that may represent early ischemic optic neuropathy. Statistical analysis revealed no significant association between ASCVD risk scores and NAION incidence (Mann–Whitney $P = 0.495$; Kruskal–Wallis $P = 0.266$). However, exploratory analysis suggested that some NAION cases might be associated with smaller cup-to-disc ratios and higher crowding disc index, though these findings did not reach statistical significance.

Conclusions: ASCVD risk scores were not significantly associated with NAION incidence but may still serve as a practical adjunct in identifying individuals with systemic vascular vulnerability. Given the absence of effective therapy, early diagnosis remains central to NAION management. The observed tendency of NAION cases to coincide with higher crowding disc index highlights its multifactorial nature. Combining systemic vascular risk assessment with ocular parameters may strengthen future screening and prevention strategies.

Seeing Beyond the Blood: A Case of Leukemic Optic Neuropathy

First Author: Aneeka Rahnuma ISLAM

Purpose: To describe a rare case of leukemic optic neuropathy and to highlight the importance of considering hematologic malignancies in cases of atypical optic neuropathy.

Methods: A 42-year-old male presented with sudden vision loss in left eye for 7 days. A thorough ophthalmic examination was conducted including visual acuity, pupillary reflex assessment, colour vision, extraocular muscle motility, anterior segment examination and dilated fundoscopy. Hematological investigations were also done. MRI of the brain was performed to evaluate for optic nerve pathology. Based on the clinical, radiological, and hematological findings, a diagnosis of leukemic optic neuropathy was established.

Results: A 42-year-old male presented with painful, sudden visual loss in left eye for 7 days. He was initially diagnosed as optic neuritis. On examination, best-corrected visual acuity was 6/18 in the right eye and CF 1m in the left. RAPD was noted on the left eye. Colour vision was impaired in left eye and extraocular motility was full in all gaze in both eyes. Vitreous cells was present in left eye. Fundus examination revealed optic disc edema with blurred margins in left eye. Complete blood count revealed marked leukocytosis and thrombocytosis. Lymphopenia and the presence of immature myeloid cells were also noted. MRI of the brain demonstrated left optic nerve swelling. A diagnosis of leukemic optic neuropathy was established. The patient was referred to hematologist.

Conclusions: Leukemic optic neuropathy is a neuro-oncologic emergency and warrants immediate intervention to avoid permanent vision loss.

Abstract No.: 201599

Seeing the Unseen: Optical Coherence Tomography and Electroretinography Reveal Hidden Retinal Changes in Chronic Progressive External Ophthalmoplegia

First Author: Cynthia VIRYAWAN
Co-Author(s): Salmarezka DEWIPUTRI

Purpose: To report optical coherence tomography (OCT) and electroretinography (ERG) findings in a patient with chronic progressive external ophthalmoplegia (CPEO) without visible retinopathy, highlighting their role in detecting subclinical retinal changes.

Methods: A 47-year-old male with a 10-year history of progressive bilateral ptosis and ophthalmoplegia presented with visual acuity of 6/6 and 6/12. He reported no blurry vision, night blindness, photophobia, or color vision problems. MRI revealed extraocular muscle atrophy. Electrophysiology showed abnormal repetitive nerve stimulation and single-fiber EMG. He had elevated lactic acid, moderate dysphagia, and premature ventricular contractions. Cholinergic testing was negative. Funduscopy was normal, consistent with CPEO plus syndrome without visible retinopathy. OCT demonstrated reduced central macular thickness with outer retinal thinning, while full-field and multifocal ERG showed rod–cone dysfunction, more pronounced in the left eye.

Results: CPEO is a mitochondrial disorder characterized by ptosis and ophthalmoplegia, with frequent retinal involvement. OCT can detect outer retinal thinning from photoreceptor loss, distinct from inner retinal thinning seen in neurodegenerative disease. In this case, OCT abnormalities correlated with ERG evidence of reduced outer retinal function. Despite variability in ERG findings, both modalities can identify subclinical dysfunction in the absence of visible retinopathy, providing complementary structural and functional evaluation.

Conclusions: OCT and ERG enable detection of subclinical retinal involvement in CPEO without visible retinopathy, supporting their use for monitoring, and differentiation from other neuro-ophthalmic disorders.

Seropositive Neuromyelitis Optica Spectrum Disorder (NMOSD)-Related Optic Neuritis in Hong Kong: Clinical Efficacy of Plasmapheresis and Immunosuppressant Therapy for Visual Recovery

First Author: Clarice SU

Co-Author(s): Carmen K.m. CHAN, Jasmine Clair CHUANG, Matthew LAM, Cherie WONG, Charlene YIM

Purpose: To review the treatment outcomes of plasmapheresis (PLEX) and immunosuppressant therapy (IST) in seropositive NMOSD-ON in Chinese patients.

Methods: In this retrospective case notes study, patients who presented to Hong Kong Eye Hospital between 2001 and 2023 with their first episode of acute ON and positive serology for NMO antibodies were identified. Demographic and clinical data were collected. Analyses were performed using multilevel linear regression modeling with adjustment for correlation between fellow eyes.

Results: 21 Chinese patients (32 eyes) were identified, with 14 patients (66.6%) developing a second episode of ON in the same eye or the fellow eye. The ON episodes of 29/32 eyes (90.6%) were treated with intravenous methylprednisolone (IVMP), and the best-corrected visual acuity (BCVA) after three days of IVMP ($P = 0.007$) and 11 days of oral steroids ($P < 0.001$) were significantly correlated with better BCVA on the latest follow-up. 12 patients (16 eyes, 50%) received PLEX, and the BCVA at latest follow-up was significantly correlated with the VA post-PLEX ($P = 0.048$). 20 patients (95.2%) were subsequently placed on second-line immunosuppressants, and a shorter time to immunosuppressant initiation was associated with better BCVA on the latest follow-up ($P < 0.001$) and longer time to the second episode of ON ($P = 0.030$).

Conclusions: Earlier initiation of second-line immunosuppressants was associated with better final

BCVA and delayed recurrence of a second episode of ON. Larger scale studies are needed to examine other factors associated with better visual prognosis in Asian/Chinese patients.

Similar Faces, Divergent Roots: Bilateral Ptosis With Distinct Genetic Etiologies

First Author: Kaveri BIRLA

Co-Author(s): Poonam, Sonali GUPTA

Purpose: To emphasize the role of detailed history taking in distinguishing between two genetically distinct causes of bilateral ptosis.

Methods: Prospective observational study. Two patients with childhood-onset bilateral ptosis were evaluated through comprehensive clinical assessment, investigations (ice pack test, CK, EMG, antibodies), and genetic testing.

Results: Case 1 had progressive, non-fluctuating ptosis, ophthalmoplegia, and facial weakness—diagnosed with mitochondrial myopathy (POLG mutation). Case 2 showed fluctuating ptosis worsening by evening, positive ice pack test, and responded well to pyridostigmine—diagnosed with congenital myasthenic syndrome (CHRNE mutation).

Conclusions: Despite similar presentations, careful history and targeted testing differentiated two distinct disorders. Clinical implications: This distinction guided appropriate treatment, informed genetic counseling, and prognosis.

The Anti-Cytotoxic Effects of Synthesized Aquaporin-4 (AQP4) Mimotope Peptides in Ex Vivo Optic Nerves

First Author: Shiqi YAO

Co-Author(s): Shaoying TAN

Purpose: To investigate the pathogenic mechanisms of neuromyelitis optica spectrum disorder (NMOSD)-optic neuritis (ON) and new therapeutic developments, we propose to test the effect of synthesized aquaporin-4 (AQP4) mimotope peptides in reducing AQP4-immunoglobulin G (IgG) cytotoxicity to ex vivo optic nerves.

Methods: We have successfully synthesized AQP4 mimotope peptides for the three extracellular loops: mLoops A, mLoops C and mLoops E. Separate experiments will be conducted on the optic nerve tissue of Sprague-Dawley rats and C57BL/6J mice. The optic nerve sections with a thickness of 10 μm were immunostained with AQP4-IgG, total IgG, and AQP4-IgG with different synthesized AQP4 mimotope peptides (mLoops A, C, E, A+C, A+E, C+E and A+C+E),

followed by the appropriate fluorescent antibody. Tissue sections were examined with a Zeiss upright confocal microscope.

Results: The co-localization of GFAP and IgG demonstrated that AQP4-IgG bound specifically to astrocytes. When the epitope peptides were added to IgG, the Loop A, C and E epitope peptide significantly reduced the human IgG-labeled area at the optic nerve ($p < 0.001$). The Loop A+C epitope peptide also eliminated the human IgG-labeled area significantly ($p < 0.01$). The Loop A+E, C+E and A+C+E peptide only reduced the human IgG-labeled area slightly.

Conclusions: Our results demonstrated that AQP4 extracellular mimotope peptides could reduce the cytotoxin by inhibit the binding of AQP4-IgG to astrocytes in ex vivo optic nerves.

The Atrophy of Gray and White Matter Volume in Concomitant Exotropia and Esotropia Adults: A Voxel-Based Morphometric Study

*First Author: Guo **XUERAN***

*Co-Author(s): Jing **FU**, Jie **HAO***

Purpose: This study employed voxel-based morphometry (VBM) analysis through resting-state functional MRI to investigate cortical structural alterations in esotropia (ES) and exotropia (EX) patients.

Methods: Gray and white matter volume (GMV, WMV) were collected from eighteen ES, fourteen EX, and sixteen age-, sex-, and handedness-matched controls (NC). Nonparametric tests assessed structural changes and clinical features across groups. Correlation analysis and multivariate linear regression validated relationships between neuroanatomical measures and clinical characteristics.

Results: Compared to controls, GMV reductions were exhibited in the occipital gyrus and cerebellum in EX patients, and the cerebellar, frontal, and precentral gyrus (PreCG) in ES patients. WMV reductions occurred in the occipital gyrus and postcentral gyrus in EX patients, whereas fusiform and frontal gyrus in ES patients. Correlation analyses identified associations between binocular functions and the GMV of the left cuneus ($r = 0.792/r = 0.736$, $p < 0.05$), left superior occipital gyrus ($r = -0.685$, $p = 0.042$), and right medial frontal gyrus ($r = 0.799$, $p = 0.010$) in EX patients. In the ES group, the near deviation angle ($r = -0.491$, $p = 0.038$) and convergence ($r = -0.517$, $p = 0.040$) were negatively correlated with WMV in the left middle occipital gyrus. Multivariate regression identified the GMV in the right PreCG as a predictor for both EX ($p = 0.005$) and ES ($p = 0.002$).

Conclusions: Concomitant exotropia and esotropia demonstrate distinct gray and white matter atrophy in visual, motor, and cognitive-related brain regions, and correlated with clinical features. PreCG appears particularly involved in strabismus occurrence. These findings provide insights into neural mechanisms underlying strabismus and inform the development of more targeted therapeutic approaches.

The Diagnostic Value of Early Serological Testing in Optic Neuritis – Lessons from Real Cases

*First Author: Yura **PRADIPTAMA***

*Co-Author(s): Salmarezka **DEWIPUTRI**, Syntia **NUSANTI**, Sita **PARAMITA**, Muhammad **SIDIK***

Purpose: Optic neuritis is a condition with overlapping clinical features. Serological testing is essential to differentiate underlying etiologies, prognosis, and optimize management strategies.

Methods: We present four patients with optic neuritis. A 19-year-old female presented with bilateral visual loss, nonspecific MRI findings, and excellent steroid response, but no serology test was performed. Second, A 10-year-old boy with unilateral visual loss and seizures. MRI revealed long optic nerve enhancement, and vision was restored post-steroids, but serology was not checked. Third, A 14-year-old boy also had unilateral visual loss with optic nerve enhancement on MRI, and anti-MOG positivity, confirming Myelin Oligodendrocyte Glycoprotein Antibody-Associated Disease (MOGAD). Lastly, A 25-year-old woman experienced recurrent optic neuritis; her first episode resolved with steroids, while recurrences showed bilateral optic nerve enhancement, and serology testing confirmed MOGAD.

Results: According to the international consensus criteria for optic neuritis 2022 (ICON), 3 patients with compatible symptoms and MRI enhancement fulfilled definite optic neuritis, while 1 patient, with nonspecific imaging, remained possible optic neuritis. However, ICON classification alone does not define etiology. Serological testing, as demonstrated in patients 3 and 4, confirmed MOGAD and supported accurate prognostication. Conversely, missed testing in patients 1 and 2 limited diagnostic certainty, delaying recognition of relapsing potential. Integrating ICON 2022 with timely serology strengthens diagnostic reasoning, enabling tailored management and counseling.

Conclusions: Integration of serological testing with ICON 2022 criteria improves diagnostic accuracy in optic neuritis, distinguishes MOGAD, and helps in long-term management while preventing relapsed disease in optic neuritis.

The Effects of Superoxide Dismutase and Methylprednisolone Administration on Histopathological Findings in a Rat Model of Optic Neuritis

First Author: Fara Haura MURADI

Co-Author(s): Bobby Ramses Erguna SITEPU, Delfi

Purpose: Optic neuritis (ON) is an idiopathic inflammatory demyelinating condition of the optic nerve, vulnerable to degeneration due to energy depletion, reactive oxygen species (ROS) accumulation, and mitochondrial dysfunction. Superoxide dismutase (SOD) may offer neuroprotective benefits by targeting redox dysregulation, helping to halt retinal and retinal ganglion cell (RGC) degeneration. When combined with methylprednisolone (MP), which reduces inflammation, this therapy may accelerate recovery and minimize optic nerve damage. The ASK1- p38 pathway further supports this combined mechanism. Aim: To evaluate the effects of SOD and MP administration on optic nerve damage in a rat model of optic neuritis.

Methods: This was a randomized, post-test only, control group laboratory experiment involving five groups: sham, control (ON only), SOD (ON + 100 mg/kg/day), MP (ON + 30 mg/kg/day), and combination therapy (SOD 50 mg/kg/day + MP 15 mg/kg/day). Data were analyzed using One- Way ANOVA or Kruskal-Wallis test.

Results: The combination group demonstrated the most favorable outcomes, with the highest average RGC count (195 cells), minimal optic nerve edema ($p < 0.001$), and demyelination levels similar to normal.

Conclusions: Combined administration of SOD and MP provided better histopathological outcomes—reflected in ganglion cell preservation, reduced edema, and minimal demyelination—than either treatment alone in this rat model of optic neuritis.

The Many Faces of Mitochondrial Dysfunction

First Author: Nishi SATISH

Co-Author(s): Sangeeta ABROL

Purpose: This prospective case series describes the various presentations of mitochondrial diseases in the eye.

Methods: Eleven patients were included in this study, broadly classified into three main presentation types - Leber Hereditary Optic Atrophy, Chronic Progressive External Ophthalmoplegia (including Kearns Sayre Syndrome) and Neuropathy Ataxia with Retinitis Pigmentosa. A thorough history, systemic and ocular examination was done in each case. With sufficient

data in the clinical examination a biopsy (where indicated) as well as genetic studies were done.

Results: Although the clinical presentation of each case seemed vastly different, a common link could be established with respect to the history and systemic findings. Sibling involvement was seen in each presentation of the disease and genetic panel testing confirmed the diagnosis of various mitochondrial gene mutations.

Conclusions: This series describes findings that should raise suspicion of mitochondrial diseases. A thorough clinical examination usually helps us arrive at a diagnosis of these mitochondrial diseases. Genetic panel testing provides the definitive diagnosis, however, it cannot be done unless one is sure of their clinical examination.

Abstract No.: 205445

Panel No.: NEU-0611

Unmasking Early Maculopathy in Short-Term Hydroxychloroquine Users

First Author: Indah SARASWATI

Co-Author(s): Salmarezka DEWIPUTRI, Anggun Rama YUDANTHA

Purpose: Hydroxychloroquine (HCQ) retinopathy often progresses silently and may evade early clinical detection. Multifocal electroretinogram (mfERG) provides an objective and sensitive method for identifying parafoveal or extramacular wave depression in the early stages of retinopathy. This study aimed to evaluate mfERG alterations in systemic lupus erythematosus (SLE) patients, stratified by HCQ treatment duration.

Methods: In this cross-sectional study, 130 eyes of SLE patients undergoing HCQ therapy were categorized into two groups: ≤ 5 years and > 5 years of treatment. Multifocal ERG was performed using a standard 61-hexagon protocol, assessing amplitude and implicit time across rings R1-R5 based on first-order kernel responses. According to established criteria, maculopathy was classified as normal, early or advanced stages. The mfERG findings was compared with spectral domain optical coherence technology (SD-OCT) and ultra-wide field fundus autofluorescence (UWF-FAF) imaging.

Results: The majority of participants were women, aged 30-45 years. Patients treated with HCQ for ≤ 5 years had significantly lower in P1 amplitudes compared with the > 5 years group, particularly in ring 2-3 ($p < 0.05$). The ring ratio of P1 amplitude in ≤ 5 years group started to decrease, and the R2:R5 amplitude ratio in this group was lower than the other group ($p = 0.046$). Early maculopathy was more prevalent in the ≤ 5 years group (58.5%) than the other group (49.2%). The outer retinal layer thinning was more prominent in the > 5 years of HCQ use, yet up to 95%

of patients with advanced maculopathy in both groups demonstrated normal UWF-FAF findings.

Conclusions: Multifocal ERG is a sensitive modality for detecting early functional changes in HCQ retinopathy and may serve as a useful adjunct to structural imaging. Screening with mfERG in combination with OCT and/or UWF-FAF imaging, might be considered particularly within the first five years of HCQ therapy.

Abstract No.: 207315

Panel No.: NEU-0632

Unmasking Metastatic Lung Cancer Through Orbital Apex Syndrome

*First Author: Nandita **TRIVEDI***

*Co-Author(s): Kanchita **PANDEY**, Pranita **SAHAY***

Purpose: Orbital apex syndrome is a rare eye disorder that can signal serious, potentially fatal systemic disease. This case underscores the need to recognize subtle ocular signs and investigate promptly, as early detection may reveal conditions like metastatic cancer.

Methods: A woman in her 60s experienced a week of worsening vision loss and limited eye movement with fever, headache, and vomiting. Examination showed fever, enlarged submandibular lymph nodes, and scalp and dorsal nodules. Vision was 20/30 in the right eye and hand movements in the left, with a left relative afferent pupillary defect, esotropia, and abduction deficit; fundus was normal.

Results: A provisional diagnosis of left eye ocular apex syndrome (OAS) was made. A comprehensive neurology and dermatology work-up was done. CE-MRI brain and orbit suggested an asymmetric enhancing lesion of the cavernous sinus, soft tissue involvement of the left orbital apex and a nodule involving the white matter of the left parietal lobe. FNAC of submandibular lymph nodes and nodules of the scalp & dorsum was suggestive of metastatic mucin-secreting adenocarcinoma. Tumor marker analysis revealed raised CEA and CA-125. Further PET scan revealed active lesions in the lungs with multi-organ spread supporting the diagnosis of primary lung carcinoma with disseminated metastases manifesting as OAS.

Conclusions: Orbital apex syndrome due to orbital metastasis can be the primary presentation in cases of lung cancer. It is associated with grave etiologies that warrant a meticulous workup. A multi-disciplinary team approach is needed in the management of these cases.

Abstract No.: 200861

Panel No.: NEU-0570

Unveiling Hidden Culprits: Posterior Ischemic Optic Neuropathy in Two Vascular-Driven Cases

*First Author: Yue **FU***

*Co-Author(s): Yang **HUI***

Purpose: To explore two rare cases of posterior ischemic optic neuropathy (PION) causing sudden monocular blindness, emphasizing advanced imaging to differentiate PION from optic neuritis.

Methods: Two patients with acute unilateral vision loss were analyzed. Case 1: A 29-year-old male with right eye no light perception post-headache. Case 2: A 41-year-old female with left eye hand motion vision post-bilateral internal carotid artery (ICA) stenting, complicated by hypotension. Evaluations included visual acuity, fundus photography, OCT, VEP, FFA, ICGA, MRI with DWI/ADC, CTA, and DSA.

Results: In Case 1, steroid-resistant vision loss and right ophthalmic artery stenosis (80% on DSA) were noted. MRI showed intracanalicular optic nerve T2 hyperintensity, enhancement, and DWI/ADC diffusion restriction. Fundus was normal initially, with optic atrophy at 1 month. In Case 2, perioperative hypotension triggered PION. MRI revealed left intracranial optic nerve DWI hyperintensity, ADC hypointensity, and mild enhancement. Both cases showed RAPD, normal initial fundus, and poor visual recovery.

Conclusions: PION, linked to intracranial vascular pathology, mimics optic neuritis but resists steroids. MRI DWI/ADC confirms ischemic diffusion restriction, while DSA/CTA reveals vascular stenoses, enhancing diagnostic precision in these vision-threatening cases.

Abstract No.: 207326

Panel No.: NEU-0633

Vision at Stake: A Multidisciplinary Steroid-Surgical Strategy in a One-Eyed Patient With Graves' Ophthalmopathy

*First Author: Hindun **ZAKIYAH***

*Co-Author(s): Anya **DEWI**, Salmarezka **DEWIPUTRI**, Michael **HARTONO**, Yunia **IRAWATI***

Purpose: To present the multidisciplinary management strategy for a one-eyed patient with sight-threatening Graves' ophthalmopathy (GO).

Methods: We report a 41-year-old man with sight-threatening active GO in his only eye, managed successfully with high-dose steroids and three-wall orbital decompression.

Results: The patient had a history of uncontrolled hyperthyroidism and right eye evisceration following severe GO-related complications 10 years earlier. At presentation, the remaining eye was markedly

proptotic, measured 28 mm by exophthalmometry, painful, red, and had reduced visual acuity to 0.70. The Clinical Activity Score (CAS) was 5. He also exhibited lagophthalmos and severe corneal exposure with diffuse punctate keratopathy and ulceration. Orbital CT demonstrated bilateral extraocular muscle enlargement, retrobulbar fat expansion, and stretched optic nerves. Corneal scraping revealed Gram-positive bacilli. A diagnosis of active thyroid eye disease with dysthyroid optic neuropathy and exposure keratitis was established. The case was deemed urgent and required immediate intervention, including tarsorrhaphy, topical antibiotics, and high-dose intravenous methylprednisolone, starting with 750 mg on alternate days followed by three cycles of 500 mg, along with immunosuppressive therapy. After the inflammation subsided, the patient underwent nasoendoscopic three-wall orbital decompression with fat removal. Postoperatively, visual acuity improved to 0.10, proptosis decreased, and corneal healing was achieved. Given the favorable functional recovery, orbital radiotherapy was scheduled to maintain long-term disease control.

Conclusions: In sight-threatening GO, particularly in one-eyed patients, combined steroid therapy and orbital decompression can preserve vision. This case highlights that early recognition of active disease, tailored immunosuppression, and planned radiotherapy within a multidisciplinary framework are essential for achieving optimal outcomes.

Abstract No.: 206654
Panel No.: NEU-0629

When Disc Swelling Isn't Papilloedema: A Pediatric Masquerade Syndrome

First Author: Nabila RAHMAN
Co-Author(s): Tasnima RAHMAN, Mostafa HOSSAIN

Purpose: To present a rare pediatric case of bilateral ODD with vitreous cells, raising suspicion of atypical retinitis pigmentosa (RP).

Methods: A 9-year-old boy presented for a routine ophthalmic checkup. His ocular history included astigmatism, corrected with spectacles for 6 months. Comprehensive ocular examination, fundus evaluation, B-scan ultrasonography, and color fundus photography were performed. Family history was obtained in detail.

Results: Fundus examination revealed bilateral disc swelling in an otherwise asymptomatic child, with no headache, vomiting, or recent systemic illness. Pupillary reactions were normal. B-scan confirmed optic disc drusen in both eyes. Unexpectedly, vitreous cells were present bilaterally, though color fundus photography showed no overt retinal pathology. Family history revealed nyctalopia in the patient, his father, and grandmother, strongly suggestive of inherited retinal dystrophy, most likely atypical RP. The

coexistence of ODD, vitritis, and hereditary nyctalopia indicated a possible masquerade syndrome.

Conclusions: This case highlights the importance of detailed evaluation in asymptomatic pediatric patients with disc swelling. Bilateral optic disc drusen associated with vitreous cells may represent more than incidental findings. The strong family history of night blindness raises suspicion of atypical retinitis pigmentosa masquerading as an inflammatory disease. Early recognition is crucial for appropriate genetic counseling, patient education, and long-term follow-up.

Abstract No.: 206531

When Pressure Builds: A Case of Bilateral Papilledema Secondary to Medulloblastoma

First Author: Joanna Mariz MENDOZA
Co-Author(s): Stephanie Suzanne GARCIA, Maria Karina MONTESINES

Purpose: To present a case of bilateral papilledema in a pediatric patient with medulloblastoma.

Methods: Case report.

Results: A 9-year-old male presented with a 2-month history of bitemporal headaches, nausea, and vomiting associated with bilateral eye pain and gait abnormality. During initial pediatric consults, he was treated for urinary tract and gastrointestinal conditions with temporary resolution of symptoms. Due to the persistence and increasing severity of symptoms, the patient was referred to the ophthalmology service. Visual acuity of the patient was 20/20 on both eyes, and pupils were 3-2 mm briskly reactive to light, with no noted relative afferent pupillary defects. Fundoscopy revealed bilateral Frisen grade IV papilledema. Cranial CT with IV contrast showed a heterogeneously enhancing mass in the cerebellar vermis measuring 3.7 x 5.0 x 3.9 cm, compressing the fourth ventricle, causing obstructive hydrocephalus. The patient underwent emergency ventriculoperitoneal shunting, tumor excision, and biopsy. Histopathology results were consistent with medulloblastoma.

Conclusions: Papilledema is a common sign seen in children with posterior fossa tumors. This case demonstrates the role of ophthalmologists and the importance of prompt multidisciplinary management to avoid delays in definitive diagnosis and management and prevent both sight and life-threatening complications.

When Treatment Threatens Vision: A Case Series of Reversible Linezolid-Induced Toxic Optic Neuropathy in Multidrug-Resistant Tuberculosis

*First Author: Sita Paramita **AYUNINGTYAS***

*Co-Author(s): Irma **NUR FADHILAH***

Purpose: Multidrug-resistant tuberculosis (MDR-TB) is prevalent in developing countries. Linezolid is a second-line treatment option for MDR-TB. Despite its effectiveness, it may harm vision. We highlight the clinical presentation and outcomes of toxic optic neuropathy related to linezolid therapy.

Methods: We report a case series of four male patients who developed visual impairment while receiving linezolid for MDR-TB. The first patient, a 43-year-old on 7 months of treatment and 3 years of antiretroviral therapy, complained of bilateral blurred vision with best-corrected visual acuity (BCVA) 6/12 of the right eye (RE), 6/9 of the left eye (LE). The second, a 60-year-old, reported bilateral vision loss on the 7th month of therapy (BCVA 1/60 in both eyes (BE)). The third, a 30-year-old on the 18th month of therapy, developed visual impairment with BCVA of 6/24 RE and 6/9.5 LE. The fourth, a 48-year-old, developed bilateral vision loss after 5 months of linezolid with BCVA 3/60 in BE. Color vision and visual field defects were observed in all patients.

Results: The first, third, and fourth patients achieved full recovery to 6/6 BE after 8, 4, and 12 weeks, respectively, following linezolid cessation. The second patient, BCVA improved to 6/24 RE and 6/6 LE at 2 months after stopping linezolid. Visual field and color vision defects also improved.

Conclusions: Close monitoring is mandatory for patients receiving prolonged linezolid therapy. Linezolid should be discontinued in patients who develop visual impairment suggestive of toxic optic neuropathy, as early discontinuation is associated with favorable visual outcomes.

When the Orbit Whispers: Diagnostic Challenges in NeuroOphthalmology From Mongolia

*First Author: Delgerzul **BAT***

*Co-Author(s): Purevdolgor **GANSUKH**, Bilguun-ochir **GANZORIG***

Purpose: To highlight the diagnostic complexity of neuroorbital disease through three illustrative cases, underscoring the role of timely neuroimaging and multidisciplinary evaluation in optimizing visual outcomes.

Methods: A retrospective review was conducted of three consecutive patients (2022–2024) who presented with atypical neuroophthalmic symptoms. Clinical presentation, imaging findings, management approaches, and visual outcomes were analyzed.

Results: A 43-year-old woman presented with painless unilateral vision loss and optic disc pallor; subsequent MRI demonstrated optic nerve sheath meningioma (ONSM) with classic “tramtrack” and “doughnut” signs. Definitive imaging and multidisciplinary consultation were obtained after initial surgical intervention by the neurosurgery department, which unfortunately resulted in irreversible vision loss. A 67-year-old woman with unilateral proptosis was initially considered for common orbital disease; later imaging identified a sphenoid wing meningioma compressing the lateral rectus muscle. Stereotactic radiotherapy was initiated. A 49-year-old woman with intermittent vertical diplopia and subtle nystagmus underwent MRI, revealing a dorsal midbrain ring enhancing lesion. Positive syphilis serology confirmed neurosyphilis, and intravenous penicillin led to lesion resolution and symptomatic improvement.

Conclusions: ONSM characteristically presents with insidious vision loss and distinctive imaging findings; sphenoid wing meningiomas may resemble benign orbital conditions; neurosyphilis remains a treatable cause of central nervous system lesions. These cases emphasize the importance of early imaging, clinical vigilance, and multidisciplinary collaboration to reduce preventable visual morbidity, particularly in resource-limited settings.

24–2C Grids to Detect Central Visual Field Function in Early-Stage Primary Open Angle Glaucoma: A Prospective Study

*First Author: Yu **CAI***

*Co-Author(s): Xunkai **MA**, Yanfei **ZHU***

Purpose: The recently introduced 24-2C SITA-Faster incorporates 10 testing points derived from 10-2 grid into the 24-2 grid, potentially increasing the sensitivity for initial central field evaluation in glaucoma. However, few studies have compared the visual field defects (VFDs) newly identified by 24-2C with 24-2 in early-stage of primary open-angle glaucoma (POAG) and newly detected “clusters” with their structure–function concordance.

Methods: This prospective, cross-sectional study enrolled 72 patients with POAG. Sixty-three eyes from 40 patients with a mean deviation (MD) < 6 dB by Humphrey 24-2 were subjected to 24-2C and 10-2. The

consistencies between 24-2C and 24-2, or 10-2 were evaluated using Bland–Altman figures. 24-2C newly discovered defects compared with 10-2 point-by-point. Patients were divided into groups I and II based on whether newly defective points met the “cluster” criterion. (at least three continuous points at $P < 0.05$, including a minimum of one point at $P < 0.01$). Both groups underwent optical coherence tomography Optovue RTVue-100 to determine if there were corresponding structural differences.

Results: There were good consistencies between either 24-2C with 24-2, or 10-2. Bland–Altman plots demonstrated most eyes fell within the 95% limits of agreement in MD, pattern standard deviation (PSD) and central mean sensitivity (CMS). Meanwhile higher consistency was detected between 24-2C and 10-2, as regression analysis revealed there were no significant trends in bias changing along with the above three index values variation between 24-2C and 10-2 ($P > 0.05$). Test duration was significantly shorter in 24-2C than 24-2 (24-2C, 157[139, 178] seconds; 24-2, 166[139, 202] seconds, respectively, $P < 0.05$). 96 defective points were newly detected by 24-2C. 57 (57/96, 59.38%) points were consistent with 10-2 through point-by-point comparison. It indicated a high reliability of 24-2C results in the early stage of POAG. The average Ganglion Cell Complex (GCC) thickness of Group I (with “clusters”) was significantly thinner than that of Group II (without “clusters”). GLV and FLV of Group I were also significantly greater than Group II ($P < 0.05$). Our study was the first to apply a more stringent «cluster» criterion in comparison to newly detected defective points by 24-2C. It indicated VFDs newly discovered correlated well with GCC.

Conclusions: 24-2C had good consistency with both 24-2 and 10-2, especially highly consistent with 10-2. The additional central VFDs identified by 24-2C comparing with 24-2 correlated well with 10-2. Newly identified VFDs meeting with the “cluster” criterion also corresponded well with GCC in the early stages of POAG. It suggests that 24-2C could assist in detecting central VFDs in 10 degrees, the same as 24 degrees, in the early stage of glaucoma with a shorter test duration. 24-2C may detect central VFDs to improve patients’ quality of life much earlier.

Adaptive Optics Cone Density Measurement as a Sensitive Structural Biomarker of Macular Progression in EYS-Associated Retinitis Pigmentosa

First Author: Masakazu **HIRAOKA**

Co-Author(s): Kiyoko **GOCHO**, Yasuo **KURIMOTO**, Akiko **MAEDA**, Yuki **TOGASHI**, Midori **YAMAMOTO**

Purpose: To determine whether macular cone density (CD) measured with adaptive optics (AO) sensitively

tracks disease progression in EYS-associated retinitis pigmentosa (RP) and to examine its relationships with visual function.

Methods: Prospective subset analysis of 27 patients (27 eyes) with EYS-associated RP. At 6-month intervals over 24 months, best-corrected visual acuity (BCVA), AO flood-illumination imaging (rtx1; CD at 2° and 4° along nasal and temporal meridians), and 10-2 Humphrey Field Analyzer (HFA) testing were obtained. CD was compared with BCVA and HFA mean deviation (MD).

Results: Mean age was 44.0 ± 11.5 years. At baseline, macular CD (cells/mm²; mean $\pm$ SD) was $11,156 \pm 4,331$ (2N), $9,786 \pm 3,280$ (4N), $11,514 \pm 3,385$ (2T), and $10,075 \pm 2,684$ (4T). CD showed a significant decrease across all loci by 6 months and continued to decline throughout follow-up; mean 6-month reductions were 9.8% (2N), 9.6% (4N), 7.6% (2T), and 11.3% (4T). BCVA and HFA mean deviation (MD) showed no significant longitudinal change over 24 months. Correlations were weak: CD vs BCVA $r = 0.22$ (2°) and 0.21 (4°); CD vs MD $r = 0.002$ (2°) and -0.20 (4°).

Conclusions: AO imaging detects short-interval loss of macular CD while BCVA and MD remain stable, supporting CD as a sensitive structural biomarker of RP progression and a tool to shorten observational periods in clinical studies.

An Efficient Approach to Estimate the Risk of Coronary Artery Disease for People Living With HIV Using Machine-Learning-Based Retinal Image Analysis

First Author: Mary **HO**

Co-Author(s): Marten **BRELEN**, Gabriel **LI**, Grace **LUI**

Purpose: People living with HIV (PLWH) have a higher risk of non-communicable diseases, particularly cardiovascular diseases (CVD). Current HIV management guidelines recommend regular cardiovascular risk screening, but existing risk models are not specific to PLWH. Improved tools are needed to accurately assess cardiovascular risk in this population.

Methods: We conducted a prospective study to evaluate automatic retinal image analysis in assessing coronary artery disease (CAD) in PLWH. Participants included PLWH with at least one cardiovascular risk factor. All underwent computerized tomography (CT) coronary angiogram and digital fundus photography. Coronary atherosclerosis was the primary outcome, while obstructive CAD was a secondary outcome. We compared three models: traditional cardiovascular risk factors alone, retinal characteristics alone, and a combined model using both traditional and retinal characteristics, by comparing the area under the curve (AUC) of receiver operating characteristic curves.

Results: Among 115 participants (mean age 54 years, 89% male, 95% with undetectable HIV RNA), 61.7% had coronary atherosclerosis and 20.0% had obstructive CAD. Models incorporating retinal characteristics (with or without traditional risk factors) outperformed traditional risk factors alone in detecting coronary atherosclerosis (AUC 0.987 and 0.979 vs. 0.746). The combined model showed sensitivity and specificity of 93.0% and 93.2%, respectively, for coronary atherosclerosis.

Conclusions: In this cohort of Asian PLWH at risk of CVD, retinal characteristics, either alone or combined with traditional risk factors, significantly improved the assessment of coronary atherosclerosis and obstructive CAD.

Atypical Occlusions: Unusual Etiologies of Central Retinal Vein Occlusion — A Case-Based Perspective

First Author: Sudha **RANABHAT**

Co-Author(s): Priya **BAJGAI**, Kiran **SHAKYA**

Purpose: To highlight uncommon etiologies of central retinal vein occlusion (CRVO) and emphasize the importance of systemic workup in patients without conventional risk factors.

Methods: We report three-cases of CRVO with atypical associations: hyperhomocysteinemia linked to alcohol dependancy, isolated hyperhomocysteinemia, and long-term Olanzapine therapy. Ocular examination, multimodal imaging, systemic investigations and multidisciplinary consultations were performed to establish the underlying etiology.

Results: Case 1: A 46-year male with chronic alcohol dependence presented with bilateral CRVO, non-ischemic in right eye (RE), ischemic in left eye (LE). Elevated plasma homocysteine (41.8 $\mu\text{mol/L}$) was identified as the primary cause, likely aggravated by alcohol-induced vitamin deficiency. Treatment with folate, vitamin B6, vitamin B12, and intravitreal bevacizumab improved macular edema but visual recovery was limited in the LE at three months. Case 2: A 26-year healthy male presented with non-ischemic CRVO in the RE and plasma homocysteine of 30.8 $\mu\text{mol/L}$. Patient responded favorably to vitamin supplementation and two intravitreal bevacizumab injections, with complete visual recovery at seven months. Case 3: A 67-year-old female on Olanzapine for schizophrenia* 22 years developed ischemic CRVO in RE. Systemic evaluation excluded vascular and infectious etiologies. Olanzapine was discontinued after psychiatric consultation. Despite intravitreal bevacizumab therapy, at six months, visual recovery was limited due to severe ischemia.

Conclusions: Hyperhomocysteinemia, alcohol consumption, and olanzapine therapy represent rare but important etiologies. Comprehensive systemic evaluation, including metabolic and drug history, is essential in atypical cases of CRVO. Early recognition of such associations allows targeted systemic intervention in addition to ocular therapy, potentially reducing recurrence and systemic thromboembolic complications.

Panel No.: OIM-0655

Automated Identification and Quantification of Nonperfusion Area (NPA) on Ultra-Widefield Swept-Source OCT Angiography (SS-OCTA) in Diabetic Retinopathy: Development of Customized Deep Learning Algorithm in the DRIVE Study

First Author: Tai Yong **LOH**

Co-Author(s): Yue **QIU**, Wei Hing **SEAH**, Juling **SIA**, Sandy **ZHOU**, Lingyi **ZHUANG**

Purpose: To evaluate the efficacy of a customized deep learning algorithm for automated quantification of nonperfusion area (NPA) on ultrawide-field swept-source OCT angiography (UWF SS-OCTA) for diabetic retinopathy (DR) severity assessment.

