CONTENTS

As part of the scientific program of the APAO 2026 Congress, this Abstract Book is compiled from accepted abstracts in the submitted program.

Acknowledgment of Reviewers 1

Part 1: English Abstracts 4

1.1	Instruction Courses	4
1.2	Free Papers	15
1.3	Posters	491
1.4	E-Posters	929
1.5	Videos	1447

Part 2: Simplified Chinese Abstracts 1523

2.1	Instruction Courses (专题发言)	1523
2.2	Free Papers (论文发言)	1524
2.3	Posters (壁报)	1704
2.4	E-Posters (电子壁报)	1825
2.5	Videos (视频)	1958

Part 3: Traditional Chinese Abstracts 1965

3.1	Free Papers (論文發言)	1965
3.2	Posters (壁報)	1967
3.3	E-Posters (電子壁報)	1968

Languages:

Abstracts are published in English, Simplified Chinese, or Traditional Chinese, according to the language submitted by the authors.

Disclaimers:

This abstract supplement has been produced using author-supplied copy. Editing has been kept to a minimum to preserve the originality of the authors' work, with corrections restricted to grammar and spelling only where essential for clarity, and style amended to comply with the AMA Manual of Style where appropriate.

No responsibility is assumed for any claims, instructions, methods, or drug dosages in the abstracts. It is recommended that these are verified independently. Commercial names of medical devices / software / equipment may appear because they are linked to specific medical procedures. However, other products in the market can be used to perform the medical procedures mentioned in the abstracts. The organizers of this Congress do not endorse any particular product.

Contents relating to program arrangements are correct at the time of publication and may be subject to change.

ACKNOWLEDGMENT OF REVIEWERS

All the abstracts published in this book have been evaluated and selected by the Abstract Reviewing Committee. We would like to thank all the reviewers for contributing their time and expertise to ensure the quality of the submitted program in the APAO 2026 Congress.

INSTRUCTION COURSES

Academia, Research, Teaching and Education in Ophthalmology

Abstract No.: 207075

Advancing Teaching Skills and Ophthalmic Education Around the World: The Ophthalmology Foundation Initiatives

Chief Instructor: Ana PALIS

Instructor(s): Helena FILIPE, Karl GOLNIK, Eduardo MAYORGA, Berthold SEITZ

Objective: To provide participants with a comprehensive understanding of the Ophthalmology Foundation's global initiatives in education and training. By presenting the objectives, structure, and experiences of programs such as international accreditation, fellowships, examinations, faculty development, and mentoring, the course aims to share best practices, highlight successful implementation across diverse regions, and inspire participants to participate in these programs to enhance their teaching skills and improve their training quality.

Synopsis: An overview of the different initiatives run by the Ophthalmology Foundation will be presented by leaders in each program (international accreditation, fellowships, exams, faculty development, mentoring, simulation, etc.), describing programs' purpose, content and experience with implementation around the world. The course will highlight the global impact of the Ophthalmology Foundation's initiatives, showing opportunities in international accreditation, fellowships, examinations, faculty development, mentoring, and simulation training for ophthalmic educators and ophthalmologists. Participants will find a variety of opportunities to improve training quality, enhance their teaching capacity, and strengthen professional networks, underscoring the Foundation's role in advancing education and capacity-building in diverse settings.

Course Outline: 1. The Ophthalmology Foundation: Mission in Ophthalmic Education Around the World (7 minutes) 2. Teaching Skills for Ophthalmic Educators Teaching Series (7 minutes) 3. Mentoring Programs (7 minutes) 4. Continuing Professional Development (7 minutes) 5. Leaders in Education (7 minutes) 6. Examinations for Ophthalmology (7 minutes) 7.

Accreditation for Residency Programs (7 minutes) 8. Fellowships (7 minutes) 9. Q&A (24 minutes)

Abstract No.: 202651

Fatty Acid and Bile Acid Metabolism in Retinal Health: From Mechanisms to Clinical Application

Chief Instructor: Guzel BIKBOVA

Objective: To provide ophthalmologists with an understanding of how systemic fatty acid and bile acid metabolism influences retinal health, inflammation, and disease progression, with emphasis on diabetic retinopathy and age-related macular degeneration (AMD).

Synopsis: Recent advances reveal that fatty acid bioavailability and integration into retinal membranes require bile acid-mediated absorption, lipoprotein transport, and receptor-regulated pathways (e.g., Mfsd2a, FXR, PPARs, TGR5). Short-chain fatty acids (SCFAs), produced by gut microbiota, exert complementary anti-inflammatory effects. Disruption of these metabolic pathways, through dysbiosis, impaired bile acid synthesis, or hyperglycemia-induced AGE accumulation, contributes to oxidative stress, vascular dysfunction, and retinal degeneration.

Course Outline: Intro: Retinal lipid composition and metabolic dependence Omega-3 and DHA in Photoreceptor Health: Structure, function, and systemic transport Gut-Derived Metabolites (SCFAs): Anti-inflammatory and immunoregulatory effects Bile Acids and Retinal Protection : UDCA, TUDCA, FXR/TGR5 pathways Crosstalk & Dysregulation: How diabetes, AGEs, and dysbiosis impair retinal metabolism Clinical Implications: Nutrition, metabolic modulation, therapeutic targets Debunking Myths: Why nasal/ eyedrop fatty acid delivery is biologically implausible Future Directions: Integrative strategies for prevention and treatment.

Cataract

Abstract No.: 201063

Conquering Capsule Complications: My Best Teaching Videos

*Chief Instructor: David **CHANG***

*Instructor(s): Ashvin **AGARWAL***

Objective: To use more than 30 edited video cases to systematically review techniques of preventing, recognizing, and handling zonular or posterior capsular complications.

Synopsis: Carefully edited videos will illustrate a spectrum of techniques for zonular and posterior capsular complications: capsular dye, torn CCC, secondary CCC enlargement, flap tear-out rescue technique, sulcus fixation with CCC/optic capture, posterior CCC, early recognition of posterior capsule rupture, conversion from top/clear corneal incision to manual ECCE, posterior polar cataracts, IOL fixation with torn anterior or posterior capsule, CTR and capsule retractors for weak zonules, spiral CTR injector, pars plana bimanual anterior vitrectomy ($\pm$ triamcinolone), and dispersive OVD posterior-assisted levitation + trap for descending nuclei.

Course Outline: Part 1: Phaco with zonulopathy. Capsulorhexis pearls, Little technique, secondary CCC enlargement, capsular retractors, CTR, spiral CTR injector, IOL fixation w/Zonulopathy, convert to manual ECCE Part 2: PCR recognition, convert to ECCE, IOL scaffold, anterior vitrectomy, OVD for PAL technique, viscoelastic trap, IOL implantation after PCR Part 3: What to say/discuss with patients following complications.

Abstract No.: 203021

Current Advances and Challenges in Suture and Sutureless Scleral Fixation Techniques for Intraocular Lens: A Comprehensive Review

*Chief Instructor: Wai-ching **LAM***

*Instructor(s): Angie **FONG**, Nicholas **FUNG**, Shrinivas **JOSHI**, Arif **SAMAD**, Sherman **VALERO***

Objective: • Understanding the management approaches of the dislocation or subluxation of the IOL. • Identify the indications for scleral fixation of intraocular lens • Describe the important preoperative evaluation when planning scleral fixation of intraocular lens. • Understand the comparative analysis between suture and sutureless fixation methods • Describe the postoperative complications of scleral fixation of intraocular lens

Synopsis: Implantation of an IOL in the absence of capsular support remains challenging for many surgeons. This instructional course reviews the various techniques of SFIOL, analyzes the advantages and

disadvantages of the different techniques, conducts comparative analysis between suture and sutureless fixation methods, highlights the salient points in the technical approaches, and discusses the postoperative complications for a better surgical outcome.