Methods: A convolutional neural network (CNN) based on a multi-scale U-Net backbone with squeeze-and-excitation attention was developed to segment NPAs on en-face SS-OCTA all-retinal-layer (ARL) images acquired using three scan protocols: 6 x 6 mm, 12 x 12 mm, and 29 x 24 mm. The manual ground truth annotations of NPAs on en-face OCTA images were provided by two independent graders and adjudicated by a vitreoretinal specialist. The en-face structural OCT image was incorporated into a separate channel to aid in identification of true NPA. In addition, we implemented a novel preprocessing pipeline to exclude non-gradable regions caused by artifacts. Segmentation outputs yielded total NPA and NPA index (NPI) as the fraction of NPA over gradable area. Pixel-level accuracy was summarized with the F1 score.

Results: Our deep learning algorithms achieved a mean F1 score of 0.83 ± 0.01 in 6 x 6 mm, 0.83 ± 0.02 in 12 x 12mm, and 0.83 ± 0.02 in 29 x 24mm. F1 score was invariant across different FOVs ($p = 0.133$). NPI quantification achieved strong agreement between the algorithm and the independent human grader, indicating its clinical utility. Both AI prediction and ground truth labelling showed NPI rising significantly with increased DR severity in 6 x 6 mm ($p = 0.03$), 12 x 12 mm ($p < 0.001$), and 29 x 24 mm images ($p < 0.001$). The magnitude of increase in NPI was the most significant in 29 x 24 mm images and the least significant in the 6x6 mm images.

Conclusions: This CNN-U-Net-based algorithm enables accurate quantification of NPAs across various FOV, including UWF on SS-OCTA.

Comparative Detection of Neovascularization and Intra-Retinal Microvascular Abnormalities in Diabetic Retinopathy: Color Fundus Photography vs. Swept-Source OCT Angiography in Cataract Patients

First Author: Pavan **PANIHARAM**

Co-Author(s): Yusra **ASAD**, Ser Koon **GOH**, Sandy **ZHOU**

Purpose: To compare the detection and quantification of neovascularization (NV) and intra-retinal microvascular abnormalities (IRMA) between color fundus photography and swept-source OCT angiography (SS-OCTA) in diabetic patients, and to assess the impact of lens status on this difference.

Methods: This prospective study included 64 eyes from 39 diabetic patients. All eyes underwent color fundus photography (graded using ETDRS criteria- gold standard) and ultra-widefield SS-OCTA (26×21 mm and 29×24 mm). Two masked graders independently assessed both modalities for the presence and number of NVs and IMRAs. Both detection rates and counts were compared between imaging modalities and stratified by lens status (phakic vs. pseudophakic) as well as cataract status using Shapiro-Wilk and Wilcoxon Signed-Rank tests.

Results: SS-OCTA identified significantly more NVs and IMRAs than fundus photography and detected a higher number of lesions overall. This difference was evident in both phakic and pseudophakic eyes, but more pronounced in the phakic group. In phakic eyes, OCTA revealed a greater number of NVs and IMRAs compared to fundus photos, likely due to cataract-related media opacity. In pseudophakic eyes, the difference in NV and IRMA counts between OCTA and fundus photography was smaller but still significant.

Conclusions: SS-OCTA outperforms color fundus photography in detecting and quantifying neovascularization and IRMA in diabetic eyes, with cataracts further limiting the sensitivity of fundus imaging. Ultra-widefield SS-OCTA is an increasingly useful tool enabling efficient and timely diagnosis as well as quantification of the severity of disease in DR patients, hence facilitating prompt initiation of treatment and optimisation of individualised follow-up intervals, enhancing patient care.

Abstract No.: 203778

Comparison of Macular Ganglion Cell Layer and Peripapillary Retinal Nerve Fiber Layer Thickness for Early Glaucoma Detection Using Optical Coherence Tomography

First Author: Ruth Lyra **YAP**

Co-Author(s): Irene **FELARCA**, Maria Imelda **YAP-VELOSO**

Purpose: To compare the diagnostic capability of macular ganglion cell layer (mGCL) thickness and peripapillary retinal nerve fiber layer (pRNFL) thickness, measured by optical coherence tomography (OCT), in differentiating normal eyes, glaucoma suspects, and early, moderate, and severe glaucomatous eyes.

Methods: A prospective cross-sectional study was conducted involving adult subjects divided into normal, glaucoma suspect, and early, moderate, and severe glaucoma groups. Mean thickness values for mGCL and pRNFL were measured using Cirrus HD-OCT. Area under the receiver operating characteristic curve (AUC), sensitivity, and specificity were calculated to determine diagnostic accuracy.

Results: Both mGCL and pRNFL thickness progressively decreased from normal to suspect to early, moderate, and severe glaucomatous eyes. For distinguishing normal from early glaucoma, mGCL achieved an AUC of 0.74 with sensitivity of 66.7% and specificity of 82.6%, while pRNFL showed an AUC of 0.72, sensitivity of 48.2%, and specificity of 91.3%. Differences in AUCs were not statistically significant across all groups. Sectoral thinning in the superotemporal and inferotemporal macula was noted early in disease progression.

Conclusions: mGCL thickness analysis may provide complementary value to pRNFL measurement in detecting early glaucomatous changes. Combined evaluation can enhance structural assessment, supporting earlier diagnosis and timely management of glaucoma.

Comparison of Ocular Parameters and Target Refractive Error in Chinese Subjects Aged 50 and Above Using CASIA2 Anterior Segment Optical Coherence Tomography and Oculus Pentacam AXL

First Author: Hoi Ching **PANG**

Co-Author(s): Kendrick Co **SHIH**

Purpose: To compare the ocular parameters and target refractive error in Chinese emmetropic, hypermetropic, and myopic eyes, obtained by two optical biometric instruments: the CASIA2 AS-OCT (Tomey, Japan) and

Pentacam AXL (Oculus, Germany), using two different IOL power calculation formulae.

Methods: The right eye of 174 consecutive subjects above 50 underwent biometric assessment using CASIA2 and Pentacam AXL devices in this random population-based cross-sectional study. Ocular parameters and target refractive error were compared using a constant IOL SEQ equal to 19.50. Measurements expressed as mean and standard deviation. Differences between devices, using Barrett UII and SRK/T formulae, and across emmetropes, hypermetropes, and myopes were determined using the Wilcoxon signed-rank test and the Kruskal-Wallis test. The agreement in ocular biometry and IOL power between the 2 devices was evaluated by the Bland-Altman method.

Results: A total of 174 eyes of 174 subjects were analyzed. Mean age was 60.49; 66.67% were female; 134 emmetropes, 7 hypermetropes, 33 myopes. No significant differences in measured ocular parameters between devices and across emmetropes, hypermetropes and myopes. For target refractive error, statistically significant differences were noted for all three groups, with the difference being highest using Barrett UII formula and in myopes (0.31 ± 0.22), followed by emmetropes (0.26 ± 0.27), then hypermetropes (0.25 ± 0.29). There were no statistically significant differences in target refractive error between the two formulae.

Conclusions: Despite using different imaging principles, the parameters obtained by the two devices are comparable across a range of axial lengths. There were statistically significant differences in target refractive error between devices, but these would be within a clinically acceptable margin of error.

Concurrent Ocular and Cerebral Toxoplasmosis: Delayed Diagnosis of HIV

First Author: Reema BANSAL

Co-Author(s): Shilpa SABU

Purpose: Concurrent ocular and cerebral toxoplasmosis are very rare. We report the role of ocular imaging in diagnosing ocular toxoplasmosis in an atypical posterior uveitis. Subsequently, cerebral imaging and serological investigations revealed cerebral toxoplasmosis and HIV.

Methods: An 18-year-old woman had decreased vision (counting fingers) in her left eye for two months. Fundus examination showed a large, creamish-yellow, subretinal lesion with exudative retinal detachment, mimicking a subretinal abscess. She reported worsening of symptoms after oral corticosteroids were prescribed elsewhere. Multimodal imaging was done. Optical coherence tomography (OCT) revealed punctate vitreous opacities, retinal thickening with loss of retinal layer details ('Smudge effect'), posterior

hyaloid thickening, choroidal shadowing, and serous retinal detachment. Ocular toxoplasmosis was suspected. Toxoplasma gondii IgG was positive and IgM equivocal. She received intravitreal and oral anti-Toxoplasma therapy.

Results: At 3 weeks, the lesion showed healing. However, the patient appeared lethargic and confused. MRI brain revealed a well-defined lesion with altered intensity in the right thalamus that was isointense on T1 and T2, suggestive of cerebral toxoplasmosis. With no known history of immunocompromised status, a detailed systemic evaluation revealed positive HIV-1. The patient was referred for Highly Active Antiretroviral Therapy. At 3 months, the fundus showed scarring, with 3/60 vision.

Conclusions: Cerebral toxoplasmosis is seen in immunocompromised individuals, particularly in HIV infected individuals without treatment or prophylaxis. In this case, a clinical diagnosis of ocular toxoplasmosis based on imaging (OCT) findings led to the diagnosis of cerebral toxoplasmosis, and a delayed diagnosis of HIV-1 in an unmarried young woman.

Detecting Visual Field Progression by Cluster MD vs Global MD Trend Analysis Among Glaucoma Patients in the Philippine National Specialty Center for Eye Care

First Author: Erick Reagan ONG

Co-Author(s): John Mark DE LEON, Daryle Jason YU

Purpose: To compare glaucomatous VF progression identified by cluster MD trend analysis versus global MD trend analysis among glaucoma patients.

Methods: This retrospective study included glaucomatous eyes with at least 4 reliable visual field (VF) tests conducted using the EyeSuite® software on the Octopus® 900 perimeter. All tests were performed with the G-standard dynamic strategy with a minimum follow-up of one year. Eyes with other ocular conditions affecting VF or those that underwent cataract surgery during the follow-up period were excluded. The perimeter software grouped VF test points into functionally related clusters, each labeled numerically for individual trend analysis. Progression analysis was performed using software-generated linear regression, identifying statistically significant changes at $p < 0.05$ and $p < 0.01$ levels for both global and cluster trends. Eyes identified with progression in at least one cluster were classified as progressing.

Results: A total of 71 glaucomatous eyes were included in the study. The mean patient age was 66 years ($SD=9.0$) and the majority were female (76.1%). The most common diagnosis was angle-closure glaucoma (32.4%), followed by normal-tension glaucoma (25.4%), and primary open-angle glaucoma (15.5%).

At baseline MD, 29 eyes (40.85%) had mild glaucoma, 31 (43.66%) had moderate, and 11 (15.49%) had severe glaucoma. Each eye had a median of 5 VF tests (IQR=4.0), with a mean follow-up duration of 11.77 ± 3.12 months between the first and last tests. The mean baseline LogMAR visual acuity was 0.096 (SD=0.175) and 0.103 (SD=0.136) at the final visit. Global MD trend analysis identified progression in 2.82% of eyes at the $p < 0.05$ level and in 1.41% at the $p < 0.01$ level. In contrast, cluster MD trend analysis detected progression in 38.03% and 19.72% of eyes at the same level of significance respectively. Among the ten clusters, cluster 5 was most frequently flagged in the uncorrected analysis at $p < 0.05$, while cluster 6 in the corrected cluster analysis. At $p < 0.01$ level, uncorrected cluster 6 showed the highest frequency of progression, whereas clusters 1 and 10 in the corrected cluster. By the end of the follow-up period, cluster analysis identified a significantly greater number of progressing visual fields compared to global analysis at both the $p < 0.05$ ($p < 0.001$) and $p < 0.01$ ($p = 0.002$) thresholds. Cluster analysis detected a higher proportion of progression in eyes with mild (55.17%) and moderate (41.94%) glaucoma compared to global analysis which identified progression in only 3.45% and 6.45% of these cases respectively ($p = 0.066$). The mean time to progression was significantly shorter in cluster analysis (6.14 ± 11.74 months) compared to global analysis (31 ± 17.32 months; $p = 0.023$).

Conclusions: Cluster-based trend analysis is more sensitive in detecting visual field progression compared to global MD trend analysis in mild to moderate glaucoma.

Abstract No.: 205597

Panel No.: OIM-0647

Diagnosis Performance of Diabetic Retinopathy Using Ultra-Wide Field Color Fundus Imaging and Artificial Intelligence: A Systematic Review and Meta-Analysis

First Author: Kunihiro HIROSAWA

Co-Author(s): Akie INOMATA, Takenori INOMATA, Ken NAGINO, Shintaro NAKAO

Purpose: To clarify the current status and diagnostic performance of diabetic retinopathy (DR) screening using ultra-wide field (UWF) color fundus images and artificial intelligence (AI)-based analysis.

Methods: We conducted a systematic review and meta-analysis in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. Articles published up to February 9, 2025, were retrieved from PubMed, Scopus, Cochrane Library, and Web of Science. Search terms included variations of "diabetic retinopathy," "artificial intelligence," and "ultra-wide field imaging." Eligible studies that assessed AI-based DR screening using UWF color fundus images were included, and

diagnostic performance outcomes were pooled for meta-analysis.

Results: Of 523 identified studies, 17 met inclusion criteria for systematic review, and 6 were eligible for meta-analysis. All included studies (2017–2024) used images obtained with Optos®. The meta-analysis showed that AI-based DR screening with UWF color fundus images achieved 85.1% sensitivity, 72.5% specificity, and an AUC of 0.870 (95% CI, 0.838–0.897). For proliferative DR, sensitivity and specificity were higher at 94.2% and 96.9%, respectively.

Conclusions: AI-based evaluation of UWF color fundus images demonstrates high sensitivity but limited specificity compared with prior standards based on conventional color fundus photographs. Nevertheless, the broader retinal coverage of UWF imaging may provide additional advantages in assessing DR severity, particularly with the development of larger, high-quality datasets.

Abstract No.: 208433

Panel No.: OIM-0659

Long-Term Sequelae of CMV Retinitis: A Review of Macular Vasculature on OCTA

First Author: Mary HO

Co-Author(s): Lawrence IU, Andrew MAK, Posey WONG, Alvin YOUNG

Purpose: The purpose of this study was to evaluate the long-term sequelae of cytomegalovirus (CMV) retinitis on macular vasculature using optical coherence tomography angiography (OCTA).

Methods: This prospective, observational study recruited patients with a prior history of CMV retinitis from 2011 to 2020 at the Prince of Wales Hospital, Hong Kong. Patients were identified through an electronic database, and diagnosis was confirmed through clinical appearance and laboratory evidence of CMV infection. Age-matched controls were included. Subjects underwent comprehensive ophthalmic examination and retinal imaging with OCT and OCT-A. Quantitative OCT-A parameters, including vascular density (VD), skeleton density (SD), foveal avascular zone (FAZ) area, vessel diameter index (VDI), fractal dimension (FD), and macular choroidal thickness (MCT), were analyzed. Statistical comparisons between affected, unaffected, and control eyes were performed using paired or two-sample t-tests as appropriate, with $p < 0.05$ considered significant.

Results: Of 27 identified patients, 8 with gradable OCT-A images were analyzed. Six had unilateral and two had bilateral CMV retinitis. The mean age was 57.9 years, with a mean follow-up of 74 months. No statistically significant differences in VD, SD, FD, VDI, FAZ area, or MCT were found between affected and unaffected eyes, or between affected eyes and age-

matched controls. Quantitative parameters of retinal microvasculature were similar across groups.

Conclusions: Peripheral CMV retinitis may not have significant long-term detrimental effects on macular vasculature as measured by OCT-A. Although transient or reversible capillary perfusion compromise cannot be excluded, this study did not identify significant chronic microvascular changes.

Abstract No.: 205696

Panel No.: OIM-0648

Magnetic Resonance Imaging Study of Primary Inferior Oblique Overaction

First Author: Ziyuan LI

Purpose: To quantitatively determine the morphology and contractility of the inferior oblique (IO) muscle in primary IO overaction (PIOOA), to facilitate the pathogenesis and diagnosis of PIOOA.

Methods: A prospective, observational study was conducted on 7 patients (14 eyes) with PIOOA and 6 (12 eyes) healthy, orthotropic subjects. High-resolution magnetic resonance imaging (MRI) was used to obtain sets of contiguous, 2-mm-thick sagittal images of the two groups of subjects repeated in multiple vertical gaze positions. Post-processing computer image system was used to measure the IO muscle maximum cross-sectional area, maximum contractility, vertical diameter, horizontal diameter, and volume of the two groups, and to analyze the combination between the clinical grade of elevation in adduction of the inferior oblique muscle and the MR image of the case group.

Results: From the contiguous, 2-mm thick sagittal images of all subjects (23 eyes), the Inferior oblique (IO) cross-sectional area was greater in supraduction than in infraduction. The plane of IO maximum cross-sectional area lay 2mm temporal to the center of the Inferior rectus muscle (IR), while the plane of IO maximum contractility lay in the center of the IR. Compared the two groups of subjects, ipsilesional IO maximum cross-sectional area ($15.15 \pm 2.08 \text{ mm}^2$) was greater than that of the normal control group ($13.20 \pm 1.62 \text{ mm}^2$) ($P=0.023$), while ipsilesional IO maximum contractility ($5.23 \pm 1.30 \text{ mm}^2$) did not differ from that of normal subjects ($4.30 \pm 1.06 \text{ mm}^2$) ($P=0.080$).

Conclusions: High-resolution sagittal MRI technology can image the inferior oblique muscle well. In PIOOA, the ipsilesional IO is greater in size than in controls, with no difference in contractility, which suggests that IO muscle hypertrophy underlies PIOOA.

Panel No.: OIM-0657

Neuroretinal Rim Width and Diabetic Retinopathy Progression: A Prospective Cohort Study

First Author: Man Wai Adrian LEE

Co-Author(s): Carol CHEUNG, Danqi FANG, Truong NGUYEN, Ka Ho SZETO, Chunwen ZHENG

Purpose: To assess whether neuroretinal rim, quantified by Bruch's membrane opening minimum rim width (BMO-MRW), predicts diabetic retinopathy (DR) progression.

Methods: This prospective cohort study included 348 eyes with either no DR or nonproliferative DR at baseline. Global and sectoral BMO-MRW thickness was measured using Spectralis OCT (Heidelberg Engineering, Heidelberg, Germany) with 24 radial B-scans. The primary endpoint was DR progression, defined as a ≥ 2 -step increase in severity according to the modified Airlie House classification. Cox proportional hazards models estimated hazard ratios (HR) per standard deviation (SD) decrease in BMO-MRW thickness, adjusting for age, diabetes duration, baseline DR severity, and axial length. Including temporal BMO-MRW improved predictive discrimination beyond established risk factors.

Results: Over a mean follow-up of 3.0 years, 33 eyes (9.5%) developed DR progression. Among all BMO-MRW sectors, only temporal sector thinning was significantly associated with increased progression risk after multivariable adjustment (HR=1.477 per SD decrease, 95% CI: 1.009-2.161, $p=0.045$). Risk stratification using a temporal BMO-MRW threshold of $\leq 183 \mu\text{m}$ (25th percentile) identified a high-risk group with a 17.0% progression rate compared to 6.9% in the low-risk group ($>183.0 \mu\text{m}$) (relative risk=2.46, $p=0.010$).

Conclusions: Temporal neuroretinal rim thinning measured by OCT independently predicts DR progression, enabling effective risk stratification and supporting personalized monitoring strategies in DR management.

Panel No.: OIM-0638

OCT Biomarkers in Predicting Outcomes of Macular Oedema Secondary to Retinal Vein Occlusion Treated With Anti-VEGF Therapy

First Author: Kin Ken TSANG

Co-Author(s): Yim Lui Carol CHEUNG, Wing-ki Vivian HUI, Yuk Yau Timothy LAI, Ming Kei Christopher PANG, Ka Ho SZETO

Purpose: To investigate the role of optical coherence tomography (OCT)-based biomarkers in predicting treatment response of macular oedema (MO)

secondary to retinal vein occlusion (RVO) to anti-vascular endothelial growth factors (VEGF) therapy.

Methods: Retrospective cohort study including RVO associated MO patients who received anti-VEGF injections between January 2020 and April 2021. Visual acuity (VA) at baseline, 12, and 24 months was correlated with a panel of OCT-based biomarkers, including vitreomacular status, size of intra-retinal cysts (IRC), presence of disorganization of retinal inner layers (DRIL), hyper-reflective foci (HRF) in the retina, integrity of the external limiting membrane (ELM), ellipsoid zone (EZ), cone outer segment tip (COST) and presence of subretinal fluid (SRF).

Results: One hundred and thirty eyes were included. There were 81 and 49 eyes in the BRVO and CRVO subgroup, respectively. In both subgroups, baseline disrupted EZ/ELM were associated with worse VA from baseline through 24 months. In the BRVO subgroup, the improvement in DRIL extent and EZ/ELM integrity were associated with higher likelihood in achieving at least 5 letters gain at 12 and 24 months.

Conclusions: A comprehensive and clinician-friendly grading system of OCT-based features could predict functional outcomes of MO secondary to RVO with anti-VEGF therapy up to 24 months.

Abstract No.: 206895

Panel No.: OIM-0654

Optical Assessment of Tear Film Thickness in Healthy and Keratoconic Eyes Using Scheimpflug Ocular Coherence Tomography Imaging

First Author: Gaurav PANDE

Co-Author(s): Raghav NARASIMHAN, Abhijit Sinha ROY, Rohit SHETTY

Purpose: To quantify tear film thickness (TFT) in early keratoconus (KC) and healthy eyes and correlate it with tear biomarkers.

Methods: One hundred eyes were included, which underwent a prospective, case-control, single-centre study and were grouped into early KC (n=50) and healthy eyes (n=50). Imaging was done with Pentacam OCT, a Scheimpflug-based ultra-high resolution, widefield OCT with axial resolution of ~1.4µm and scan diameter of 12mm. Custom edge detection and segmentation software were developed to calculate TFT. 25 radial OCT B-scans were also acquired. Additionally, tear samples were analysed for 8 biomarkers. Artificial Intelligence (AI) predicted scores were derived from these biomarkers.

Results: In the central 5 mm zone of imaging, the mean TFT was found to be 3.09 µm (KC) and 3.16 µm(healthy). As the zone size increased, the mean TFT decreased in KC patients (p<0.05). It was also found that all biomarkers were elevated in KC eyes. Matrix Metalloproteinase Protein (MMP-9) strongly correlated

with the AI predicted score (Spearman correlation coefficient $r = 0.684$, $P = 0.0291$) in KC.

Conclusions: A new Scheimpflug-based optical imaging technique can be used to quantify TFT and correlate with the incidence of ocular inflammation. Routine evaluation of TFT can provide refined clinical assessment in conjunction with using AI models, one could support the treatment of patient symptoms in healthy and KC eyes.

Optical Coherence Tomography Angiography Biomarkers for Predicting Visual Outcome in Epiretinal Membrane Patients

First Author: Jeffrey LO

Co-Author(s): Ivan CHOW, Nicholas FUNG

Purpose: To compare Optical Coherence Tomography Angiography (OCTA) biomarkers in epiretinal membrane eyes (ERM) and normal eyes and to investigate the association between each biomarker and visual acuity.

Methods: A prospective cross-sectional population study of the right eye of 6011 participants aged above 50 was performed. Central subfield thickness (CST_A), foveal avascular zone (FAZ_A), mean vessel density (mVD_full) and mean capillary perfusion density (mCPD_full) were measured by OCTA. The cut-off values of significantly associated biomarkers for different best corrected visual acuity (BCVA LogMar $\geq 0 / 0.2 / 0.3$) in ERM eyes were determined using receiver operating characteristic (ROC) and Area under curve (AUC) analysis.

Results: ERM eyes had a significantly higher CST_A ($P=0.0000$) and a smaller FAZ_A ($P=0.0002$) compared to normal eyes. Both mVD_full and mCPD_full were lower in ERM eyes when compared with normal eyes ($P=0.0001$). No significant association was found between FAZ_A and BCVA LogMAR. Better visual outcome is associated with smaller CST_A (beta =0.0005858), larger mVD_full (beta=-0.0106) and mCPD_full (beta=-0.3913). Cut off values of the three significantly associated OCTA biomarkers were demonstrated, with CST_A having an acceptable diagnostic power for predicting BCVA LogMar ≥ 0.3 in 0.3 in ERM eyes (AUROC value =0.708). The AUROC values of other biomarkers were less than 0.7 in predicting BCVA in ERM eyes.

Conclusions: OCTA biomarkers such as CST_A, mVD_full and mCPD_full had a significant association with BCVA in ERM eyes. However, FAZ_A had no significant correlation with best corrected visual acuity. CST_A was found to have an acceptable diagnostic power for predicting BCVA in ERM eyes.

Abstract No.: 206344**Panel No.: OIM-0649**

Predicting Gonioscopic Angle Closure Using Optical Coherence Tomography Parameters in Chinese Individuals

*First Author: Catherine Yik Tsz LAM**Co-Author(s): Kin Pong LAU, Kendrick Co SHIH*

Purpose: To evaluate the predictive performance of optical coherence tomography (OCT)-derived angle parameters — angle opening distance (AOD), angle recess area (ARA), trabecular-iris space area (TISA), and trabecular-iris angle (TIA) — in identifying gonioscopic angle closure among Chinese subjects.

Methods: This cross-sectional, population-based study included 1,599 right eyes from 1,599 consecutive Chinese individuals aged ≥ 50 years. Anterior segment imaging was performed using CASIA2 swept-source OCT (SS-OCT) (50,000 A-scans/s; 800 A-scans/B-scan). Each eye underwent three scans under dark-room conditions (0.26s per scan). Angle parameters (AOD500, TISA500, ARA500, TIA500) were computed 500 μm anterior to the scleral spur after manual spur localization by a single observer in nasal and temporal angles. For analysis, each metric was summarized at the eye level as the minimum of the two angles. A single-threshold classifier per metric was trained with 5-fold cross-validation. In each fold, the decision threshold was derived on the training partition by maximizing Youden's index. Performance was computed from out-of-fold predictions. Sensitivity, specificity, and area under the receiver operating characteristic curve (AUROC) were reported.

Results: Gonioscopic angle-closure prevalence was 24/1,599 (1.5%). AOD500 ≤ 0.17 mm yielded 79% sensitivity and 83% specificity (AUROC=0.876). TIA500 $\leq 22^\circ$ had 79% sensitivity and 77% specificity (AUROC=0.875). TISA500 ≤ 0.088 mm² had 88% sensitivity and 67% specificity (AUROC=0.844). ARA500 ≤ 0.082 mm² had 58% sensitivity and 79% specificity (AUROC=0.776).

Conclusions: Among the OCT-derived parameters, AOD500 had the best balance between sensitivity and specificity in predicting gonioscopic angle closure. These validated thresholds support technician-friendly triage using OCT to prioritise gonioscopy and rule out angle closure in low-prevalence settings.

Abstract No.: 206668**Panel No.: OIM-0652**

Prevalence and Clinical Characteristics of Dark Without Pressure Retinal Changes in a Chinese Hospital-Based Population

*First Author: Junmeng LI**Co-Author(s): Jianchen HAO, Liu YANG, Ruilin ZHU*

Purpose: This study investigates the clinical characteristics and prevalence of dark without pressure

(DWP) retinal changes in a hospital-based Chinese population and evaluates its association with common fundus diseases.

Methods: This cross-sectional study analyzed data from 6787 eligible patients recruited from the Ophthalmology Department of Peking University First Hospital between April and July 2023. All participants underwent ultra-wide-field color fundus photography (UWF CFP) for the detection of DWP. Patients were screened by excluding those without UWF CFP images, with blurred images, or who had undergone intraocular surgery, while consolidating duplicate visits. Participants were categorized into diseased ($n = 3741$) and control ($n = 3046$) groups. Prevalence rates were compared between the control group and various disease subgroups (including age-related macular degeneration [AMD], diabetic retinopathy, high myopia, uveitis, retinal hole [RH], retinal detachment [RD], and retinal vein occlusion), as well as across demographic strata, using chi-square tests.

Results: The overall prevalence of DWP was 21.84% (1481/6787), with a prevalence of 18.55% (565/3046) in the control group. Patients with RH showed the highest prevalence (35.33%, 59/167), whereas those with AMD exhibited the lowest (19.50%, 86/441). There were significant differences in prevalence between the control group and most disease subgroups (all $P < 0.05$), except for AMD ($P = 0.632$). Additionally, DWP prevalence was inversely associated with age ($P < 0.05$) but did not differ by gender ($P > 0.05$). Longitudinal observation revealed diverse DWP patterns, including complete progression, gradual reduction, and bidirectional progression-regression.

Conclusions: DWP is common in Chinese cohorts, especially younger adults and those with retinal disorders, necessitating individualized monitoring. Its progression is a potential biomarker, warranting further study.

Abstract No.: 206569**Panel No.: OIM-0651**

Retinal Microvascular Signature and Risk of Incident Polyvascular Disease in Patients With Pan-Vascular Disease: A Population-Based Cohort Study

*First Author: Yun REN**Co-Author(s): Cong LI, Lei LIU, Xiaohong YANG, Honghua YU*

Purpose: A major limitation in pan-vascular medicine is the reliance on organ-specific assessments, which may inadequately capture the systemic risk of progression to polyvascular disease. This study aimed to determine if a quantitative retinal microvascular signature could serve as a novel biomarker for a more holistic risk stratification.

Methods: This prospective cohort study included 2,592 UK Biobank participants with prevalent single-vessel disease at baseline. A fully automated system was used to quantify the retinal microvascular signature, a multidimensional panel of metrics assessing vascular branching, calibre, tortuosity, density, and complexity, from fundus photographs. Multivariable Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for incident polyvascular disease.

Results: During a median follow-up of 10.06 years, 334 incident cases of polyvascular disease were documented. In the fully adjusted model, metrics of arteriolar branching angle (HR, 1.15; 95% CI, 1.04-1.28) and arteriolar tortuosity (HR, 1.17; 95% CI, 1.06-1.28) were significantly associated with an increased risk of incident polyvascular disease. Conversely, metrics of network density (HR, 0.84; 95% CI, 0.77-0.96) and complexity (HR, 0.84; 95% CI, 0.75-0.94) were associated with a lower risk.

Conclusions: The retinal microvascular signature is an independent predictor of incident polyvascular disease beyond conventional risk factors. These findings validate the retinal microvasculature as a source of novel biomarkers for systemic vascular risk. Quantitative retinal analysis therefore represents a promising modality to advance beyond organ-specific paradigms towards a more integrated approach to patient management in pan-vascular medicine.

The Application of Optical Coherence Tomography Angiography Examination in Preoperative Differential Diagnosis of Ocular Surface Tumor

First Author: Jing XU

Purpose: To investigate the efficiency of optical coherence tomography angiography (OCTA) in auxiliary diagnosis for ocular surface tumor.

Methods: On initial visit, detailed medical history collection, visual acuity, intraocular pressure, slit-lamp examination, and OCTA were performed. The histopathological examination was conducted for postoperative definitive diagnosis. The patient with a clear diagnosis of ocular surface tumor was recruited for the study.

Results: A 77-year-old woman presented to the ophthalmology department with a 5-year history of a painless neoplasm in her left eye. She had no history of tumors and no family history of ocular disease. On initial examination, her visual acuity was 20/40 OD and 20/50 OS. Intraocular pressures were 16.6 mmHg OD and 19.7 mmHg OS. Pupils were round and reactive without a relative afferent pupillary defect. Slit-lamp examination showed an isolated papillary tumor on the

limbal conjunctiva with prominent conjunctival blood vessels extending to the tumor. OCTA demonstrated the blood vessels of the neoplasm in the shape of "popcorn" and blood vessels extending beneath the surface of sclera.

Conclusions: Preoperative OCTA examination could contribute to distinguishing between malignant and benign tumors through the visualization of vessel depth. It can also evaluate the blood supply of ocular-surface abnormalities.

A Case of Orbital Solitary Fibrous Tumor Recurring With Extensive Sinonasal Invasion Following Eyeball Enucleation

First Author: Jiayin CAI

Co-Author(s): Jian LI, Jianguang ZHONG

Purpose: To describe the clinical features, differential diagnosis, management, and clinical significance of a rare case of orbital primary solitary fibrous tumor (SFT) characterized by multiple recurrences and extensive invasion into the paranasal sinuses.

Methods: A systematic case description, comprehensive data collection, and literature review were performed. The patient presented with complaints of «left periorbital swelling, frontal and facial discomfort, decreased tear secretion, and occasional headache and dizziness.» Histopathological and imaging findings confirmed the diagnosis as a recurrent orbital primary solitary fibrous tumor with extensive spread to the paranasal sinuses. Notably, this recurrence occurred after three previous episodes and subsequent enucleation of the affected eye.

Results: This case demonstrates that orbital solitary fibrous tumor can exhibit an insidious early onset, a protracted disease course, a propensity for frequent recurrence, significant invasiveness, and poses substantial challenges for disease management.

Conclusions: As a rare orbital tumor, SFT possesses a high potential for recurrence and invasion, warranting considerable clinical attention. Complete resection remains the treatment of choice for SFT. Postoperative adjuvant radiotherapy or chemotherapy should be considered, accompanied by stringent and long-term follow-up.

Abstract No.: 200403**Panel No.: OPA-0660****Against the Odds: Globe Preservation in Group D and E Retinoblastoma With Intra-Arterial Chemotherapy***First Author: Taryaba MALIK**Co-Author(s): Noor UL AIN*

Purpose: The objective of this study was to evaluate the effectiveness of IAC in Group D and E retinoblastoma, with a specific focus on globe salvage, in a retinoblastoma center in Pakistan.

Methods: It was a retrospective study in which patients with retinoblastoma of groups D and E were included. Demographic and clinical data were retrieved from the ophthalmology department of Lahore General hospital. Patients received six cycles of intravenous chemotherapy followed by IAC. Up to four IAC sessions were administered. Tumor regression was assessed one month post-IAC, and globe salvage was defined by sustained stability over six months.

Results: There were 55 eyes of 55 patients. Mean age was 20.96 ± 14.03 months. Twenty-nine eyes had group D, and 26 had group E retinoblastoma. Tumor regression was noted in most of both groups, with no significant difference. Globe salvage with vision was observed more frequently in Group D (44.8%) compared to Group E (19.2%). Enucleation and loss of visual function were more common in Group E. Ischemic toxicity was rare, signifying the relative safety of IAC.

Conclusions: IAC is an effective globe-sparing treatment for retinoblastoma, achieving high rates of tumor regression and globe salvage, even in advanced disease stages.

Abstract No.: 206819**Panel No.: OPA-0689****An Unusual Case of Retinoblastoma Masquerade***First Author: Tapashree GHOSH**Co-Author(s): Bhavna CHAWLA*

Purpose: We report a unique and interesting case of leukocoria in a child, with clinical and imaging findings suggestive of retinoblastoma, but subsequently proven otherwise on histopathology.

Methods: Case report.

Results: A 5-year-old female presented with a whitish reflex and mild proptosis in the left eye (LE). Visual acuity was 6/6 in the right eye and light perception only in LE. Examination revealed a normal right eye, while the LE showed a cataractous lens, mild proptosis, posterior synechiae, and elevated intraocular pressure (35 mmHg). Fundus visualization was not possible in LE. Ultrasound B scan demonstrated an intraocular mass with calcification in LE. MRI orbits revealed a

retinal mass extending upto the lens, hyperintense on T1, hypointense on T2 sequences, without optic nerve or coat involvement, consistent with retinoblastoma. Given the poor visual prognosis and raised IOP, enucleation was recommended. Enucleation with implant placement was performed. Histopathology unexpectedly revealed large epithelial granulomas with giant cells, consistent with ocular tuberculosis, without evidence of malignancy.

Conclusions: This case demonstrates the diagnostic complexity of pediatric ocular conditions. Despite clinical presentation and imaging findings strongly suggesting retinoblastoma, histopathological examination revealed tuberculosis infection.

Abstract No.: 204944**Panel No.: OPA-0680****Analysis of the Current Status of Stigma and Factors Affecting Parents of Children With Retinoblastoma***First Author: Wei XU*

Purpose: To understand the current status of stigma among parents of children with retinoblastoma (RB) and its influencing factors.

Methods: The fathers or mothers of 135 children with RB were selected and surveyed using the General Information Questionnaire, Social Influence Scale, Social Support Rating Scale, General Self-Efficacy Scale, and Simple Coping Styles Scale.

Results: The total score of the Caregiver Stigma Scale for children with RB was 55.00 (49.00, 63.00), the total score of the Social Support Scale was 31.00 (23.00, 37.50), the total score of the General Self-Efficacy Scale was 21.00 (16.50, 26.00), and the Positive Coping Score was (26.44 ± 8.599) , and the Negative Coping Score was (12.54 ± 5.406) points. The results of multifactorial analysis showed that total social support score, disease stage, coping tendency, and type of health insurance were the influencing factors of parental stigma in RB, which together explained 37.2% of the total variance.

Conclusions: Parental stigma in children with RB is at a high level and needs to be further improved. Clinical caregivers should pay attention to the disease stage, type of medical insurance, and coping tendency of children with RB, correctly guide and improve the use of social support, reduce the level of the sense of shame of the parents of children with RB, and comprehensively cooperate with the better treatment of children with RB.

Angiogenic Markers in Ocular Tumors: Exploring VEGF Expression and Microvascular Density in Ocular and Eyelid Malignancies

First Author: Priyanka

Co-Author(s): Apjit KAUR, Nibha MISHRA

Purpose: This study investigates the role of angiogenesis in ocular tumors by evaluating vascular endothelial growth factor (VEGF) expression and microvascular density (MVD), aiming to assess the potential utility of antiangiogenic therapy.

Methods: All patients undergoing surgical excision for ocular and eyelid tumors underwent detailed clinical examination, and immunohistochemistry for VEGF and CD105. MVD was quantified using digital image analysis by counting CD105-positive vessels per mm².

Results: A total of 53 patients with eyelid lesions were included, of which 48 (90.5%) were neoplastic and 5 (9.5%) non-neoplastic. Among neoplastic cases, 5 (10.4%) were benign and the majority were malignant, including sebaceous gland carcinoma (25.5%), squamous cell carcinoma (20.9%), basal cell carcinoma (18.6%), and others. Clinical aggressiveness was noted in 56.5% of malignant cases, with metastasis in 4%. VEGF expression in tumor-associated vessels was significantly higher in malignant tumors (60%) compared to benign tumors, and MVD was also elevated in malignancies (65%) ($p=0.023$). However, VEGF expression in tumor cells did not significantly differ between benign and malignant tumors ($p=0.15$), nor did it correlate with clinical aggressiveness. Higher MVD was strongly associated with clinically aggressive tumors ($p=0.0001$).

Conclusions: These findings suggest that increased vascular VEGF and MVD in malignant ocular tumors support the potential use of antiangiogenic therapy, which may help reduce tumor growth and mitigate the need for extensive surgical interventions. Such strategies could be particularly beneficial given the anatomical and functional challenges of eyelid tumor management. Further studies with larger cohorts are warranted to explore therapeutic implications.