Course Outline: - Introduction (5 mins) - Dr. Wai-Ching Lam - Management of dislocated/subluxated IOL (10 mins) - Dr. Sherman Valero - Step by step approaches: Sutureless fixation of SFIOL-Yamane (10 mins) – Dr. Angie Fong - Step by step approaches: Suture fixation of SFIOL – Gortex vs Prolene sutures fixation (10 mins) – Dr. Wai-Ching Lam - Special considerations of SFIOL: Gortex, Canabrava, internal fixation techniques, CMT flex IOL technique (10 mins) – Dr. Shrinivas Joshi - Comparative analysis between suture and sutureless fixation methods (10 mins) - Dr. Nick Fung - Management of postoperative complications of scleral fixation of intraocular lens (SFIOL) (10 mins) - Dr. Arif Samad - Panel discussion (15mins).

Abstract No.: 201999

Fix It With a Claw: A Practical Solution for the Aphakic Eye

*Chief Instructor: Nina **HANDAYANI***

*Instructor(s): Aulia **ABDUL HAMID**, Ahmad **THOHIR***

Objective: By the end of this course, participants will: Understand the indications, technique, patient selection and complication of iris claw implantation Be proficient in both anterior and posterior (retropupillary) fixation techniques Understand iris claw implantation in special cases

Synopsis: Aphakia, the absence of the crystalline lens, can occur following complicated cataract surgery, trauma, or congenital conditions. The management of aphakia aims to restore visual function by providing adequate optical correction. Traditional options include spectacles, contact lenses, and intraocular lens (IOL) implantation. Among the surgical approaches, the iris-claw lens has emerged as a reliable option for aphakic correction, particularly in cases where capsular or zonular support is insufficient. The iris-claw lens is a rigid, polymethyl methacrylate (PMMA) lens that is fixated to the mid-peripheral iris stroma using claw-like haptics. It can be implanted either in the anterior chamber (anterior fixation) or behind the iris (retropupillary fixation). Advantages include surgical simplicity, stable centration, reversibility, and avoidance of scleral sutures, which reduces the risk of suture-related complications.

Course Outline: Iris Claw Lens Implantation as Management of Aphakia Target Participants : Ophthalmologist, Residents Session 1 : Management of Aphakia with Anterior or Posterior Iris Claw Session 2 : Iris-Claw Intraocular Lenses: A Viable Option for Aphakic Glaucoma Patients? Session 3 : Surgical Techniques of Iris Claw Implantation in post Vitrectomy Eye with Aphakia Group Discussion and Q&A.

Abstract No.: 201145

Fixation Matters: From Elective Refractive Phakic to Rhexis-Fixated Pseudophakic Implants. Where and How We Place Intraocular Lenses

Chief Instructor: David **LUBECK**

Instructor(s): Robert **ANG**, Haripriya **ARAVIND**, David **BECKERS**, Fam **HAN BOR**, Jod **MEHTA**

Objective: This course has been designed to give ophthalmologists a better understanding and surgical skills transfer of theoretical and surgical aspects of intraocular lens placement.

Synopsis: This all-in-one instruction course explores the full range of IOL fixation strategies used in modern anterior segment surgery: 1) Phakic IOLs – posterior chamber, iris-supported, and anterior chamber lenses for refractive enhancement. 2) Capsule-fixated IOLs – in-the-bag and sulcus techniques for standard and secondary implants. 3) Iris-fixated IOLs – enclavation and iris suturing for capsular-deficient eyes. 4) Anterior chamber IOLs – angle-supported solutions for aphakia without posterior support and 5) Rhexis-fixated IOLs – modern approaches using the capsulorrhexis for secure fixation & ELP.

Course Outline: Participants will learn surgical principles, decision algorithms, case selection, and complication management across all modalities. With step-by-step videos, real-case discussions, and expert faculty, this course offers practical tools to handle both routine and complex IOL challenges with confidence.

Abstract No.: 206067

Hands-On Scleral Fixation IOL Wet Lab

Chief Instructor: Abdul **HANNAN**

Instructor(s): Aziz Jan **ASHIR**, Nauman **HASHMANI**

Objective: To teach young ophthalmologists the basics of the Scleral Fixation IOL technique (Yamane Technique)

Synopsis: The Yamane Technique is currently the gold standard for Scleral Fixation IOL techniques amongst many others. This technique has a sharp learning curve which deters many young ophthalmologists from learning it and ultimately abandoning it altogether. I aim to teach this technique hands-on in such a simple way that any surgeon would get confident enough, after the course, to go back to his institute and practice it much more comfortably. I bring with me a surgical experience of more than 2500 Yamane fixation cases experience. I want to teach others the hacks I have learned across my experience which have made this technique much easier and safer to perform. I believe such a course is a need of the hour and would attract a lot of attention amongst participants.

Course Outline: I, along with 2 other colleagues, can manage 3 wet lab stations. where we can train

between 6-10 people per station. The session would start with a small introduction video to the technique and what hack can make it easier to perform. Instruments required: 1. 3-piece IOL 2. retinal max-grip forcep 3. 3mm keratome 4. IOL injector 5. Visco Elastic 6. Simul eye fixation eyes or animal eyes.

Abstract No.: 207032

Immediate Bilateral Sequential Cataract Surgery

Chief Instructor: Mehran **ZAREI GHANAVATI**

Instructor(s): Mohamed **BAHGAT BADAWI GOWEIDA**, Ahmed **BARDAN**, Christopher **LIU**

Objective: By the end of this session, participants will be able to: 1. Identify appropriate patient selection criteria and apply ISBCS protocols 2. Evaluate strategies to optimize visual outcomes 3. Understand the benefits and risks of ISBCS in comparison with delayed sequential surgery. 4. Apply best practices to streamline workflow and enhance surgical outcomes in bilateral same-day cataract surgery.

Synopsis: Immediate bilateral sequential cataract surgery (ISBCS) has increasingly become a standard offering, with significant uptake in the UK in recent years. This session will provide an evidence-based update on its advantages, risks, and practical considerations, aiming to streamline protocols and enhance patient outcomes.

Course Outline: 1. Introduction • Overview of ISBCS and its growing adoption in the UK and worldwide • Rationale for bilateral same-day cataract surgery 2. Patient Selection and Protocols • Criteria for appropriate patient selection • Contraindications and risk stratification • ISBCS protocol • Strategies to minimize intraoperative and postoperative complications 3. Optimizing Visual Outcomes • Advances in ocular biometry • Considerations in IOL selection for ISBCS • Addressing refractive targets and minimizing postoperative surprises 4. Clinical Evidence and Practical Considerations • Review of current literature and guidelines • Comparative outcomes: • Patient perspectives and satisfaction 5. Case Discussions and Q&A.

Abstract No.: 203875

The Art of Pupilloplasty and Iris Reconstruction: Tips and Tricks

Chief Instructor: Hazem **YASSIN**

Instructor(s): Rania **ZAKI**

Objective: Improve management of surgical complications and develop skills to manage complex cases and master difficult surgical techniques

Synopsis: The course will be video-based, highlighting important aspects of pupilloplasty and iris reconstruction. It will include surgical planning guidelines, basic suturing techniques, advanced iris

repair techniques, materials and methods, artificial iris implantation, and combined iris surgeries. The participants will have the opportunity to gain knowledge from a selection of instructional videos from highly experienced instructors. This will help a smoother learning curve, improve outcomes, and reduce complication rates.

Course Outline: 1-Introduction: -Overview of iris anatomy and physiology - Importance of iris reconstruction in ophthalmic surgery 2-Plan of Surgery: -Preoperative evaluation -Indications of iris repair -Patterns of iris defects - Surgical Plan of iris reconstruction - Surgical Repair Techniques - 3-Basic sutures techniques and surgical principle of iris reconstruction : •Surgical principles of iris reconstruction • Reconstruction techniques : A-Iris defects reconstruction:asModified Seipser Sliding Knot and SingleFour-Throw(SFT) Pupilloplasty B-Iridodialysis Repair: Hang Back technique, Hoffman pocket, Sewing Machine Technique C-Pupil reconstruction: Modified Seipser Sliding Knot, Single Four-Throw (SFT) Pupilloplasty, Iris Cerclage and Laser pupilloplasty Types Of Iris Repair (video based) 1-Pupillary border sutures 2-Pupillary cerclage without iris atrophy 3-Pupillary cerclage with iris atrophy 4-Iridodialysis repair 5- Combined iridodialysis repair and pupillary cerclage 6- Change pupil location 7-Iris Prosthesis 4-Prosthetic Iris devices 5-Complications of Iris surgery 6- Discussion.

Cornea, Dry Eyes, External Eye Diseases and Eye Banking

Abstract No.: 206579

How to Avoid the Mistakes We Made Starting DMEK and DSO

Chief Instructor: Federico **BADALA**

Instructor(s): Sadeer **HANNUSH**, Shaowei **LI**, Theophilos **TOURTAS**

Objective: Attendees will learn simple steps that help avoid common complications in DMEK surgery and DSO procedures. The instructors will show different graft preparation, insertion, and positioning techniques, supplemented by videos to emphasize surgical challenges and how to overcome them.

Synopsis: All DMEK and DSO complex cases will be presented. The handout outline will include different steps with references, that will lead to fewer complications and a greatly shortened learning curve.

Course Outline: Course will enable participants to learn from our mistakes and avoid complications while shortening the learning curve for DMEK and DSO. Videos and panel discussion will illustrate how to avoid

the most common pitfalls in DMEK and DSO surgery in both straightforward and complex cases (phakia, anterior chamber IOLs, post glaucoma surgery etc).

Abstract No.: 206388

Intracorneal Ring Implantation for Keratoconus and Other Irregular Astigmatism: An Understanding Course From A to Z

Chief Instructor: Marta **SARTORI**

Instructor(s): Carlos **ARCE**, Sandra **BEER**, Claudia **FRANCESCONI**, Bernardo **MOSCOVISC**, Pablo **RODRIGUES**, Walton **NOSE**, Marta **SARTORI**

Objective: To take an overview of the disease and the mandatory tools to identify suitable candidates, explain choices of treatment, choose the appropriate device and placement plan, with individualized ICRS procedures, perform the surgical steps safely and recognize intraoperative issues. Detect and manage complications.

Synopsis: Provides a structured understanding of intracorneal ring segments (ICRS) implantation in keratoconus covering corneal biomechanics, patient selection, device types, surgical planning and technique, complications outcomes and evolving combined approaches, with both theoretical foundations and practical training.

Course Outline: 1-Foundations of keratoconus and Corneal Biomechanics 2- Patient Selection and Clinical Decision-Making 3-ICRS devices and Nomograms 4-Surgical Planning 5-Surgical Technique 6-Postoperative Care, Complications and Management 7-Outcomes and Evidence 8-Combined and Future Approaches. 9- Practical and Case-based Simulation.

Abstract No.: 206429

Optimizing the Ocular Surface Before Ocular Surgery

Chief Instructor: Purnima **DHAND**

Instructor(s): Sheetal **BRAR**, Sonu **GOEL**, Sonal **KALIA**, Tushya **OM PARKASH**, Namrata **SHARMA**

Objective: This instruction course will provide ophthalmic surgeons with a comprehensive framework to evaluate and optimize the ocular surface prior to intraocular and corneal surgeries. Participants will learn why the ocular surface is central to surgical success across subspecialties and how to detect subtle ocular surface disease that compromises outcomes.

Synopsis: The ocular surface is a silent determinant of surgical outcomes across cataract, refractive, and glaucoma procedures. This course highlights why surface health matters, how to detect hidden disease preoperatively, and the consequences of ignoring it- ranging from inaccurate biometry in premium Intra Ocular Lens to poor epithelial healing after

Photorefractive Keratectomy and bleb failure in glaucoma surgery. Through didactic lectures and case-based discussions, participants will gain a structured approach to integrate ocular surface management into routine surgical planning ensuring better and faster recovery, and higher patient satisfaction.

Course Outline: Why the Ocular Surface Matters across Surgeries Spotting the hidden Enemy: Preoperative Diagnostics Cataract and Premium IOLs: Biometry Lies Without a healthy Surface PRK Success Lies in the Surface Ocular Surface optimization Before LASIK Calm The conjunctiva, Save the Bleb: Ocular surface Management Before Glaucoma Surgery Panel Discussion Question and Answers.

Glaucoma

Abstract No.: 200401

Anterior Segment OCT in Glaucoma: From Angle Assessment to Surgical Monitoring

Chief Instructor: Tanyaba MALIK

Objective: To equip participants with the knowledge and skills to use anterior segment OCT for comprehensive angle assessment, diagnosis of angle-closure mechanisms, and monitoring of glaucoma surgical outcomes.

Synopsis: A one-hour instructional course on Anterior Segment OCT (AS-OCT) in Glaucoma is a timely and practical topic, especially with the increasing availability of swept-source and Fourier-domain AS-OCT in clinics. It helps bridge the gap between anatomical understanding and clinical decision-making, particularly in angle-closure disease, filtering surgery, and MIGS.

Course Outline: 1. Introduction to AS-OCT (5 minutes) 2. AS-OCT in Angle Assessment (15 minutes) • Identifying angle structures: scleral spur, Schwalbe's line, iris root • Quantitative parameters: • Classification of angle closure: 3. Pre- and Post-Laser Imaging (10 minutes) • Before and after Laser Peripheral Iridotomy (LPI) 4. AS-OCT in Glaucoma Surgery (15 minutes) • Filtering surgery: 5. Summary & Take-Home Messages (5 minutes).

Abstract No.: 200600

Glaucoma Laser Therapy: Innovations and Advice for Primary Open Angle Glaucoma Eyes and Primary Angle Closure One

Chief Instructor: Michele LANZA

Instructor(s): Rosa BOCCIA, Luigi SERRA

Objective: This course will provide information about all the last innovations in glaucoma care, and, particularly, about laser treatments that could be a very valuable option in difficult cases too.