Abstract No.: 205430

Panel No.: OPA-0684

Bilateral Uveal Metastases as the Initial Manifestation of Lung Adenocarcinoma

First Author: Tongtong OU

Co-Author(s): Fang LU

Purpose: To report a pioneering case of biopsy-proven bilateral uveal metastases as the initial sign of lung adenocarcinoma, highlighting how pathologic confirmation-guided targeted therapy led to exceptional systemic and ocular outcomes.

Methods: A 40-year-old male presented with unilateral blurred vision (BCVA 0.4 OD). Ophthalmoscopy revealed bilateral uveal masses. After systemic workup confirmed stage IVB lung adenocarcinoma, a transscleral biopsy of the ocular tumor was performed. Immunohistochemistry (TTF-1 positive) provided definitive pathologic confirmation of the metastatic lung origin.

Results: Guided by the pathologic diagnosis, the patient received a combination of local ocular therapy and systemic targeted treatment with the EGFR-TKI entrectinib. This strategy resulted in excellent systemic tumor control. Notably, the patient's BCVA recovered fully to 1.0 in both eyes, and he has survived with stable disease for 3 years.

Conclusions: This case is the first to provide conclusive pathologic evidence (TTF-1 positive) for bilateral uveal metastasis from lung adenocarcinoma. It demonstrates that biopsy-guided targeted therapy with entrectinib can achieve remarkable survival and visual recovery (from 0.4 to 1.0), challenging the dismal prognosis associated with this condition and advocating for a more integrated diagnostic and therapeutic approach.

Abstract No.: 204462

Panel No.: OPA-0677

Choroidal Osteoma in a Young Filipino Female

First Author: Marie Camilla GARGANTA

Co-Author(s): Gary John MERCADO

Purpose: To discuss a rare case of choroidal osteoma and describe clinical features and diagnostic findings.

Methods: Case report.

Results: A thirteen-year-old female presented with a six-year history of progressive blurring of central vision in the left eye. Fundus examination showed an elevated, calcified choroidal lesion in the macula. Multimodal ocular imaging, including Macular optical coherence tomography (OCT-M), B-scan ultrasound, fluorescein angiography (FA), fundus autofluorescence (FAF), and optical coherence tomography-angiography (OCT-A), was done. Macular Optical coherence tomography showed a hyperreflective choroidal elevated mass, disrupting the foveal contour with a lamellar pattern consistent with the appearance of bone. Ocular ultrasound showed a thick, homogenous, high-amplitude echo with posterior shadowing. FA showed early hyperfluorescence with a foveal hypofluorescence. FAF showed a hypoautofluorescent area at the level of the fovea. OCT-A showed vascular flow at the fovea. Physical examination and diagnostic findings were consistent with a choroidal osteoma with foveal decalcification, a sign of poor visual prognostication. The patient is on regular follow-up with stable ophthalmic findings.

Conclusions: Choroidal osteoma can mimic other intraocular tumors and is frequently misdiagnosed. A multimodal imaging approach is essential for accurate diagnosis and detection of secondary complications. While no standardized treatment exists, management is directed at sequelae such as choroidal neovascularization and subretinal fluid, with options including anti-VEGF therapy, photodynamic therapy, and transpupillary thermotherapy, but these have yielded mixed results. Early recognition and close monitoring are critical to maximizing visual potential.

Abstract No.: 206079

Panel No.: OPA-0686

Clinical Characteristics and Treatment Outcomes of Iris Metastasis

First Author: Vidhi **BAJPAI**

Co-Author(s): Vishal **RAVAL**

Purpose: To describe the clinical profile and management of patients with iris metastasis.

Methods: Retrospective case series of patients with clinically or histopathologically confirmed iris metastasis from systemic cancer managed at a tertiary eye care center between 2019 and 2023.

Results: A total of 6 patients with a mean age of 54 years were included. Presenting symptoms included blurred vision with pain (3), pain (2), and eye discoloration (1). All eyes had unilateral amelanotic vascularised iris mass arising from the root of the iris (except one arising near the pupillary margin), irregular anterior chamber depth, and circumferential congestion. Iris neovascularization was noted in 3 eyes with high intraocular pressure in 1 eyes. UBM (4 eyes) showed heterogenous (2)/homogenous (2) echogenic mass arising from the iris stroma, involving the ciliary body in 2 cases. Of 6 patients, 3 patients had a prior cancer diagnosis; in others, iris metastasis led to its diagnosis. The primary sites of cancer were the lung (3), the breast (2), and the renal (1). Treatment included plaque brachytherapy (1), tumor excision (1), and bevacizumab (1). All showed tumor regression and no local recurrence. At the last follow-up (mean 15.6 months), 1 patient died, 2 were alive, and 3 were lost to follow-up.

Conclusions: Iris metastases exhibit distinctive clinical features that can guide diagnosis. Biopsy is especially useful in patients without a known systemic cancer or when the primary tumor is not readily accessible for sampling. Various treatment modalities are effective and should be individualized according to the patient's systemic status and visual prognosis.

Abstract No.: 205262

Clinicopathologic Review of 42 Cases of Ocular Adnexal Sarcoma

First Author: Yi **WU**

Co-Author(s): Weimin **HE**

Purpose: To study the clinicopathologic features and prognosis of ocular adnexal sarcomas diagnosed at a tertiary comprehensive hospital in China over 13 years.

Methods: We retrospectively reviewed cases with histopathological diagnoses of ocular adnexal sarcomas. Demographics, clinicopathologic features, treatment, and prognosis were analyzed.

Results: Forty-two cases of ocular adnexal sarcomas were found, with a mean age of 37.1 years (27 males, 15 females). The most common clinical manifestations were exophthalmos (61.9%), and the median time to diagnosis was 6 months. Fifteen different histological types were identified; rhabdomyosarcoma was the most frequent (21.4%), followed by liposarcoma and malignant solitary fibrous tumor (16.7%). The diagnosis of each subtype depends on its histomorphologic characteristics, supplemented by immunohistochemistry and molecular pathology. Among 37 patients with follow-up, 24 (64.9%) survived, 13 (35.1%) died, 19 (51.4%) relapsed (mean recurrence interval 16.8 months, up to 6 times), and 13 (35.1%) developed metastasis. Multivariate analysis showed tumor diameter > 3.5cm as a significant predictor of mortality ($P=0.025$).

Conclusions: Ocular adnexal sarcoma is extremely rare, mostly affecting young males. There are numerous histological variants; rhabdomyosarcoma is the most common in children, while liposarcoma and malignant solitary fibrous tumor predominate in adults. Pathological diagnosis requires a combination of histomorphology, immunohistochemistry, and molecular pathology. Prognosis is often poor, and there is a high risk of relapse and metastasis. Tumor diameter greater than 3.5cm is the main factor of poor prognosis.

Comparison of Topical Mitomycin-C and 5-Fluorouracil As Primary Treatment for Ocular Surface Squamous Neoplasia: A Randomized Controlled Trial Study

First Author: Khyati **ROOP**

Co-Author(s): Sima **DAS**, Namita **KUMARI**

Purpose: 1. To compare the efficacy of topical MMC 0.04% vs topical 5-FU 1% as the primary treatment for OSSN. 2. To compare the safety and tolerance of topical MMC 0.04% vs topical 5-FU 1% as primary therapy for OSSN.

Methods: This is a randomized controlled trial conducted from February 2024 to August 2025. Patients with non-invasive treatment naive OSSN were recruited for the study after taking informed consent. Participants were then randomized into 2 treatment groups, namely 5-FU(1%) and MMC(0.04%), using a computer-generated randomization sequence. Clinical history and examination, along with AS-OCT, slit lamp, and external photos, were performed, and response to therapy and side effects were noted at each visit. Participants were followed up 2 weeks till complete resolution of the tumor was noted clinically and on AS-OCT. All cases with no response to the treatment regimen and/or sight-threatening complications due to chemotherapy were removed from the group and managed with alternate treatment options.

Results: This is an analysis of 60 patients enrolled in the study. Complete resolution rates were comparable between groups with (21/28)81.2% in MMC group and (23/26)85.7% in 5-FU group ($p=0.03$) with time to resolution 9.7 ± 5.0 weeks and 9.1 ± 7.3 weeks ($P=0.72$), and number of treatment cycles 2.1 ± 1.3 vs. 2.1 ± 1.5 ($p=0.85$) in MMC and 5-FU respectively, with no statistically significant results. The 5-FU group had more side effects, with 64.2% and 76.9% of patients experiencing at least one adverse event, respectively.

Conclusions: Our study suggests that both drugs have comparable efficacy with higher occurrence of corneal epithelial toxicity is seen with 5-FU.

Congenital Uveal Malignant Melanoma: Oversight or Overreaction? Navigating the Fear of Recurrence

First Author: Shivohn Annalie DA SILVA

Co-Author(s): Pallavi M P, Shruthi TARA

Purpose: To report a rare case of congenital uveal malignant melanoma and illustrate how meticulous follow-up enabled the recognition of suspected recurrence and its distinction from benign pigmentation.

Methods: An 8-month-old male was diagnosed with congenital uveal malignant melanoma and underwent enucleation with myoconjunctivalization technique and placement of a 16-mm acrylic orbital implant at 8 months of age. Metastatic workup was done biannually with clinical examination, orbital imaging, and systemic metastatic workup, including abdominal ultrasonography, complete blood counts, and annual FDG whole-body PET scans, all of which were unremarkable. At 3 years 10 months, following an orbital implant exchange elsewhere for cosmetic concerns, the child presented with lower lid ectropion, poorly fitting prosthesis, shallow fornices, and inferotemporal implant displacement. Surgical exploration revealed dense jet-black pigmentation over

the posterior Tenon's capsule, which was excised and sent for histopathological and immunohistochemical analysis as recurrence was feared.

Results: Histopathology showed no evidence of malignancy. Immunohistochemistry demonstrated CD68 and SOX 10 positive whilst HMB-45, Melan-A and Ki 67 were negative confirming melanophages or benign melanocytes populations rather than malignant recurrence. The possibility of unrecognized congenital ocular melanocytosis was also considered.

Conclusions: This case highlights the complexity of follow-up in Congenital uveal malignant melanoma, where benign pigmentation may mimic recurrence. Careful histopathological and immunohistochemical evaluation, combined with a high clinical suspicion, is essential to distinguish true recurrence from mimickers and prevent unnecessary interventions and patient anxiety in this exceptionally rare pediatric malignancy.

Conjunctival Angiosarcoma Masquerading as Recurrent Pterygium

First Author: Asha DEVI

Co-Author(s): Sanjay BOSAK, Priyanka, Rajendra MAURYA

Purpose: Angiosarcoma is a rare, dangerous vasoformative malignant tumor. We report a rare case of primary conjunctival angiosarcoma masquerading as recurrent pterygium.

Methods: A 55-year-old male was operated on for right eye pterygium one year ago by a private ophthalmologist. After recurrence, he referred the patient to us for further management. On examination, in right eye BCVA was 6/36 and in left eye was 6/60. A diffuse, flashy sub-conjunctival mass of vascular appearance, size 3 x 2 x 1.5 cm, involving the temporal bulbar conjunctiva up to the limbus. The epibulbar conjunctival vessels were injected, and a chemosis was present. The rest of the anterior segment was normal except for early lental changes. In his left eye, he was having an immature cataract. His past medical history was otherwise unremarkable. We operated on the right eye for recurrent temporal pterygium, but the histopathology report was sclerosing haemangioma.

Results: The postoperative period was uneventful, and he underwent another eye cataract surgery. After a 7-month postoperative period, the conjunctival mass recurred and became more extensive. Anterior OCT showed sclera infiltration. Map biopsy was done and immunohistochemistry showed angiosarcoma. The patient underwent a right orbital exenteration followed by orbital irradiation. On follow-up after 6 months, the patient is alive.

Conclusions: Primary conjunctival angiosarcoma is the rarest malignant tumor; its diagnosis and management are highly challenging.

Panel No.: OPA-0678

Correlation Analysis Between FGF2 With Incidence of Ocular Tumor in Medan City

First Author: Destrie Cindy **NADHILA**

Co-Author(s): Fithria **ALDY**, Rodiah Rahmawaty **LUBIS**

Purpose: Ocular tumors are rare conditions that may pose a threat to vision and life. They encompass various types, including intraocular and extraocular tumors, which may be either benign or malignant. Fibroblast Growth Factor-2 (FGF2) is a potent pro-angiogenic factor suspected to play a critical role in tumor pathogenesis, including ocular tumors, due to its ability to stimulate tumor cell proliferation and neovascularization.

Methods: This observational study employed a case-control design and was conducted at Prof. Dr. Chairuddin P. Lubis Hospital, Universitas Sumatera Utara, and its affiliated network hospitals. Study subjects consisted of patients diagnosed with ocular tumors (both benign and malignant) and healthy controls. Serum levels of FGF2 were measured using the ELISA method. Statistical analyses were performed using SPSS software version 24.0.

Results: A total of 38 patients were included in the study, with 65.8% being female. The mean age of participants was within the fifth decade of life. FGF2 levels were significantly higher in the tumor group compared to the control group ($p = 0.04$). Furthermore, FGF2 levels were significantly elevated in patients with malignant tumors compared to those with benign tumors ($p = 0.001$), indicating a correlation between elevated FGF2 levels and tumor malignancy.

Conclusions: There is a significant association between FGF2 levels and the occurrence of ocular tumors. FGF2 also has potential as a biomarker to differentiate between benign and malignant ocular tumors.

DHA Inhibits the Proliferation, Migration, and Invasion of Uveal Melanoma Cells by Targeting Ferroptosis

First Author: Yuxuan **ZHAO**

Co-Author(s): Chen **HOU**, Longqian **LIU**, Lirong **XIAO**, Naihong **YAN**

Purpose: Uveal melanoma (UM) is a rare but highly aggressive primary intraocular malignancy. Dysregulation of ferroptosis, a form of programmed cell death, has been implicated in UM progression. Dihydroartemisinin (DHA), a natural derivative of

Artemisia annua, exhibits potent antitumor activity with a favorable safety profile, yet its role in ferroptosis regulation in UM remains unclear. The aim of this study is to explore the effects and mechanisms through which DHA induces ferroptosis and its associated mitochondrial damage.

Methods: Cell viability, migration, invasion, proliferation, and apoptosis were evaluated by CCK-8, wound healing, Transwell, colony formation, and flow cytometry. RNA-seq with qRT-PCR/WB validated transcriptomic changes. Ferroptosis and mitochondrial alterations were assessed by biochemical assays, fluorescent probes, TEM, and mito stress tests.

Results: In this study, we found that DHA strongly inhibited the proliferation, migration, and invasion of both primary and metastatic UM cells in a dose- and time-dependent manner. Transcriptomic analysis indicated that DHA exerted antitumor effects by modulating the ferroptosis pathway. Specifically, it upregulated heme oxygenase-1 (HO-1) and downregulated the xCT/GPX4 axis, leading to elevated Fe^{2+} , ROS, and MDA levels; reduced GSH levels; mitochondrial shrinkage; cristae loss; decreased membrane potential; and impaired respiratory chain function. Moreover, iron chelators and pancaspase inhibitors partially reversed these effects, whereas HO-1 inducers enhanced them.

Conclusions: Collectively, these findings suggest that DHA suppresses UM progression by inducing ferroptosis and mitochondrial dysfunction through the HO-1 and xCT/GPX4 pathways, supporting its potential as a therapeutic strategy for UM.

Decoding IGLL5 Mutation-Mediated BCR Signaling: A Novel Mechanism of CD8^+ T Cell Exhaustion and Ocular MALT Lymphoma Progression

First Author: Andi **ZHAO**

Co-Author(s): Xuejuan **CHEN**, Hu **LIU**

Purpose: To elucidate the functional consequences and molecular mechanisms by which IGLL5 mutations drive the progression of ocular adnexal mucosa-associated lymphoid tissue (OAML) lymphoma, focusing on their role in B-cell receptor (BCR) signaling and immune modulation.

Methods: Transcriptomic analyses were performed on an OAML cohort to characterize the gene expression signatures associated with IGLL5 mutations. Molecular and functional assays were conducted to investigate the interaction between IGLL5 and the CD79A/CD79B complex and to assess downstream BCR signaling and immune responses.

Results: IGLL5 mutations, predominantly located in the N-terminal signaling domain, enhance binding to the

CD79A/CD79B receptor complex, leading to sustained activation of BCR signaling. This activation upregulates CXCL10 and CXCL11, promoting initial CD8⁺ T-cell infiltration but subsequently causing T-cell exhaustion within the tumor microenvironment. These effects collectively facilitate OAML progression and immune evasion.

Conclusions: IGLL5 mutations drive OAML progression through constitutive BCR signaling and CXCL10/11-mediated CD8⁺ T-cell exhaustion, establishing a mechanistic link between genetic alterations and immune dysfunction. These findings provide novel insights into the interplay between tumor genetics and immune modulation, highlighting potential therapeutic targets for OAML.

Diagnostic Value of Genetic Mutation Analysis and Mutation Profiling of Cell-Free DNA

First Author: Xiaqing CHEN

Co-Author(s): Yunwen HU, Dan LIANG

Purpose: To explore whether the ctDNA of intraocular fluid (IOF) samples of either the aqueous humor (AH) or the vitreous fluid can diagnose vitreoretinal lymphoma (VRL).

Methods: In this study, we used the cell-free DNA (cfDNA) genetic mutation analysis based on liquid biopsy to diagnose VRL. The genetic mutation analysis was performed by NGS using a panel of 446 hematopoietic tumor-related genes. We enrolled patients with VRL or uveitis who were diagnosed according to the criteria (presented in the "diagnostic criteria" subsection below), into a training cohort. The genetic mutation results were analyzed retrospectively. A validation cohort consisting of patients with VRL or uveitis from another ophthalmic center was included to verify the diagnostic value of the panel for VRL. Meanwhile, we analyzed the mutations of our patients with VRL to establish the genetic profile of VRL and to identify the genetic heterogeneity and molecular characteristics of VRL.

Results: The genetic mutation analysis for VRL diagnosis resulted in a sensitivity of 100%, a specificity of 66.7%, positive and negative predictive values of 89.5% and 100%, and a test efficiency of 91.3%. Some clonal hematopoietic mutations were detected in the patients with uveitis, which increased the false positive rate of our panel. The sensitivity and specificity of this genetic mutation analysis in the validation cohort for the diagnosis of VRL were both 100%.

Conclusions: CfDNA genetic mutation analysis of IOF samples was feasible and had 100% sensitivity for the diagnosis of VRL.

Evaluation of Macula Toxicity Following Chemoreduction in Retinoblastoma, Using Swept-Source Optical Coherence Tomography

First Author: Usha SINGH

Co-Author(s): Deeksha KATOCH, Manu SAINI, Kavita

Purpose: Intravenous chemotherapy is the mainspring treatment in majority of retinoblastomas (RB), chiefly to reduce tumor size prior to consolidation local therapy. Systemic toxicities associated though minimal, range from neurotoxicity to myelosuppression and are dose related. Reported literature on local toxicity following systemic chemotherapy lacks consensus. The aim of this study was to assess toxicity to macula by evaluating the macular thickness post chemotherapy on Swept-source optical coherence tomography (SS-OCT) in relation to cumulative dose, number of chemotherapy cycles, at different time intervals after completion.

Methods: Study was carried out in a specialty RB clinic of a tertiary care institute from July 2023 to October 2024 in 0-10 years age group. All patients received combination chemotherapy of VEC. SS-OCT was done after completion of Intravenous chemotherapy (IVC) course in Group A with ≤ 1 year (15 eyes) and Group B > 3 years (35 eyes) of follow up.

Results: There were 69 eyes of 69 patients, of which 19 were controls. The total mean macular thickness (MT) was significantly lower in group A compared to MT in group B and the control group (P-value = 0.001 each). There was significant difference, among the study groups vs control. MT was inversely related to > 6 cycles of chemotherapy vs < 6 cycles vs controls. MT was inversely related to the duration of completion of treatment follow up.

Conclusions: Macular thinning is directly affected by the number of systemic chemo-cycles, probably reflecting higher drug exposure to the globe.

Indocyanine Green Enhanced Transpupillary Thermotherapy in Circumscribed Choroidal Hemangioma

First Author: Shivayan SRIVASTAVA

Co-Author(s): Bhavna CHAWLA, Rohan CHAWLA, Neiwete LOMI, Radhika TANDON, Pradeep VENKATESH

Purpose: To evaluate tumor response, changes in visual acuity (VA), and subretinal fluid (SRF) resorption in the treatment of circumscribed choroidal hemangioma (CCH) following transpupillary thermotherapy (TTT) and ICG-TTT.

Methods: Two groups of 15 patients each with circumscribed choroidal hemangioma (CCH) were treated with transpupillary thermotherapy (TTT). One group received conventional TTT, while the other was treated with ICG-Enhanced TTT. Baseline assessments included visual acuity (VA), tumour size via B-scan ultrasonography, subretinal fluid (SRF) height using swept-source OCT, and tumour features were observed on ultra-widefield fundus photography. TTT was performed with an 810 nm diode laser through an indirect ophthalmoscope, following a standardised protocol, with treatment parameters documented. Both groups were followed monthly for four months and changes in baseline characteristics were noted. Additional treatment was given as needed based on disease activity.

Results: SRF resorption was noted in all 15 patients treated with ICG TTT and in 14 patients who received TTT. VA improvement was significantly greater in the ICG-enhanced TTT group compared with the TTT group ($p = 0.04$). A significant decrease in axial thickness and largest basal diameter was observed in both groups. Notably, the mean power used was significantly lower in the ICG TTT group compared to the TTT group (p value - 0.002). No significant difference was found in the number of TTT sessions required for treatment success.

Conclusions: ICG-enhanced TTT constitutes an efficacious therapeutic modality for circumscribed choroidal hemangioma. It yields superior visual outcomes compared to conventional TTT and necessitates substantially lower power to attain successful treatment results.

Abstract No.: 200992

Panel No.: OPA-0662

Invasive Squamous Cell Carcinoma of the Conjunctiva: A Case Report

First Author: Jamuna GURUNG

Co-Author(s): Hom GURUNG

Purpose: To describe the clinical findings and management of a patient with invasive squamous cell carcinoma (SCC).

Methods: A case report.

Results: We present the case of a patient with a conjunctival mass with progressive growth in the right eye and decreased visual acuity. He had undergone excision of a limbal conjunctival mass one month before this condition. Examination revealed a fleshy conjunctival lesion on the temporal limbus that extended intraocularly. An irregular gray mass measuring 3 x 2 mm in size was observed in the anterior chamber. Modified enucleation with the implant was performed to control local invasion. Histopathological analysis showed recurrent conjunctival SCC, well-differentiated tumors infiltrating

the sclera, choroid, and ciliary body, TNM (American Joint Committee on Cancer classification) stage: pT3Nx. The patient was treated with adjuvant chemotherapy postoperatively.

Conclusions: Invasive squamous cell carcinoma of the conjunctiva is a rare condition. The management of a locally advanced tumor is enucleation, and disease-free resection should be performed as this will impact the patient's prognosis and survival time.

Abstract No.: 203650

Panel No.: OPA-0675

Malignant Melanoma of the Lacrimal Sac: A Case Report and Review of the Literature

First Author: Danielle Colleen TIU

Co-Author(s): Annabelle DY, Waldemar SIY, Armida SULLER - PANSACOLA, Alexander TAN

Purpose: To review existing literature and to describe the presentation, diagnostic approach, and therapeutic management of lacrimal sac melanoma.

Methods: Review of related literature, case report.

Results: An 83-year-old female presented with a months-long history of palpable hard swelling at the right medial canthal area, with associated erythema, tearing, and black discharge. The patient was initially assessed as a case of dacryocystitis and was prescribed unrecalled eye drops. Further work-up, including computed tomography scan, biopsy, and immunohistochemistry, revealed malignant melanoma of the right lacrimal sac. The patient underwent wide excision, right medial maxillectomy, ethmoidectomy, middle turbinectomy via lateral rhinotomy, and orbital exenteration with frozen section. PET CT scan results showed hypermetabolic activity along the hard palate, left fossa of Rosenmuller, and right upper jugular cervical lymph node. Image-guided biopsy of the lymph node was attempted; however, no definite target for biopsy was noted. The patient is on follow-up with Plastics, Lacrimal, and Otorhinolaryngology.

Conclusions: Diagnosing lacrimal sac melanoma is challenging, as it often mimics common conditions such as dacryocystitis. In patients who present with epiphora, bloody discharge, and swelling of the medial canthal area, it is important to consider lacrimal sac melanoma. There is currently no clear consensus in the treatment of lacrimal sac melanoma, although most authors suggest tumor resection combined with radiotherapy. The patient should be followed up closely due to the possibility of recurrence and metastasis. This can lead to early diagnosis, which is critical for a favorable prognosis.

Abstract No.: 202377

Panel No.: OPA-0668

One Tumor, Two Targets: Malignant Epithelial Tumor of Extraocular Muscles and Lacrimal Gland

First Author: Nikunj GUPTA

Co-Author(s): Nehal KAPOOR

Purpose: To report an unusual presentation of a malignant epithelial tumor simultaneously involving multiple extraocular muscles and the lacrimal gland.

Methods: This is a case report of an elderly male who presented with proptosis and ocular motility restriction. Clinical evaluation, multimodal radiological imaging were found to be suspicious of non specific orbital inflammation. Further histopathological analysis was done to establish the diagnosis.

Results: Imaging revealed bulky lacrimal gland and extraocular muscles involving the medial, superior and lateral rectus with fat stranding, suggesting the possibility of orbital pseudotumor. Biopsy, however, confirmed the diagnosis of a malignant epithelial tumour in both the extraocular muscles and lacrimal gland. The dual involvement of the lacrimal gland and multiple extraocular muscles by the same tumour is exceedingly rare.

Conclusions: Malignant epithelial tumours of the orbit typically originate from the lacrimal gland; however, simultaneous primary involvement of multiple extraocular muscles is exceptionally uncommon. This case highlights the importance of considering atypical presentations of orbital epithelial tumours, careful imaging interpretation, and timely histopathological confirmation for accurate diagnosis and management.

Optic Nerve Sheath Meningioma: Clinico-radiological features and Management Outcomes

First Author: Sonam NISAR

Co-Author(s): Shahid ALAM, Varsha BAKIAVATHY, V BALASAUNDARAM, Kirthi KOKA, Bipasha MUKHERJEE, Ambika SELVARAJ, Prithvi VISHWANATHAN

Purpose: To analyze the clinico-radiological profile and management outcomes of optic nerve sheath meningioma (ONSM).

Methods: A retrospective analysis of 26 patients diagnosed radiologically with optic nerve sheath meningiomas was carried out between July 2014 to February 2023. Patients were divided into 3 groups: ONSMs observed, received external beam radiotherapy (EBRT), and those who underwent surgical debulking.

Results: The mean age of the study population was 41.96 $\pm$ 13.31 years (Range: 6-71 years) There was a female preponderance (n=18,69.23%). The most

common complaints were deterioration of vision (n=15, 57.7%) and proptosis (n=9, 34.6%). Optic disc edema was seen in 38.46% (10) cases and 46.15% (12) presented with disc pallor. Unilateral involvement was seen in 24 patients. Fifteen received EBRT and 8 patients remained under observation at the initial presentation. Three patients with no vision and disfiguring proptosis underwent surgical debulking. Amongst those under observation, five had worsening of vision and/or visual fields, as well as an increase in the size of the lesion on imaging, and eventually received EBRT. Improvement in visual fields was seen in 75% of patients and regression in the size of the lesion on imaging was noted in 53.33% of patients who received EBRT. Median follow-up was 1.8 years.

Conclusions: Optic nerve sheath meningiomas may present with decreased vision and/or proptosis. Radiotherapy is the preferred treatment modality for symptomatic ONSM. The presence of disc edema at presentation has a favorable outcome.

Orbital Mass Mystery: From Mucocele to Tuberculosis

First Author: Cecillia Apriliana WULANDARI

Co-Author(s): Prika Maulina AGARISTI, Neni ANGGRAINI

Purpose: Orbital lesions represent a diagnostic challenge due to diverse etiologies, from benign mucoceles to aggressive malignant tumors. Clinical and radiological features often overlap, making histopathological confirmation essential for accurate diagnosis and management. This poster presents an orbital tuberculosis case initially misdiagnosed as a mucocele or malignancy, highlighting the critical role of pathology.

Methods: A 50-year-old woman presented with a progressively enlarging right upper orbital mass for 2 months, associated with localized pain. She had a long-standing history of multiple cutaneous nodules consistent with Neurofibromatosis type 1. CT-scan revealed a cystic lesion with irregular thick walls, heterogeneous enhancement, and focal bony destruction extending to the frontal sinus, raising suspicion of malignancy. The patient underwent anterior orbitotomy and excision. Intraoperatively, thick yellowish-green pus and irregular masses were identified, also raising suspicion of malignancy. But, histopathological analysis demonstrated granulomatous inflammation with necrosis and nuclear debris, compatible with Mycobacterium tuberculosis infection, and excluded malignancy. The patient was referred to internal medicine and started on a 9-month course of antituberculosis therapy, with gradual resolution of the orbital mass and symptoms.

Results: This case illustrates how orbital tuberculosis can clinically and radiologically mimic mucocoeles or malignant tumors, particularly in patients with neurocutaneous disorders where suspicion for malignancy is high. Imaging alone is insufficient; histopathology remains the gold standard to establish a definitive diagnosis and prevent mismanagement.

Conclusions: Accurate diagnosis of orbital masses requires a multidisciplinary approach. Histopathology is central in distinguishing infectious from neoplastic processes, ensuring proper treatment and improved outcomes.

Pediatric Ocular Surface Squamous Neoplasia in the Absence of Known Risk Factors and Systemic Conditions

First Author: Purnima RAJKARNIKAR STHAPIT

Co-Author(s): Ashiyana NARIANI, Rohit SAIJU

Purpose: Pediatric ocular surface squamous neoplasia (OSSN) is rare, with few reported cases. We present a series of 16 pediatric and adolescent OSSN cases without known genetic or infectious risk factors.

Methods: Descriptive case series at a single tertiary eye care center in Nepal where children with histopathologically proven OSSN were identified, and their disease was characterized.

Results: Unilateral OSSN was observed in 16 pediatric patients (6–18 years old) with no identifiable risk factors. All lesions were histopathologically proven as OSSN and characterized by type. Nine (56%) were conjunctival intraepithelial neoplasia (CIN) I, 5 (31%) were CIN II, and 2 (13%) were CIN III. There were no cases of squamous cell carcinoma. None of the patients had xeroderma pigmentosum, HIV, or hepatitis B or C.

Conclusions: This work reports a case series of pediatric OSSN in the absence of risk factors and systemic conditions. More than half of the patients had mild CIN. Though rare, this case series highlights the importance of considering OSSN in the differential diagnosis of pediatric ocular surface lesions, perhaps especially in this geographic location.

Panel No.: OPA-0687

Proptosis to Diagnosis: A Case of Systemic Amyloidosis Presenting As Painless Proptosis in a 75-Year-Old Male

First Author: Erika Mae GALEOS

Co-Author(s): Kristianne Chyna DABUET, Justine May TORREGOSA

Purpose: To report a rare case of systemic amyloidosis with an initial presentation of an orbital mass mimicking malignancy.

Methods: We present a case of a 75-year-old Filipino male with a four-year history of progressive right eye proptosis and vision loss. CT scan showed a non-enhancing soft tissue mass with calcifications encasing the right globe, raising suspicion for a neoplasm. He was advised to undergo further workup at a tertiary hospital. Examination revealed a firm, immobile, non-tender orbital mass causing marked proptosis, lagophthalmos, and ophthalmoplegia. Repeat CT demonstrated an ill-defined retrobulbar mass compressing the optic nerve with internal calcifications. The initial incision biopsy showed equivocal findings of pseudoepitheliomatous hyperplasia. The patient subsequently underwent lid-sparing exenteration as a palliative treatment for possible metastatic disease and to secure a definitive diagnosis. Intraoperatively, the mass was yellowish-white, firm, and friable.

Results: Histopathology revealed fibroadipose and fibromuscular tissues extensively infiltrated by amorphous, eosinophilic, acellular material involving the interstitium and vessel walls. Congo red staining confirmed amyloidosis by demonstrating characteristic apple-green birefringence under polarized light. Further systemic workup showed a partially calcified left upper lung mass, a hypodense left thyroid nodule, and irregular gastric wall thickening with calcified lymph nodes, raising concern for systemic amyloidosis or metastatic disease.

Conclusions: This case illustrates the diagnostic challenge of amyloidosis, which can closely mimic malignancy both clinically and radiographically. Definitive diagnosis relies on tissue biopsy with appropriate staining. A high index of suspicion and multidisciplinary coordination are vital, especially in elderly patients with systemic findings suggesting additional pathology.

Panel No.: OPA-0693

Removing Small Cavernous Hemangioma Located in the Deep Orbital Apex Extending Into the Cavernous Sinus Under Endoscopic Transnasal Approach

First Author: Wu WENCAN

Purpose: To present a new surgical technique for the excision of cavernous hemangioma(CH) located in the orbital apex extending into the cavernous sinus.

Methods: A total of 6 patients with CH extending from the orbital apex to the cavernous sinus were enrolled. Patients were diagnosed by clinical manifestations, computed tomography (CT), and magnetic resonance imaging (MRI) of the orbit, and pathologically confirmed to be CH after surgery. The indication for surgery was visual impairment due to the CH mass, which was completely removed via the endoscopic transnasal approach. Complete ophthalmologic examinations of all patients in the preoperative and postoperative

periods were collected and compared, including visual acuity (VA), visual field (VF), eye motility and proptosis, intraocular pressure (IOP), and the thickness of the retinal nerve fiber layer (RNFL).

Results: CH masses of all patients were completely removed, and surgeries were uneventful. All patients with VA impairment experienced varying degrees of improvement after surgery, the mean VA improved from LogMAR 4.4±0.1 preoperatively to LogMAR 4.8±0.2 postoperatively ($p=0.120$). The mean deviation index of VF was -16.13±15.4 dB preoperatively and -7.96±12.80 dB postoperatively ($p=0.223$), improved in 3 patients. The VF index was 53.25±51.00% preoperatively and 77.25±43.52% postoperatively ($p=0.305$), and the pattern standard deviation was 3.64±2.60 dB preoperatively and 4.01±4.54 dB postoperatively ($p=0.913$). The preoperative and postoperative mean degree of proptosis was 13.7±3.1mm and 12.3±1.5mm, respectively ($p>0.05$). The preoperative and postoperative IOP and the thickness of RNFL were normal in all patients. Two patients occurred transitory diplopia after surgery without other serious complications observed.

Conclusions: CHs located in the deep orbital apex extending into the cavernous sinus remain a surgical challenge. The endoscopic transnasal approach seems to be a safe and feasible, less invasive surgical technique for the treatment of CHs in this area.

Panel No.: OPA-0692

Synergistic Killing Effects of Melphalan and the Focal Adhesion Kinase Signaling Suppression on Retinoblastoma

First Author: Hoi Tung CHOW

Co-Author(s): Hoi Ying CHAN, Wai Kit CHU, Ivan KONG, Cheuk Sing YAM, Linbin ZHOU

Purpose: Melphalan is an effective chemotherapeutic drug for treating retinoblastoma (RB) cases with vitreous seedings, but its adverse effects impose an urgent need to develop an effective combined treatment modality with less toxicity. We previously showed that inhibiting growth hormone-releasing hormone signaling impaired RB cell viability by suppressing the focal adhesion kinase (FAK) axis. This study investigates the synergistic killing effects of Melphalan and FAK signaling suppression on RB.

Methods: Y79 and WERI-Rb1 cells were co-treated with various doses of an FAK inhibitor, PF-573228, and Melphalan for 72 hours, followed by cell viability determination via cell counting kit-8 assays. Significance of the difference between treatment groups was analyzed by an unpaired Student's t-test.

Results: PF-573228 and Melphalan respectively dose-dependently decreased Y79 and WERI-Rb1 cell viability. In Y79 cells, 10μM PF-573228 with 10μM Melphalan

resulted in a more substantial decrease in cell viability than 10μM Melphalan treatment alone ($n=3$ in each group and $p<0.05$). Notably, a remarkable reduction in cell viability was observed in 15μM PF-573228 with Melphalan (2.5μM, 5μM, and 10μM) treatment versus Melphalan (2.5μM, 5μM, and 10μM) single treatment ($n=3$ in each group and $p<0.05$ in all comparisons). In WERI-Rb1 cells, cell viability substantially decreased in PF-573228 (5μM, 10μM, and 15μM) combined with Melphalan (2.5μM, 5μM, and 10μM) treatment versus Melphalan (2.5μM, 5μM, and 10μM) treatment alone ($n=3$ in each group and $p<0.05$ in all comparisons).

Conclusions: Blocking the FAK signaling synergizes Melphalan killing effects on RB.

Panel No.: OPA-0694

The Chemotherapy-Potentiating Effects of the Growth Hormone-Releasing Hormone Receptor Antagonist MIA-602 on Retinoblastoma

First Author: Linbin ZHOU

Co-Author(s): Hoi Ying CHAN, Wai Kit CHU, Jiahui LI, Chi Pui PANG, Cheuk Sing YAM

Purpose: Chemotherapy is a common treatment modality in retinoblastoma (RB). Growth hormone-releasing hormone receptor (GHRH-R) is expressed in RB cells. MIA-602, a GHRH-R antagonist, has been shown to potentiate chemotherapy effects on numerous cancers. Nevertheless, it remains unclear whether MIA-602 can potentiate chemotherapy effects on RB. This study investigates the chemotherapy-potentiating effects of MIA-602 on RB.

Methods: Y79 cells were co-treated with 10μM MIA-602 and various doses of chemo drugs, carboplatin or vincristine for 48 hours. Cell counting kit-8 assays and flow cytometry analyses were used to measure cell viability and apoptosis, respectively. Data were analyzed by an unpaired Student's t-test.

Results: In Y79 cells, 10μM MIA-602 treatment decreased the cell viability ($-0.18±0.02$, $p=0.0007$) and increased the sub-G1 population ($1.09±0.11$, $p=0.0006$). In comparison with carboplatin (10μM or 25μM) single treatment, a combined treatment with 10μM MIA-602 and carboplatin (10μM or 25μM) resulted in a more substantial cell viability impairment ($-0.14±0.03$, $p=0.0057$; $-0.16±0.02$, $p=0.0006$) and a higher proportion of the sub-G1 population ($1.96±0.27$, $p=0.002$; $5.33±0.40$, $p=0.0002$). Co-treatment with 10μM MIA-602 and vincristine (2.5nM or 10nM) led to a more significant decrease in cell viability ($-0.13±0.01$, $p<0.0001$; $-0.05±0.01$, $p=0.013$) as well as a more markedly increased proportion of the sub-G1 population ($13.70±0.52$, $p<0.0001$; $8.50±0.52$, $p<0.0001$) than vincristine (2.5nM or 10nM) single treatment.