Synopsis: The course will provide details of indications, techniques and recent innovations concerning laser procedures to treat the different kinds of glaucoma. Topics will include laser trabeculoplasties - selective (SLT), micropulsed (MLT) and direct (DSLT); transscleral cyclophotocoagulation - threshold (FT-TSC) and micropulse (MP-TSC); iridotomy and iridoplasty. Moreover, last innovation about the use of femtosecond laser and excimer one in glaucoma eyes will be included. Videos, results and complications of these procedures in primary open angle glaucoma, primary angle closure glaucoma and secondary glaucoma will be covered. Particular attention will be focused on complex cases and the decision making involved. At the conclusion of this course, the attendee will be aware of the latest innovations in laser treatment of glaucoma and able to select the appropriate procedure for their patients.

Course Outline: Introduction: Michele Lanza; Innovations in trabeculoplasty: Michele Lanza; How to properly perform iris laser procedures: Rosa Boccia; What has changed in transscleral cyclophotocoagulation?: Luigi Serra; Femto and excimer laser in glaucoma: Michele Lanza; Complex Cases: Rosa Boccia, Luigi Serra (15 min); Discussion

Intraocular Inflammation, Uveitis and Scleritis

Abstract No.: 207401

Episcleritis and Scleritis: A Patient Is Walked In, How Do I Deal With This in My Clinic?

Chief Instructor: Somasheila MURTHY

Instructor(s): Peter MCCLUSKEY, Uwe PLEYER, Namrata SHARMA, Jay SHETH

Objective: Episcleral inflammation is a common condition which has several etiologies. Scleritis, though rare, is often missed and additionally is often an enigma to the general ophthalmologist. In this course, we intend to provide clear guidelines on how the general ophthalmologist can diagnose and manage cases of episcleral and scleral inflammation, and when they should refer these cases to specialists.

Synopsis: Episcleritis and scleritis are inflammation of the outer coats of the eye. Often immune mediated, scleritis can be associated with systemic disease, whereas episcleritis can be associated with other ocular conditions. In this course, the participants will be able to differentiate between the two conditions, be able to manage episcleritis and also be able to investigate and start initial therapy for scleritis.

Course Outline: 1. Overview of episcleritis: differential diagnosis and management 2. Overview of scleritis: classification, clinical features presented through cases

3. Non-infectious scleritis: learning through cases
 4. Infectious scleritis: what to look for? 5. Posterior scleritis: often-missed entity.

Ocular Imaging

Abstract No.: 206613

Corneal Imaging for Modern Cataract Surgery

Chief Instructor: Mazen SINJAB

Objective: Understand the critical role of corneal imaging in preoperative assessment for cataract and refractive lens exchange surgeries. Recognize the importance of detecting corneal irregularities before planning for toric, EDOF, or trifocal IOL implantation. Interpret corneal aberrometry and apply its findings to clinical decision-making. Plan surgical incisions based on corneal tomography data. Strategize appropriate methods for astigmatic correction. Appreciate the impact of undetected corneal irregularities on biometric accuracy. Identify the influence of prior corneal surgeries on biometry and surgical outcomes.

Synopsis: Corneal Imaging for Modern Cataract Surgery

Course Outline: Detection of corneal irregularities and previous corneal surgeries before cataract - 15 min
 Mazen Sinjab Impact of corneal irregularities on the accuracy of biometry - 15 min
 Mehran Importance of corneal imaging in astigmatic management - 15 min
 Mazen Corneal wavefront and IOL selection - 15 min
 Mazen Case discussion - 15 min
 Christopher Liu Q&A 15 min.

Abstract No.: 200173

Instructional Course on Ultrasound and UBM: Basic Exam and Clinical Cases

Chief Instructor: Mario DE LA TORRE ESTREMADOYRO

Objective: Describe the possibilities and limitations of ocular ultrasound. Explain basic physical principles, diagnostic potential and limitations of Standardized A-mode, B mode and UBM. Perform systematic and comprehensive examinations, developing skills for probe positions and scanning techniques in A- and B-Scan (8, 15, 20 and 50MHz) Differentiate normal from abnormal findings, making presumptive diagnoses. Present new technologies, including annular devices.

Synopsis: This course covers when and how to use ocular ultrasound. Despite the emergence of new imaging studies, it remains valuable for diagnosis. Many ophthalmologists are unfamiliar with its precise indications, scope, limitations, proper use of the equipment, and image interpretation. This course aims to fill this gap.

Course Outline: Basic examination with A and B mode, Basic definitions in sound physics: acoustic impedance, phenomena of sound versus tissues (absorption, reflection, acoustic shadow, sound attenuation). Transducers. Signal processing. Types of amplification. Impact of standardization: Gain (dB), time-gain-compensation, gain adjustment, T, T+9, CT, Cineloop and Varigain, zoom types: orbit eye and 20 μ s, A scan modes: Tumor Q1, Retina A1, Retina Q11, Muscle Profile, Axial Length. Kappa Angle Eye examination (scanning, special techniques) Longitudinal and transverse projections. Paraocular and transocular, with Mode A and Mode B. Study of the vitreous, retina and choroid, PVD, RD hemorrhage Asteroid hyalosis. Intraocular tumors: differential diagnosis, melanoma, hemangioma, nevus, retinoblastoma etc. Uveitis endophthalmitis, Study of the Orbit, Tumors, examination of the optic nerve, extraocular muscles pathology, UBM in glaucoma, tumors, trauma, infections and other conditions, Sulcus to sulcus measurements for ICL implantation.

Ocular Oncology and Pathology

Abstract No.: 205798

Challenges in Ocular Oncology

Chief Instructor: Duangnate ROJANAPORN

Instructor(s): Hung-da CHOU, Vishal RAVAL, Gavin TAN

Objective: By course end participants will (1) recognize presentations and mimics of intraocular tumours; (2) apply multimodal diagnostic pathways; (3) choose evidence-based local and systemic treatments; (4) manage complications and coordinate multidisciplinary care.

Synopsis: This practical, case-driven course reviews diagnostic pitfalls, staging, and modern management of intraocular tumours (retinoblastoma, uveal melanoma, choroidal metastasis, vascular tumors, other benign retinal and choroidal tumors). Through case-based presentation, high-resolution imaging, operative/video highlights and interactive cases with audience polling, learners receive concise algorithms for diagnosis, treatment selection (plaque brachytherapy, intra-arterial and intravitreal chemotherapy, systemic options, enucleation) and follow-up — with emphasis on resource-adapted care and patient communication.

Course Outline: 1. Intro & learning goals (5 min) 2. Four case presentations by leading ocular oncologists (each 10 min): diagnostic challenge, imaging pearls, critical decision point, and practical tip (40 min) 3. Panel discussion: Management strategies highlighted by cases — treatment selection and complication

avoidance (25 min) 6. Audience polling, take-home algorithms, Q&A (10 min).

Abstract No.: 206694

Retinoblastoma - Protocols, Challenges and Solutions: An Asian Insight

Chief Instructor: Shaifali **CHAHAR**

Instructor(s): Jason **CS YAM**, Julie D. **BARLIANA**, Fairouz P. **MANJANDAVIDA**, Purnima **RAJKARNIKAR STHAPIT**, Duangnate **ROJANAPORN**, Junyang **ZHAO**

Objective: To provide a comprehensive overview of retinoblastoma and its management in the Asia-Pacific region, highlighting unique challenges, innovative approaches, and evolving protocols that aim to improve life, eye, and vision salvage, while fostering cross-country collaboration and learning.

Synopsis: The Asia-Pacific region carries the highest burden of retinoblastoma worldwide. This instruction course will cover the entire spectrum of care — from early detection, referral pathways, and advances in management, to success stories in orbital retinoblastoma. Distinguished faculty from across the region will share practical insights while addressing the unique socio-economic, cultural, and infrastructural challenges faced in Asia-Pacific. Drawing on region-specific experiences, the course will equip participants with evidence-based strategies to optimize outcomes, improve survival, preserve vision, and enhance quality of life for children with retinoblastoma. Importantly, we will also highlight how Asia, with its largest disease burden, is poised to lead the way in shaping the future of retinoblastoma care.

Course Outline: 1. The Global Landscape of Retinoblastoma: Where We Stand Today 2. Retinoblastoma in Nepal: Overcoming Diagnostic Delays and improving outcomes 3. From Late Presentation to Life and Vision Salvage: Insights from the Indian Experience 4. Evolving Protocols and Multidisciplinary Care for Retinoblastoma in Hong Kong 5. Retinoblastoma Management in Thailand: Advances and Remaining Gaps 6. Socio-economic Barriers and Innovative Solutions in Retinoblastoma Care: The Indonesian Perspective Panel- How can Asia lead way in Retinoblastoma care?

Abstract No.: 205743

Systematic Approach to Transscleral Resection of Anteriorly Located Uveal Tumors

Chief Instructor: Andrey **YAROVVOY**

Objective: To present the different techniques of transscleral resections of anteriorly located uveal tumors of different size, location, extension, and origin.

Synopsis: Over 250 anterior intraocular tumor resections were fulfilled from 1992 to 2025 in patients aged from 1 to 83 years. The size of anterior uveal tumors was from 1.5 to 9.0 mm in thickness, from 3

to 15.1 mm in basal diameter, located in the iris (58), iris and ciliary body (101), iris, ciliary body and choroid (92), ciliary body and choroid (1). Seven tumors had extraocular growth of different extension. Special attention will be focused on various surgical techniques of blockexcision. Every kind of technique depends on tumor size, location, extension, and invasion into neighboring tissues, including sclera and cornea. Iris stromal cysts were resected partially after internal de-epithelization. Histological diagnoses included uveal melanoma (132), leiomyoma (22), iris cysts (22), adenoma, adenocarcinoma, nevus, melanocytoma, epithelioma, medulloepithelioma, metastasis. Eye preservation, mortality data, and functional results will be presented in brief. Follow up is from 6 to 259 months, mean 43 months. Conclusions: Transscleral resection is a successful treatment method of anterior uveal tumors and needs to take into account various special features of the tumor and the eye, and possible advantages over radiotherapy.

Course Outline: Surgical techniques of blockexcision will be presented – iridectomy, iridocyclectomy, partial lamellar sclerouvectomy, and full thickness eyewall resections with different size and shape (round or irregular) donor sclera patch grafting.

Orbital and Oculoplastic Surgery

Abstract No.: 208467

Controversies in Thyroid Eye Disease/Graves' Orbitopathy (TED/GO) – East Meets West From the International Thyroid Eye Disease Society (ITEDS) and Asia Pacific Society of Ophthalmic Plastic & Reconstructive Surgery (APSOPRS)

Chief Instructor: Kam Lung **CHONG**

Instructor(s): Kasturi **BHATTACHARJEE**, Peter **DOLMAN**, Constantin **HINTSCHICH**, Dong Mei **LI**, Suryasnata **RATH**, Diego **STRIANESE**, Tim **SULLIVAN**, Jack **TSAI**

Objective: After this course, the attendees will understand the latest management algorithm across the TED/GO spectrum and the diversity of patient presentations, the pros and cons of various medical and surgical treatments, their combinations, and treatment-related complications.

Synopsis: This course aims to engage the audience through scenarios that are often encountered in daily practice to highlight important controversies in thyroid eye disease/Graves orbitopathy (TED/GO). Established consensus on and emerging evidence for various management options will be explained by colleagues from around the world. Individualized treatment plans and step-by-step demonstrations of surgical techniques

will be discussed, using video clips and pre-/post-treatment photos. The debate topics will range from initial assessment to management of mild, moderate-to-severe, vision-threatening TED/GO and surgical rehabilitation, highlighting the dilemmas and distinct features in different age and ethnic groups.

Course Outline: 1. Assessing and treating mild TED/GO-“Clinical” and “injectables”-experiences from the West 2. Assessing and treating low CAS, progressive TED/GO-“Radiological” and “triple therapy”-experiences from the East 3. Visual loss in TED/GO- “investigations”-experiences from the West 4. Treating mild TED/GO-»antioxidants»-experiences from the East 5. Treating moderate-to-severe TED/GO-“biologics”-experiences from the East 6. Treating moderate-to-severe TED/GO-“biologics”-experiences from the West 7. Surgical rehabilitation of TED/GO-experiences from the East 8. Surgical rehabilitation of TED/GO-experiences from the West 9. Panel discussion-“Controversies in TED/GO-where East meets West”.

Abstract No.: 203900

Cutting-Edge Techniques in Minimally Invasive Aesthetic Eyelid and Periocular Surgeries

Chief Instructor: Naseem Vanessa **MANSURALI**
Instructor(s): Cat **BURKAT**, Dong Mei **LEE**, Min Joung **LEE**, Micheal **YEN**, Stephanie **YOUNG**

Objective: The demand for minimally invasive and quick recovery periocular aesthetic procedures is on the rise. Hence, it is beneficial for doctors to master techniques to enhance surgical outcomes. The aim of this course is to teach the participants simple, minimally invasive aesthetic eyelid procedures that enhance appearance and improve patient satisfaction.

Synopsis: Minimally invasive aesthetic eyelid and periocular surgeries are designed to have small hidden incisions which minimize tissue damage, reduce scarring, promote quick recovery, reduce complications rate and cut costs. The course teaches common surgeries by Oculoplastic Aesthetic Experts that one can perform to beautify the appearance of the eyebrows, upper and lower eyelids. This is a surgical video-based skill transfer course.

Course Outline: The course starts off with a minimally invasive technique for brow contouring. From eyebrow, we then move on to the important section of minimally invasive eyelid procedures. The procedures covered will be lid crease formation with sutures, mini incision blepharoplasty and scarless cosmetic ptosis surgery, followed by a technique on scarless epicanthoplasty. The course will then end with mini pin hole transconjunctival lower eyelid blepharoplasty for eye bag correction.

Abstract No.: 200502

Orbital Infections and Inflammation in Asia: Clinical Experience and Emerging Insights

Chief Instructor: Kyung In **WOO**
Instructor(s): Kelvin **CHONG**, Tarjani **DAVE**, Pimkwan **JARU-AMPORN PAN**, Min Joung **LEE**, Dongmei **LI**, Sunny **SHEN**

Objective: To provide a regionally tailored and up-to-date overview of orbital infections and inflammatory diseases in Asia, emphasizing diagnostic challenges, emerging regional patterns, and advances such as artificial intelligence and immunomodulatory therapies.

Synopsis: Orbital infections and inflammatory disorders manifest with diverse clinical features across Asia, influenced by regional pathogens, genetic factors, and variable healthcare resources. Despite this, most clinical guidelines are based on Western populations, limiting their applicability in Asian settings. This course brings together leading experts from the region to share practical experiences and emerging insights. Topics include atypical and challenging presentations of orbital cellulitis, shifting trends in orbital fungal infections in the post-COVID era, and the distinctive phenotypes and management strategies of thyroid eye disease (TED) in Asian populations. The session will also explore the role of artificial intelligence in enhancing diagnostic accuracy of TED, and provide practical updates on the use of immunomodulatory agents in orbital inflammation. The course also covers idiopathic orbital inflammation and IgG4-related ophthalmic disease, both of which pose diagnostic dilemmas in Asia.