Conclusions: GHRH-R antagonists MIA-602 can potentiate chemotherapy effects on RB.

Panel No.: OPA-0667

The Enigma of Orbital Fibrosarcomatous Dermatofibrosarcoma Protuberans: Diagnostic and Management Challenges in a Rare Aggressive Case

First Author: Hindun **ZAKIYAH**

Co-Author(s): Neni **ANGGRAINI**, Michael **HARTONO**, Mutmainah **MAHYUDDIN**, Florentina **PRISCILIA**

Purpose: To describe the diagnostic and management challenges in a case of orbital fibrosarcomatous dermatofibrosarcoma protuberans (FS-DFSP).

Methods: We report the case of a 60-year-old Asian man with orbital FS-DFSP, confirmed by immunohistochemistry, who eventually underwent exenteration.

Results: The patient presented with painful progressive proptosis of the right eye following mild trauma. Orbital CT revealed a solid intraconal mass in the inferomedial orbit. Initial excision was successful, and histopathology demonstrated a low-grade spindle cell neoplasm. After an eight-month loss to follow-up, He returned with profound vision loss and a rapidly enlarging intra-extraconal mass, nearly double the original size. Second excision confirmed transformation into spindle cell sarcoma. Immunohistochemistry was positive for CD34 and EMA but negative for S100, consistent with FS-DFSP. He was started on Imatinib (400 mg daily) and considered for adjuvant intensity-modulated radiotherapy (35 × 2 Gy). Despite dose escalation, within two months, he developed a recurrent orbital mass with malignant features, accompanied by complete vision loss. CT demonstrated extensive infiltration involving the entire orbit, right ethmoid and frontal sinuses, and intracranial extension. Orbital exenteration was subsequently undertaken as the most appropriate measure for achieving local control. A systemic metastasis workup was performed thereafter.

Conclusions: Orbital DFSP is an exceedingly rare malignancy, with the FS-DFSP variant carrying a higher risk of recurrence and metastasis. Diagnosis depends on immunohistochemical and molecular analysis. Wide-margin resection remains the mainstay of treatment, while exenteration is required in aggressive infiltrative disease, supported by adjuvant therapy. Therapeutic decisions should involve an interdisciplinary team, especially when transformation to high-grade sarcoma occurs.

The Role of Lactate Metabolism in Retinoblastoma Tumorigenesis and Ferroptosis Resistance

First Author: Zhihui **ZHANG**

Co-Author(s): Rong **LU**, Junjie **TANG**

Purpose: The Warburg effect, a hallmark of cancer, describes the preference of cancer cells for glucose metabolism via aerobic glycolysis, leading to substantial lactate accumulation. However, the role of lactate metabolism in retinoblastoma, the primary intraocular malignancy in children, remains unclear. This study aims to elucidate the gene expression profiles associated with lactate metabolism in retinoblastoma and their impact on tumorigenesis and ferroptosis resistance.

Methods: The involvement of metabolic characteristics in retinoblastoma was analyzed by comparing single-cell RNA sequencing transcriptome profiles from normal retina tissues and retinoblastoma tissues from patient samples. The effects of lactate on retinoblastoma cell line activity and its mechanisms were examined both in vitro and in vivo.

Results: Single-cell RNA sequencing analysis revealed enhanced glycolysis in retinoblastoma cells and significant differences in lactate metabolism-related gene expression among various retinoblastoma cell types. Retinoblastoma cell lines with moderate lactate levels exhibited increased viability and resistance to ferroptosis induced by ferroptosis inducers. Additionally, lactate promoted the upregulation of monocarboxylate transporter 1 (MCT1), which facilitated lactate transport, in a dose-dependent manner in retinoblastoma cell lines. Knocking down MCT1 reduced both viability and ferroptosis resistance of retinoblastoma cell lines in a lactate-rich environment. In vivo, disrupting lactate transport through MCT1 inhibition suppressed retinoblastoma tumorigenesis and invasion in a mouse xenograft model, and this effect was reversed by the ferroptosis inhibitor liproxstatin-1.

Conclusions: These findings highlight the crucial role of lactate metabolism in retinoblastoma tumorigenesis and resistance to ferroptosis.

Panel No.: OPA-0669

Topical Tacrolimus in the Management of Conjunctival Lymphoproliferative Disorders: A Case Series

First Author: Neeraja T G

Co-Author(s): Shruthi Tara V

Purpose: To evaluate the efficacy of topical tacrolimus 0.03% eye ointment as a monotherapy for Conjunctival Lymphoproliferative Disorders.

Methods: We report a case series of three patients (five eyes) who presented to us with classical conjunctival "salmon patch" lesion. Incisional biopsy followed by histopathological examination with immunohistochemistry confirmed Conjunctival Benign Lymphoid Hyperplasia (bilateral) in 2 patients and Extra-nodal Marginal Zone B-cell Lymphoma in 1 patient. All patients initially responded to topical corticosteroids but experienced relapse upon steroid cessation. 4 out of 5 eyes were treated with other steroid-sparing agents such as topical cyclosporine 1%, topical 5-fluorouracil 1%, topical alpha-interferon and intralesional Ranibizumab, but with either no resolution or frequent recurrences. Oncologist referral was sought to rule out systemic involvement in conjunctival lymphoma. Tacrolimus 0.03% eye ointment was prescribed twice daily till clinical resolution and then maintained on once daily dosage for 6 months.

Results: At one month review, all 5 eyes achieved complete clinical resolution. Only one out of five eyes developed a recurrence (benign lymphoid hyperplasia) at 8 months, and the dosing of Tacrolimus 0.03% ointment was increased to twice daily for one month following which remission was achieved.

Conclusions: The overall prognosis for conjunctival lymphoproliferative disorders is excellent, with high long-term survival rates. However, the potential for local and systemic relapse necessitates a paradigm shift from a short-term «cure» to a safer alternative that can provide long-term immunomodulation. Topical tacrolimus 0.03% appears to be an effective steroid-sparing monotherapy agent for conjunctival lymphoproliferative disorders, achieving sustained clinical resolution and reducing recurrence risk.

Two Decades of Kissing Nevus Management Experiences in Tertiary Eye Hospital: Unusual Cases of Nevus, From Macroscopic to Microscopic Findings

First Author: Rabiul PRIYANTONO

Co-Author(s): Niluh AYU, Shanti BOESOIRIE, Mohamad DAHLAN, Raden KARTIWA, Pradistya YUDIASARI

Purpose: To report six cases of kissing nevus in eyelids, highlighting clinical, surgical, and histopathological findings.

Methods: A retrospective review was performed on six patients who underwent treatment for a divided eyelid nevus using direct closure and skin flap procedures between 2004 and 2024. Depending on the nevus location, shape, and size of the upper and lower eyelids, reconstruction was carried out using a direct closure or full-thickness skin graft from the supraclavicular region. Histopathological analysis was performed. Postoperative outcomes were monitored for up to one month.

Results: We showed that the lesion was randomly located in both eyes, with all patients being females with a range of ages from 9 to 54 years. The lesion size varied, ranging from 1.4cm to 5 cm. About 3 of 6 patients were treated using direct closure, and the rest of them were treated using a full-thickness skin graft from the supraclavicular region. All other reconstructions demonstrated good survival. No additional complications were observed during the 1-month follow-up. All donor sites were closed primarily and healed well with minimal scarring. Histopathological findings from 4 of 6 patients show an intradermal nevus, and 2 patients show a compound nevus.

Conclusions: Kissing nevus is a rare congenital melanocytic lesion that may enlarge with age, leading to cosmetic and functional concerns. Surgical excision with direct closure or skin flap reconstruction provides effective management and favorable cosmetic results. Most cases show an intradermal nevus as histopathological findings.

Uncommon Ocular Findings in Extraconal Neurofibroma Type I: A Case Series

First Author: Andi YASMIN

Co-Author(s): Suliati AMIR, Halimah PAGARRA, Andi PRATIWI, Imeldy PURNAMA, Syukriyah SOFYAN

Purpose: To present a case series of four patients with extraconal neurofibromas (NF1), each exhibiting distinct and uncommon ocular manifestations. This series highlights the diagnostic challenges and emphasizes the importance of a multidisciplinary approach in their management.

Methods: We conducted a retrospective review of four NF1 patients presenting with uncommon ocular manifestations. All patients underwent comprehensive ophthalmologic examination, systemic evaluation for NF1 diagnostic criteria, and multimodal imaging, including computed tomography and/or magnetic resonance imaging. Histopathologic analysis utilized hematoxylin-eosin staining, with immunohistochemical studies employing S-100 and Ki-67 markers.

Results: Four NF1 patients with rare ocular manifestations, including proptosis, eyelid tumors, pulsating proptosis, and conjunctival tumors. All patients met at least 3 of the 7 NIH diagnostic criteria for NF1. Imaging studies revealed abnormalities in all cases: an inferior orbital mass in case 4 and bone erosion or sphenoid wing absence in cases 1, 2, and 3. Vascular malformations associated with pulsating proptosis were identified in case 3. Histopathologic examination revealed spindle-shaped Schwann cells, while S-100 and Ki-67 immunohistochemistry confirmed benign neurofibroma.

Conclusions: Uncommon ocular manifestations of NF1 may mimic other orbital pathologies and require careful clinical evaluation. Integration of NIH diagnostic criteria, imaging, histopathology, and molecular tools such as S-100 and Ki-67 immunohistochemistry enables differentiation from ANNBP or MPNST. Early diagnosis and multidisciplinary care are crucial for managing functional and aesthetic complications in NF1.

Panel No.: OPA-0691

Unusual Pediatric Orbital Mass: A Rare Case of Solid Cystic Hidradenoma

First Author: Mutmainah MAHYUDDIN

Co-Author(s): Neni ANGGRAINI, Evelina KODRAT, Andintia Aisyah SANTOSO, Muhammad Dio SYAPUTRA

Purpose: Solid cystic hidradenoma (SCH) is a benign tumor of eccrine sweat glands, most often presenting as intradermal nodules in cutaneous sites. Orbital involvement is exceedingly rare and usually appears as a slowly enlarging solitary mass, although in some cases it may progress rapidly and mimic malignant orbital tumors. Confirmation with electron microscopy and enzymatic histochemical studies is essential to avoid misdiagnosis and inappropriate treatment.

Methods: We report the case of a 2-year-old girl presenting with a one-month history of rapidly progressive unilateral proptosis. A mass had initially been noted five months earlier and had enlarged significantly after an incisional biopsy performed at another center. Orbital imaging, including MRI, revealed a solid-cystic hypervascular mass with intracystic hemorrhage located in the superotemporal orbit, involving the lacrimal gland but without evidence of bone destruction or intracranial extension.

Results: The patient underwent complete excision through a lateral orbitotomy, with intraoperative aspiration performed to facilitate dissection. Histopathological examination confirmed the diagnosis of solid cystic hidradenoma. Postoperatively, ptosis and limited ocular motility were observed but improved gradually during follow-up. No recurrence was documented.

Conclusions: This case highlights the diagnostic challenge of orbital SCH in children, particularly when presenting as a rapidly enlarging orbital mass that clinically resembles malignancy such as rhabdomyosarcoma. Although rare, SCH should be included in the differential diagnosis of pediatric progressive proptosis. Early recognition and complete surgical excision are crucial to prevent recurrence and preserve visual function.

Unveiling the Mystery: Case of a Medial Canthal Mass and Its Management

First Author: Nidhi MUNDADA

Co-Author(s): Rekha KHANDELWAL, Gaurav PATIL

Purpose: To demonstrate a case of a squamous cell carcinoma (SCC) involving the medial canthus, detailing the diagnostic approach and management using a paramedian glabellar flap followed by radiotherapy.

Methods: A 73-year-old male presented to the OPD with a large, non-tender, and gradually progressing mass in the left lower eyelid for three months. Complete clinical assessment was performed, including ocular and systemic examination and radiological investigations. The CT scan imaging revealed a well-defined lesion with involvement of the lower and common canaliculi. The patient was planned for wide local excision with dacryocystectomy, and the reconstruction was done with a paramedian forehead flap. The patient was subjected to 30 cycles of immunomodulatory radiotherapy. There has been no recurrence.

Results: The histopathological examination features were consistent with squamous cell carcinoma without involvement of the nasolacrimal duct.

Conclusions: The medial canthal masses are difficult to treat. Early detection with a detailed clinical and radiological examination of such masses is pivotal in planning the management. The management plan includes radiotherapy to reduce the chances of systemic metastasis, closely following up the patient.

Visual and Oncological Outcomes of Cataract Surgery After Retinoblastoma: A Decade of Experience in South India

First Author: Vinitha Loganathan RASHME

Co-Author(s): Usha KIM

Purpose: To evaluate the visual and oncological outcomes of cataract surgery in patients previously treated for intraocular retinoblastoma.

Methods: A retrospective analysis was conducted on 13 eyes of children with retinoblastoma who underwent cataract surgery.

Results: The mean age at retinoblastoma diagnosis was 20.7 months (range: 1–60); 5 patients were female. Based on the International Classification of Intraocular Retinoblastoma, 5 eyes were Group E, 5 Group C, 2 Group D, and 1 Group B. All patients received intravenous chemotherapy; 9 eyes (69.2%) received external beam radiotherapy (EBRT), 2 underwent intra-arterial chemotherapy and others. The mean interval between EBRT and cataract diagnosis was

36 months (range: 2–168), and the mean duration between tumor regression and cataract surgery was 26 months (range: 0–160). Cataract extraction with intraocular lens (IOL) implantation was performed in 11 eyes, while 2 eyes underwent lens extraction alone due to suspected tumor activity; both subsequently required enucleation. At the final follow-up, 7 eyes achieved best corrected visual acuity of 20/200 or better. Postoperative complications included visual axis opacification in 2 eyes and secondary glaucoma in 1 eye. Tumor regression was maintained in all 11 eyes with IOL implantation. Globe salvage was achieved in 11 eyes (84.6%) with a mean follow-up of 49 months (range: 10–192). Germline RB1 mutation was detected in 8 patients.

Conclusions: Cataract surgery in eyes with adequately regressed retinoblastoma provides meaningful visual rehabilitation while maintaining oncological safety.

Ophthalmic Epidemiology and Prevention of Blindness

Abstract No.: 200529

Panel No.: OEP-0697

A Study of Visual Impairment Severity and Refractive Profile in Albinism Patients Using Genetic Testing

First Author: Chonglin **CHEN**

Co-Author(s): Daming **DENG**, Jun **LI**, Xinping **YU**

Purpose: The purpose of this study was to evaluate the characteristics of visual impairment severity and the refractive profile in Chinese patients with albinism.

Methods: In this study, patients with a clinical diagnosis of albinism were enrolled. Comprehensive ophthalmic examinations and whole-exome sequencing were performed.

Results: In this consecutive, cross-sectional study, 70 OCA probands were enrolled, ranging in age from 1 to 67 years. Most probands (47.1%, 33/70) had moderate vision impairment, 14.3% (10/70) had severe visual impairment, and 4.3% (3/70) exhibited blindness. Myopia predominated (61.4%) over hyperopia (38.6%), with severe refractive errors prevalent in both groups: high hyperopia affected 40.7% (11/27) of hyperopic patients, while high myopia affected 32.6% (14/43) of myopic patients. Significant astigmatism (mean 2.56 ± 1.81 D) was universally present. OCA1 demonstrated the most severe visual phenotype: blindness (10.0%, 3/30), severe (23.3%, 7/30), and moderate (53.3%, 16/30). This subtype also exhibited significant refractive heterogeneity, comprising both high myopia (18 cases; 5 high, 13 medium/low) and high hyperopia (12 cases; 4 high, 8 medium/low).

Conclusions: In our albinism cohort, over 65% exhibited moderate-to-severe visual impairment or blindness. Myopia predominated (61.4%, 43/70) over hyperopia (38.6%, 27/70). OCA1 demonstrated the most severe visual phenotype, encompassing all blindness cases and most (70%, 7/10) of the severe visual impairment. OCA1 represented 35.7% (5/14) of all high myopia cases. OCA2 exhibited pronounced myopic predominance (75%, 15/20). These novel findings could provide insight into the understanding of albinism.

Panel No.: OEP-0704

Acute Blindness in an 18-Year-Old Male: A Case Study of Bilateral Optic Papilla Edema and Cryptococcal Meningitis

First Author: Zhouyu **LI**

Co-Author(s): Wenli **DENG**, Rui **YU**, Yanlai **ZHANG**

Purpose: Through the diagnostic odyssey of an 18-year-old male presenting with acute painless bilateral vision loss and chronic headache over one month, a rare etiopathological factor was ultimately identified.

Methods: Comprehensive ophthalmic assessments were conducted, including best-corrected visual acuity (BCVA) testing, fundus photography, optical coherence tomography (OCT), and optical coherence tomography angiography (OCTA). A multidisciplinary consultation involving neurology and infectious disease specialists was arranged, alongside parallel serologic testing, cerebrospinal fluid (CSF) analysis, thoracoabdominal computed tomography (CT), and cranial magnetic resonance imaging (MRI) to establish a definitive diagnosis and guide therapeutic management.

Results: Neurology consultation and cerebrospinal fluid (CSF) analysis revealed elevated CSF pressure of 230 mmH₂O, and microbiological studies confirmed positive cryptococcal antigen testing with India ink staining identifying *Cryptococcus neoformans*. The patient was diagnosed with AIDS, *Cryptococcus neoformans* meningitis complicated by elevated intracranial pressure, and secondary optic papilla edema (bilateral eyes). The treatment regimen included intracranial pressure reduction measures, combination antifungal therapy with amphotericin B and flucytosine, antiretroviral therapy (ART), and neurotrophic support. Following the treatments, there was no improvement in right eye vision, while left eye vision improved to 4/200.

Conclusions: 1. Sudden visual loss with optic disc edema in young adults, particularly when accompanied by unexplained headache, warrants vigilance for possible cryptococcal meningitis. 2. This condition often indicates underlying immunodeficiency and represents an ocular manifestation of opportunistic infection. 3. Multidisciplinary collaboration is critical for the precise diagnosis and treatment of complex cases.

Abstract No.: 203066**Panel No.: OEP-0710**

Association of Screen Time, Sleep Quality, and Its Association With Dry Eye Among Medical Students: A Study From North India

*First Author: Amandeep HANS**Co-Author(s): Vaishali RAKHEJA, Sonia VADIYA*

Purpose: To estimate the association of daily screen time and quality of sleep with Dry eyes in medical students.

Methods: A cross-sectional, observational study was conducted on 400 MBBS students at a tertiary medical college. Participants completed a pre-validated Google Form comprising the Standard Patient Evaluation of Eye Dryness (SPEED) questionnaire and the Mini Sleep Questionnaire. Data on screen time, contact lens use, and eye drop usage were also collected. Associations were analyzed using the chi-square test, and p-values <0.05 were considered statistically significant.

Results: Of the 401 participants, 59.5% were female and the most common age was 21 years. A majority (96.2%) used an iPad, and 51.8% reported daily screen time exceeding 4 hours. Mild dry eye symptoms were present in 84.7% of participants, while 8.3% and 8.3% reported moderate and severe symptoms, respectively. Sleep quality showed a significant association with dry eye severity (Chi-square = 27.838, $p < 0.001$). Moderate association was found between screen time duration and dry eye severity ($p < 0.001$).

Conclusions: Dry eye disease is highly prevalent among medical students and is significantly associated with prolonged screen time, poor sleep quality, and contact lens use. Awareness and early preventive strategies targeting modifiable lifestyle factors are critical to reduce the dry eye symptoms.

Abstract No.: 202956**Panel No.: OEP-0711**

COVID-19's Impact on Blindness and Vision Loss: Machine Learning Predicts Rising Burden and Shifting Risk Factors to 2050

*First Author: Jiaying LIU**Co-Author(s): Gengchen JIANG, Zhaohuai LI, Wenru SU, Zihan YAO, Yehong ZHUO*

Purpose: To comprehensively characterize the prevalence and disease burden of Blindness and Vision loss (BVL)—as well as specific eye diseases—over the 30 years (1990–2021), to investigate shifts in risk factors for BVL, to examine the impact of COVID-19, and to enhance projections of future ophthalmic disease burden.

Methods: Calculated the prevalence and disease burden of BVL-specific eye diseases at global, regional, and national levels. Using Joinpoint to explore the impact of COVID-19, besides, we employed descriptive

and decomposition analyses to examine the risk factors, and finally constructed time-related features to capture temporal patterns in BVL to project disease burden up to 2050.

Results: Global BVL cases nearly tripled (1990–2021), with AAPC of 0.78% (95%CI 0.62%–0.94%). Peak prevalence at 50–54 years; Near-vision loss showed highest burden. Preliminary analyses suggest that COVID-19 may have influenced the prevalence of several specific eye diseases, although the magnitude and direction of these effects vary. Strong negative SDI-ASPR ($p = -0.62$, $p < 0.05$) and SDI-ASDALY ($p = -0.78$, $p < 0.05$) correlations were observed. Population growth remains the primary driver of rising BVL. As for risk factors, during the COVID-19 period, ASDALY attributable to air pollution and tobacco declined, whereas those linked to high BMI and high FPG increased. Finally, projections to 2050 indicate that BVL burden will continue to rise, surpassing 40 million DALYs. High BMI is expected to make an increasingly large contribution, and high FPG is poised to overtake air pollution as the dominant factor. The elderly will bear the heaviest burden, yet a clear shift toward younger age groups is anticipated.

Conclusions: We predict that the disease burden caused by BVL will continue to increase and trend toward younger populations globally. Going forward, the primary risk factors for vision impairment are expected to transition to metabolic risk factors. The COVID-19 pandemic has altered the burden of eye diseases, and the leading drivers vary by country. Moreover, our study demonstrates the feasibility of using an XGBoost model to forecast disease burden, potentially improving predictive accuracy.

Abstract No.: 201229**Panel No.: OEP-0703**

Correlation of Obesity and Hyperlipidemia With Thyroid Eye Disease: A Systematic Review

*First Author: Lik San Alex CHENG**Co-Author(s): Kam Lung Kelvin CHONG, Ka Hei Kenneth LAI, Chi Pui Calvin PANG, Chee Yung Clement THAM, Tsz Hin Marcus YUNG*

Purpose: This systematic review aims to investigate the relationship between obesity and hyperlipidemia with thyroid eye disease (TED). This review seeks to synthesize existing evidence and provide insights into the clinical implications for thyroid patients with concurrent obesity and hyperlipidemia for the development of TED.

Methods: A systematic search was conducted using databases PubMed, MEDLINE, EMBASE, Web of Science, and ClinicalTrial.gov during July 2025. Two researchers independently screened abstracts and reviewed full text of relevant studies.

Results: For 968 studies identified, 17 of them met the predefined inclusion criteria. Data from 5 papers, comparing 246 Graves' Disease (GD) patients with TED and 254 GD patients without TED suggested that patients with TED had higher BMI and waist circumference than those without TED. Importantly, obesity-related factors, such as Body Mass Index (BMI), fasting plasma insulin and insulin resistance, correlated to the presence and severity of TED. BMI is also an independent factor predicting both orbital fat volume and proptosis severity. Furthermore, we analysed 6 cross-sectional studies in which 499 GD patients with TED and 481 patients without TED are included. Serum total cholesterol and low-density lipoprotein cholesterol (LDL) levels were significantly associated with TED. Hyperlipidemia may also be associated with Clinical Activity Score.

Conclusions: Both obesity and hyperlipidemia were found to be independent risk factors of TED and associated with disease activity and severity. Weight control and lipid-lowering therapy might be additional beneficial effects for TED.

Abstract No.: 200863

Panel No.: OEP-0700

Diabetic Retinopathy Screening in Australian General Practice: Geographic, Demographic, and Temporal Disparities From a National-Level Analysis

First Author: Sanil JOSEPH

Co-Author(s): Mingguang HE, Wenyi HU, Catherine JAN, Thulasiraj RAVILLA, Xianwen SHANG, Balagiri SUNDAR, Hugh TAYLOR, Zhuoting ZHU

Purpose: To examine the geographic and demographic variability in diabetic retinopathy (DR) screening uptake and factors influencing screening disparities in Australian general practice.

Methods: A retrospective, population-based observational study using Medical Benefits Schedule (MBS) claims data for DR screening using non-mydriatic fundus cameras, under items 12325 and 12326 from 2016 to 2024 across Australia. MBS data were obtained from Services Australia, and the demographic and socioeconomic indicators from the Australian Bureau of Statistics (ABS). Screening uptake was stratified by state, age, gender, and socioeconomic indicators.

Results: A total of 15,817 DR screenings were conducted, representing only 1.2% of the estimated diabetic population. MBS item 12325 (Indigenous Australian) accounted for 50.8% of screening, despite this group being a small proportion of the diabetic population. New South Wales and Western Australia had the highest total screening, while Tasmania recorded the lowest uptake. Screening uptake was highest in the <25 age group and lowest in those aged ≥75 years. Females had higher screening rates under MBS 12325, whereas males had higher rates under

MBS 12326. The COVID-19 pandemic contributed to a significant decline in screening uptake during 2020-2022, with partial recovery in 2023-2024. DR screening uptake showed no significant association with socio-demographic factors.

Conclusions: Despite national guidelines, GP-led DR screening uptake remains low, with substantial geographic, demographic and temporal disparities in Australian general practice settings. Addressing systemic barriers, strengthening GP-led screening, and implementing targeted interventions are crucial for improving DR screening uptake in Australia.

Abstract No.: 200689

Panel No.: OEP-0699

Enhancing Visual Function in Low Vision Patients Through Microperimetry Biofeedback Training: A Systematic Review and Meta-Analysis

First Author: Shafira Aulia HANIFA

Co-Author(s): Fairuziah Hetizta MAHARANI, Farhan WIRAJATI

Purpose: Microperimetric biofeedback training is an emerging neuroplasticity-based rehabilitation approach for patients with central vision loss. However, the therapeutic efficacy across various macular pathologies has not been fully characterized. This systematic review and meta-analysis evaluated the effectiveness of microperimetric biofeedback training in enhancing visual function among low vision patients with macular disease.

Methods: PubMed, Cochrane Library, CINAHL, Scopus, ScienceDirect, and Trip Database were searched following PRISMA guidelines. Randomised controlled trials and prospective comparative studies in adults with macular disorders were eligible. Primary outcomes included best-corrected visual acuity (BCVA), reading speed, and macular sensitivity changes. Standardized mean differences (SMD) were calculated using random-effects models, with heterogeneity assessed via I^2 statistics. Quality assessment employed the Newcastle-Ottawa Scale.

Results: Four studies encompassing 104 participants met the inclusion criteria and evaluated patients with Stargardt disease, age-related macular degeneration, and post-surgical macular holes. Microperimetric biofeedback training demonstrated significant BCVA improvement with SMD = -0.71 (95% CI: -1.12 to -0.31; $p < 0.01$; $I^2 = 0\%$), equivalent to 1-2 lines visual acuity gain. Reading speed showed substantial enhancement with SMD = 0.79 (95% CI: 0.32 to 1.26; $p < 0.01$; $I^2 = 0\%$). Macular sensitivity improvements were non-significant (SMD = 0.55, 95% CI: -0.18 to 1.27; $p = 0.14$) with considerable heterogeneity ($I^2 = 51\%$). Training protocols ranged from 6-16 sessions with follow-up periods of 6 weeks to 12 months.

Conclusions: Microperimetric biofeedback training achieves clinically meaningful improvements in visual acuity and reading performance across diverse macular pathologies, with consistent effects regardless of underlying etiology. The intervention addresses the most debilitating functional limitations experienced by low vision patients. Variable macular sensitivity responses suggest condition-dependent outcomes requiring individualised protocols. Standardized training guidelines and extended follow-up studies are needed to optimize clinical implementation.

Abstract No.: 202039

Panel No.: OEP-0706

Epidemiology of Rhegmatogenous, Serous, Tractional Retinal Detachment (RRD, SRD, TRD) and Associated Break or Defect: A UK Biobank Study

First Author: Edison Chak-fung HO

Co-Author(s): Philip Yawen GUO, Alexander KA NGAI LAM, Ryan Tak Chun WONG

Purpose: To investigate the epidemiology of RD and related conditions in UK adults.

Methods: The retrospective study included 502250 adults (aged 37-70 years) conducted with the UK Biobank. Baseline RD = % Had RD in first visit on 2006-2010, while incidence = RD developed in those who were free of disease in baseline/ 10000 person-year, with censored on date of death, date of losing follow-up, disease occurrence, or 2022-10-31. We calculated the prevalence and incidence of different types of RD and associated diseases in different subgroups classified by age, sex, ethnicity, and myopic state.

Results: A total of 2,078 patients (59% male) with RD and associated disease were identified in the baseline, with a prevalence of 0.414% in all and 0.538% in males. Incidence is 6.23/10000-person-year in all, while 7.82 in males. By ethnicity, White show the highest prevalence, followed by Asians and then Black (0.420%, 0.331% and 0.310%), and incidence in the same hierarchy (6.3, 5.02, 4.21/10000-person-year). Among RRD, SRD, TRD, and break, they show prevalence of 0.148%, 0.134%, 0.136% and 0.007% while incidence are 3.36, 1.65, 1.5, 0.24/10000-person years, indicating RRD is the most common, and TRD is the least common. Both prevalence and incidence of different subgroups show an increasing trend with increasing age and myopic grade.

Conclusions: RD prevalence and incidence vary with sex and ethnicity and are more common with increasing age and myopia. These findings overstate the need for investigation of underlying pathogenicity of retinal detachment and better screening in at-risk subjects for enhancing vision prognosis

Abstract No.: 201877

Panel No.: OEP-0705

Feasibility of Promotion Eye Examinations With the Smartphone Application for Children in Siem Reap, Cambodia

First Author: Hiroaki KATO

Co-Author(s): Yoshimune HIRATSUKA, Tatsukata KAWAGOE, Tean MENGHEANG, Seang POVCHAMREUN, Mayumi UETA

Purpose: In Cambodia, pediatric vision screening is virtually nonexistent. This study reports on local activities conducted to support the future implementation of vision screening programs.

Methods: A questionnaire survey was conducted among elementary school students in public schools in Siem Reap Province to assess awareness of visual impairment and prior vision testing. Visual acuity tests and basic eye examinations were then performed. Additionally, in a local orphanage, visual acuity was measured using both a standard vision chart and the Almirun application (Khmer version). Correlation and agreement between the two methods were evaluated.

Results: A total of 779 children (mean age: 8.96 years) participated in vision testing and ophthalmologic exams, with all responding to the questionnaire. While 24% reported subjective visual difficulties, unaided visual impairment was confirmed in 20.3%. Only 7.9% had prior experience with vision testing, indicating limited access. In the orphanage cohort (85 children, 170 eyes; mean age: 9.35 years), results from Almirun and the vision chart showed high correlation ($r = 0.91$, $R^2 = 0.83$). Bland-Altman analysis showed a mean logMAR difference of -0.0023 ($SD = 0.0039$) without fixed or proportional bias. Detection agreement for impaired vision ($\log MAR > 0$) was substantial ($\kappa = 0.70$).

Conclusions: Children in Siem Reap have limited access to vision screening. The Almirun app shows strong potential as an alternative screening tool and could help expand access to eye care in underserved areas

Foundation Models in Ophthalmology: A Preliminary Study on AI-Assisted Diagnosis of Pathologic Myopia Using Ultra-Widefield Fundus Images

First Author: Juzhao ZHANG

Co-Author(s): Xian XU, Tao YU, Haidong ZOU

Purpose: This study aims to detect characteristic fundus changes in pathological myopia using deep learning (DL)-based analysis of ultra-widefield (UWF) fundus imaging.

Methods: Following the exclusion of low-quality images, this cross-sectional study utilized 1,105 UWF images from 543 patients with high myopia to develop

the model, along with 293 images from 150 high myopia patients for external testing. All images were retrospectively collected from high myopia patients at Shanghai General Hospital and Shanghai Eye Diseases Prevention and Treatment Center between 2018 and 2024. We trained a DL model based on an ophthalmology foundational model to detect myopic maculopathy (MM) and posterior staphyloma (PS).

Results: The proposed RETFound-enhanced model demonstrated robust performance. For the five-category classification of MM, it achieved 65.4% accuracy and an F1 score of 0.648, outperforming other methods. In the three-category MM classification, it achieved 79.4% accuracy and an F1 score of 0.793. For PS detection, the model reached 84.1% accuracy, an F1 score of 0.814, and an AUROC of 0.886, highlighting its effectiveness as a screening tool. External validation showed consistent performance, with 64.4% accuracy for five-category MM classification, 79.8% accuracy for three-category classification, and 81.2% accuracy for PS, confirming robustness across cohorts.

Conclusions: This study presents an effective diagnostic model for pathological myopia using UWF fundus imaging and a foundation model. The integration of DL with non-mydratic UWF fundus imaging demonstrates promising potential for applications in primary healthcare, particularly in underserved areas, enabling accessible screening for high myopia-related fundus changes.

From Needle Jabs to Surgical Zen: A Safer Way to Block in Community Operation Theatres

First Author: Disha AGARWAL

Co-Author(s): Meenakshi DOGRA, Meena MENON

Purpose: To analyze the impact of shifting from peribulbar to sub-Tenon's anaesthesia in high-volume community cataract OTs.

Methods: Medical record data of 18,482 sub-Tenon's and 17,822 peribulbar cases were reviewed. Complications—globe perforation, retrobulbar hemorrhage (RBH), and occupational risks like needle stick injuries—were analyzed.

Results: No complications were reported in the Sub-Tenon's group. In contrast, the peribulbar group had 26 complications (0.15%)—3 globe perforations, 2 RBH, and 21 needle stick injuries ($z = -5.25$, $p < 0.001$).

Conclusions: Sub-Tenon's anaesthesia demonstrated a significantly safer profile than peribulbar, eliminating both surgical and occupational risks. It offers a safer alternative for high-volume community ophthalmic settings. In community OTs, sub-Tenon's anaesthesia reduces risk of serious complications, enhances safety, & improves overall surgical efficiency. It's a preferred

choice for large-scale programs, where managing adverse events is challenging due to limited resources or immediate access to specialized care.

Abstract No.: 205638

From Retina to Nerve: Unraveling the Intricate Clinical Association of Diabetic Retinopathy With Cranial Nerve Palsy in a South Indian Cohort

First Author: P.sangavi SAMRITHA SELVI

Co-Author(s): Virna.m.shah, Aseela NAZAR

Purpose: To examine the association between Diabetic Retinopathy (DR) and Ocular cranial nerve palsies (CN III, IV, VI) in a South Indian cohort and explore relationships with DR severity, systemic factors, and sociodemographic features.

Methods: This retrospective observational study reviewed records of patients diagnosed with ocular cranial nerve palsies at a tertiary centre in South India from January 1 to April 30, 2025. Data included DR status and grade, type of cranial nerve palsy, systemic comorbidities (HbA1c, random blood sugar, hypertension, nephropathy), and socio-demographic indicators (state of residence, urban/rural background, and paid vs free care).

Results: Among 170 patients, Most patients were from Tamil Nadu (67.6%), followed by Kerala (31%) and a very small fraction from Andhra Pradesh (0.01%). A large majority (84.9%) belonged to the paying group and were predominantly urban residents. There were 68.2% Male patients and 31.8 %Female patients. Sixth nerve palsy was most frequent (51.2%), followed by Third (31.2%) and Fourth (17%) nerve palsies; Multiple nerve involvement was rare (2%). Ischemic causes accounted for 69.4% of palsies, Trauma (13%), Inflammatory causes (9.4%), Space-occupying lesions(3.5%) and ICT and IIHT (6%). Overall, 30.8% of patients with cranial nerve palsy had coexisting DR related to Diabetes mellitus.

Conclusions: Nearly one-third of diabetic patients with ocular cranial nerve palsy had DR, with stronger links to third and sixth nerve involvement and Severe NPDR with male predominance. The predominance of urban, paying patients from Tamil Nadu highlights regional referral patterns and underscores the need for early Neuro-ophthalmic screening in diabetics with advanced DR in South India. Retina Warns, Nerve Weeps—Act Early.

Fundus Examination in Emergency Medicine: A National Survey of Practice Patterns, Barriers, and Diagnostic Confidence

*First Author: Yujie WANG**Co-Author(s): Raphael CHANG, Wenyi HU, Zhuoting ZHU*

Purpose: Fundus examination is critical for the early detection of serious ocular and neurological conditions in the emergency department (ED), yet it remains underused. This study aimed to investigate current practice, perceived barriers, and diagnostic performance related to fundus examination among ED doctors in Australia.

Methods: A national cross-sectional online survey was distributed to members of the Australasian College for Emergency Medicine. The 28-item questionnaire included multiple-choice and Likert-scale items assessing demographics, equipment availability, training on fundus examination, confidence, practice patterns, perceived barriers, and diagnostic accuracy based on five representative fundus images. Descriptive statistics and multivariable logistic regression were used for analysis.

Results: A total of 135 ED doctors participated (58.5% female; mean experience 12.3 ± 8.3 years; 25.9% from regional/remote areas). While 82% considered fundus examination important, only 51% reported performing it when clinically indicated. Commonly cited barriers included low interpretive confidence, inadequate training, time constraints, and limited equipment. Most had access to direct ophthalmoscopes (94.5%) or slit lamps (63.7%), but only 8.3% reported access to portable fundus cameras. Although 42.2% had received some training, over half reported receiving it less than once every five years. Only 26.5% expressed confidence in performing and interpreting fundus examinations. The overall diagnostic accuracy across five representative fundus images was 43.6% (95% CI, 39.4%–47.8%) and was significantly associated with perceived importance, ED training, gender, and practice location.

Conclusions: Underutilization of fundus examination in emergency care highlights gaps in training, confidence, and access. Addressing these barriers is key to improving neuro-ophthalmic triage and early detection of sight-threatening and life-threatening conditions.

Abstract No.: 205216

Gaps and Gray Zones: A Study of Non-Consensus and Clinical Outcomes in Conjunctivitis Treatment Practices

First Author: Rakhi P DCRUZ

Purpose: This study exposes the strikingly heterogeneous management of conjunctivitis among

ophthalmologists in South India, critically evaluating antibiotic overuse, inconsistent steroid and antiviral regimens, and the glaring absence of standardized steroid protocols. It further assesses the real-world consequences, including the high prevalence of complications such as superficial punctate keratitis (SPK), raised intraocular pressure (IOP), and uveitis. The investigation also highlights the underutilization of culture and sensitivity testing and contrasts private versus institutional treatment paradigms.

Methods: Responses from 77 experienced ophthalmologists (50 general and 27 cornea specialists) across Kerala, Tamil Nadu, and Telangana were collected via a structured Google Form during the peak conjunctivitis season. Analysis focused on prescribing trends, protocol adherence, and management of complications.