Course Outline: Atypical Orbital Cellulitis (Jarupornpan) Post-COVID Orbital Fungal Infections (Dave) TED in Asia: Clinical Patterns & Management (Chong) AI in TED Diagnosis (Li) Idiopathic Orbital Inflammation in Asians (Lee) IgG4-related Ophthalmic Disease (Woo) Immunomodulatory Therapy: Asian Updates (Shen) Discussion and Q&A.

Abstract No.: 202471

Surgical Techniques of Ptosis Correction: Pearls & Pitfalls

Chief Instructor: Ben **LIMBU M.D.**
Instructor(s): Sayeed Mehbub **AL KADIR**, Golam **HAIDER**, Akshay **NAIR**, Samata **SHARMA**

Objective: To provide concise, targeted knowledge on selecting the appropriate surgical approach for each type of ptosis, with the goal of maximizing surgical effectiveness and minimizing complications.

Synopsis: The instructional course delivers extensive training about ptosis surgical management for ophthalmologists and oculoplastic surgeons and residents who want to improve their eyelid surgery skills and knowledge. The course begins with an examination of ptosis anatomy followed

by preoperative evaluation methods and decision-making algorithms for selecting appropriate surgical approaches. The course provides attendees with video demonstrations and case discussions and expert commentary to teach them how to select surgical approaches according to levator function and patient-specific factors and etiology. The course will focus on achieving optimal functional and cosmetic results with reduced postoperative complications.

Course Outline: Duration: 80 minutes (60 minutes lectures + 20 minutes of panel discussion, Q&A) Target Audience: Ophthalmologists, Oculoplastic Surgeons, Residents and Fellows Format: Didactic lectures, surgical videos, interactive case discussions, Q&A.

Abstract No.: 204737

When the First Time Fails – Revision Oculoplastic Surgery

Chief Instructor: Gangadhara **SUNDAR**

Instructor(s): Peter **DOLMAN**, Ana **DUARTE**, Santosh **HONAVAR**, Yunia **IRAWATI**, Timothy **SULLIVAN**

Objective: To share experts input from various countries, on why and what happens resulting in failure of primary management and what measures they take to deliver optimal outcomes

Synopsis: Despite best intervention, primary surgery or medical intervention may fail - in various Eyelid, Lacrimal & Orbital disorders. This Instruction course shall share experts' inputs on delivering the best outcome when common oculoplastic surgeries, such as Congenital ptosis correction, Adult ptosis correction, Lacrimal drainage Surgery (DCR), Orbitotomies for tumors and Orbital reconstruction following trauma fails with functional and structural consequences.

Course Outline: When congenital ptosis surgery fails Yunia Irawati, Indonesia When adult ptosis surgery fails Tim Sullivan, Australia When an external DCR fails Peter Dolman, Canada Managing recurrent/residual orbital tumors Santosh Honavar, India When IVMP firstline doesn't work for Active TED Ana Duarte, Portugal Revision Orbital Fractures Gangadhara Sundar, Singapore.

Pediatric Ophthalmology and Strabismus

Abstract No.: 206153

Ocular Genetics: From Principles to Practice

Chief Instructor: Seo Wei **LEO**

Instructor(s): Saadia **FARROOQUI**, Beau **FENNER**, Savleen **KAUR**

Objective: To equip ophthalmologists with a practical understanding of ocular genetics, covering inheritance

patterns, major genetic eye diseases, testing strategies, counselling, and emerging therapies. The clinically orientated and interactive course aims to provide participants with confidence to recognise genetic eye disease, make informed decisions on genetic testing, and integrate genetic advances into clinical care.

Synopsis: Ocular genetics is reshaping the way ophthalmologists diagnose, manage, and counsel patients with inherited eye diseases. With genetic testing, gene therapy, and precision medicine becoming increasingly available, ophthalmologists in every subspecialty now face situations where genetic knowledge is directly relevant to patient care. This introductory instructional course offers a structured and clinically oriented overview of ocular genetics. It is designed for practising ophthalmologists with no prior genetics training, focusing on practical applications rather than laboratory details. The course highlights inheritance principles, common genetic eye conditions, and the growing impact of gene-based therapies.

Course Outline: 1. Foundations of Ocular Genetics • Principles of inheritance relevant to ophthalmology • Pitfalls in family history assessment 2. Genetic Eye Diseases • Inherited retinal diseases • Paediatric cataracts • Glaucoma and corneal dystrophies 3. Genetic Testing in Practice • When to order tests • How to interpret reports • Applying results to clinical care 4. Genetic Counselling and Ethics • Communicating results with patients and families • Ethical considerations and implications for relatives 5. Emerging Therapies • Gene replacement and RNA-based interventions • Genome editing approaches • Clinical trial updates in the Asia-Pacific region.

Abstract No.: 203794

Surgical Management of Superior Oblique Palsies (Congenital and Acquired)

Chief Instructor: Maria **THEODOROU**

Instructor(s): Janice **LAM**, Leena **PATEL**

Objective: 1. To 'demystify' the orthoptic assessment 2. To be able to individualise surgical planning 3. To revise different surgical techniques

Synopsis: The aetiology of superior oblique palsies can range from straightforward decompensated longstanding/congenital to acquired with consequential disabling torsion, which acts as a barrier to fusion. Surgical management requires careful assessment and at times, a staged approach.

Course Outline: In this short course, we will describe the pre-operative assessment of superior oblique palsies, and the surgical decision-making process. We will then discuss the different surgical techniques (inferior oblique recession/myectomy/anterior or antero-nasal transpositioning, inferior rectus recess & resect, superior oblique tuck/Harada-Ito) and work through cases. Talk 1: The pre-operative

assessment of the patient with superior oblique palsy
 Talk 2: Surgical Techniques: Inferior Oblique, Inferior Rectus, Superior Oblique surgeries Case Discussions
 Target audience: • Ophthalmology trainees / residents
 • Orthoptists • Paediatric Ophthalmology/ Strabismus consultants • General ophthalmologists interested to brush up on their knowledge on superior oblique palsies.

Refractive Surgery

Abstract No.: 204172

Refractive Lensectomy and Premium (Multifocal, EDOF and Accommodative) Intraocular Lenses: Unveiling the Mystery of How to Match Patients With Lenses

Chief Instructor: Jorge L. ALÍO

Instructor(s): John CHANG

Objective: This course will offer the audience updated information on how to make a correct indication of refractive lensectomy based on evidence and how to distinguish and use different premium lenses, (multifocal, EDOF, accommodative) in the different types of patients, according to refractive error, eye anatomy, age and patient needs in order to accomplish spectacle independence at all distances.

Synopsis: Refractive lensectomy is used to correct refractive errors of the eye using a variety of intraocular lenses. The goal is to correct the refractive defect and to achieve emetropia and, as much as possible, spectacle independence at all distances. This course will make an overview of the best clinical practice to follow in order to accomplish this goal within ethical limits

Course Outline: 1. Introduction: what is the dysfunctional lens syndrome? 2. Methods for the diagnosis and categorization of the dysfunctional lens syndrome. The new definition of cataract. 3. Surgical techniques for refractive lens exchange: minimally invasive lens surgery 4. Patient indications and selection. Red lines not to cross for the safety of the patient. 5. Intraocular lens choice for spectacle independence. How to choose the best based on objective criteria: multifocal, EDOF, monofocal? 6. IOL calculation 7. Results, outcomes, complications. 8. Panel discussion.