Results: A concerning 60% routinely prescribed broad-spectrum empirical antibiotics, irrespective of bacterial or viral suspicion, while only 30% utilized antivirals in viral cases. Steroid prescription was more prevalent among generalists and private practitioners; institutional strategies preferred initial lubricants with delayed antibiotic intervention. SPK affected over 60% of viral conjunctivitis patients, who subsequently received low-dose steroids despite lacking uniform protocols. Clinical diagnosis dominated with minimal microbiological testing. Viral conjunctivitis emerged as the most frequent subtype, with fluoroquinolones favored for bacterial infections. Steroid regimens displayed marked inconsistency in dose and timing. Supportive care and patient hygiene education were widely advocated.

Conclusions: Our study reveals critical gaps marked by protocol variability and indiscriminate antibiotic use, spotlighting an urgent need for unified, evidence-based, region-specific guidelines. This foundational study lays the groundwork for future research to refine conjunctivitis care.

Abstract No.: 208267**Panel No.: OEP-0721**

Global Burden of Blindness and Vision Loss Among Children and Adolescents: A Systematic Analysis for the Global Burden of Disease Study 2021

First Author: Yinwen LI

Purpose: This study investigates the global burden of vision impairment caused by refraction disorders, near vision loss, and other vision loss among children and adolescents from 1990 to 2021. The analysis is categorized globally by sex, age, and socio-demographic index (SDI), with a focus on predicting trends to 2035.

Methods: Data was obtained from the Global Burden of Disease Study 2021. We reported the prevalence and disability-adjusted life-years (DALYs) of vision

impairment due to refraction disorders, near vision loss, and other vision loss globally. Then, we described the prevalence and DALYs numbers and rates by sex, SDI and age. Next, we analyzed the relationship between rate and SDI. Finally, Bayesian age-period-cohort (BAPC) analysis model was used to predict the trends from 2022 to 2035 globally by sex and age.

Results: The prevalence and DALYs rates for refraction disorders had a statistically significant trend of reduction in four age groups globally and were positively associated with SDI. The prevalence and DALYs rates for near vision loss were increasing in four age groups, and were negatively associated with SDI. The BAPC model indicates that the age-specific prevalence and DALYs rates of refraction disorders and other vision loss in both men and women will remain on a downward trend until 2035, while near vision loss continues to rise.

Conclusions: The findings underscore that there are extensive variations based on the type of vision impairment, age group, sex and SDI. Policies should be tailored to specific types in order to effectively alleviate the burden.

Global, Regional, and National Burden of Age-Related Macular Degeneration From 1990 to 2021 and Projections for 2050: Findings From the Global Burden of Disease 2021 Study

First Author: Jiaying LIU

Co-Author(s): Lian HAN, Zhaohuai LI, Xingyu LIU, Wenru SU, Yehong ZHUO

Purpose: To provide a foundation for future preventative strategies against blindness caused by AMD by examining the global, regional, and national disease burden.

Methods: Trends were analyzed via joinpoint regression for Average Annual Percentage Change (AAPC). Spearman's rank correlation and LOESS regression assessed the association between AMD burden and Socio-Demographic Index (SDI), and projected 2050 AMD prevalence, DALYs, and AAPC.

Results: In 2021, the global AMD prevalence and DALYs were 102.11 (95% uncertainty interval (UI): 84.97 to 124.48) and 7.32 (95% UI: 5.08 to 10.10), respectively. From 1990 to 2021, the AMD burden increased globally, in most regions and countries/territories, and it is projected to rise further by 2050. The prevalence and disease burden of AMD were found to be higher in females ($P < 0.05$) and increased with age. World Bank low-income regions exhibited the highest burden. Negative correlations were found between SDI and AMD burden. The research also shows intensifying global population aging.

Conclusions: The rising vision impairment and disease burden due to AMD, coupled with population aging, underscore the urgent need for prevention and management, particularly for the elderly and females. AMD's global prevalence and burden show notable socioeconomic, geographical, and potential racial disparities. Targeted interventions, enhanced medical services, and international cooperation are vital to reduce AMD's burden and ensure care equity worldwide.

Panel No.: OEP-0708

Global, Regional, and National Burden of Vision Impairment From 1990 to 2021, With Projections of Prevalence to 2050: A Trend Analysis

First Author: Shi-nan WU

Co-Author(s): Zuguo LIU

Purpose: This study provides a descriptive analysis of the global burden of disease for different levels of visual impairment from 1990 to 2021, focusing on health inequities and projections to 2050.

Methods: A secondary analysis of the Global Burden of Disease (GBD) Study 2021 data was conducted, focusing on Years Lived with Disability (YLDs) due to moderate and severe vision loss and blindness. A Bayesian age-period-cohort (BAPC) model was used to predict the prevalence and YLDs of vision impairment at different severity levels up to the year 2050.

Results: Among the 204 countries and regions in the GBD 2021, the top three countries with the highest number of YLDs cases of moderate vision loss, severe vision loss, and blindness are India, China, and Brazil; India, China, and Indonesia; and India, China, and Pakistan, respectively. There is a significant negative correlation between the YLDs for different levels of visual impairment and the Socio-demographic index (SDI) in 204 countries (Moderate Vision Loss: $R = -0.22$ [$P = 0.002$], Severe Vision Loss: $R = -0.46$ [$P < 0.001$], Blindness: $R = -0.73$ [$P < 0.001$]). The average annual percent change (AAPC) values of the age-standardized prevalence rate (ASPR) for moderate vision loss, severe vision loss, and blindness from 1990 to 2021 are 0.07 (95%CI: 0.06 to 0.08), -0.23 (95%CI: -0.24 to -0.21), and -1.27 (95%CI: -1.31 to -1.25), respectively. The BAPC prediction model projects that by 2050, the global ASPR for moderate vision loss, severe vision loss, and blindness will be 2879.25 (95%CI: 1113.78 to 4644.72), 292.6 (95%CI: 79.22 to 506.04), and 321.95 (95%CI: 104.53 to 539.38), respectively.

Conclusions: Subgroup analysis of vision impairment by age, gender, region, country, etiology, and SDI level was conducted to assess the differences in the disease burden caused by vision impairment at different severity levels. Epidemiological data characteristics

indicate a shift in vision impairment from blindness to moderate or severe vision loss.

Kidney Function Markers Mediate the Protective Association Between Estimated Glucose Disposal Rate and Ocular Diseases: A Cross-Sectional Study

First Author: Jian DENG

Co-Author(s): Guo HUI, Pan LIDUO, Song XI, Yu XIAOYI

Purpose: Vision impairment due to eye diseases represents a significant global public health concern. This study investigates the association between eGDR and ocular diseases and evaluates the mediating role of kidney function.

Methods: This cross-sectional study included 4877 adults aged 40 years or older from the US National Health and Nutrition Examination Survey 2005–2008. We analyzed the relationship between eGDR and ocular diseases, including cataract, glaucoma, age-related macular degeneration, diabetic retinopathy (DR), and any ocular disease using weighted multivariable logistic regression, restricted cubic spline analysis, subgroup analyses, E-value analysis, and mediation studies.

Results: Higher eGDR was associated with reduced odds of five ocular diseases in crude analysis. After fully adjusted models, the highest eGDR tertile conferred significant protection against diabetic retinopathy (OR:0.25, 95% CI: 0.12–0.53, $P = 0.002$) and any ocular disease (OR:0.81, 95% CI: 0.69–0.94, $P = 0.011$) compared to the lowest. Restricted cubic splines confirmed linear inverse associations. The protective association of eGDR with DR and any ocular disease was partially mediated by kidney function, with blood urea nitrogen and serum creatinine explaining 13.11% and 8.33%, and 22.08% and 9.09% of the effect, respectively. The robustness of these findings was supported by subgroup analyses, E-value estimation, and random forest-based multiple imputation method.

Conclusions: This study demonstrates a protective association between higher eGDR levels and a reduced risk of ocular diseases in adults aged 40 years or older, particularly DR, with kidney function playing a mediating role. eGDR is expected to serve as a target for ocular disease prediction and intervention.

Machine Learning Models for Risk Prediction of Diabetic Retinopathy in Fujian Eye Study

First Author: Yang LI

Co-Author(s): Qinrui HU, Xiaoxin LI, Bin WANG

Purpose: Diabetic Retinopathy (DR) is one of the most severe microvascular complications of diabetes,

which seriously affects the visual acuity and quality of life of patients. This study explores multiple machine learning-based models for the risk prediction of DR, providing a foundation for future research in the field of information and big data. Additionally, the optimal model is utilized to identify the associated risk factors for DR.

Methods: Utilizing the dataset from the Fujian Provincial Epidemiological Eye Disease Study, which includes 8211 records and 51 features, we constructed and evaluated five machine learning models through steps such as data preprocessing, feature selection, and model training. These models include Logistic Regression (LR), K-Nearest Neighbors (KNN), Support Vector Machine (SVM), Decision Tree (DT), and Random Forest (RF), with the aim of assessing their predictive accuracy. Moreover, we complemented Shapley Additive exPlanations (SHAP) analysis with three unsupervised and nonparametric methods: Factor Analysis (FA), Highly Variable Feature Selection (HVGS), and Spearman's rank-order correlation.

Results: This study evaluated multiple machine learning models, including LR, KNN, SVM, RT, RF, LightGBM, and XGBoost. Ultimately, the SVM model achieved the highest performance with F1-score of 92.83% and AUC of 0.99. The SHAP method revealed that history of diabetes, age, blood pressure difference, near visual acuity of the left eye, and height were the top five influencing predictors of DR.

Conclusions: The proposed integrated system is poised to serve as an invaluable tool for identifying critical predictors, enabling the early-stage prediction of patients at high risk for DR in China.

Perioperative Care Practices and Antibiotic Prophylaxis in Cataract Surgery: A Local Ophthalmology Society Survey

First Author: Abigail MONTES

Co-Author(s): Sharlene NOGUERA, George Michael SOSUAN

Purpose: This study aims to determine the perioperative care practices and antibiotic prophylaxis in cataract surgery among surgeons from a local Ophthalmology society.

Methods: A cross-sectional, web-based survey was conducted among 35 cataract surgeons from a local Ophthalmology society using a modified, validated instrument adapted from the Asian study on Peri-operative Antibiotic Prophylaxis (APAX) questionnaire. The survey assessed routine practices related to lid scrubs, lid drapes, povidone-iodine application, and antibiotic prophylaxis, including route, timing, frequency, and dosing during the preoperative,

intraoperative, and postoperative phases of cataract surgery.

Results: Routine lid scrubs and preoperative application of povidone-iodine were consistently performed in both low and high-risk cataract surgery cases. Preoperative antibiotics were used selectively in 31.4% of low-risk cases and 51.4% of high-risk cases. Intraoperatively, ~90% of surgeons administered antibiotics, with the intracameral route as the preferred method. Postoperatively, all respondents prescribe topical antibiotics, most commonly Levofloxacin 0.5% and Moxifloxacin 0.5%. In low-risk patients, antibiotics were typically prescribed for 2–4 weeks, whereas high-risk patients received higher dosing frequencies (up to eight times daily) and extended durations exceeding four weeks.

Conclusions: This study shows a strong consensus on antiseptic measures, including routine use of povidone-iodine, lid scrubs, and plastic eyelid draping, as well as using intracameral and postoperative antibiotics. While the longer courses seen in low-risk patients raise the possibility of overtreatment, extended regimens in high-risk patients demonstrate a customized, risk-based approach. These results highlight the need for evidence-based, locally tailored guidelines to improve patient outcomes, promote antibiotic stewardship, and standardize perioperative care.

Population Aging and Glaucoma-Related Vision Loss: Global vs Asia

First Author: Jianqi CHEN

Co-Author(s): Zhidong LI, Yingting ZHU, Yehong ZHUO

Purpose: As a key public health concern, population aging is closely associated with the increasing glaucoma prevalence. This study aims to assess its impact on both the Asian and global populations.

Methods: This study used data from the Global Burden of Disease Study 2021. We assessed the impact of population aging on glaucoma vision loss from 1990 to 2021 by decomposing changes in cases into contributions from population growth, aging, and epidemiological rate changes, and further calculated attributed cases and proportions. To compare the effects of epidemiological rates (reflecting the preventive effect) and population aging, we calculated the epidemiological rate change/population aging ratio (E-A ratio).

Results: From 1990 to 2021, the prevalence of glaucoma-related vision loss rose from 4,072,106.53 (95% uncertainty interval [UI], 3,204,763.73–5,131,929.57) to 7,587,672.87 (95% UI, 5,969,840.61–9,582,253.77) worldwide and from 1,980,482.59 (95% UI, 1,548,959.57–2,502,831.02) to 3,969,356.7 (95% UI, 3,114,247.84–5,026,564.23) in Asia. From

1990 to 2021, the increase in glaucoma-related vision loss attributable to population aging was 636,981.26 (attributed proportion: 15.64%) globally, and 513,516.46 (attributed proportion: 25.93%) in Asia. The global E–A ratio was –2.40, compared to –2.26 in Asia.

Conclusions: This study reveals that aging has exerted a relatively greater influence in Asia compared to the global context. However, preventive strategies have effectively offset its impact, although their effect remains slightly below the global average.

Predictors and Barriers in the Uptake of Referral Services From Secondary Eye Care to Tertiary Eye Care Centers in Southern India

First Author: Harinikrishna B

Co-Author(s): Ram SUDARSHAN

Purpose: To identify factors influencing adherence and non-adherence to referral from secondary to tertiary eye care centers.

Methods: Patient records from September 2023 to March 2024 were reviewed for those referred from a secondary to a tertiary center in southern Tamil Nadu. Structured questionnaires were used for adherent and non-adherent groups. For pilot study, we had a sample of 60 patients with 30 in each arm. A pilot study involved interviews with patients by senior data entry operators. Data was analyzed using Stata.

Results: Non-adherence was more common in patients with mild visual impairment. 33% of patients who were non-adherent were those referred to the glaucoma department. No gender differences were found. Key non-adherence factors included a lack of an accompanying attendant and time constraints. Adherence was mainly due to the consultant's recommendation, and adherent patients were generally satisfied with their experience.

Conclusions: Our study highlights areas for improving compliance, such as comprehensive counseling, follow-up calls, and telemedicine services. The study identifies areas for potential intervention to improve compliance with higher-level eye care services. Comprehensive and effective counselling, follow-up phone calls to referred patients, and a dedicated staff to handle referrals could lead to increased uptake of referral services.

Abstract No.: 205529**Panel No.: OEP-0716**

Prevalence and Clinical Correlates of Subretinal Drusenoid Deposits (SDDs) in Dry Age-Related Macular Degeneration (AMD): A Cross-Sectional Study in Hong Kong

*First Author: Wing Hei LOK**Co-Author(s): John BUCHAN*

Purpose: Age-related macular degeneration (AMD) is a leading cause of irreversible visual loss globally and in Hong Kong's ageing population. Subretinal drusenoid deposits (SDDs) are extracellular deposits above the RPE that are linked to outer-retinal dysfunction and a faster risk of progression to late AMD. East-Asian population data remain sparse, and CFP-based surveys under-detect SDD relative to SD-OCT. We therefore quantified SDD burden, staging, and clinical correlates in older Hong Kong Chinese.

Methods: Cross-sectional analysis of community participants aged ≥ 70 years from the Southern District Signature Project (Hong Kong). Spectral-domain OCT volumes were graded for SDD presence and stage (0–4). Eye-level prevalence used Wilson 95% CIs. Independent associations with SDD were estimated using multivariable logistic regression with cluster-robust SEs across pre-specified demographic, systemic and lifestyle covariates. Structure-function relationships across stages were assessed using Spearman's ρ and age-adjusted linear models for outer-nuclear-layer (ONL) thickness, subfoveal ellipsoid-zone (EZ) and EZ–RPE thickness, subfoveal choroidal thickness (SFCT), and best-corrected visual acuity (BCVA). Sensitivity analyses (GEE; one-eye sampling) and intra-observer agreement were performed.

Results: We analysed 596 participants (1,192 eyes; mean age 74.6 ± 4.2 years). SDD prevalence was 29.3% (95%CI 26.8–31.9); stage distribution (0, 1, 2, 3, 4): 70.7%, 16.6%, 10.4%, 2.2%, 0.1%, respectively. In adjusted models, age (OR 1.71 per 5 years, 95%CI 1.38–2.12; $p < 0.001$) and hyperlipidaemia (OR 1.98, 95%CI 1.30–3.03; $p = 0.002$) were independently associated with SDD. Higher SDD stage correlated with thinner ONL, EZ, EZ–RPE and SFCT ($p = -0.233, -0.799, -0.789, -0.788$, respectively; all $p < 0.0001$) and worse BCVA ($p = +0.164$; $p < 0.0001$). Per one-stage increase, mean changes were: ONL $-3.64 \mu\text{m}$, EZ $-3.44 \mu\text{m}$, EZ–RPE $-6.14 \mu\text{m}$, SFCT $-70.6 \mu\text{m}$, and BCVA $+0.020 \log\text{MAR}$ (all $p \leq 0.0016$). Repeatability was high (presence $\kappa = 0.89$; stage weighted $\kappa = 0.94$). Findings were consistent in GEE and one-eye sensitivity analyses (one-eye prevalence 30.4%).

Conclusions: In community-dwelling older Hong Kong Chinese, SDDs are common and track a graded loss of outer retinal and choroidal integrity, accompanied by modest acuity decline. Age and hyperlipidaemia are independent correlates. Findings support OCT-centred

detection and risk-stratified monitoring to anticipate late AMD trajectories.

Abstract No.: 201016**Panel No.: OEP-0702**

Prevalence of Ocular Trauma and Barriers to Use of Personal Protective Devices Among Welders in Hetauda, Nepal

*First Author: Hom Bahadur GURUNG**Co-Author(s): Dikshya BISTA, Aleena GAUCHAN, Mohini SHRESTHA, Sunil THAKALI*

Purpose: Assess ocular trauma prevalence, PPE use, and barriers among Hetauda welders.

Methods: Cross-sectional study of 111 welders via interviews and eye exams.

Results: Comprehensive eye examinations and structured interviews revealed a high ocular trauma prevalence of 62.16%, primarily caused by metal chips (60.87%) and flames (37.84%). Although 78.39% of welders reported using PPE, 72.97% relied on non-certified sunglasses, and only 1.80% used certified protective goggles. Key barriers to appropriate PPE use included the absence of workplace mandates (62.50%) and a belief that protection was unnecessary (64.52%). Significant risk factors for trauma included male gender, lack of safety training (43.48%), and age between 46 and 60 years. Common ocular morbidities were corneal opacity (20.72%) and conjunctival congestion (10.36%), with only 8.11% of welders using prescription safety eyewear.

Conclusions: Despite reported PPE usage, the continued high rate of ocular trauma highlights deficiencies in equipment quality and training. Mandating certified eye protection (e.g., shade-10 filters), enforcing workplace safety policies, and integrating occupational health education are critical steps for preventing eye injuries in Nepal's industrial sector.

Abstract No.: 204564**Panel No.: OEP-0715**

The Asia Pacific (APAC) Vision Health Survey Report: An Urgent Challenge and a Critical Conjunction

*First Author: Marten BRELEN**Co-Author(s): Andrew CHANG, Shilpka DAS, Rancy KHOSLA, Paisan RUAMMIBOONSUK, Seung-young YU*

Purpose: APAC Vision Health Survey (27 August–2 September 2024) aimed to address the region's disproportionate burden of vision impairment by exploring unmet needs, perceptions of vision health, links to ageing and diabetes, and retinal disease awareness.

Methods: A total of 4,354 individuals aged 40+ from Australia, Hong Kong, Malaysia, the Philippines,

Singapore, South Korea, Taiwan, and Thailand participated. Data self-reported via an online, multilingual questionnaire—weighted by age, gender, and education for population representation. Margins of error (4-5%) suggest reliable estimates. APAC's first region and population-wide dataset on eye health behaviours and awareness.

Results: Concern-action gaps: 91% worry about vision health, yet only 28% get yearly exams; 32% delay care until symptoms appear. Among respondents with diabetes, 32% skip yearly exams, 11% have never had one. 42% of those aged 60+ forego regular eye checks. Low retinal disease awareness (1–4 scale): DME (1.9), AMD (2.1), wet-AMD (1.7), RVO (1.6). Multi-dimensional care barriers, highlighted by respondents with diabetes: cost (37%), inconvenience/lack of time (24%), low awareness (20%), fear/anxiety (20%), no perceived need (17%), and access difficulties (16%). Anticipated vision impairment impact: daily life (68%), quality of life (49%), employment (46%), finances (41%), mental health (38%). 95% of caregivers expressed financial, physical, and emotional burdens.

Conclusions: Survey data highlights vision impairment as a pressing health and socioeconomic challenge requiring both policy and clinical responses—from early detection and accessible care for high-risk groups to public awareness, digital innovation, workforce investment, and multi-sector partnerships that scale prevention and impact.

The Association of Alcohol Consumption With Rhegmatogenous Retinal Detachment and Retinal Break: Findings From the UK Biobank

First Author: Edison Chak-fung HO

Co-Author(s): Philip Ya Wen GUO, Alexander Ka Ngai LAM, Ryan Tak Chun WONG

Purpose: To investigate the association of alcohol consumption with rhegmatogenous retinal detachment and retinal breaks.

Methods: The retrospective study included 100587 UK adults conducted with the UKBiobank database. Participants were categorized according to self-reported drinking behaviors, and alcohol intake (g/week) was estimated from touchscreen questionnaires and food composition tables. Rhegmatogenous retinal detachment is defined as ICD10: H330 + ICD9: 3610, while the subgroup analysis includes retinal detachment and break + ICD10: H333 also. We perform a 2-step analysis that first compares infrequent drinkers to never, regular, or former drinkers. While the second step is evaluating the dose-response through multivariable logistic regression adjusted for covariates, including age, sex, ethnicity, spherical equivalent

refraction, BMI, and Townsend Deprivation index, to examine the association.

Results: In all subgroup analyses, never and former drinkers show no difference from infrequent drinkers. Regular drinkers show no statistical difference to infrequent drinkers OR=1.35, P=0.056 in all participants, however, if we only consider the myopia population (SE<=-0.5, n=34416) (OR=1.58, p=0.038) and the high myopia population (SE<=-5, n=6217) (OR=3.59, p=0.013), regular drinkers increase 58% and 260% risk, respectively causing retinal break or detachment. If considering retinal detachment only in the high myopia population, there has been an increase of 190% risk (OR=2.94, P=0.037). For dose-response analysis, a per SD increase (114g/week) in intake increases 12% risk of having retinal detachment for all participants.

Conclusions: Although we cannot infer causality, the results suggest that frequent alcohol consumption are correlate of development of retinal detachment or break, especially in high myopia patient who are at risk of developing rhegmatogenous retinal detachment.

The Competency Activation and Integration Model (CAIM): Strengthening Diabetic Retinopathy Screening Through Community and Allied Health Workers

First Author: Sunita MOHAN

Co-Author(s): Govindasamy KUMARAMANICKAVEL, Albert SCHERPBIER, Fred STEVENS

Purpose: To propose and validate the Competency Activation and Integration Model (CAIM), a framework to integrate community and allied health workers (CAHWs) into diabetic retinopathy (DR) screening in underserved urban slums.

Methods: A global narrative review of 32 studies from Asia, Africa, and Latin America was conducted to examine the roles and competencies of community and allied health workers in diabetic retinopathy (DR) screening. Thematic synthesis identified recurring barriers (e.g., lack of training, poor system integration) and enablers (e.g., community trust, structured supervision). These patterns were analyzed using a competency-focused lens and mapped to health system functions. The findings were iteratively refined to derive four key domains forming the CAIM framework, ensuring both contextual relevance and theoretical robustness in model development.

Results: CAIM consists of four interdependent domains: (1) Competency Activation (recruitment, motivation, skill development); (2) System Integration (task alignment, referral coordination, supervision); (3) Environmental Enablement (community trust, infrastructure support, cultural alignment); and (4) Human Capital Reinforcement (incentives, recognition,

long-term career pathways). The model illustrates how fragmented DR screening tasks can be systematically allocated to trained CAHWs, with supportive supervision and embedded feedback loops. It also highlights the role of localized adaptation and policy engagement in sustaining CAHW performance. CAIM thus operationalizes both micro-level (worker) and macro-level (system) readiness for DR screening scale-up.

Conclusions: CAIM offers a practical, scalable model to guide people-centered DR screening programs. It bridges workforce capacity and health system integration, supporting WHO's IPEC goals in fragile urban contexts.

Unseen Barriers: Socioeconomic and Logistical Challenges to Cataract Surgery Uptake in Bangladesh

First Author: Pradipta CHOWDHURY

Co-Author(s): Anindita CHOWDHURY, Prakash CHOWDHURY, Mohammad MURAD, Altaf UDDIN

Purpose: Cataract blindness remains curable, yet surgery uptake in LMICs is strikingly low. This study reveals the hidden barriers: fear of surgery, financial strain, socio-cultural, and logistical barriers that continue to block vulnerable patients in both outreach and hospital settings from regaining sight.

Methods: A cross-sectional preoperative survey was conducted among 595 cataract patients attending hospital outpatient services ($n = 222$) and community outreach camps ($n = 373$) in Bangladesh from May to August 2025. Socio-demographic characteristics, awareness of cataracts and treatment, and barriers to surgery were assessed. To compare the baseline characteristics of the socio-demographic properties, chi-square tests were used for categorical variables, and the Mann-Whitney U test was applied for continuous variables. A linear regression was also used to examine the associations between patient characteristics and the number of reported barriers to accessing cataract surgery.

Results: The mean age was 62 years (50.3% female). Camp patients were predominantly rural (76.1%) and had lower education levels (43% with no schooling vs. 13% in OPD, $p < 0.001$). 74% of the participants presented with bilateral cataracts. While 88.6% had heard of cataracts, only 41.3% were aware of the treatment options. Key barriers included affordability (72.3%), worry about the surgical outcome (27.1%), fear of surgery (25.9%), transportation (27.7%), lack of escort (22%), and time constraints due to work or family responsibilities (18.2%).

Conclusions: Cost of surgery, socio-cultural attitudes, low literacy & geographical access hinder cataract

surgery uptake in Bangladesh. Innovative solutions such as subsidy models, gender sensitive counselling and mobile outreach are key to dismantling health inequities and protecting the vulnerable populations.

Why Rural Communities in India Delay Seeking Eye Care?

First Author: Maneck NICHOLSON

Co-Author(s): Snehal GAWADE, Radhika KRISHNAN, Ashwini ROGYE

Purpose: To assess the willingness to use eye care services among individuals with self-reported visual difficulties in rural Maharashtra, and to identify demographic and psychosocial factors influencing service uptake.

Methods: A cross-sectional survey was conducted among participants with visual complaints during rural outreach camps. Data on sociodemographic characteristics, duration of visual symptoms, and willingness to utilize various eye care services were collected. Logistic regression was used to evaluate associations between demographic variables and the desire to use each service.

Results: While willingness to undergo an eye examination was high (91.6%), the uptake of treatment services was significantly lower: 67.4% for eyeglasses, 56.7% for medications, and 58.5% for surgery. Older age, longer symptom duration, and unemployment were negatively associated with willingness to use eyeglasses. Literacy and employment status showed no consistent link with willingness to accept surgery or medications. Notably, no demographic variable strongly predicted willingness for surgery, indicating that broader awareness and perception-related barriers are influential.

Conclusions: Despite the availability of free services, a significant number of individuals with visual complaints remain hesitant to seek treatment particularly surgery and medications. These results underscore the importance of targeted educational efforts, community awareness programs, and trust-building initiatives to promote service utilisation among underserved populations.

Ophthalmic Trauma

Panel No.: OTR-0729

A Retrospective Study of Ophthalmologic Presentation, Management, and Outcomes in Pediatric Patients Admitted With Abusive Head Trauma

First Author: Jiawei YIN

Co-Author(s): Xuerui ZHANG, Peiquan ZHAO

Purpose: Purpose: Abusive head trauma (AHT) is a severe form of child abuse with high morbidity and mortality. Ophthalmologic findings, though often underexplored, may provide important clues for early diagnosis and management. This study aimed to investigate ophthalmologic manifestations, management, and outcomes of AHT in a single center in China.

Methods: A retrospective case series was conducted at a single institution, involving infants diagnosed with AHT from 2019 to 2023. Data on demographics, medical histories, and clinical management were collected. Ophthalmologic examinations, including fundus photography, ocular B-scan ultrasound, and fundus fluorescein angiography (FFA), were performed to evaluate retinal vasculature and identify peripheral ischemic retina (PIR). Statistical analyses were performed using SPSS version. 26.0.

Results: Eight AHT patients (16 eyes) were included in the study. Bilateral ocular involvement was observed in all patients, with 81.25% exhibiting retinal hemorrhages (RH). Other manifestations included retinal detachment (31.25%) and optic nerve atrophy (18.75%). Clinical interventions varied, with 68.75% of patients undergoing treatments such as laser photocoagulation and anti-vascular endothelial growth factor (VEGF) injections. Among all eyes, 75% showed resolution of RH. Despite treatment, some patients progressed to severe conditions such as retinal detachment (RD) and iris neovascularization (INV).

Conclusions: This study emphasizes the importance of a multidisciplinary approach in the diagnosis and management of AHT, particularly by integrating ophthalmological perspectives into patient care. These findings contribute to the understanding of ophthalmologic presentations in AHT.

Abstract No.: 202866

Case Report: Post-Traumatic Iris Cyst After Being Pecked by a Stork 30 Years

First Author: Y HUYNH

Co-Author(s): Trang Thanh NGHIE, Huong NGUYEN

Purpose: Epithelial iris cysts can be classified as either primary or secondary. The management of secondary iris cysts, particularly those occurring after ocular trauma, presents considerable clinical challenges. This report describes the successful surgical intervention for a post-traumatic iris cyst.

Methods: Case report.

Results: A 40-year-old male patient presented with left eye pain and blurred vision for about 5 months. Medical history: trauma to the left eye caused by a stork 30 years ago. Clinical examination: Secondary ocular hypertension, corneal scar at the 7 o'clock limbus, and a light brown, semi-translucent cyst iris cyst extending from 5 to 12 o'clock occupying nearly the entire anterior chamber, closely adherent to the posterior corneal surface, making other assessments difficult; cataract. Surgical treatment consisted of total removal of the external cyst layer following cataract extraction and intraocular lens implantation. Postoperatively, the patient demonstrated favorable visual recovery with minimal intraocular inflammation.

Conclusions: Surgical intervention should be considered as a final option when less invasive treatments fail, particularly in cases involving extensive lesions.

Clinical Management and Outcomes of Ocular Perforation Injuries Induced by Acupuncture: A Case Study

First Author: Huping SONG

Purpose: Ocular perforating injuries caused by acupuncture are serious injuries that can damage multiple tissues within the eye. We aim to report two cases of eye perforation injuries caused by acupuncture needles, which showed significant clinical improvement.

Methods: We reported two cases of eye perforation injuries caused by acupuncture. Based on the patient's condition, we chose a treatment plan combining vitrectomy with retinal laser therapy, and antibiotic treatment was provided after the operation.

Results: Puncture injury of the needle hole, with the entry and exit of the needle hole located in different quadrants of the retina, leads to retinal damage and vitreous hemorrhage. This trauma cannot be completely resolved by retinal laser treatment alone. Therefore, vitrectomy is necessary to prevent retinal

detachment, proliferative vitreoretinopathy, and endophthalmitis.

Conclusions: Ocular perforation injury caused by acupuncture is relatively rare, but the prognosis is poor. Early treatment of this kind of ocular trauma is of vital importance. Vigorously carry out standardized acupuncture operations, conduct education on ocular trauma, and reduce the incidence of ocular trauma.

Evaluating Ciliary Body Damage Induced by Blunt Low-Speed Impact Using Finite Element Simulation

First Author: Qiong CHENG

Purpose: To evaluate the ciliary body mechanical load during low-speed impact using the finite element method to explain the mechanism of angle recession and cyclodialysis cleft.

Methods: Optical Coherence Tomography (OCT) images were obtained to assess the patient's ciliary body angle recession. A finite element eye model was established based on the Virginia Tech Eye Model (VTEM) with the consideration of the dynamic impact of a projectile striking an eye. The mechanical properties of the ocular tissues were obtained from literatures. The stress and strain were evaluated.

Results: The stress distribution of the eye was calculated. The stress concentration at zonules 3.8MPa. The maximum stress at the ciliary body was 57KPa, which has a high probability of causing ciliary body injury. The maximum stress at zonules was 0.98MPa. The lateral expansion also reduces the forces transmitted along the sclera to the rear part of the eye.

Conclusions: The eye under frontal impact will result in lateral expansion, which increases the stretch force of the lens, zonules, and ciliary body. This mechanism can be seen as the protection for the retina. The boundary of the ciliary body is the most vulnerable position, where angle recession and cyclodialysis cleft will occur before the occurrence of retina damage.

Abstract No.: 200986

Exploration of Retinal Explant Culture Model for Iron Intraocular Foreign Body Injury

First Author: Xiaoting MAI

Co-Author(s): Haoyu CHEN

Purpose: To explore the effects of iron intraocular foreign bodies on the retina through the retinal explant culture experiments.

Methods: The retinal explant culture experiments were conducted. After 24 hours of treatment with the pure iron block on the retinal explants, samples were collected for scanning electron microscopy (SEM)

and energy dispersive spectroscopy (EDS) analysis to examine the release of iron particles from the iron block and its impact on the retinal surface.

Results: In the iron block treatment group, the entire retina turned brownish-yellow, with the most obvious changes around the foreign body bed. SEM scanning showed that the retinal vessels were exposed in the foreign body bed area, and the retinal surface around was rough with scattered particles. Iron particles were also found on the retinal surface far from the foreign body bed, with extensive infiltration marks at the edges. In the blank control group, the retinal surface was tight and dense, and the vessels were not exposed. EDS analysis indicated that iron was generally present on the retinal surface after iron block treatment, with the highest concentration (high iron atom content) in the foreign body bed area and the infiltration marks around the particles. No iron was detected in the control group.

Conclusions: The iron block foreign bodies can release iron particles, causing iron infiltration on the retinal surface and inducing damage reactions.

Abstract No.: 206725

Panel No.: OTR-0738

Functional Outcomes of Early Bicanalicular Intubation in Traumatic Canaliculalaceration at a Tertiary Hospital

First Author: Prianggara Rostu PRAYOGA

Co-Author(s): Niluh Putu AYU DEWI, Shanti F

BOESOIRIE, Mohamad Rinaldi DAHLAN, Raden Angga KARTIWA, Pradistya Syifa YUDIASARI

Purpose: Traumatic canaliculalaceration represents a vision-threatening eyelid injury that, if left untreated, may lead to chronic epiphora and poor quality of life. This study aimed to describe the clinical profile and functional outcomes of patients with canaliculalaceration managed with bicanalicular silicone intubation at a tertiary hospital.

Methods: We conducted a descriptive observational study of 102 patients with confirmed canaliculalaceration who underwent surgical repair between January 2021 and April 2025 at Cicendo Eye Hospital, Indonesia. Data on demographics, etiology, mechanism of trauma, affected canaliculus, associated injuries, timing of surgery, and postoperative results were collected from medical records. Functional success was defined as the absence of postoperative epiphora following stent removal.

Results: A total of 102 patients were included, with a male predominance (83.3%) and a median age of 33 years. Road traffic accidents were the leading cause of injury (41.1%), followed by domestic accidents (30.3%). The inferior canaliculus was most frequently affected (55.8%). Most patients (78.4%) underwent surgery within 72 hours. Functional success was achieved in

97.1% of cases, while postoperative complications were rare (9.9%) and generally mild, including exposed knots or spontaneous stent dislodgement, all of which were managed successfully absence of postoperative epiphora.

Conclusions: Early surgical repair of canalicular lacerations using bicanalicular silicone intubation provides excellent functional outcomes and minimal complications. These findings reinforce the importance of timely intervention in lacrimal trauma and highlight this technique as a reliable standard of care in oculoplastic practice.

Panel No.: OTR-0724

Immediate Management of Corneal Bee Sting Injury Results in Better Visual Outcome

First Author: Husnaini

Purpose: Corneal bee sting injuries are rare but can cause severe ocular complications, including toxic keratopathy, keratouveitis, secondary glaucoma, and toxic endophthalmitis. Prompt diagnosis and intervention are critical to preserving vision.

Methods: A 17-year-old male presented with severe pain, tearing, and decreased vision (hand movement) in the right eye, one day after being stung by a bee while driving. Examination revealed a corneal stinger with surrounding infiltration, stromal edema, Descemet's folds, and hypopyon. Under general anesthesia, a corneal incision was made over the sting site for removal, followed by suturing with nylon 10-0. Postoperatively, the patient received intravenous ceftriaxone and methylprednisolone, along with topical moxifloxacin and fluorometholone. By day one, hypopyon had resolved, and therapy was tapered to oral methylprednisolone and ciprofloxacin. At three weeks, corneal edema markedly improved, and visual acuity reached 20/200. At six weeks, vision improved to 20/30, though corneal scarring remained.

Results: Bee venom causes both direct tissue trauma from the stinger and toxic inflammatory damage from venom components. Management strategies vary, but literature supports urgent removal when the stinger is accessible, especially with significant inflammation or visual axis involvement. This case supports the use of immediate surgical extraction, combined with systemic and topical corticosteroids and antibiotics, to control inflammation, prevent infection, and promote visual recovery.

Conclusions: Early stinger removal with aggressive anti-inflammatory and antimicrobial therapy can result in rapid resolution of inflammation and favorable visual outcomes in corneal bee sting injuries.

Abstract No.: 207934

Panel No.: OTR-0740

Inferior Rectus Myositis After Orbital Fracture Repair With a Medpor Implant in a 38-Year-Old Male: A Case Report

First Author: Kelvin Kam Lung CHONG

Co-Author(s): Fatema ALJUFAIRI, Kenneth K.h. LAI, Chi Pui PANG, Jake SEBASTIAN, Clement Cy THAM, Thomas Ting Hei TSANG

Purpose: We report a rare case of Medpor® Orbital implant-related inferior rectus (IR) myositis post-orbital fracture repair.

Methods: A 38-year-old gentleman underwent an uneventful orbital floor fracture repair done elsewhere, using a Medpor® implant, one day after sustaining a blunt force facial trauma. The patient presented to our center, three weeks post-operatively, complaining of diplopia and marked dull ache around the region of the left orbit, with left hypotropia and intractable primary and up-gaze diplopia and extraocular muscle restriction of (-3) up-gaze and (-2) down-gaze on the left eye. A multi-parametric, dynamic orbital MRI showed focal IR myositis and entrapment due to incomplete defect coverage with restricted elevation on T2 cine sequence.

Results: The symptoms were gradually relieved after a revision surgery for the left orbital floor fracture using a biplanar, trans-orbital and trans-antral approach with release of entrapped soft-tissues, removal of the orbital Medpor® implant and replacement with an autologous dermis fat graft. Complete coverage of the fracture site and absence of any entrapped soft tissues were ascertained by direct visualization using the trans-antral view.

Conclusions: Medpor myositis is a rare complication associated with the use of the Medpor® orbital implant. Direct trans-antral visualization allows for a pressure-less, precise identification of the extent of the fracture and any soft-tissue entrapment after implant insertion without retracting the orbit. In view of myositis resulting from a possible negative reaction to a foreign material, an autologous dermis fat graft can be a suitable alternative material used for repair and to augment orbital volume.

Isolated Traumatic Non-expulsive Partial Aniridia With Iris Necrosis in a Pseudophakic Eye: a Case Report

First Author: Carmen Sze Ching LO

Co-Author(s): Gillian Denise Ji-yee SIU

Purpose: To report a rare case of isolated non-expulsive partial aniridia with iris necrosis in a pseudophakic eye after blunt trauma.

Methods: Case report.

Results: A 73-year-old woman, who underwent phacoemulsification with an intraocular lens (IOL) implanted 5 years prior, presented after a 7-foot fall with right eye pain and blurred vision. Examination revealed visual acuity of hand motion, raised intraocular pressure (IOP) of 56 mmHg, an injected right eye with Descemet folds, and grade 3 hyphema. Superior partial aniridia from 9 to 2 o'clock was observed with an exposed IOL rim. The IOL was stable; the globe intact. The initial B-scan was unremarkable. She was given topical steroids, antibiotics, and IOP-lowering agents. At 2 weeks, hyphema persisted with the development of anterior synechiae with iridocorneal touch, uncontrolled IOP, and new vitreous hemorrhage. Anterior chamber washout was performed. Intraoperatively noted near-total iris necrosis with egg-custard consistency fused with clots. No normal iris tissue for iridoplasty. The inferior iris remnant was retained to mitigate photophobia. On the latest follow-up, the inferior iris remained intact; IOP normalized with tolerable photophobia.

Conclusions: Prior studies described expulsive complete aniridia in pseudophakic eyes following blunt trauma, with the proposed mechanism being iris expulsion via phacoemulsification wounds. We present a unique case of isolated non-expulsive partial aniridia resulting in iris necrosis, illustrated by serial clinical photos. It supports an alternative mechanism of intraocular phagocytosis and liquefaction, influencing management paradigms.

Locked Jaw in the Orbit: A Rare Case of Trismus Following Intraorbital Foreign Body Injury

First Author: Shipra SINGH

Co-Author(s): Ashok PATHAK

Purpose: To present a rare case of trismus due to an intra-orbital foreign body.

Methods: A 27-year-old male sustained a trans orbital penetrating glass injury to the left orbit following a physical assault. Remarkably, the globe was spared, and the patient had no visual complaints or diplopia. His chief complaint was persistent trismus with inability to chew food, which prompted presentation to our hospital four months post-trauma. Initial treatment at a local hospital included suturing of a left zygomatic laceration. Imaging examination revealed a radiodense foreign body measuring approximately 41 x 14 mm, penetrating the posterolateral orbital wall into the intraconal space.

Results: A temporobasal approach was employed, allowing visualization and successful retrieval of the embedded glass fragment. Postoperatively, there was a significant improvement in mouth opening with only minimal residual orbicularis weakness. Ocular integrity

was preserved without visual compromise. This case highlights the unusual clinical presentation of trismus in the absence of ocular involvement following trauma.

Conclusions: Trismus is an uncommon but important manifestation of intraorbital foreign body injury. Early recognition, detailed imaging, and meticulous surgical planning are critical for safe removal and favourable outcomes. This case emphasizes that careful extraction of retained intra orbital foreign body can prevent long-term morbidity and preserve both function and cosmesis.

Abstract No.: 203259

Mechanism Study of PI3K δ Mediated Mesenchymal Transition in Retinal Pigment Epithelial Cells

First Author: Jing LUO

Purpose: This study investigates whether vitreous humor from patients with macular epiretinal membranes (mERM) induces epithelial-mesenchymal transition (EMT) in retinal pigment epithelial cells (ARPE-19). Based on evidence that the p110 δ subunit of PI3K mediates related pathways, we aimed to elucidate the specific mechanism by which PI3K δ contributes to this pathogenic process.

Methods: P110 δ expression in mERM patients was detected by immunofluorescence. ARPE-19 cells were treated with mERM vitreous, and changes in morphology, EMT markers (E-CAD, FN, N-CAD, VIM, α -SMA), proliferation, and migration were assessed. p110 δ function was validated using CRISPR knockout and the inhibitor idelalisib. A laser-induced murine subretinal fibrosis model received idelalisib, and fibrotic lesions were quantified via RPE/choroid flatmounts stained for Collagen-1 and IB4.

Results: Vitreous humor from mERM patients induced p110 δ expression, a mesenchymal morphology, and increased proliferation and migration in ARPE-19 cells, alongside upregulating specific mesenchymal markers. These pro-EMT effects were completely suppressed by either genetic knockout or pharmacological inhibition (idelalisib) of p110 δ . Furthermore, in a laser-induced fibrosis model, idelalisib treatment significantly reduced the size of subretinal fibrotic lesions.

Conclusions: In summary, our results indicate that vitreous humor from mERM patients promotes EMT of retinal pigment epithelial cells and inhibits p110 δ to alleviate vitreous-induced EMT. These discoveries contribute to a better understanding of mERM formation mechanisms and provide innovative intervention strategies for future precision therapies based on p110 δ .

Panel No.: OTR-0728

Ocular Trauma Leading to Enucleation Due to a Homemade Bamboo Gun Toy – Case Report of a Rare Ocular Trauma Incident in a 7-Year-Old Child in Papua

First Author: Janice Eloise TAN

Co-Author(s): Nyssa Alexandra TEDJONEGORO, Evander Samuel BANUA ROUW, Jannes Fritz TAN, Nathaniel Farrel TAN

Purpose: A rare case of trauma caused by a homemade gun toy in a 7-year-old boy was reported. The patient's right eye was struck by a bamboo bullet fired from a distance of 0.5 meters by his friend 5 days ago. In the right eye, visual acuity was 1/∞, there was subconjunctival bleeding, laceration of 5mm on the eyelid, sclerocorneal laceration with irregular edges measured 4mm, iris prolapse. No corpus alienum was found. Proper management, administration of local and systemic antibiotics, enucleation, and reconstructive surgical techniques were performed.

Methods: Case report on ocular trauma resulting in enucleation. Patients were reviewed for clinical history, clinical examination, and indications for enucleation.

Results: After stabilizing the patient's general condition, the ruptured right eyeball, including part of the optic nerve, was removed in the operating room. Orbital reconstruction was performed for the eye prosthesis and palpebral reconstruction. Post-operation, the patient showed no signs of developing sympathetic ophthalmia, persistent postoperative pain, hematoma, or infection, and it is regrettable that the patient was asked to go home immediately.

Conclusions: Enucleation from a homemade bamboo gun toy-related ocular damage in children is a very uncommon blunt trauma that can develop from close-range gunshots. Appropriate and prompt treatment involving enucleation and reconstruction of the eyelid and orbital cavity achieves a favorable aesthetic outcome. The distance between the patient's home and a healthcare facility worsens the prognosis.

Abstract No.: 206268

Pattern of Ocular Trauma in Sabah, Malaysia: A Prospective Observational Study in A Tertiary Centre

First Author: Rongkai TAN

Co-Author(s): Chui Yain CHEN, Chenshen LAM, Joan MARIE PALIKAT, Chin Yee NG, Diing Sheng WONG

Purpose: To describe the sociodemographic profile and clinical characteristics of patients presenting with ocular trauma to Queen Elizabeth Hospital, Sabah.

Methods: This is a prospective observational study. All patients presenting for the first time with eye

injury from July 1st 2022 until April 30th 2023 were recruited. Clinical features, including visual acuity on arrival and types of eye injuries, were recorded. Additionally, sociodemographic data, occupation, setting of injury, duration from injury to presentation, and the application of protective eyewear were also documented.

Results: A total of 102 patients (114 eyes) were included in the study. The mean age of presentation was 39.08 ± 17.26 years old, with most cases occurring among those aged 21–40 years old, 47.1% (n=48). Most patients presented within 24 hours of injury. Men had fourfold higher rates of ocular injury than women, and the majority were of Dusun ethnicity, 19.6% (n=20). Construction and manufacturing workers constituted the largest occupational group that suffered from ocular trauma, 28.4% (n=29). Injuries most frequently occurred at home, 34.3% (n=35), followed by industrial premises, 27.5% (n=28). Surprisingly, only 2.9% (n=3) of patients reported the use of protective eyewear. The majority of patients presented with an initial visual acuity of $\geq 20/40$, 55.3% (n=63). Closed-globe injuries were more common than open-globe injuries.

Conclusions: Young adult males were found to be at high risk of ocular injuries, and the majority did not use protective eyewear at work. There should be widespread awareness of protective eyewear and strict adherence policies to its use in the workplace.

Abstract No.: 206070

Panel No.: OTR-0735

Penetrating Corneal Injury Caused by Fish Hook: A Case Report and Surgical Management

First Author: Faria Tilat TIMA

Co-Author(s): Tanvir AHMED, Ashraful ISLAM

Purpose: To report a rare case of penetrating corneal trauma caused by a fish hook, highlighting the clinical presentation, surgical removal technique, and visual outcome. This case emphasizes the importance of prompt and careful intervention in ocular trauma caused by sharp embedded foreign objects.

Methods: Patient: 32-year-old female. Presentation: Sudden eye injury while fishing; hook rebounded and penetrated the right eye. Examination Findings: • Visual acuity: Hand Movement. OS • Slit-lamp exam: Fish hook embedded in central cornea, penetrating stroma, full-thickness; no uveal prolapse, corneal rusting • No hyphema, lens damage present; anterior chamber shallow but formed • Tetanus prophylaxis given Management: • Under local anesthesia in the operating room • Eye draped and speculum placed • hook shaft retracted back through entry wound • Wound irrigated with balanced salt solution • Corneal entry wound closed with 10-0 nylon sutures • Topical antibiotics and steroids initiated

Results: No intraocular involvement confirmed on B-scan and post-op evaluation • Sutures removed after 3 weeks • Visual acuity improved in follow-up • No signs of infection, corneal opacity outside the visual axis • No complications such as endophthalmitis or cataract formation observed during 3-month follow-up

Conclusions: Penetrating corneal injury from a fish hook is a rare but potentially vision-threatening trauma.

Abstract No.: 206596

Panel No.: OTR-0737

Shattered Spectacle to Sight Saved: Pediatric Scleral Laceration, Repaired

First Author: Adi Rakhmadi **KURNIAWAN**

Co-Author(s): Muhammad **FIRMANSJAH**, Anas **JATIKUSUMA**

Purpose: To report the clinical course and management of a pediatric patient with a large scleral laceration caused by shattered spectacles.

Methods: A 9-year-old boy presented with acute pain and profound visual loss in the left eye following blunt trauma. Examination revealed a 14-mm full-thickness scleral laceration from 12 to 5 o'clock with iris prolapse. Orbital computed tomography excluded an intraocular foreign body and fracture. The patient underwent emergency surgery, including conjunctival peritomy, repositioning of viable iris tissue, layered scleral and corneoscleral suturing, and adjunctive intracameral, intravitreal, and subconjunctival antibiotics.

Results: Visual acuity improved from hand movement to 5/20 with pinhole correction after surgery. Ultrasonography confirmed an attached retina without vitreous hemorrhage. Mild trauma-related scleritis was noted and controlled with anti-inflammatory therapy. Prompt repair within 24 hours combined with intravitreal antibiotics restored globe integrity and minimized endophthalmitis risk. Preservation of viable iris tissue reduced the likelihood of secondary glaucoma and pupillary dysfunction.

Conclusions: Early recognition, timely surgical repair, and comprehensive postoperative management can achieve favorable anatomical and functional outcomes in pediatric scleral laceration. Long-term follow-up remains essential to monitor for complications such as scleral thinning, staphyloma, or secondary glaucoma.

Surgical Approaches and Outcomes in the Management of Vitreoretinal Incarceration Following Open Globe Injury

First Author: Devesh **KUMAWAT**

Co-Author(s): Ritweez **SAHU**, Pradeep **VENKATESH**

Purpose: Open globe injury (OGI) with posterior segment involvement poses significant surgical challenges. This study analysed patterns of injury, surgical interventions employed, and outcomes in cases of vitreoretinal incarceration (VRI) following OGI.

Methods: An ambispective study was conducted, including patients who underwent surgery for VRI following OGI by a single vitreoretinal surgeon at a tertiary trauma referral center in North India over 24 months (January 2023–December 2024). Demographics, type, location, and grade of injury, incarceration characteristics, preoperative visual acuity (VA), surgical details, retinal attachment status, repeat interventions, and VA at last follow-up were assessed. Statistical analysis evaluated the prognostic factors.

Results: Thirty-four eyes of 34 patients (age 30.8 ± 14.0 years; 88.2% male) were included. Types of injury were rupture ($n=8$), penetrating ($n=17$), intraocular foreign body ($n=2$), and perforation ($n=7$). Most injuries were grade 4. Indications were vitreous hemorrhage with incarceration ($n=3$) or with retinal detachment ($n=31$). Surgery included 25G vitrectomy alone ($n=19$), vitrectomy with encircling band ($n=24$), or scleral buckle ($n=1$). Relaxing retinotomy was performed in 22 eyes, and oil tamponade was used in 31 eyes. Median time to retinal surgery was 30 days (range, 7–180). With a median follow-up of 11.5 months, the retina remained attached in 32 eyes (94%), and repeat intervention was required in 5 eyes for re-detachment. Final mean VA was 1.36 ± 0.54 logMAR; $VA \geq 20/200$ and $>20/400$ was achieved in 32.4% and 61.8% eyes, respectively. Early surgery correlated with better anatomical and functional outcomes.

Conclusions: VRI after OGI can be managed successfully with timely, aggressive surgery, achieving high attachment rates and modest visual recovery. Early surgery remains a key prognostic factor.

Abstract No.: 204839

Panel No.: OTR-0732

Swift Emergency Management of Complex Orbital Trauma in a 14-Year-Old: Expedited ORIF for Suprabrow Rupture With Multi-Fragment Orbital Wall Fractures

First Author: Hisar **DANIEL**

Co-Author(s): Amirah D. **DIBA**, Yelsi **KHAIRANI**, Kindah **MAHDIYAH**, Natassha P. **WIBOWO**

Purpose: To demonstrate the critical importance of rapid assessment and immediate surgical intervention

in complex pediatric orbital trauma, we present a case of expedited management within 24 hours of hospital admission.

Methods: A 14-year-old boy presented to our emergency department 12 hours post-trauma with a 5.6 cm full-thickness suprabrow rupture and exposed bone following a sickle assault. Within hours of admission, immediate ophthalmological assessment, emergency non-contrast orbital CT with 3D reconstruction, and multidisciplinary consultations (Pediatrics, Anesthesiology, Oculoplastic) were completed. CT revealed a lateral orbital wall fracture and a comminuted zygomatic frontal process fracture with anterolateral fragment displacement. Emergency ORIF was performed within 24 hours of admission using mini-plate fixation (1.2 mm system, 4 mm depth) after thorough debridement and anatomical reduction.

Results: Swift preoperative optimization, including blood transfusion for anemia (Hb 7.8 g/dL) and immediate antibiotic prophylaxis, enabled same-day surgical intervention. Postoperative recovery was uneventful with rapid resolution of hematoma, stable visual acuity, normal intraocular pressure, and complete wound healing. The patient was discharged on postoperative day 2 with excellent functional and cosmetic outcomes.

Conclusions: Expedited multidisciplinary management and immediate surgical intervention within 24 hours of admission are crucial for optimal outcomes in complex pediatric orbital trauma. Swift decision-making, rapid preoperative clearance, and early definitive repair prevent complications and preserve both function and aesthetics.

When Blue Means Trouble: Prognostic Importance of Recognizing Blue Sclera at Presentation in Patients With Open Globe Injury

First Author: Mariya DOCTOR

Co-Author(s): Sahithi EERETI

Purpose: To study the outcomes of patients with corneal tear associated with blue sclera.

Methods: This is a retrospective descriptive hospital-based study performed at L V Prasad Eye Institute. All patients from 2004 to 2024 who presented with an open globe injury to the emergency clinic and were noticed to have blue sclera, corneal thinning, or keratoglobus during any of their follow-up visits were included.

Results: A total of 17 patients were included. Presence of blue sclera and corneal thinning along with the open globe injury was picked up in 50% cases at the first visit. 8 patients were diagnosed as Ehler-Danlos 2, Marfan's Syndrome 1, and Alport's syndrome. Intra-

operatively, corneal cheese wiring extension of corneal perforation, unable to seal the perforation, were the various complications noted. Adjunctive use of tissue adhesive was needed in 45% cases. No significant difference between the visual acuities was noted from the date of presentation to the last visit. 20% eyes went into phthisis bulbi. Early detection showed a better prognosis for the fellow eye.

Conclusions: Identifying associated blue sclera is crucial at presentation of open globe injury since the management of corneal perforation is challenging in these cases due to fragile tissues. The adolescent age group, parental consanguinity, and history of trivial trauma should raise suspicion. Surgical intervention should focus on tectonic stabilization. Special emphasis should be given to protecting the unaffected eye to avoid bilateral blindness. Use of protective eye shields during sleep should be advocated.

Orbital and Oculoplastic Surgery

A Case Report on Eyelid Reconstruction Using a Nasal Septum Graft and Upper Eyelid Flap Transposition

First Author: Isabella BONDOC

Co-Author(s): Alfonso BENGZON, Camille SISON

Purpose: Basal cell carcinoma (BCC) is the most common malignancy of the eyelid, accounting for 90% of cases. The definitive treatment would be a complete surgical excision with appropriate margins; however, this may cause functional impairment and significant disfigurement for the patient. This study aims to guide and support ophthalmologists in making the appropriate surgical decisions for patients with BCC.

Methods: This is a case of a 44-year-old female presenting with right upper eyelid drooping and tearing. She previously underwent a wide excision biopsy of the right lower eyelid 6 years prior for BCC, resulting in an ill-defined right lower eyelid with poor lid closure. In the interim, she also noted progressive drooping of the right upper eyelid. In this admission, right lower eyelid reconstruction with ptosis repair was done. A nasal septum graft and its mucosa were harvested to recreate the posterior lamella. On the other hand, an eyelid transposition flap from the incision site for the ptosis repair) was performed to recreate the anterior lamella.

Results: With the graft and flap, the patient was able to regain an improved eyelid appearance and function, in turn, alleviating the patient from their significant and chronic eye pain.

Conclusions: Lid reconstruction is a challenge in cases of BCC, especially with large defects after excision. In spite of this, there are still many innovative ways to recreate the anterior and posterior lamella in order to maintain functionality and cosmesis.

A Case of Acute Dacryocystitis Rapidly Progressing to an Orbital Cellulitis Resulting in Complete Vision Loss

First Author: Hiroki **TAN**

Co-Author(s): Tomoyuki **KAMAO**, Arisa **MITANI**, Tomoharu **SHINOZAKI**, Atsushi **SHIRAISHI**, Yoshitaka **TASAKA**

Purpose: To highlight a rare case of acute dacryocystitis progressing to orbital cellulitis with abscess formation and irreversible vision loss due to central retinal artery occlusion, emphasizing the importance of early recognition of orbital involvement.

Methods: A 48-year-old man presented with ocular pain and eyelid swelling after a one-year history of untreated epiphora and discharge. Clinical findings, imaging, treatment, and outcomes were reviewed.

Results: Initial examination showed localized swelling around the lacrimal sac with preserved vision. Computed tomography revealed lacrimal sac distension and preseptal edema, and oral antibiotics were started. Within 24 hours, eyelid swelling worsened and vision deteriorated to light perception. Fundus examination showed a cherry-red spot consistent with central retinal artery occlusion, and repeat imaging demonstrated an orbital abscess displacing the globe. Emergent orbital abscess drainage with external dacryocystorhinostomy was performed, followed by intravenous meropenem. A second drainage was required because postoperative magnetic resonance imaging revealed residual orbital abscess. Although orbital inflammation resolved, vision remained no light perception.

Conclusions: Acute dacryocystitis can rarely extend into the orbit and cause serious vision loss despite prompt management. Clinicians should pay attention to signs of orbital involvement, including ocular pain, diffuse eyelid swelling, or deterioration of vision. Early imaging, urgent surgical drainage, and systemic antibiotics are crucial to prevent irreversible complications.

A Case of Delayed Onset Retrobulbar Hemorrhage Following Anterior Orbitotomy for Orbital Hemangioma in a Pediatric Patient

First Author: Maria Gieniv **VALERIANO**

Co-Author(s): Steffani **CHUA**, Jonnah **TEOPE**

Purpose: Acute retrobulbar hemorrhage (RBH), a collection of blood in the retrobulbar space, is a rare ophthalmic emergency, usually occurring within 24 hours post-surgery. This is a case of delayed onset retrobulbar hemorrhage following an anterior orbitotomy with orbital hemangioma in a pediatric patient.

Methods: Case report.

Results: A 9-year-old female patient presented with a cystic mass in her right medial canthal area. An elective anterior orbitotomy and excision biopsy were done, revealing an orbital hemangioma. Post-operative recovery was initially unremarkable. However, on 72 hours post op, the patient developed sudden right eye pain accompanied by blurring of vision, proptosis, extraocular muscle movement limitations, and elevated intraocular pressure. Lateral canthotomy with cantholysis of the right eye was performed. An emergency cerebral angiogram with sclerotherapy using bleomycin was done by interventional radiology. On the post-operative follow-up, the vision improved, and the proptosis and intraocular pressure had decreased.

Conclusions: RBH is one of the surgical complications that may lead to irreversible vision loss. RBH can occur beyond 24 hours. Therefore, close postoperative monitoring, especially for pediatric patients, is crucial for optimal safety and recovery following surgery.

A Clinical Case of the Repair of Symblepharon Caused by Chemical Burns Using a Circular Amniotic Membrane Ring

First Author: Ariunbold **TUMENJARGAL**

Co-Author(s): Mandakh **BAYARAA**, Uyen **BOLD**

Purpose: Eye injuries represent a significant public health concern, being one of the leading causes of low vision and blindness worldwide. Annually, approximately 55 million individuals experience eye injuries, and this condition leads to 19 million people losing their ability to work due to vision impairment. Population-based studies in Asian countries reveal notable prevalence rates, with 4.4% in Singapore and 3.6% in China.

Methods: A 30-year-old man, while working on a building, encountered a notable eye injury when cement particles accidentally fell into his eye. Initially,

coworkers offered assistance, using available water sources to rinse his eye before he returned home. Medical Intervention: Recognizing the need for professional care due to his persistent symptoms and lack of improvement, Patient B sought treatment at an eye clinic. There, the medical team implemented a comprehensive approach, incorporating both medical and surgical interventions to address the complications arising from his eye injury.

Results: This approach guarantees that the surgical materials align seamlessly with the anatomical features of the patient's eye, thereby minimizing trauma and optimizing clinical outcomes. The circular configuration of the tube is instrumental in maintaining consistent pressure and stability, which contributes to improved healing and a reduction in postoperative complications. Overall, the single-use holy drop system represents a notable.

Conclusions: The circular configuration of the tube is instrumental in maintaining consistent pressure and stability, which contributes to improved healing and a reduction in postoperative complications. Overall, the single-use holy drop system represents a notable.

A Rare Syndromic Cause of Nasolacrimal Duct Obstruction Presenting As Chronic Tearing and Lash Matting

First Author: Katrina FELICIANO

Co-Author(s): Yvette SANTIAGO-GATMAITAN, Reginald Robert TAN, Sandra WORAK-TAN

Purpose: To describe the case of a patient with a rare syndrome that presents with nasolacrimal duct obstruction and chronic ocular surface abnormalities.

Methods: This is a case report of a then 13-year-old male with a chronic tearing of both eyes with recurrent periorbital swelling and lash matting, along with various systemic findings.

Results: A 13-year-old male presented with tearing of both eyes since birth with recurrent periorbital swelling, discharge, and lash matting on waking up. He also had various systemic findings, including cleft lip and palate, unilateral hearing loss, syndactyly, and oligodactyly, along with a history of cheiloplasty and palatoplasty as a child. On physical examination, the patient was noted to have erythematous eyelid margins, thick lashes with collarettes, scant mucoid discharge, papillae, and pannus bilaterally. The dye disappearance test was negative bilaterally, and a lacrimal probe could not be inserted into the lacrimal canaliculi. Dacryoscintigraphy showed a complete obstruction in both lacrimal sacs. After serial lacrimal probing, the patient was then eventually diagnosed as a case of Ectrodactyly Ectodermal Dysplasia Syndrome, presenting as complete nasolacrimal duct obstruction,

punctal stenosis, and chronic staphylococcal blepharoconjunctivitis. The patient then underwent regular follow-up to treat the ocular surface infection and obtain an otorhinolaryngology evaluation of the nasal cavity and pharynx prior to undergoing bilateral external dacryocystorhinostomy.

Conclusions: This report details the clinical presentation and course of a patient with a rare syndromic cause of nasolacrimal duct obstruction and ocular surface abnormalities, underscoring the need for long-term multidisciplinary care in such cases.

Abstract No.: 207505

Panel No.: OOP-0809

A Spectrum of Primary and Metastatic Neoplasms Arising in the Extraocular Muscles: A Case Series

First Author: Wang YI

Purpose: To characterize tumors arising within extraocular muscles (EOMs) and broaden the differential by reporting 9 cases.

Methods: Single-center, 2-year retrospective review. Eight patients with imaging-suspected intra-EOM masses underwent excision under general anesthesia for histopathology; one patient with bilateral, multifocal intra-EOM lesions had metastatic carcinoma on systemic work-up. Exclusions: secondary invasion from adjacent lesions, inflammatory pseudotumor, thyroid eye disease, and IgG4-related ophthalmic disease. Clinical, imaging, and treatment data were collected.

Results: Nine patients (3 men, 6 women; 35–72 years). Ocular motility: normal 1, paresis 6, contracture 1, fixed globe 1. Pathology: schwannoma 2 (medial rectus; inferior oblique), granular cell tumor 1 (inferior oblique), dermoid cyst 1 (lateral rectus), mesenchymal chondrosarcoma 1 (superior rectus), epithelioid sarcoma 1, PEComa 1 (lateral rectus), renal clear cell carcinoma 1 (lateral rectus). One patient had bilateral EOM metastases from breast cancer. Post-op motility was unrestricted after removal of the schwannoma, dermoid, and granular cell tumor. Adjuvant radiotherapy (50 Gy) was given for chondrosarcoma (no recurrence at 3 mo) and epithelioid sarcoma (no recurrence at 1 mo). PEComa had systemic metastases and received targeted therapy; renal clear cell carcinoma switched from a trial drug to chemotherapy; the breast cancer case received chemo-targeted therapy—systemic/ocular status remained stable.

Conclusions: Intra-EOM lesions comprise diverse benign and malignant entities, including metastases. Diagnosis typically requires histopathology. Complete excision can preserve EOM function in benign tumors; malignant disease often needs multimodal therapy (surgery ± radiotherapy, chemotherapy, targeted therapy).

Abstract No.: 204633**Panel No.: OOP-0773****A Successful Case of Refractory MRSA Infection in an Anophthalmic Socket***First Author: Ega SEKARTIKA**Co-Author(s): Sutjipto, Priyo BUDI PURWONO, Musofa RUSLI*

Purpose: Chronic discharge and recurrent infection are common in anophthalmic sockets among ocular-prosthesis users. While *Staphylococcus aureus* is a frequent colonizer, methicillin-resistant *S. aureus* (MRSA) is uncommon and may be overlooked when empiric therapy fails.

Methods: Case Report: A 28-year-old man with a right anophthalmic socket after evisceration and dermis-fat graft developed persistent mucopurulent discharge after custom prosthesis fitting. The infection proved refractory to empiric topical fluoroquinolones and oral ciprofloxacin. Conjunctival culture isolated MRSA resistant to fluoroquinolones but susceptible to chloramphenicol and doxycycline. Culture-guided treatment with topical chloramphenicol and oral doxycycline led to complete resolution within three weeks.

Results: This case highlights that refractory infections in anophthalmic sockets of prosthesis wearers may involve atypical pathogens such as MRSA. The persistence of infection may relate to biofilm formation on polymethyl-methacrylate prosthetic surfaces, which reduces the efficacy of empiric fluoroquinolone therapy. Suboptimal hygiene practices, such as cleaning the prosthesis with tap water, may further facilitate bacterial colonization. Culture-guided antimicrobial selection using agents that retain activity, specifically chloramphenicol with adjunctive doxycycline, combined with reinforced prosthesis-hygiene education, is critical to successful management.

Conclusions: In non-resolving socket infections, clinicians should consider fluoroquinolone-refractory MRSA. Early culture and susceptibility testing, biofilm-aware antibiotic choices, and standardized cleaning protocols can improve outcomes.

Abstract No.: 200881**Panel No.: OOP-0750****A Systematic Review of Direct Versus Indirect Corneal Neurotization In Neurotrophic Keratopathy***First Author: Erdenezul GANTULGA*

Purpose: Corneal neurotization (CN) surgery is indicated for moderate to severe grades of neurotrophic keratopathy when medical treatment is ineffective. We conducted a systematic review comparing direct (DCN) versus indirect corneal neurotization (ICN) surgery. In particular, we compare the improvement in visual

acuity and corneal sensitivity, as well as the surgical recovery time, after DCN and ICN.

Methods: MEDLINE and Embase were searched for studies using keywords synonymous with neurotrophic keratopathy and corneal neurotization within the last five years in English. We used the PICO format to structure our topic. We followed the PRISMA guidelines. We used synthesis without meta-analysis in accordance with systematic review reporting guidelines.

Results: We included 7 studies, 127 patients, and 134 eyes. Eighty-five percent of the patients reported an improvement in visual acuity after corneal neurotization surgery, regardless of the type of surgery. All studies reported an improvement in corneal sensitivity after corneal neurotization. Only one study reported the surgical recovery time; the DCN showed a shorter recovery time.

Conclusions: We confirmed that all of the seven studies reported an improvement in visual acuity and corneal sensitivity after both types of CN surgery. One out of seven studies reported surgical recovery time. The DCN group showed shorter recovery time compared to ICN group. However, since we don't have enough homogenous data to perform meta-analysis, further prospective studies needed to document visual acuity and corneal sensitivity in DCN and ICN groups separately to make a comparison.

Abstract No.: 201194**Panel No.: OOP-0755****A Typical Presentation of an Atypical Condition—Erdheim-Chester Disease: A Case Report From Pakistan***First Author: Rashid BAIG*

Purpose: As literature suggests, Erdheim-Chester disease (ECD) is a rare entity with a wide array of clinical presentations. So we are reporting a case of this rare disease with Atypical symptoms.

Methods: Case report. Informed Consent was taken from the patient.

Results: As we have seen in our case, the patient truly did present with a 'typical' presentation of ECD of the Orbit, the disease having a male preponderance (3:1) in middle-aged adults (mean age at diagnosis: 55 years). However, the rarity of the condition, with only about 1500 reported cases as of July 2019, together with diverse systemic involvement mimicking several other disease presentations, was a barrier to earlier diagnosis. So in our case, the biopsy proved ECD of the orbit.

Conclusions: Rare diseases can also present with atypical symptoms. Proper History Examination and Investigation are key to reaching a diagnosis. And

Management needs a multidisciplinary approach and discussion.

Adjuvant High-Dose-Rate Interstitial Brachytherapy for High-Risk Eyelid Carcinomas: Preserving the Globe, Ocular Function and Cosmesis

First Author: Kervin Luke DELLOSA

Co-Author(s): Karen Kar-wun CHAN, Kelvin Kam Lung CHONG, David JOHNSON, Kenneth Ka Hei LAI

Purpose: Interstitial brachytherapy (ISBT) has emerged as a valuable treatment modality in eyelid malignancies, offering optimal dose delivery to target tissue while mitigating dose spill to adjacent structures. This report aims to describe the use of adjuvant ISBT and its clinical outcomes in two patients with non-melanoma eyelid malignancy.

Methods: Two patients with histologically confirmed eyelid carcinoma were treated with postoperative ISBT. A 76-year-old woman presented with a left lower eyelid mass and underwent excisional biopsy, which revealed moderately differentiated squamous cell carcinoma with close margins (<0.1cm). Secondly, a 60-year-old woman presented with a right upper lid mass and underwent Moh's micrographic surgery which demonstrated sebaceous gland carcinoma with complete tumor excision, but positive conjunctival map biopsy. Both had no lymph node involvement and an unremarkable metastatic work-up. High-dose-rate brachytherapy was administered using Iridium-192 isotope with a total dose of 49 Gy, delivered at 3.5Gy per fraction twice daily for 14 fractions. Follow-up evaluation included local control, acute and late reactions, and cosmetic outcomes.

Results: The implantation and treatment course were well-tolerated. At follow-up, both achieved local control and had satisfactory cosmetic outcomes. Transient conjunctival and periocular erythema were observed. No vision-threatening complications were recorded.

Conclusions: Adjuvant high-dose-rate ISBT provides effective tumor control and excellent cosmetic outcomes without significant acute or late toxicities. This highlights ISBT as a valuable, eye-sparing alternative to invasive surgical treatment in patients with high-risk eyelid malignancies.

Age-Stratified Microbial Trends in Orbital Infections: Implications for Empirical Antibiotic Therapy

First Author: Ajeeth Samuel

Co-Author(s): Usha KIM

Purpose: To evaluate the microbiological spectrum and antibiotic susceptibility patterns of eyelid and orbital infections across age groups, and to guide empirical antibiotic therapy based on local resistance profiles.

Methods: This prospective cross-sectional study was conducted over one year at a tertiary care centre in South India. A total of 189 patients with clinically diagnosed eyelid or orbital infections, who had not received prior antibiotic therapy, were enrolled. Samples were collected from the infection site and subjected to Gram staining and culture using 5% sheep blood agar. Antibiotic susceptibility testing was performed according to CLSI (Clinical and Laboratory Standards Institute) guidelines.

Results: Out of 189 samples, 157 (83.07%) demonstrated bacterial growth on culture. Gram-positive organisms accounted for 73.8% of isolates, with *Staphylococcus aureus* being the most common in both adults and children. Among Gram-negative organisms, *Haemophilus influenzae* was predominant in children, while *Enterobacter* spp. was most frequent in adults — marking a shift from previously reported patterns. Fluoroquinolones exhibited poor sensitivity against Gram-positive isolates, while Chloramphenicol was the most effective topical antibiotic across age groups. Polymyxin B and Chloramphenicol were also effective against Gram-negative isolates, including *Pseudomonas* spp.

Conclusions: This study highlights the importance of age-specific microbial profiling and empirical antibiotics in orbital infections. The high yield from culture, even in Gram stain-negative cases, underscores the necessity of culture testing. Findings support revising empirical regimens—favouring Cefuroxime in children and continuing the use of Polymyxin B and Chloramphenicol for Gram-negative infections.

Abstract No.: 200333

Panel No.: OOP-0744

An Atypical Presentation of Pleomorphic Adenoma in the Upper Eyelid

First Author: Erika Thenese FLORO

Co-Author(s): Armida SULLER-PANSACOLA

Purpose: Early identification and management of eyelid masses are paramount to prevent further complications which may lead to a radical surgical management.

Methods: Case report.

Results: A 49-year-old female presented with a 16-year history of a progressively enlarging painless, non-ulcerating, eyelid margin-involving nodular mass on the right upper eyelid. The patient had an initial excision of a chalazion-like mass, which recurred and progressed at the same location. Incisional and wide excisional biopsies of the mass showed a benign mixed tumor with a biphasic arrangement composed of an epithelial layer with ductal elements with an eccrine appearance and spindle-shaped cells arranged in sheets surrounding a dense chondromyxoid stromal center. Full-thickness eyelid reconstruction was done via the orbicularis sandwich technique. Pleomorphic adenomas are benign tumors with a mixed cellular nature. Ophthalmologically, they commonly form at the lacrimal gland of the orbit. In this case, we have identified a mass with mixed cellular features, classically presenting as a biphasic tumor – consistent with pleomorphic adenoma. The glandular component of the epithelial layer of the tumor showed a single layer of cuboidal cells lining the ducts, pointing to a probable eccrine gland origin for the mass.

Conclusions: Pleomorphic adenoma is a common benign tumor that rarely presents at the eyelid. Given its progressive appearance, they might be mistaken for a malignant mass. Although benign, the management is still complete excision of the mass since these types of masses have a chance of recurrence and malignant transformation.

Abstract No.: 201988

Panel No.: OOP-0761

An Unusual Case of Combined Orbital and Skull Base Arteriovascular Malformation in a Child and Literature Review

First Author: Ho Lam WONG

Co-Author(s): Kristy Hiu Ching YIM, Hunter Kwok Lai YUEN

Purpose: Orbital arteriovenous malformations (AVMs) are rare congenital malformations characterized by abnormal high-flow connections between arteries and veins. We present an uncommon case of paediatric intraorbital and intracranial AVM, leading to dense amblyopia.

Methods: A review of the clinical and radiological report of the patient diagnosed with AVM along the optic pathway, together with a literature review, was performed.

Results: A 4-year-old Chinese female was treated elsewhere for right eye strabismic amblyopia. Despite maximal patching, there was no improvement in the right eye visual acuity after 6 months, which was 0.1. Therefore, magnetic resonance imaging of the brain and orbit was performed, showing serpiginous flow voids along the right optic pathway. Digital subtraction angiogram identified AVM with intra-orbital and intracranial components, with the major arterial feeder

being the hypertrophied right ophthalmic artery. On follow-up after 9 months, visual acuity of the right eye was 0.08. She developed right optic disc pallor and a right relative afferent pupillary defect. Given the limited prognosis, the parents opted for conservative management. Amongst reported cases of optic AVM from 1989 to 2024, 3 paediatric patients aged 8 to 16, in whom risk of amblyopia is lower, presented with reduced visual acuity and constricted visual field. All paediatric cases underwent craniotomy and coagulation of feeders, which improved their visual outcomes.

Conclusions: This report illustrates a rare case of optic AVM with intraorbital and intracranial components in a 4-year-old child, the youngest case ever reported. Prompt investigation and microsurgical intervention may improve the visual outcome of patients.

Abstract No.: 201496

Panel No.: OOP-0756

Autologous Fat Grafting Using Buccal Fat Harvest in a Post-Lower Blepharoplasty Fat Removal Patient: A Case Report

First Author: Brenda HAYATULHAYA

Co-Author(s): Tomoyuki KASHIMA

Purpose: The most recommended method for under-eye dark circles is the orbital fat repositioning technique, which involves releasing the Orbicularis Retaining Ligament (ORL) at the lower orbital margin and transferring orbital fat to that area. However, in cases where fat removal has been previously performed, there may be insufficient orbital fat to relocate, making treatment challenging. In this study, we report the surgical results of buccal fat for autologous fat transplantation in patients who previously had lower eyelid surgery with fat removal.