Abstract No.: 204974

The Art of PTK (Photo Therapeutic Keratectomy)

Chief Instructor: Sami ALRABIAH

Objective: PTK is applying laser treatment on the corneal surface for corneal disease, other than correcting refractive errors. The objective is to

simplify it for ophthalmologists and promote more understanding and working with such an important tool.

Synopsis: It is to differentiate between types of PTK, either customized or non-customized. A- Customized PTK 1- Topography Guided PTK (Auto-topo PTK, Contact lens fitting PTK, Customized selective PTK) 2- Ocular Wave Front Guided PTK 3- Regular cornea to induce Irregular cornea, inducing high spherical aberration in one eye to increase depth of focus to treat presbyopia B- Non Customized PTK 1- Dry Plain PTK 2- Wet Plain PTK according to the severity of corneal irregularities a- thin fluid shield technique b- thick fluid shield technique

Course Outline: First: to discuss different broad types of PTK either a- customized or b- plain non-customized. Second: Each has subdivisions that need special techniques and for special indications. Videos and slides will assist the course.

Retina (Surgical)

Abstract No.: 201998

Early Use of Intravitreal Triamcinolone to Inhibit Traumatic Proliferative Vitreoretinopathy: A Randomized Clinical Trial

Chief Instructor: Hua YAN

Objective: To evaluate the efficacy and safety of intravitreal triamcinolone acetonide (TA) injection at the end of emergency surgery for open globe injury (OGI) to suppress traumatic proliferative vitreoretinopathy (TPVR).

Synopsis: This randomized clinical trial investigates the early use of intravitreal TA administered the end of emergency surgery for OGI as a means to suppress the development of TPVR. The study involved 68 patients with zone III globe rupture, randomly assigned to receive either 0.1 mL TA or 0.1 mL balanced salt solution at the end of emergency surgery. Primary outcomes focused on TPVR assessment during subsequent vitrectomy performed 10±3 days later, while secondary outcomes included visual acuity, retinal and macular attachment rates, PVR recurrence, and side effects at 6 months post-vitrectomy.

Course Outline: The trial was conducted as a single-center, participant-masked, prospective, randomized controlled study. Results demonstrated a statistically significant reduction in TPVR severity ($p=0.028$) and improved TPVR scores in the TA group (9.30 ± 0.82) compared to controls (6.44 ± 1.06) during vitrectomy ($p=0.036$). Final visual acuity improvement was observed in 92% of TA-treated eyes versus 63.64% in the control group ($p=0.008$). Retinal attachment rates

were also significantly higher in the TA group (88%) than in the control group (63.64%) ($p=0.049$). However, no significant differences were found in macular repositioning or PVR recurrence between groups.

Abstract No.: 204523

Old Tricks and New Trends in MTM Surgeries - Flaps, Belts, Amnions, Viscoat Plus Heavies, But Gasless

Chief Instructor: Chi-chun LAI

Instructor(s): Hung-da CHOU, Shu Yen LEE, Simon SZETO, Gavin TAN, Andrew TSAI

Objective: This evidence-based, state-of-the-art session focuses on the surgical management of myopic traction maculopathy. Experienced surgeons from Taiwan, Singapore, and Hong Kong will discuss both established strategies and the latest advances in the field.

Synopsis: Each presentation will provide a concise review of historical perspectives and current literature, followed by narrated surgical videos that highlight key techniques. The faculty will also introduce novel technical approaches and instrumentation, and present six cutting-edge papers published in 2025. Topics include sub-perfluorocarbon viscoat injection, no gas surgery, amniotic membrane grafting, internal limiting membrane flaps, macular buckling, and optimal timing of surgical intervention. By the end of the course, participants will gain a comprehensive understanding of the surgical options, techniques, and expected outcomes in the management of myopic traction maculopathy.

Course Outline: Session 1: Close the hole on the SPOT - macular hole retinal detachment made easy (10 min) Speaker: Hung-Da Chou (Male, Taiwan) Session 2: Amniotic membrane cradles the macular hole retinal detachment like a baby (10 min) Speaker: Chi-Chun Lai (Male, Taiwan) Session 3: Does macular buckling still have a chance when vitrectomy rules (10 min) Speaker: Gavin Tan (Male, Singapore) Session 4: Early vitrectomy in myopic foveoschisis before it's too late (10 min) Speaker: Andrew Tsai (Male, Singapore) Session 5: High myopic holes are not regular holes (10 min) Speaker: Shu-Yen Lee (Female, Singapore) Session 6: No Bubble, no trouble: gas-free macular hole closure (10 min) Speaker Simon Szeto (Male, Hong Kong) Discussion (20 min).

A Deep Learning Model for Recognising Leukemia Retinopathy From Retinal Fundus Images

First Author: Wenzhou XIAO

Co-Author(s): Kinji HASHIMOTO, Yumeng LI, Wenbo LIU, Xuan SHI

Purpose: To develop a deep learning model to achieve non-invasive methods for leukemia recognition and diagnosis through the assessment of fundus photography.

Methods: A total of 675 participants were included, comprising 315 leukemia patients and 360 non-leukemia patients. All participants underwent fundus imaging with the Optos California non-dilated ultra-wide field fundus camera. The dataset was split into a training set (n=540) and an internal test set (n=135) via stratified random sampling. A dual-branch convolutional neural network (2 ResNet-50 LVM) was employed. Patient-level predictions were produced by calculating the average of the probability outputs from both eyes, resulting in a binary leukemia risk label. An independent external validation set (n=169) was used to assess model generalizability. Performance was evaluated by the area under the receiver operating characteristic curve (AUROC), precision, recall, specificity, accuracy, and F1-score.

Results: In the internal validation, the model achieved an AUROC of 0.9054. And in the external validation, our model achieved an AUROC of 0.8946, precision of 0.8452, recall of 0.8659, specificity of 0.8506, accuracy of 0.8580, and an F1-score of 0.8554.

Conclusions: We construct a deep learning model providing an effective non-invasive way of recognising patient's leukemia risk only by fundus images and it may offer clinical assistance for ophthalmologists to recognise leukemia by retinal fundus photography.

Abstract No.: 203608

A Lattice Boltzmann Method for Simulating Blood Flow in Complex Anterior Segment Vessels

First Author: Yicong PENG

Co-Author(s): Deteng HANG, Xinli YU

Purpose: Ocular hemodynamic alterations are implicated in numerous ophthalmologic pathologies. Traditional computational fluid dynamics methods rely on macroscopic continuity assumptions and have limitations when simulating complex microvascular networks. In this study, the lattice Boltzmann method (LBM) was used to simulate the anterior segment blood flow, and a simulating method that is more suitable for simulating the microvascular blood flow of the eye was proposed.

Methods: A three-dimensional vascular segment was reconstructed from OCTA images using MATLAB. A custom 3D LBM solver was implemented to simulate hemodynamics. Boundary conditions were handled via a modified bounce-back scheme at the walls and a non-equilibrium extrapolation method at the inlets/outlets. Blood was modeled as a Newtonian fluid using literature-derived density and viscosity parameters.