Methods: A 45-year-old patient visited our clinic one year after lower eyelid orbital fat removal surgery at another hospital, as the dark circles did not improve. Due to insufficient orbital fat volume, fat repositioning was not possible, so we removed 5.2 cc of buccal fat from both sides by an intraoral approach. We performed surgery using a transconjunctival approach, dissecting the ORL to create a pocket. We placed 0.7 cc of buccal fat into the pocket on each side, injected triamcinolone around the graft, and performed a sutureless closure. We conducted clinical evaluations, standardized photography, and postoperative follow-up to assess aesthetic outcomes and complications at the donor site.

Results: Postoperatively, the patient showed improved lower eyelid contour, symmetry, and overall appearance. No significant complications, including infection, severe hematoma, or donor site morbidity, were observed on 6-month follow-up.

Conclusions: Buccal fat transplantation has proven to be a safe and reliable method for the fat repositioning technique in patients who have lost orbital fat volume. To achieve optimal results, careful patient selection and meticulous technique are essential.

Abstract No.: 206017

Avoidance of Orbital Exenteration in Invasive Fungal Rhino-Sino-Orbital Cellulitis With Repeated Transcutaneous Retrobulbar Amphotericin B Injections

First Author: Varan **VONGSILPAVATTANA**

Co-Author(s): Karen Kar-wun **CHAN**, Kelvin Kam Lung **CHONG**, Kervin **DELLOSA**, Kenneth Ka Hei **LAI**, Chi-lai **LI**, Emily Suhan **WONG**

Purpose: To report a rare case of invasive fungal rhino-sino-orbital cellulitis due to *Exserohilum rostratum*, successfully managed with repeated transnasal debridement and adjunctive transcutaneous retrobulbar amphotericin B (TRAMB), thereby avoiding orbital exenteration.

Methods: A 52-year-old female with ANCA-associated vasculitis previously treated with Rituximab presented with progressive nasal obstruction, facial pain, and orbital swelling. Imaging demonstrated left ethmoid and maxillary sinusitis with extension into the orbit and adjacent facial soft tissues. Nasoendoscopy and microbiological culture confirmed *Exserohilum rostratum*. The patient underwent functional endoscopic sinus surgery with serial nasal debridements. Endonasal endoscopic examination revealed fungal mold growths over the lamina papyracea, medial periorbita, and lacrimal sac. She received systemic antifungal therapy and was treated with repeated TRAMB injections (3.5 mg/ml).

Results: The infection improved with resolution of orbital signs and preservation of vision. The patient tolerated TRAMB without major complications, and fungal infection was controlled without the need for exenteration.

Conclusions: Invasive fungal rhino-sino-orbital cellulitis in immunocompromised hosts is often associated with poor prognosis and the need for radical surgery. This case illustrates that aggressive surgical debridement combined with systemic antifungal therapy and adjunctive TRAMB can preserve vision and the globe. TRAMB may serve as a valuable adjunct in selected patients with orbital involvement.

Abstract No.: 200790

Panel No.: OOP-0749

CT-Guided Biopsy via the Anterior Approach in the Diagnosis of Orbital Lymphoma: A Case Series

First Author: Shuyi **LIU**

Co-Author(s): Wei **LU**

Purpose: To evaluate the clinical efficacy of CT-guided biopsy via the anterior approach in diagnosing orbital lymphoma.

Methods: From November 2018 to July 2021, 11 patients suspected of having orbital lymphoma based on imaging were selected from the Second Hospital of Dalian Medical University. Each patient underwent a CT-guided biopsy using a semi-automatic 18G needle. Biopsies were performed under local anesthesia, and the obtained tissue samples were analyzed for a definitive diagnosis.

Results: Adequate tissue samples were successfully obtained in all 11 cases. Of these, 7 patients (63.6%) were diagnosed with lymphoma, including subtypes such as mucosa-associated lymphoid tissue lymphoma, diffuse large B-cell lymphoma, and mantle cell lymphoma. Other diagnoses included IgG4-related ophthalmic disease (9.1%), chronic inflammatory hyperplasia (18.2%), and normal tissue hyperplasia (9.1%). A small amount of subcutaneous hematoma, occurred in 1 patients (9.1%), which resolved without additional intervention.

Conclusions: CT-guided biopsy via the anterior approach is an effective technique for diagnosing orbital lymphoma. It is cost-effective, minimally invasive, allows for quicker recovery, and is associated with fewer adverse events compared to traditional surgical biopsy.

Case Report – a Rare Case of New Delhi Metallo-Beta-Lactamase (NDM-1)-Producing *Pseudomonas aeruginosa* Associated Panophthalmitis

First Author: Lexley **ONG-SY**

Co-Author(s): Wenqi **CHIEW**, Daniel **CHIN**, David **LAW**, Stephanie **SUTJIPTO**

Purpose: We report a rare case of NDM-1 *P. aeruginosa*-associated panophthalmitis in a patient who underwent evisceration with good healing of his right eye socket, resolution of infection, and restoration of his upper and lower fornices.

Methods: We describe a case of a 63-year-old Singaporean-Chinese man who developed a small corneal epithelial defect in his right eye that developed into a corneal ulcer. The patient subsequently presented with right eye periorbital swelling,

prompting him to seek emergency consultation. Assessment was panophthalmitis, which prompted evisceration. Postoperatively, the patient was administered empirical intravenous antibiotics with antibiotic eye drops. The intra-operative samples from his right eye showed growth of multi-drug resistant *P. aeruginosa*. Further antimicrobial susceptibility testing confirmed the presence of the NDM-1 gene.

Results: Although panophthalmitis caused by *P. aeruginosa* has been widely reported globally, to the best of our knowledge, this is the first documented case of NDM-1-producing *P. aeruginosa*-associated panophthalmitis. Given the multidrug-resistant nature of this bacterium and the poor visual prognosis of *P. aeruginosa* endophthalmitis and panophthalmitis, it can only be surmised that NDM-1-producing *P. aeruginosa*-associated panophthalmitis would present an even graver visual prognosis, with challenges in treatment and potential persistent implant-related infections following evisceration surgery.

Conclusions: Through multi-disciplinary team effort, early identification, appropriate antibiotic treatment, and close monitoring, patients with the highly drug-resistant NDM-1-Producing *P. aeruginosa*-associated panophthalmitis managed via evisceration and use of an orbital implant may still have favourable outcomes.

Clinical Use of Allogenic Fascia Lata for Wound Complications in Anophthalmic Patients

First Author: Seongwook SEO

Co-Author(s): Hyeonjeong JEONG, Daeun YOO

Purpose: To assess the clinical use of allogenic fascia lata for the treatment of orbital implant exposure in anophthalmic patients.

Methods: This case series included four anophthalmic patients with exposed orbital implants. Infection was controlled preoperatively with systemic antibiotics. Allogenic fascia lata, provided by the Korea Public Tissue Bank (KPTB), was harvested from cadaveric donors within 24 hours of death. The grafts were chemically treated, sterilized by γ -irradiation, and cryopreserved before use. Under general anesthesia, the exposed implant was removed and exchanged with a new implant, the anterior surface of which was covered with allogenic fascia lata and sutured with interrupted 6-0 nylon. We tried to completely cover the graft with tenon's capsule and conjunctiva, but in two cases it was partially exposed. Postoperative outcomes were assessed during a 6-month follow-up period.

Results: Stable graft integration was observed in all cases. Sutures were removed after the conjunctiva had completely covered the allogenic fascia lata, at a mean of 49.3 days (range, 29–61 days). No implant re-

exposure, recurrent infection, or major complications were observed. New ocular prostheses were successfully fitted at a mean of 58 days (range, 43–68 days). Symblepharon occurred in two cases but did not interfere with prosthesis use.

Conclusions: Allogenic fascia lata appears to be an effective option for managing orbital implant exposure associated with anophthalmic patients. Further large-scale, long-term studies are expected to validate these findings and establish their sustained efficacy.

Clinical Utility of the Phenylephrine Test in Ptosis Evaluation and Surgical Planning: A Review of Current Evidence

First Author: Fatema ALJUFAIRI

Co-Author(s): Safa ALKALAITI, Alice GOH

Purpose: To summarize current evidence regarding the use of the phenylephrine test in ptosis evaluation, including administration methods, response definitions, surgical planning implications, and its predictive value for postoperative outcomes and brow position.

Methods: A targeted review of published studies and national surveys examining phenylephrine testing in ptosis management was conducted, focusing on test protocols, MRD1 response, surgical decisions, and outcome correlations.

Results: Most studies used 5% phenylephrine, instilled as 1–2 drops of 2%, 5%, or 10% into the superior or inferior fornix. MRD1 was measured 5–15 minutes post-instillation, though some responses peaked at 30 minutes. A positive response was defined as MRD1 elevation ≥ 1 –2 mm. Resection lengths were guided by response: 8 mm for matched elevation, 9–10 mm for partial response, and 7 mm to prevent overcorrection. The test also aided in revision surgery planning. Evidence on predictive accuracy is mixed—a May 2024 study found no outcome correlation, while earlier work showed maximal response within 2 minutes lasting up to 30 minutes. Limited data suggest absence of brow depression post-test predicts minimal postoperative brow change.

Conclusions: The phenylephrine test remains a valuable adjunct for assessing ptosis and guiding MMCR. While useful for tailoring resection, its ability to predict final eyelid height and brow position remains inconsistent, underscoring the need for standardized protocols and further prospective studies.

Clinicopathological Features and Management of Caruncular Lesions: A 23-Year Retrospective Analysis in North China

First Author: Zhao YUN

Purpose: The aim of this study was to provide a comprehensive description of the clinicopathological features and management of caruncular lesions, presenting the first Chinese case series on this topic.

Methods: This was a retrospective, single-centre, observational case series, comprising a retrospective review of 276 patients with caruncular lesions at Tianjin Eye Hospital in North China between January 2002 and October 2024, as well as a review of the literature.

Results: The patients were between 6 and 85 years of age. Among the 276 patients, 161 were female, and 115 were male. Benign tumours largely predominated over malignant tumours and represented 98.2% of all cases. The three most common benign tumours were naevus, sebaceous hyperplasia, and papilloma. Five cases of malignant tumours accounted for 1.8% of all the caruncular lesions. Among the five patients with malignant tumours, two had mucoepidermoid carcinoma, one had basal cell carcinoma, one had malignant melanoma, and one had lymphoma. One case of malignant melanoma was confirmed by pathological examination as a malignant transformation of a naevus. The accuracy of the clinical diagnosis in all patients was 70.1%. A total of 226 patients completed the follow-up. The average follow-up time was 3.5 years. Postoperative recurrence occurred in 6 patients with caruncular lesions in our study.

Conclusions: A thorough understanding of the clinicopathological features of caruncular lesions can improve the accuracy of diagnosis and the timeliness of treatment. Complete resection of caruncular tumours has a good prognosis, but both benign and malignant tumours may recur and should be followed up regularly.

Closing the Gap, Facing Residual Notching: The Tenzel Flap in Goldenhar-Suspect

First Author: Arafani Putri YAMAN

Co-Author(s): Riani ERNA

Purpose: Eyelid coloboma and epibulbar dermoid are typical ocular signs of Goldenhar syndrome. It describes the surgical procedure and postoperative outcomes of the Tenzel flap technique in an infant with suspected Goldenhar syndrome, focused on restoring eyelid function.

Methods: A one-year-old girl with a suspected case of Goldenhar syndrome was referred with a coloboma

visible on her upper eyelid. The examination found a full-thickness defect in the right upper eyelid, measuring 10 × 6 mm in the medial third of the eyelid margin. Epibulbar dermoids were found at the 4 o'clock (2x2 mm) and 6 o'clock (5x5 mm) limbal position, without hair growth. A semicircular Tenzel flap was decided for reconstruction, considering it is best for mild to moderate eyelid defects (33%–50%), restoring the eyelid function, and lowering the risk of amblyopia.

Results: Following the procedure, the lids completely covered the ocular surface. In the first month's follow-up, a slight residual medial notching (4x1mm) was noticed with no sign of infection or functional impairment.

Conclusions: The semicircular Tenzel flap is a safe method for managing upper eyelid coloboma in pediatric patients, providing optimal corneal protection and preserved eyelid function. The discovered residual notching indicates the requirement for further evaluation of nutrition status, suturing control, tissue tension, and postoperative care to improve functional outcomes.

Congenital Eyelid Colobomas: Demographics, Histological Features and Surgical Outcomes in a Bangladeshi Population

First Author: Narayon Chandra BHOWMIK

Co-Author(s): Md.Golam HAIDER, Mukti Rani MITRA, Syeed Mehbub UL KADIR

Purpose: To describe our experience in the surgical management of congenital eyelid coloboma in Bangladeshi population.

Methods: A descriptive, observational, retrospective study was performed in patients with congenital eyelid colobomas between 2010 and 2024.

Results: Fifty-four eyelids were included in this study. Eyelid colobomas predominantly affected the upper lid 83.33 % (45), and were typically unilateral in 55.56 % (30) patients, isolated in 62.9% (34), and as part of a syndrome in 37.01% (20) patients. Congenital upper eyelid coloboma was commonly located in the medial upper lid (33 lids, 73.33%) and mostly involved the full thickness of the lid (38 lids, 70.37%). Corneal adhesion (25 eyes, 46.3%) and poorly formed eyebrows (29 eyebrows, 53.7%) were the most common ocular/adnexa associations. Histopathological features were epidermal acanthosis 40.74 % (22), scarred dermis 79.63 % (43), atrophic orbicularis oculi 88.89% (48) and atrophic or absent tarsus 70.37%(38). Visual acuity at the final follow-up was 20/50 or better in 18 (33.3%) eyes. Complete lid closure without lagophthalmos after one or more surgical procedures was achieved in 22 (41.1%) cases.

Conclusions: Eyelid colobomas are a potential threat to vision. In children, it requires close monitoring of the visual development. Dermal scarring and defective orbicularis muscles are common. Achieving a good cosmetic and functional success after management is always challenging.

Correlation Between the Severity of Blepharoptosis and Pathological Changes in the Levator Aponeurosis

First Author: Hideyuki **SHIMIZU**

Co-Author(s): Koji **NISHIGUCHI**

Purpose: To analyze the correlation between histological changes in the levator aponeurosis and clinical indicators in degenerative blepharoptosis.

Methods: Thirty eyelids (15 patients) underwent levator muscle shortening for degenerative ptosis. Male: 8 eyelids; Female: 7 eyelids; Age: 54–96 years (mean 79 years). Elastica-Masson staining was performed on levator aponeurosis specimens collected during surgery, and the proportion of collagen fibers was evaluated using the ImageJ Colour Deconvolution 2 plugin. A pathologist assessed the percentage of fat in the levator aponeurosis. Spearman's rank correlation was used to evaluate correlations between the percentage of collagen fibers in the levator aponeurosis, the percentage of fat, age, sex, levator function, and marginal reflex distance-1 (MRD-1).

Results: The mean collagen fiber percentage in the levator aponeurosis was $15.21 \pm 9.77\%$. A significant positive correlation was found between levator function and MRD-1 ($r = 0.42$, $p = 0.02$). A significant negative correlation was found between age and levator function ($r = -0.57$, $p < 0.001$). A significant positive correlation was found between the percentage of collagen fibers in the levator aponeurosis and being male ($r = 0.44$, $p = 0.02$). A significant positive correlation was found between the percentage of collagen fibers in the levator aponeurosis and levator function ($r = 0.42$, $p = 0.02$). A significant negative correlation was found between the percentage of collagen fibers in the levator aponeurosis and the percentage of fat ($r = -0.52$, $p = 0.003$).

Conclusions: A decrease in the percentage of fibers in the levator aponeurosis may promote laxity of the levator aponeurosis and its detachment from the tarsal plate, potentially contributing to the development of blepharoptosis.

Demographic and Clinical Manifestations of Thyroid Eye Disease in Pediatric Populations Across Different Ethnic Groups: A Systematic Review and Meta-Analysis

First Author: Fatema **ALJUFARI**

Co-Author(s): Kelvin **CHONG**, Kenneth **LAI**, Sayed **NAEMA**, Calvin **PANG**, Clement **THAM**

Purpose: To summarize the demographic patterns and clinical features of pediatric thyroid eye disease across diverse ethnic populations and geographic regions.

Methods: This PRISMA 2020–based systematic review and meta-analysis (PROSPERO: CRD420251121822) searched five databases without language or year limits, including studies on demographic and clinical features of pediatric thyroid eye disease across ethnic groups.

Results: Fifteen studies (11–115 subjects) from diverse ethnic groups—seven Western, three East Asian, two Southeast Asian, one South Asian, one Middle Eastern, and one Netherlands–Iran cohort—were included. Pediatric TED mainly affected early-to-mid adolescents (mean age 9–14 years) with a strong female predominance. Hyperthyroidism was most common, though euthyroid cases were more frequent in South Asian and Western groups. Smoking was rarely reported, while 19–69% had a family history of thyroid disease. Exophthalmos and eyelid retraction appeared in over two-thirds of patients, extraocular motility restriction in up to 30%, and dysthyroid optic neuropathy in 0–1.7%. Bilateral disease predominated (88–100%), showing overall ethnic similarity with minor regional variations in onset and presentation.

Conclusions: Pediatric thyroid eye disease most commonly presents during early-to-mid adolescence, with a strong female predominance and hyperthyroid association across all ethnic groups. While overall clinical patterns were similar worldwide, subtle regional differences were observed in age of onset, thyroid status, and specific ocular findings. These findings highlight the need for ethnicity-tailored diagnostic awareness and early recognition strategies in pediatric TED.

Diffuse, Deceptive, and Aggressive: Pagetoid Sebaceous Carcinoma of the Eye — a Case Series

First Author: Gowtham **KIM**

Co-Author(s): Vikas **MENON**

Purpose: To present a case series of 12 patients with ocular sebaceous gland carcinoma showing pagetoid spread, a rare and aggressive variant often associated with delayed diagnosis and poor outcomes.

Methods: Clinical records, histopathological findings, management strategies, and outcomes of 12 patients diagnosed with pagetoid sebaceous gland carcinoma of the eyelid and ocular adnexa were retrospectively reviewed. Emphasis was placed on presentation, diagnostic challenges, treatment modalities, and recurrence patterns.

Results: Twelve patients (mean age: 60 years; 8 male, 4 female) were included. Most presented with diffuse conjunctival involvement, clinically mimicking chronic blepharoconjunctivitis or unilateral keratoconjunctivitis. Histopathological confirmation with map biopsies was required in all cases. Management included wide excision with margin control, conjunctival map biopsies, and exenteration in select cases. Adjuvant cryotherapy and topical chemotherapy (mitomycin-C) were employed for extensive intraepithelial spread. Two patients (16.6%) developed recurrence during follow-up. Visual morbidity and systemic metastasis occurred in a minority of cases.

Conclusions: Pagetoid sebaceous gland carcinoma of the eye is a diagnostic and therapeutic challenge due to its ability to mimic benign inflammatory conditions and its tendency for diffuse intraepithelial spread. Early suspicion, meticulous use of map biopsies, and aggressive surgical and adjuvant treatment are crucial for improving outcomes. This 12-case series highlights the importance of timely recognition and multidisciplinary management in addressing this rare but potentially sight- and life-threatening malignancy.

Effect of Previous Temporary Nasolacrimal Stent Implantation on Endoscopic Dacryocystostomy

First Author: Xinyu LI

Co-Author(s): Hongfei LIAO, Wencan WU, Bo YU, Guangming ZHOU

Purpose: We compared the outcomes of endoscopic dacryocystorhinostomy (En-DCR) in patients with chronic dacryocystitis (CD), with or without previous temporary nasolacrimal stent implantation (TNLSI), then explored whether previous TNLSI influenced postoperative outcomes.

Methods: This retrospective study included consecutive patients with CD and previous TNLSI who underwent En-DCR (group A) between September 2019 and May 2022, and an age- and sex-matched control group of patients with CD who had not undergone previous implantation (group B). Lacrimal sac parameters were measured by computed tomography-dacryocystography, and surgical findings were recorded during surgeries. The surgical success rates were compared between the two groups at 12 months after surgery.

Results: There were 53 patients in group A and 106 patients in group B. In group A, the mean horizontal, sagittal, and vertical lengths were 4.94 ± 1.30 mm, 4.88 ± 1.17 mm, and 7.85 ± 2.03 mm; in group B, these three lengths were 6.16 ± 1.25 mm, 5.97 ± 1.20 mm, and 10.00 ± 2.18 mm, respectively. All three parameters were significantly smaller in group A than in group B. Scar formation in the sac was observed in all patients in group A; it was not present in group B. At 12 months after surgery, the anatomical and functional success rates were 75.47% (40/53) and 71.70% (39/53), respectively, in group A; they were 93.40% (99/106) and 91.51% (97/106) in group B. The success rates were significantly higher in group B than in group A.

Conclusions: Previous TNLSI may reduce lacrimal sac parameters and cause scar formation, thereby reducing the likelihood of success after En-DCR.

Panel No.: OOP-0786

Efficacy and Safety of Sirolimus (Rapamycin) for the Treatment of Thyroid Eye Disease: A Systematic Review

First Author: Jacky Ka Kit LO

Co-Author(s): Kelvin Kam Lung CHONG, Kenneth Ka Hei LAI, Marco Shing Yan MAN, Calvin Chi Pui PANG, Clement Chee Yung THAM

Purpose: To review the efficacy and safety of sirolimus (rapamycin) for managing thyroid eye disease (TED).

Methods: We searched on PubMed, Web of Science, and Medline databases up to May 2025. Two independent reviewers selected studies with the use of sirolimus with or without combined therapy in patients with moderate-to-severe TED. We independently extracted the proportion of patients whose clinical activity score (CAS) reduced by at least 1 point, and Gorman diplopia score (GDS) improved. The quality of studies was assessed by the Risk Of Bias In Non-Randomized Studies – of Interventions (ROBINS-I).

Results: The initial search identified 831 publications, of which six were screened and assessed for eligibility. Sirolimus was used as a second-line treatment in steroid-refractory patients, with a regimen of either 2mg per day or 2-mg loading dose followed by 0.5mg daily oral dosage. In every study, around 80% of subjects at 24 weeks and greater than 70% of them at 48 weeks endpoint showed at least 1 grade of CAS reduction. Two studies conducted in Hong Kong demonstrated a resolution of at least 1 grade of GDS at 48 weeks in over half of the patients with intractable diplopia. Sirolimus may offer superior or comparable efficacy to methylprednisolone in the short term and to mycophenolate mofetil in the mid-to-long term. There were no severe adverse events reported, with mainly hyperlipidaemia and infections.

Conclusions: Sirolimus demonstrated its therapeutic potential with a promising safety profile in managing moderate-to-severe TED. A longer, randomized controlled trial is warranted to elucidate its efficacy and safety.

Abstract No.: 202435

Panel No.: OOP-0766

Endoscopic Revision of Unsuccessful Dacryocystorhinostomy Under Local Anesthesia

First Author: Ben LIMBU

Purpose: To evaluate etiological factors for unsuccessful Dacryocystorhinostomy (DCR) surgeries and surgical outcome after revisional endoscopic endonasal dacryocystorhinostomy (Re-EEDCR) surgery.

Methods: All the consecutive cases of previously failed DCRs who underwent revisional endoscopic endonasal DCR under local anesthesia were included. Patients' medical records were reviewed for demographic profile, pre- and intra-operative endoscopic findings during revisional surgery, and post-operative outcome of surgery. The potential causative factors for unsuccessful DCR were assessed, and the surgical outcome of Re-EEDCR was evaluated.

Results: A total of 15 patients, 13 (86.7%) female and 2 (13.3%) male, with failed DCR, who had undergone revisional En-DCR were evaluated. The mean age at revisional surgery was 40.53 ± 15.88 (range, 18-74 years). The mean duration from primary to Re-EEDCR was 19.93 ± 31.73 months (range, 1-120). The most common causes attributed to a failure of unsuccessful DCR were intranasal adhesion 9(60%), followed by the inappropriate site of ostium 8(53.3%), inadequate marsupialization of sac 6(40%), granuloma formation 2(13.3%), and inadequate ostium site (6.6%). The overall success rate was 93.3% (14/15) without any important intra- or postoperative complications

Conclusions: The most common cause of failed DCR was intranasal adhesions. A revision surgery with an endoscopic endonasal approach under local anesthesia can significantly reduce overall surgery time and avoid the risk of further skin scarring. It is a safe and effective option in the management of unsuccessful DCR surgery.

Panel No.: OOP-0791

Evaluating Ocular and Periocular Sensory Symptoms in Thyroid Eye Disease

First Author: Hunter FISCHER

Co-Author(s): Patrick BARLOW, Keith CARTER, Rupin PARIKH, Chau PHAM, Erin SHRIVER

Purpose: Patients with thyroid eye disease (TED) experience variable signs and sensory symptoms.

Symptoms such as "pain behind the globe," "pain with eye movement," and "retrobulbar ache" "at rest" or "with gaze" have been described in validated scales; however, a broader understanding of the sensory experience is limited in the literature. This study aims to enhance the characterization and quantification of the full range of symptoms experienced by TED patients.

Methods: A retrospective review was conducted of all patients with TED seen at an academic Oculoplastic Surgery Clinic between 1/1/2020 and 12/31/2024. Ocular and periocular sensory symptoms reported in the clinic visit History of Present Illness section, with attention to descriptors and location, were recorded.

Results: A total of 562 symptomatic patients over 1,412 appointments noted 46 unique ocular and periocular sensory descriptors. Most symptoms localized to the ocular surface (88%), with tearing (316 patients, 56%) and dryness (281, 50%) being the most common. The next most frequent symptom locations were retrobulbar (19%), periorbital (12%), intraocular (10%), and eyelid (3%). 20% of patients had generalized ocular/periocular sensory symptoms without localization. Movement-evoked symptoms were noted by 27% of patients. Pain with eye movement (115, 20%) and pain behind the globe (53, 9%) were the most common non-surface descriptors. Women reported more sensory symptoms than men (2.83 vs 2.45, $p=0.02$).

Conclusions: Patients experienced a wide range of sensory symptoms in both ocular and periocular locations. Ocular surface symptoms were the most frequently endorsed, followed by retrobulbar, periorbital, and intraocular symptoms. Over a quarter of patients experienced movement-evoked symptomatology.

Abstract No.: 205793

Everting Sutures With Lateral Canthopexy for Involutional Entropion: A Case Series of Treatment Room-Based Repairs

First Author: Daniel CHIN

Co-Author(s): Petrina TAN

Purpose: To evaluate the outcomes, complications, recurrence rates, and potential cost benefits of performing entropion repair using everting sutures combined with lateral canthopexy in a treatment room setting rather than in the operating theatre.

Methods: We conducted a retrospective case series of patients with involutional lower eyelid entropion who underwent repair using everting sutures and lateral canthopexy under local anaesthesia in a treatment room between 1st September 2024 to 1st September 2025. Data collected included patient demographics,

laterality, recurrence rates, complication rates, and costs.

Results: A total of 10 eyelids in 9 patients were treated. The mean patient age was 77.2 years. (range:67 - 87). 3 patients were male and 6 were female. At a mean follow-up of 6.7 months, 100% of eyelids remained anatomically corrected without recurrence. Minor complications included wound infection with subsequent loosening of the lateral canthopexy suture and ectropion in 1 patient. No cases required conversion to an operating theatre-based procedure. Treatment room procedures had shorter waiting times and costs compared to operating theatre cases, did not require additional anaesthesia support for sedation, and patients were not required to fast. All patients tolerated the procedure well, and no sedation or systemic monitoring was required.

Conclusions: Entropion repair using everting sutures with lateral canthopexy can be safely and effectively performed in a treatment room setting. This approach offers advantages in terms of accessibility, convenience, and potential cost savings, particularly in outpatient or resource-limited environments. Outcomes appear comparable to those achieved in operating theatre-based surgery.

Abstract No.: 206402

Panel No.: OOP-0792

Feeling Versus Seeing: Rethinking Diagnosis of Lacrimal Obstruction

First Author: Maryanne ROMERO

Co-Author(s): Blanche LIM, Gangadhara SUNDAR

Purpose: This study aimed to correlate conventional probing and irrigation diagnoses of lacrimal obstruction with findings from dacryoendoscopy.

Methods: We retrospectively reviewed 21 patients referred to a single-center lacrimal clinic who underwent dacryoendoscopy. An initial diagnosis was made following probing and irrigation, and a second diagnosis was established after dacryoendoscopy. Pre- and post-endoscopy diagnoses were then compared.

Results: A total of 21 patients underwent dacryoendoscopy by a single surgeon. Based on probing and irrigation, initial diagnoses were: partial NLDO (n=6), canalicular obstruction with partial NLDO (n=6), complete NLDO (n=5), and canalicular obstruction alone (n=4). Following dacryoendoscopy, 15 cases (71%) required revision: 8 (38%) were incomplete diagnoses, and 7 (33%) were inaccurate.

Conclusions: Dacryoendoscopy substantially improved diagnostic accuracy, with over two-thirds of initial diagnoses revised. Direct visualization of the lacrimal system provides critical insights that probing and irrigation alone may miss.

Abstract No.: 205344

Panel No.: OOP-0778

Flap or Flapless: Rethinking Endonasal DCR

First Author: Roopa HIREMATH

Co-Author(s): Roopa HIREMATH

Purpose: Endonasal dacryocystorhinostomy (DCR) has traditionally been performed with mucosal flaps to maintain ostium patency. However, flap-related complications may compromise outcomes. This study compares surgical success and complications between flap-based and flapless techniques, challenging the necessity of flap creation.

Methods: In this prospective comparative study, 52 patients with primary acquired nasolacrimal duct obstruction were randomized into two groups. Group A (n = 26; 18 females, 8 males) underwent flap-preserving endonasal DCR, while Group B (n = 26; 14 females, 12 males) underwent flapless endonasal DCR. Patients were followed for ostium patency and complications.

Results: Group A: 5 patients (19.2%) developed ostium block with postnasal bleeding due to flap dislodgement. Group B: 1 patient (3.8%) developed an ostium block from granulation tissue. Surgical success rate was 80.8% in Group A versus 96.2% in Group B. The difference in complication rates was statistically significant ($\chi^2 = 3.90$, $p < 0.05$).

Conclusions: Flapless endonasal DCR yielded significantly higher success with fewer complications compared to the conventional flap technique. Flap dislodgement was the major cause of failure in the flap group, whereas flapless surgery minimized bleeding, as we can safely pack the nose post-surgery and ostium obstruction by adhesions. These findings suggest that routine flap creation may not be essential, and flapless DCR could represent a safer, simpler, and more effective approach for modern lacrimal surgery.

Panel No.: OOP-0760

Functional and Aesthetic Outcomes of a Novel Tissue-Sparing Approach for Cicatricial Ectropion Repair

First Author: Vinit TANWAR

Purpose: Cicatricial ectropion (CE) mostly requires invasive surgical modalities such as full-thickness skin graft, lateral tarsal strip procedure, etc., associated with donor site morbidity and additional scars. To the best of our knowledge, this is the first study on the use of Autologous Fat Graft (AFG) for the correction of the CE of the lower lid.

Methods: This was a prospective, interventional pilot study that included 5 patients with CE (grade I-III). Fat was harvested from the abdomen using the Coleman liposuction method and injected into the cicatricial lid.

All these patients underwent a pre-injection workup to assess anatomical outcomes (grade of ectropion, vertical palpebral aperture (VPA), lagophthalmos, and eyelid retraction), functional outcomes (dry eye status), and aesthetic outcomes (change of scar color, thickness, pain, and consistency).

Results: At 6 months, all patients had improvement in the grade of ectropion, vertical palpebral aperture, eyelid retraction, and almost complete resolution of lagophthalmos. There was a significant improvement in scar color, thickness, and consistency on the Visual Analogue Score with no donor site complications. Surgery was avoided in 4 out of 5 patients.

Conclusions: AFG transfer for CE not only eludes the need for invasive surgery but also provides satisfactory correction with a stable outcome and an improved texture of scar and has a low risk.

Functional and Cosmetic Improvement After Surgical Treatment of Three Cases of Divided Nevus of the Eyelid

First Author: Marina OGAWA

Co-Author(s): Tomoyuki KASHIMA, Ryo KIKUCHI, Shohei SUETAKE

Purpose: A divided nevus, also known as a kissing nevus, is a congenital melanocytic nevus that develops during fetal development when the upper and lower eyelids are fused and subsequently separated with the formation of the palpebral fissure. Although it is benign, it may cause both functional and cosmetic impairment, often necessitating surgical excision. Here, we report three surgically treated cases with favorable outcomes.

Methods: This case series included three patients. Patient 1 is a 52-year-old female who presented with a congenital pigmented lesion involving the medial parts of her right upper and lower eyelids, which had gradually enlarged over 5 years. Serial excisions were performed along the lid margin while preserving the eyelash roots. Patient 2 is a 31-year-old female with a congenital nevus on the left upper eyelid that gradually enlarged over a period of 10 years. Serial shaving excisions were performed. Patient 3 is a 61-year-old female who underwent bilateral ptosis repair and the excision of a divided nevus with skin grafting. Postoperatively, trichiasis developed, necessitating the additional excision of the eyelash roots.

Results: All three cases achieved significant functional and cosmetic improvement by tumor excision. No meibomian gland dysfunction was observed following eyelid margin excision, although eyelash loss occurred only in Patient 1.

Conclusions: A divided nevus can cause significant functional and cosmetic disturbances. Although

surgical excision carries risks such as trichiasis and lagophthalmos, it generally results in very high patient satisfaction. We achieved favorable postoperative outcomes in the above three cases.

Geometry-Inspired Aesthetics: Using a Rhomboid Flap for Medial Canthal Defects

First Author: Sofia IQBAL

Co-Author(s): Aleena KHAN, Bakht KHAN

Purpose: To demonstrate rhomboid flap reconstruction for medial canthal defects following excision of biopsy-proven basal cell carcinoma (BCC) and squamous cell carcinoma (SCC) in terms of functional and cosmetic outcomes.

Methods: This case series describes three patients with lower lid medial canthal tumors (two BCC and one SCC) confirmed on histopathology. The patients included a 64-year-old male, a 52-year-old female, and a 45-year-old female. Wide local excision were confirmed for tumor-free margins, rhomboid flaps were designed and oriented along relaxed skin tension lines to optimize tissue closure and camouflage scarring. Flaps were raised in the subcutaneous plane so that their vascular integrity was maintained. Rotation and advancement were performed carefully to prevent undue tension and preserve medial canthal anatomy. Layered closure with 6-0 absorbable sutures ensured precise approximation. Postoperative outcomes were assessed for flap viability, lid position, tear function, scar aesthetics, and recurrence.

Results: All three cases showed complete flap survival without necrosis or wound breakdown. Cosmetic results were graded highly satisfactory by both surgeon and patient, with good color and texture match. Functional outcomes were preserved, with no cases of lagophthalmos, canthal distortion, or epiphora. No tumor recurrence was observed over a six-month follow-up period.

Conclusions: The rhomboid flap provides an aesthetically pleasing and geometrically sound reconstructive option for medial canthal defects. It offers excellent cosmesis and functional restoration, particularly when designed and executed with attention to aesthetic subunit boundaries and tension-free closure.

Hodgkin Disease Presenting With Bilateral Ptosis

First Author: Anna Sofia SERRANO

Co-Author(s): Felice Katrina RANCHE

Purpose: To describe an orbital lymphoma with a rare type and unusual presentation

Methods: Case report

Results: A 79-year-old male presented with gradually progressive bilateral blepharoptosis, worse on the left. After five years, a mass was palpated under the left superior orbital rim. On examination, there was resistance to retropulsion of both globes, and left proptosis with limited upgaze. CT scan showed bilateral homogeneous masses extending posteriorly from the lacrimal gland, with moulding around the globes. Bilateral tumor debulking was performed. The specimens showed atypical round cell proliferation. PAX5 and CD30 were positive, indicating B-cell lineage, with a final histopathologic diagnosis of Classic Hodgkin Lymphoma. PET CT revealed hypermetabolic nodules in the pancreas and lung. The patient underwent 4 cycles of chemotherapy (AVD regimen). Repeat PET CT will be done after six months. He is on regular follow up, with a marked reduction in proptosis and ptosis, and no signs of recurrence.

Conclusions: An adult Filipino male presenting with bilateral ptosis and orbital masses was diagnosed with Hodgkin lymphoma. Moulding of a mass around the globe on imaging indicates lymphoproliferative disease and warrants biopsy and immunohistochemistry to determine clonality and classification. PET CT is the imaging modality of choice to determine the extent of the disease. In Hodgkin lymphoma, orbital involvement is stage IV disease, and is treated with chemotherapy. In contrast, for non-Hodgkin lymphoma, orbital involvement is considered localized disease, and is treated with radiotherapy.

Increased Pupil Constriction Latency in Immunoglobulin G4-Related Ophthalmic Disease

First Author: Yiu Man **WONG**

Co-Author(s): Kar Mun Carmen **CHAN**, Chi On Andy **CHENG**, Kar Yee Joyce **CHIN**, Kam Lung Kelvin **CHONG**, Zhichao **HU**, Kin Ting Andrew **KUK**, Chi Ho **KWONG**, Ka Hei Kenneth **LAI**, Pui Fan Wendy **LAM**, Polin **LEOW**, Pok Yiu Angus **LEUNG**, Kai Wang Kenneth **LI**, Kai Chun Jeffrey **MAK**, Chi Pui Calvin **PANG**, Chenhui **TANG**, Chee Yung Clement **THAM**, Ngai Simon **YANG**, Yifei **YANG**, Kwok Foo Nelson **YIP**, Alvin Lerrmann **YOUNG**, Kwok Lai Hunter **YUEN**

Purpose: To examine the pupillary light reflex (PLR) in Immunoglobulin G4-related ophthalmic disease (IgG4-ROD) patients in comparison to healthy controls.

Methods: This study included 25 biopsy-proven IgG4-related ophthalmic disease patients without a history of optic neuropathy (aged 60.6±11.4 years, 15 males), and 50 age-, sex-, and smoking-matched healthy subjects (aged 59.7±10.1 years, 30 males). The PLR was assessed using the virtual reality head mount display. 27 pupillometry light reflex features were

extracted and analyzed. Independent paired t-test, multinomial logistic regression and backward stepwise variable selection were used to find significant group differentiating features. The performance of machine learning algorithms on group classification based on these features were also evaluated.

Results: The pupillometry results between the two groups were analyzed. The pupil constriction latency is significantly longer in IgG4-ROD eyes (0.3 ms versus 0.2 ms, P<0.05) at the third stimulus (LAT3rd). Other PLR features were comparable between the two groups. LAT3rd was also found to be significant in group classification by multinomial logistic regression (P<0.05) and backward stepwise variable selection. Machine learning on all features data showed good performance for some models (Random Forest, 0.875/0.900 for Accuracy/AUC). With LAT3rd only and bootstrapped data, more models showed good performance, including K-nearest Neighbors (0.885/0.885) and Decision Tree (0.840/0.840).

Conclusions: An increased constriction latency can result from both the afferent and efferent pathways of the pupil light reflex. The application of a virtual reality head mount display may be a useful non-invasive tool for early detection of IgG4-ROD.

Abstract No.: 208280

Panel No.: OOP-0811

Inferior Rectus Myositis After Orbital Fracture Repair With a Medpor Implant in a 38-Year-Old Male: A Case Report

First Author: Ting Hei **TSANG**

Co-Author(s): Fatema **ALJUFAIRI**, Kelvin **CHONG**, Kenneth **LAI**, Jake **SEBASTIAN**

Purpose: We report a rare case of Medpor® Orbital implant-related inferior rectus (IR) myositis post-orbital fracture repair.

Methods: A 38-year-old gentleman underwent an uneventful orbital floor fracture repair done elsewhere, using a Medpor® implant, one day after sustaining a blunt force facial trauma. The patient presented to our center, three weeks post-operatively, complaining of diplopia and marked dull ache around the region of the left orbit, with left hypotropia and intractable primary and up-gaze diplopia and extraocular muscle restriction of (-3) up gaze and (-2) downgaze on the left eye. A multi-parametric, dynamic orbital MRI showed focal IR myositis and entrapment due to incomplete defect coverage with restricted elevation on the T2 cine sequence.

Results: The symptoms were gradually relieved after a revision surgery for the left orbital floor fracture using a biplanar, trans-orbital, and trans-antral approach with release of entrapped soft tissues, removal of the orbital Medpor® implant, and replacement with an autologous dermis fat graft. Complete coverage of the

fracture site and absence of any entrapped soft tissues were ascertained by direct visualization using the trans-antral view.

Conclusions: Medpor myositis is a rare complication associated with the use of the Medpor® orbital implant. Direct trans-antral visualization allows for a pressure-less, precise identification of the extent of the fracture and any soft-tissue entrapment after implant insertion without retracting the orbit. In view of myositis resulting from a possible negative reaction to a foreign material, an autologous dermis fat graft can be a suitable alternative material used for repair and to augment orbital volume.

Intra-Lesional Bleomycin for the Treatment of Orbital and Peri-Orbital Vascular Malformations

First Author: Muhammad MOIN

Co-Author(s): Mehreen AKRAM, Sadia IMTIAZ

Purpose: To evaluate the safety and efficacy of intralesional Bleomycin in the management of orbital and peri-orbital vascular malformations.

Methods: This quasi-experimental study was conducted at the Institute of Ophthalmology, Eye Unit-III, Mayo Hospital, Lahore, over 12 months (Dec 2023–Nov 2024). Fifteen patients (ages 10–40 years; radiologically confirmed orbital/peri-orbital vascular malformations) were enrolled. Exclusion criteria included prior steroid/surgical treatment, isolated intraconal malformations, and a history of lung disease. Preoperative assessment included baselines, viral markers, orbital B-scan, CT/MRI/CTA/MRA. After informed consent, intralesional Bleomycin (0.5 mg/kg, max 10 IU/session) was administered with local anesthetic, following aspiration of intralesional fluid. Patients were monitored in emergency care settings and followed at 1 week, 1 month, and 3 months.

Results: The cohort included 10 males (67%) and 5 females (33%). Lesion types were lymphangioma (n=5, 33%), varices (n=5, 33%), capillary hemangioma (n=3, 20%), and arteriovenous malformation (n=2, 13%). Mean injections per patient were 1.5 ± 0.52 . Preoperative mean lesion size was $2.5 \times 3.0 \text{ cm} \pm 1.23$, reducing to $0.5 \times 0.6 \text{ cm} \pm 0.75$ at 1 month ($p=0.012$). Complications occurred in only 4 patients (26.6%): eyelid swelling (2 hemangioma), sore throat (1 lymphangioma), and hematoma (1 varix). No life-threatening events occurred.

Conclusions: Intralesional Bleomycin is less traumatic, inexpensive, and relatively easy to administer. This study recommends it as a first-line treatment option for peri-orbital vascular malformations due to its efficacy and favorable safety profile.

Investigation of Improvement of Eye Movement After Orbital Fracture Surgery

First Author: Shohei SUETAKE

Co-Author(s): Tomoyuki KASHIMA, Ryo KIKUCHI, Marina OGAWA

Purpose: The effectiveness of orbital fracture repair in primary versus revision cases remains debated. This study assessed ocular motility before and after surgery using the Hess Chart and the binocular single vision test.

Methods: Patients who underwent orbital fracture repair at the Oculofacial Clinic Tokyo between January 2022 and December 2023 were reviewed. They were classified into Group A (primary surgery) and Group B (revision after surgery elsewhere). Forty-five patients (mean age 38.6 ± 14.2 years) were included. Ocular motility disturbance was evaluated using the Hess Area Ratio (HAR%) and Fusion Image Area (FIA). Since all Group B patients had old fractures, Group A was subdivided into fresh and old cases for additional comparison.

Results: Forty-eight patients (32 in Group A, 16 in Group B; male: female = 31:17) were analyzed. Group A showed significant improvement in HAR% and FIA at 3 months ($p < 0.05$). Group B showed no significant change ($p > 0.05$). Outcomes in Group B were significantly poorer than in Group A ($p < 0.05$). Among old fractures, improvement was limited in both groups, but Group B consistently showed worse results pre- and postoperatively ($p < 0.05$).

Conclusions: Primary orbital fracture repair improves ocular motility, while revision cases show limited benefit. Proper initial management is critical for a favorable recovery.

Isolated Bilateral Orbital and Unilateral Conjunctival Amyloidosis: A Rare Case

First Author: Alene, Ker Hsin NG

Co-Author(s): Pimkwan JARU-AMPORN PAN, Kanograt PORN PANICH

Purpose: To report a rare presentation of isolated bilateral orbital amyloidosis with concurrent right conjunctival amyloidosis.

Methods: A 59-year-old Thai woman with diabetes mellitus and hypertension presented with an 8-month history of progressive right upper lid swelling, conjunctival growth and redness. Visual acuity was 6/30 in the right eye with no pinhole improvement, and 6/15 (pinhole 6/12) in the left eye. Examination revealed a right upper lid mass, associated with skin hyperpigmentation, mechanical ptosis, and restricted

ocular motility. A diffuse yellow-pink conjunctival mass with intrinsic vascularization was observed in the right eye, along with bilateral proptosis. Imaging demonstrated bilateral extraocular muscle and optic nerve involvement, with infiltration of the right lacrimal gland. Histopathology confirmed amyloid deposition of the conjunctiva, while further investigations excluded systemic involvement. The patient was treated with intravenous corticosteroids, followed by radiotherapy.

Results: Clinical response was favourable, with marked reduction in swelling, proptosis, and lesion size. The patient is scheduled for surgical excision of the lid mass. Literature review revealed that simultaneous bilateral orbital and conjunctival amyloidosis with muscle, optic nerve, and lacrimal gland involvement is exceedingly rare.

Conclusions: Isolated bilateral orbital amyloidosis with conjunctival involvement, in the absence of systemic disease, is an uncommon and challenging condition. This case emphasizes the importance of histopathological confirmation, systemic evaluation, and a multidisciplinary approach. The favourable response to radiotherapy suggests its potential as a therapeutic option, although long-term outcomes remain uncertain, necessitating close follow-up.

Lacrimal Gland Adenoid Cystic Carcinoma: A Case Report

First Author: Lexus Neil CAHIMAT

Co-Author(s): Maria Donna SANTIAGO

Purpose: To describe the clinical features and outcome of a 37-year-old female with adenoid cystic carcinoma (ACC) of the right lacrimal gland who underwent lateral orbitotomy with beveled osteotomies, en bloc excision of the lesion, and adjuvant radiotherapy.

Methods: This is a case report.

Results: This report details a 37-year-old Filipino female with lacrimal gland ACC, with a 4-month history of eye pain with associated proptosis. Plain orbital computed tomography scan (CT) revealed a right orbital mass. Right lateral orbitotomy with beveled osteotomies and en bloc excision of the tumor under general anesthesia was done. Frozen section revealed a malignant tumor, favoring ACC. The lateral orbital bone was not repositioned for adjuvant radiotherapy. Final histopathologic diagnosis of ACC of the right lacrimal gland was made based on the histologic features consistent with said pathology. Systemic surveillance with cranial MRI and chest CT, both with contrast, showed absence of regional and distant metastases. Patient completed adjuvant radiotherapy as part of her comprehensive treatment plan. Five months post-

operatively, vision remained excellent at 20/20 without signs of tumor recurrence.

Conclusions: ACC is the most common malignant epithelial tumor of the lacrimal gland, but it accounts for less than 2% of tumors arising in the head and neck area. It is an aggressive malignancy; hence, meticulous examination to arrive at a diagnosis cannot be overemphasized. Advances in orbital imaging correlated with clinical findings, surgical judgment, and skill should allow us to define the most efficient management. Eye-sparing surgery could significantly preserve quality of life.

Lateral Eyelid Block Technique for Ectropion Correction: Surgical Steps and Results From a Case Series

First Author: Adinda Mulya PERTIWI

Co-Author(s): Hisar DANIEL, Diannisa Paramitha SUSANTONO

Purpose: To highlight the effectiveness of the lateral eyelid block as an updated technique for ectropion correction. Explaining its surgical steps and demonstrating favourable outcomes in a case series.

Methods: This case series included three patients with horizontal eyelid laxity. Significant laxity was defined by an abnormal snap-back test in conjunction with lower eyelid malposition. Three patients, comprising two with involutional ectropion and one with paralytic ectropion, all of whom underwent correction using the same lateral eyelid block technique. The surgical technique was performed as follows. Following subconjunctival infiltration of lidocaine compositum, an inferior lateral canthal incision was performed. After determining the amount of tissue to be excised, a block resection was conducted. The lateral inferior tarsus was then sutured with 5-0 vicryl to the lateral canthal ligament and to the inferior aspect of the superior tarsus to achieve adequate eyelid support. Lastly, skin closure was completed with interrupted 6-0 prolene sutures.

Results: Surgical outcomes showed satisfactory postoperative apposition and alignment with minimal scarring. Postoperative follow-up demonstrated resolution of ocular surface exposure, improved eyelid position, and restoration of functional lid closure. No wound dehiscence or infection were found. At the final follow-up, all patients maintained stable eyelid position without recurrence of ectropion.

Conclusions: The lateral eyelid block technique provides a reliable and effective approach for correcting both involutional and paralytic ectropion, offering stable eyelid apposition, satisfactory functional outcomes, and minimal complications.

Abstract No.: 206304**Panel No.: OOP-0788****Management and Outcomes of Traumatic Globe Luxation and Dislocation — a Case Series***First Author: Kirthi KOKA**Co-Author(s): Md Shahid ALAM, Varsha BACKIAVATHY, Bipasha MUKHERJEE***Purpose:** To report a case series of traumatic globe luxation and dislocation, and their management outcomes.**Methods:** A retrospective analysis of all patients with traumatic globe luxations over 15 years, from January 2009 to January 2024, was conducted. The analyzed data included demographic profile, nature of trauma, imaging characteristics, management, and outcomes.**Results:** Fifteen patients were included in this study. The mean age of the population was 28.6 ± 15.8 years (range 8-62 years) with a male predominance ($n=13$, 86.66%). Fourteen patients (93.33%) presented with no perception of light. The most common etiology was road traffic accidents ($n=7$, 46.66%). The globe was anteriorly luxated in thirteen patients and inferiorly into the maxillary sinus in two. Optic nerve avulsion was noted in nine patients. Globe repositioning, along with tarsorrhaphy, was done for nine patients, whereas enucleation was performed for four. Two patients underwent repair of the fractured floor with repositioning of the luxated globe from the maxillary sinus. At an average follow-up of 20 ± 26 months (range 1-96 months), good cosmesis was achieved in ten patients (66.66%), and an improvement in vision was seen in two patients (13.33%).**Conclusions:** Traumatic globe luxation is a rare and challenging ophthalmic emergency resulting from blunt or penetrating injuries. It is usually associated with profound visual loss. Early recognition and prompt management result in improved cosmesis and the possibility of visual recovery.**Abstract No.: 201729****Panel No.: OOP-0759****Medial Vertical Lid Split Posterior Orbitotomy: A Case Report From Limited Resource Setting***First Author: Suresh RASAILY***Purpose:** To present a case utilizing a medial vertical lid split posterior orbitotomy approach for intraconal tumor excision in a limited resource setting.**Methods:** A single case of a patient with a posterior intraconal mass was managed using the medial vertical lid split approach. Clinical presentation, imaging, surgical technique, and postoperative outcomes were documented. Emphasis was placed on adaptations made due to resource constraints.**Results:** The approach allowed adequate exposure for complete excision of the mass with preservation of visual function and sparing deep lateral orbitotomy. No intraoperative or major postoperative complications were noticed. Despite limited resources, the procedure was safely performed with favorable cosmetic and functional outcomes.**Conclusions:** Medial vertical lid split posterior orbitotomy is a viable and effective technique for deep intraconal vascular tumors even in resource-limited settings. With careful planning and anatomical knowledge, it can offer good outcomes without the need for advanced equipment.**Abstract No.: 204107****Panel No.: OOP-0771****Not-So-Lovely Erosion and Infection of Love Band Implant***First Author: Kristy Hiu Ching YIM**Co-Author(s): Matthew Chun Wah LAM, Hunter Kwok Lai YUEN***Purpose:** Surgical augmentation of the love band, commonly referred to as "aegyo sal" in Korean, is gaining popularity in East Asian culture for its perceived youthfulness. We hereby present a case of delayed implant erosion and infection.**Methods:** Case notes were reviewed, followed by a comprehensive review of the literature on pretarsal augmentation blepharoplasty.**Results:** A 29-year-old Chinese woman presented with progressive left lower eyelid swelling and discharge for 2 years. She had undergone bilateral lower lid pretarsal augmentation by surgical implantation twice elsewhere a decade ago. Examination showed bilateral palpable lower lid hard implants, with pretarsal swelling of the left lower eyelid. Slit lamp examination revealed granulation tissues over the left lower lid palpebral conjunctiva with mucoid discharges, but no obvious implant protrusion. Her condition was unresponsive to topical and oral antibiotics. Lower lid exploration under general anaesthesia revealed an eroded conjunctival wound; 10 strips of plastic implants were removed. Microbiological culture yielded *Streptococcus pneumoniae*. Temporary (hyaluronic acid injection) and permanent methods (autogenous grafts and implants) have been reported for enhancing lower eyelid pretarsal fullness. Expanded polytetrafluoroethylene (ePTFE; i.e. Gore-tex), is a common synesthetic implant of choice for such procedures. Review of literature revealed one reported case of early infection 2 months after implantation of Gore-tex. Delayed erosion and infection, as demonstrated by our case, were not previously reported.**Conclusions:** Synthetic implant augmentation of lower eyelid pretarsal fullness can be complicated with

delayed implant erosion and infection many years after the initial procedure.

Novel Application of Biodegradable Temporising Matrix (BTM) in Exenteration of Sebaceous Gland Carcinoma (SGC)

First Author: Ryan LEE

Co-Author(s): Karen Kar-wun CHAN, Kelvin Kam Lung CHONG, Alvin Lerrmann YOUNG

Purpose: Biodegradable Temporising Matrix (BTM) is a synthetic polyurethane dermal matrix designed for complex wound reconstruction by facilitating vascularized neo-dermis formation, and is commonly used in wound reconstructions in limbs and trunk.

Methods: BTM was applied in a case of extensive sebaceous gland carcinoma (SGC) requiring orbital exenteration.

Results: A 64-year-old male presented with a 5-month history of right-eye foreign body sensation. Clinical examination revealed a 10mm x 24mm infiltrative mass involving the bulbar and palpebral conjunctiva of the right lower lid. Conjunctival incisional biopsy confirmed SGC. Due to the extensive involvement of his ocular surface limiting R0 resection margin, the patient underwent a right anterior exenteration. Contrary to reconstruction with a flap, which masks observation for tumour recurrence, and primary split-skin graft, which risks fistula formation and delayed granulation, BTM was lined over the socket for staged reconstruction. Despite the 3-dimensional configuration of the orbit, good matrix adhesion was achieved, and the socket appeared well-vascularized 1 month after surgery. A staged split-skin graft was performed, with satisfactory graft adherence without fistula, erosions, or flap necrosis. Adjuvant radiotherapy was performed due to high tumor grading (AJCC 8th edition T3bN0M0), and the socket appeared healthy at the latest follow-up, 4 months after surgery.

Conclusions: This case demonstrates the effectiveness of BTM in assisting recovery following exenteration, highlighting its novel utilization in the bony socket to avoid surgical complications in orbital exenteration reconstruction.

Ocular Dominance in Aponeurotic Ptosis: A Pilot Study

First Author: Akruti DESAI

Co-Author(s): Komal BAKAL, Jenil SHETH

Purpose: Ocular dominance, the preferential use of one eye, can influence binocular vision and adaptation to eyelid pathology. In aponeurotic ptosis, upper eyelid

drooping may obstruct the dominant eye's visual axis, potentially triggering compensatory mechanisms such as chin-up posture or frontalis muscle overaction. This pilot study investigated ocular dominance patterns in aponeurotic ptosis and changes following surgical correction.

Methods: Twenty patients (8 women, 12 men) with aponeurotic ptosis were prospectively evaluated. Laterality included 8 right-eye, 4 left-eye, and 8 bilateral cases. Dominance was assessed using Scobee's test and the hole-in-the-card test. Severity of ptosis was graded using marginal reflex distance 1 (MRD1). Patients with strabismus or poor vision were excluded from dominance interpretation. Ten patients underwent ptosis surgery and were re-evaluated postoperatively.

Results: Dominance could not be determined in 2 patients due to unstable fixation or very poor vision. Among the remaining 18, left-eye dominance was found in 14 (77.8%), and right-eye dominance in 4 (22.2%). One patient retained dominance in the severely ptotic eye (MRD1 = 0) via frontalis overaction, indicating a compensatory mechanism. Of the 10 surgical cases, one patient showed a shift in ocular dominance postoperatively.

Conclusions: Left-eye dominance was more frequent in this aponeurotic ptosis cohort. Surgical correction led to a dominance shift in one patient, highlighting the dynamic nature of ocular dominance in relation to eyelid position. Recognition of ocular dominance and compensatory strategies may help explain variability in functional outcomes after ptosis surgery.

Panel No.: OOP-0774

Periorbital and Subconjunctival Ocular Dirofilaria by Dirofilaria Hongkongensis – Clinical and Radiological Presentations and the Treatment Outcomes in a Case Series of 7 Patients

First Author: Chun Wah Alex WONG

Co-Author(s): Chi On Andy CHENG, Cheuk Yin Brian WONG

Purpose: A retrospective case series to identify the different clinical presentations of this rare ocular parasitic infection: to increase the awareness of ophthalmologists for early diagnosis, and to identify the risk factors. The surgical method of removing a live «worm» intact from the subconjunctival space in 2 cases, and the final treatment outcomes were discussed.

Methods: Seven cases of ocular dirofilaria were identified from Aug 2017 to Aug 2025 in our retrospective case study. The clinical presentations, radiological findings, blood tests, diagnostic methods, surgical records, and treatment outcomes were reviewed.

Results: Two patients presented with acute conjunctivitis and chemosis with a live «worm» seen under the subconjunctival space under the slit lamp, 4 presented with painless progressive periorbital mass, and 1 presented as a red subconjunctival nodule. CT/MRI scans were done in 4 cases before operations but no worms were identified in the report. Two mobile dirofilaria were successfully paralysed and surgically removed using topical 0.5% proparacaine. Complete surgical excision of the periorbital mass cases identified the dead “worm” inside the mass. PCR was used to make the final diagnosis of *Dirofilaria hongkongensis*. Only one patient took Stromectol and Vibramycin after surgery. All 7 patients had no recurrence.

Conclusions: It is the largest case series of ocular dirofilariasis by *D. hongkongensis*. There are two presentation forms: an acute inflammatory form with acute conjunctivitis and chemosis with a living “worm” found in the subconjunctival space and an indolent form presenting with a painless progressive periorbital mass. Complete surgical removal is usually sufficient to offer a cure to ocular dirofilariasis.

Abstract No.: 206568

Postoperative Results of Triple-Loop Everting Suture With Lower Eyelid Retractor Plication for Involutional Lower Eyelid Entropion

First Author: Miho TAKENAKA

Co-Author(s): Shuichiro AOKI, Ryo KIKUCHI, Koichiro SUGIMOTO

Purpose: The purpose of this study was to evaluate the surgical outcomes of Triple-Loop Everting Suture with Lower Eyelid Retractor Plication, a new procedure designed to correct both vertical and horizontal laxity in involutional lower eyelid entropion.

Methods: This retrospective study analyzed patients with involutional lower eyelid entropion who underwent Triple-Loop Everting Suture with Lower Eyelid Retractor Plication at Kameda Medical Center between September 15, 2021, and April 1, 2025. Only patients with a postoperative follow-up period of at least three months were included. Recurrence was defined as eyelashes touching the cornea with associated corneal epithelial damage. Recurrence rate, time to recurrence, and postoperative complications were investigated.

Results: Fifty-seven patients and sixty-nine eyelids met the inclusion criteria. The mean age was 76.7 ± 7.3 years, and the mean postoperative observation period was 12.5 ± 12.5 months. During the follow-up period, recurrence occurred in two eyelids, corresponding to a recurrence rate of 2.9%. No significant postoperative complications, including infection or granuloma formation, were observed.

Conclusions: Triple-Loop Everting Suture with Lower Eyelid Retractor Plication simultaneously corrects vertical and horizontal eyelid laxity and achieves a low recurrence rate. This minimally invasive procedure may provide more durable correction of involutional lower eyelid entropion than previously reported everting suture techniques.

Potential Complications of Using Dermal Filler in Upper Lid Retraction in TED – Two Case Reports

First Author: Pricila Tien Yan WANG

Co-Author(s): Andre MA, Hunter Kwok-lai YUEN

Purpose: Upper eyelid retraction is the most common sign in Thyroid Eye Disease (TED). It not only causes functional problems such as exposure keratopathy, but also contributes significantly to the aesthetic concerns of patients. With recent advancements, minimally invasive procedures such as injection of hyaluronic acid (HA) have become more and more popular. Local injection-related side effects, including edema, are most commonly seen. A lot of retrospective studies and case reports have demonstrated the effectiveness of hyaluronidase on the management of dermal filler-related swelling in aesthetic practice; however, there is no report on hyaluronidase use specifically for upper lid retraction filler-related swelling. Herein, we report one case of upper eyelid lump and one case of persistent upper eyelid edema following HA filler injection; both cases were successfully treated with hyaluronidase, and we also conduct a literature review on the potential complications of using dermal fillers for upper lid retraction.

Methods: Case reports.

Results: N/A

Conclusions: N/A

Precise Repair of Multiple Orbital Fractures

First Author: Wei LU

Purpose: Zygomatic-orbito-maxillary fracture is a kind of complex orbital fracture with high morbidity, which can lead to severe physical dysfunction and deformity. The orbital mechanical environment has a great influence on fracture repair and reconstruction. If the internal fixation is not consistent with the mechanical environment after the reconstruction, it is easy to lead to complications such as poor fracture healing, implant deformation, malposition, and even breakage, which not only bring trouble to patients but also increase financial burden.

Methods: This study developed finite element models of absorbable material and titanium material for repair and fixation, respectively. By applying a force of 120 N to the model to simulate the masseter muscle strength, the maximum stress and displacement of the repair materials and the fracture ends were measured.

Results: The maximum stress values of absorbable and titanium materials are less than their yield strength, and the maximum displacement values of the titanium material and fracture end were less than 0.1 mm and 0.2 mm. The maximum displacement values of absorbable material and fracture end in incomplete zygomatic fracture and dislocation were less than 0.1 mm and 0.2 mm. While in the zygomatic complex, complete fractures and dislocations, the maximum displacement values of the absorbable material and the fracture end exceeded 0.1 mm and 0.2 mm.

Conclusions: In this study, the finite element biomechanical analysis method improved the operative success ratio of zygomatic-orbito-maxillary fracture and reduced postoperative complications, which provided a new research method and objective quantitative basis for the accurate treatment.

Panel No.: OOP-0795

Prevalence of Anxiety, Depression, and Poor Sleep Quality in Thyroid Eye Disease Patients and Their Impact on Quality of Life

First Author: Eric Ka Ho **CHOY**

Co-Author(s): Kelvin Kam Lung **CHONG**, Kenneth Ka Hei **LAI**

Purpose: To report the prevalence of anxiety, depression, and poor sleep quality in thyroid eye disease (TED) patients, identify predictors, and evaluate their impact on quality of life (QoL) and psychometric properties of questionnaires.

Methods: A cross-sectional study. TED patients were interviewed face-to-face with the Chinese version of Generalized Anxiety Disorder-7 (GAD-7) scale, Patient Health Questionnaire (PHQ-9), Pittsburgh Sleep Quality Index (PSQI), and Graves' Ophthalmopathy Quality of Life (GO-QoL) questionnaire. Rasch analysis was performed to evaluate the psychometric properties of questionnaires using WINSTEPS. Correlations with sociodemographic and clinical data were analysed using SPSS version 29.0.

Results: Sixty-eight patients were interviewed by the same researcher, with a mean age 53.0 ± 2.0 , 44 were female. All questionnaire subscales demonstrated satisfactory psychometric properties. The prevalence of moderate-to-severe anxiety and depression was 27.9% and 30.9% respectively. Self-harm or suicidal ideation was reported in 8% patients. The prevalence of poor sleep quality was 82.4%. Mean scores of GO-QoL total, visual functioning, and appearance subscales

were 61.6 ± 3.3 , 59.2 ± 3.7 and 63.4 ± 3.7 respectively. Younger patients had worse anxiety and depression (all $P < 0.02$, $r = 0.27$, 0.28). Patients with unemployment and higher NOSPECS scores had higher PHQ-9 scores ($P < 0.05$). The patient with conjunctival injection had worse depression and poorer sleep ($P < 0.03$). Worse visual acuity (VA), extraocular muscle (EOM) restriction, and presence of conjunctival injection correlated with poorer sleep quality ($P < 0.05$, $\rho = 0.24$, 0.28). No clinical predictors were identified for the GAD-7 scale. Higher NOSPECS but not clinical activity score correlated with GO-QoL scores (all $P < 0.03$). All GO-QoL scores correlated moderately well with GAD-7, PHQ-9, and PSQI scores (all $P < 0.01$, $\rho > 0.4$). Anxiety and depression correlated better with the GO-QoL appearance than the visual functioning subscale ($\rho = -0.60$ vs $\rho = -0.35$).

Conclusions: GAD-7, PHQ-9, and PSQI can be used in TED patients for screening purposes. Anxiety, depression, and poor sleep were common among TED patients and impaired disease-specific QoL. Young age, unemployment, more severe TED, worse VA, EOM restriction, and presence of conjunctival injection were associated with anxiety, depression, and/or poor sleep. Disfigurement might cause more anxiety and depression than visual dysfunction in TED patients.

Quantification of Clinico-radio-histopathological Correlation for Accurate Diagnosis of Orbital Tumors

First Author: Rolika **BANSAL**

Co-Author(s): Santosh **HONAVAR**, Kaustubh **MULAY**, Ravi **VARMA**

Purpose: Orbital masses present with a diverse spectrum ranging from benign to malignant, with ambiguous clinical manifestations, confounding imaging, and overlapping histopathological characteristics. Therefore, we quantified the clinico-radio-histopathological correlation for the diagnosis of orbital tumors.

Methods: Retrospective, consecutive case series of 100 orbital masses assessed clinically, imaged pre-operatively, and managed surgically with histopathological confirmation.

Results: Mean age was 39.7 ± 14.2 (range 8 to 77) years, ranging from benign (72%) to malignant (28%), primarily vasculogenic (27%); lacrimal gland tumors (26%); inflammatory lesions (11%), etc. Based on location (extraconal vs intraconal vs diffuse), accuracy was higher with clinico-radiological correlation (78.9%, 80.0%, 78.4%) than isolated clinical (75.8%, 76.7%, 72.9%) or radiological diagnosis (63.6%, 66.7%, 51.4%). Based on the nature of disease (benign vs malignant), overall accuracy was higher by clinico-radiological correlation (78.9%, 79.2%) than isolated clinical (76.3%, 70.8%) or radiological diagnosis (61.8%, 54.2%) and for

malignant tumors clinical diagnosis than radiological diagnosis had higher sensitivity (83.3% vs 66.7%) and specificity (92.1% vs 84.2%) ($p < 0.05$). However, a combination of clinico-radiologico-histopathological correlation, especially for intraconal and diffuse lesions, showed 100% accuracy ($p < 0.05$). Oncology has no room for diagnostic errors.

Conclusions: Management of orbital mass lesions can be complex. It is crucial to strike a balance between relying on clinical expertise and utilizing imaging studies to arrive at a pre-operative diagnosis to help triage the management protocol. By combining thorough clinical evaluation with judicious use of imaging, clinicians can make more accurate diagnoses and develop effective treatment plans. As ocular oncology has no room for diagnostic error, a crucial balance between clinic-radio-histopathological diagnosis is mandatory for accurate diagnosis and treatment planning.

Rebuilding the Ravaged Eyelid: A Tale of Mucosa, Cartilage, and Flap Against Extensive Defect Following Basal Cell Carcinoma Wide Excision

*First Author: Prika Maulina **AGARISTI***
*Co-Author(s): Neni **ANGGRAINI**, Yunia **IRAWATI**, Cecillia Apriliana **WULANDARI***

Purpose: Reconstructive surgical planning is influenced by the characteristics of the defect, including its size and depth, the patient's age, surrounding tissues, and the surgeon's preference and experience. Selecting the optimal repair method presents a significant challenge. We present a case of full-thickness eyelid reconstruction using a combination technique following wide excision of the tumor.

Methods: An 86-year-old female presented with a nodular, irregular, pigmented mass occupying the entire inferior tarsal plate, with ulceration and madarosis. A wide excision with a 5-mm free margin of the lower eyelid was performed, resulting in a total full-thickness lower eyelid defect measuring 12 mm vertically, extending to the lateral canthus and one-third of the lateral upper eyelid. Reconstruction consisted of a lip mucosal graft for conjunctival lining, an auricular cartilage graft for posterior lamellar support, and a modified Fricke's cheek flap for anterior lamellar coverage. Frozen section confirmed an infiltrative type of basal cell carcinoma.

Results: The combination technique successfully restored both eyelid structure and function while preserving ocular surface integrity. The lip mucosal graft provided an adequate conjunctival substitute, while auricular cartilage maintained structural support without significant donor site morbidity. The flap offered an excellent match in color and texture with minimal scarring. Postoperatively, the patient

achieved satisfactory eyelid closure, preserved corneal protection, and an optimal cosmetic outcome.

Conclusions: Complex eyelid defects following tumor excision can be effectively managed with free grafts and local flaps. The integration of vascularized anterior lamellar flap with free posterior lamellar grafts ensures both functional and aesthetic benefits, presenting a reliable approach for challenging eyelid reconstructions.

Restoring Form and Function: Full Thickness Skin Graft in Eyelid Reconstruction

*First Author: Sofia **IQBAL***
*Co-Author(s): Aleena **KHAN**, Bakht Danyal **KHAN***

Purpose: Acknowledging the functional and cosmetic outcomes of full thickness skin grafts (FTSG) in eyelid reconstruction among patients with eyelid morbidity resulting from trauma, burns, or previous surgeries

Methods: This poster presents a case series of four patients undergoing FTSG for upper or lower eyelid reconstruction between 2023 and 2025 at a tertiary burn and reconstructive center. Each patient had distinct etiologies: a 28-year-old male with upper eyelid cicatricial ectropion and lid defect following previous trauma and cosmetic concerns; a 14-year-old male with post-traumatic lower lid cicatricial ectropion secondary to a dog bite; a young female survivor of extensive burns with bilateral lower lid ectropion and exposure keratopathy; and a patient with bilateral eyelid ectropion due to contractures. FTSG was harvested from the supraclavicular or postauricular region and applied to respected defects. Outcomes were assessed based on graft survival, eyelid position, exposure symptoms, and cosmetic satisfaction over 3–6 months of follow-up.

Results: All the grafts fulfilled their intended purposes. Lid position improved significantly in all cases, with resolution of lagophthalmos and exposure symptoms in the burn and trauma-related ectropion cases. Cosmetic outcomes were graded as satisfactory by both patients and independent reviewers. No major complications were observed.

Conclusions: Full thickness skin grafting is a reliable and effective technique in the reconstruction of cicatricial eyelid defects. It offers unparalleled functional rehabilitation and cosmetic restoration, particularly in complex post-traumatic and burn-related ectropion cases.

Restoring Function and Form: An Eye-Sparing Strategy With Complex Eyelid and Periorbital Reconstruction After Wide Tumor Excision

*First Author: Cecillia Apriliana **WULANDARI***

*Co-Author(s): Prika Maulina **AGARISTI**, Neni **ANGGRAINI**, Yunia **IRAWATI***

Purpose: In eyelid carcinoma extending to the periorbital region where exenteration is refused, the goal is to achieve sufficient tumor clearance while preserving the eye. Reconstruction of extensive eyelid and periorbital defect after wide excision is highly challenging due to complex anatomy and functional-aesthetic demands. We present a case of full-thickness eyelid and periorbital reconstruction involving bone exposure and periosteal loss.

Methods: A 45-year-old woman with a 2-year history of a left medial canthal mass, recurring 8 months after excision at another hospital, refused exenteration. After two chemotherapy cycles, a wide excision was performed, leaving a large full-thickness defect of the upper and lower eyelids, involving 50% of the horizontal length with exposed bone. Reconstruction used a dermato-fat graft to fill the cavity. The posterior lamella was restored with tarso-conjunctival graft, lip mucosa, along with amnion membrane. A glabellar flap was fashioned to reconstruct the medial canthus and anterior lamella of both eyelids after orbicularis reposition, while a cheek V-flap closed the remaining lower eyelid defect. A symblepharon ring was placed to maintain fornices.

Results: Eye-sparing surgery provides an alternative to exenteration in selected eyelid carcinoma with orbital invasion, preserving the globe with oncologic clearance. Complex defects require composite reconstruction using grafts, flaps, and adjuncts to restore function and aesthetics. Careful follow-up is essential to detect recurrence, and adjuvant therapy should be considered to optimize outcomes.

Conclusions: Eye-sparing strategy can be considered in selected malignancy cases refusing exenteration. Despite reconstructive challenges, this approach is feasible and can achieve functional, aesthetic, and patient satisfaction outcomes.

Role of Tranexamic Acid and Triamcinolone Acetonide in Blepharoplasty

*First Author: Diwa **HAMAL***

*Co-Author(s): Roshani **AGRAWAL**, Pratikshya **AMATYA***

Purpose: Blepharoplasty is the surgery of the upper or lower eyelids that can be both therapeutic and aesthetic. The commonest complication of this surgery is bruising and oedema.

Methods: All patients planned for blepharoplasty were informed about the surgical procedure and possible complications. The patients were given oral 1gram of tranexamic acid before the surgery. Local anesthesia was added with 0.25ml, 10mg (40mg/ml) of triamcinolone acetonide, and was injected just 5 minutes before surgery at the surgery site. During the surgery, if there is minor bleeding, the site is dabbed with tranexamic acid mixed with Normal saline 20mg/ml. Postoperatively, patients were advised to take tranexamic acid 500mg three times daily for 2 more days, then stop. Patients contraindicated for triamcinolone acetonide, such as those with glaucoma, ocular hypertension, or allergic to triamcinolone acetonide, were not included in this study. Patient contraindicated for tranexamic acid as acquired defective color vision, Subarachnoid hemorrhage, and coagulopathy were not included in the study. The patient was followed on postoperative days 1, 7, and 30.

Results: All the patients showed satisfactory results. There was no bruising, oedema, or any other complications post-surgery. IOP was measured before surgery and on the first postoperative day, and after 1 week, none of the patients showed raised IOP.

Conclusions: Use of tranexamic acid preoperatively, intraoperatively, and postoperatively during blepharoplasty surgery gives very satisfying results. Use of triamcinolone acetonide mixed with local anesthesia reduces postoperative lid oedema.

Severe Conjunctival Papillomas as a Rare Presentation of Malignant Acanthosis Nigricans

*First Author: Warisara **PATTANAPONGPAIBOON***

*Co-Author(s): Mingkwan **LUMYONGSATIEN***

Purpose: To report a case of malignant acanthosis nigricans presenting with severe papillomatous lesions of the conjunctiva, eyelid margins, and associated paraneoplastic syndrome.

Methods: Case report.

Results: A 45-year-old Burmese woman presented with extensive, cauliflower-like, vascular core lesions affecting the eyelid margins, palpebral and bulbar conjunctiva in both eyes over a period of four months. She subsequently developed masses on the lips and anus, which progressively increased in size. She also reported abdominal discomfort, progressive dysphagia, and a weight loss of 10 kilograms over five months. On physical examination, her visual acuity was 20/40 in the right eye and 20/30 in the left eye. Multiple velvety, hyperpigmented skin lesions were observed on the posterior neck and tripe palms. Histopathological examination of conjunctival biopsy confirmed a

squamous papilloma. The lesions were managed with topical interferon alpha 2b, followed by surgical excision and interferon alpha 2b intralesional injection. Esophagogastroduodenoscopy revealed multiple papilloma-like exophytic lesions in the oropharynx and esophagus, with a rigid, diffusely thickened stomach wall containing multiple poorly demarcated erosions. Biopsy of gastric tissue showed poorly differentiated adenocarcinoma consistent with linitis plastica. The patient passed away two months after diagnosis.

Conclusions: Conjunctival papillomas are an extremely rare manifestation of malignant acanthosis nigricans, particularly in cases associated with malignancy. Rapidly enlarging conjunctival papillomas accompanied by systemic signs should prompt thorough and extensive systemic investigations to detect potential internal malignancies.

Simultaneous Versus Sequential Immunosuppressants in Progressive Thyroid Eye Disease: A Systematic Review

First Author: Venice Sze Wai LI

Co-Author(s): Kelvin Kam Lung CHONG, Kenneth Ka Hei LAI, Pak Kiu Michael LUI, Toby Siu Ki NG

Purpose: Intravenous methylprednisolone (IVMP) is considered first-line treatment for progressive Thyroid Eye Disease (TED), but optimal timing of adjuvant immunosuppressants remains controversial. This systematic review compares the efficacy and safety of simultaneous versus sequential adjuvant immunosuppressants with systemic steroids.