Results: The developed LBM simulation demonstrated robust stability and successfully computed the flow field for the prescribed case, yielding clear visualization of flow patterns. This model establishes a validated computational framework for quantifying physiological parameters in ocular vasculature.

Conclusions: This study demonstrates LBM's utility in ocular hemodynamic modeling. The framework provides a foundation for investigating microcirculatory flow alterations under pathological conditions, potentially offering insights into the hemodynamic mechanisms of ocular diseases.

Abstract No.: 202123

A Mixture-of-Experts Network for Infectious Keratitis Classification Using Multimodal Slit-Lamp Images

First Author: Fen-fen LI

Co-Author(s): Qi DAI

Purpose: Infectious keratitis remains one of the leading causes of corneal blindness worldwide, and subtype distinguishing continues to pose significant clinical challenges. Existing deep learning approaches typically

rely on a single imaging modality, which overlooks the distinct diagnostic cues present in other modalities.

Methods: To address this limitation, we propose KeraFusionNet, a novel deep learning framework that simultaneously processes three imaging modalities—diffuse white light, slit beam, and cobalt blue light with fluorescein staining. The model integrates three modality-specific expert subnetworks, and employs a dynamic gating network to adaptively fuse their feature representations for final classification. We validated the method using a multicenter dataset comprising 3236 images from 820 patients at Zhejiang Eye Hospital (ZEH) and 862 images from 261 patients at Aier Guangming Eye Hospital (AGEH).

Results: On the ZEH dataset, the model achieved an overall classification accuracy of 87.40%, with AUCs of 0.9899, 0.9177, 0.9653, 0.9803, and 0.9635 for normal cornea, herpes simplex keratitis, bacterial keratitis, fungal keratitis, and other cornea abnormalities, respectively. On the independent AGEH dataset, the accuracy reached 83.49%. Moreover, the model outperformed ophthalmologists (66.7%).

Conclusions: These results demonstrate the effectiveness and generalizability of our multimodal fusion framework, offering a promising tool for automated IK diagnosis and subtype differentiation.

Abstract No.: 206802

A Multimodal AI Agent for Clinical Decision Support in Ophthalmology

First Author: Danli SHI

Co-Author(s): Xiaolan CHEN, Mingguang HE

Purpose: To develop and validate EyeAgent, the first interpretable, multimodal agentic framework designed to support complex clinical decision-making in ophthalmology.

Methods: EyeAgent was constructed by integrating a large language model with 53 validated ophthalmic tools, enabling dynamic orchestration across 23 imaging modalities and multiple task types (classification, detection, segmentation, generation, and quantitative analysis). The framework was grounded in domain-specific knowledge using retrieval-augmented generation from 14 ophthalmology textbooks. Validation was performed across 862,490 samples from both internal and external datasets, including: Agentic ablation analysis to measure tool contribution. Benchmarking against GPT-4o on complex and adversarial ophthalmic tasks. Real-world validation on clinical cases with expert evaluation. A multi-center human–AI reader study comparing EyeAgent with ophthalmologists at different experience levels.

Results: Diagnostic accuracy increased from 69.7% (5 general tools) to 80.8% (all 53 specialized tools) in agentic ablation analysis. EyeAgent outperformed GPT-4o in complex and adversarial ophthalmic tasks. In real-

world clinical cases, EyeAgent achieved 93.7% tool-selection accuracy and high expert-rated performance in clinical accuracy (88.0%), reasoning (94.0%), and interpretability (88.5%). In a multi-center human–AI reader study, EyeAgent matched or exceeded senior ophthalmologists' performance, and as an assistant improved diagnostic accuracy by 18.5% and report quality by 19%, with the largest benefit observed among junior clinicians.

Conclusions: EyeAgent represents a scalable agentic AI framework for medicine, shifting from static models to dynamic, task-driven systems. It demonstrates real-world clinical utility, achieving senior-clinician performance and enabling effective human–AI collaboration.

Abstract No.: 205481

AI-Driven Insights Into Pegcetacoplan: Preserving EZ and RPE in Geographic Atrophy

First Author: Anna TAN

Co-Author(s): Caroline BAUMAL, Philip FERRONE, Amir SADEGHIPOUR, Ursula SCHMIDT-ERFURTH, Roy SCHWARTZ

Purpose: To report the effect of pegcetacoplan on geographic atrophy (GA) progression and ellipsoid zone (EZ)/retinal pigment epithelium (RPE) ratio loss.

Methods: The 24-month OAKS and DERBY studies evaluated the efficacy and safety of intravitreal pegcetacoplan vs sham in GA. Upon completion, patients could enter the GALE open-label extension. Patients on pegcetacoplan monthly (PM) or every-other-month (PEOM) in OAKS and DERBY continued the same regimen in GALE, and those on sham crossed over to active treatment (delayed treatment). The main efficacy outcome was the change in fundus autofluorescence (FAF)-based GA growth. Optical coherence tomography (OCT)-based AI further quantified EZ and RPE changes with pegcetacoplan treatment. Data was analyzed with a mixed model for repeated measures.

Results: In OAKS and DERBY, pegcetacoplan reduced GA growth by 26% (PM) and 22% (PEOM) in nonsubfoveal (NSF) GA compared to sham. With continuous treatment for 48 months, PM and PEOM reduced GA growth by 32% and 27%, respectively, compared to the projected sham (all $p < 0.0001$). GALE results demonstrated that patients receiving early treatment experienced better outcomes than delayed treatment. Change from baseline in EZ and RPE loss (Month 24) was significantly reduced with pegcetacoplan (all $p < 0.001$): PM reduced EZ loss by 52.8% and 46.9% vs sham in OAKS and DERBY, respectively; PEOM by 46.0% and 46.4%. PM reduced RPE loss by 22.3% and 27.1% vs sham in the respective trials; PEOM by 19.7% and 20.6%. Patient cases will be presented.

Conclusions: Long-term efficacy and safety of pegcetacoplan were demonstrated in GA with support for earlier treatment.

Abstract No.: 202976

AI-Enhanced OCT Angiography- Retinal and Choroidal Biomarkers for Predicting Preclinical Diabetic Retinopathy

First Author: Chethan N MURTHY

Co-Author(s): Ranjitha KC

Purpose: To identify quantitative OCT angiography (OCTA) biomarkers associated with preclinical diabetic retinopathy (DR) and to develop a machine learning (ML) model for accurate detection of subclinical disease.

Methods: Cross-sectional study included 240 eyes from 130 patients with type 2 diabetes without clinically visible DR (ETDRS level 10) and 80 age-matched control eyes. Swept-source OCTA (Topcon Triton) was used to quantify foveal avascular zone (FAZ) area and circularity, superficial capillary plexus vessel density (SCP VD) and deep capillary plexus vessel density (DCP VD), perfusion density (PD), choriocapillaris flow void density, and choroidal vascularity index (CVI). Independent t-test/Mann-Whitney U test for healthy vs preclinical DR was used. Between-group differences were analysed using ANCOVA adjusting for age and diabetes duration. Data were split into training (70%) and testing (30%) cohorts. Random forest (RF), support vector machine (SVM), and logistic regression (LR) models were trained.

Results: Preclinical DR eyes exhibited significant alterations compared to controls: larger FAZ area (0.32 ± 0.12 vs. 0.25 ± 0.10 mm² ($p < 0.01$), lower FAZ circularity (0.70 ± 0.07 vs. 0.78 ± 0.05 , $p < 0.01$), reduced SCP VD: 47.0 ± 3.2 vs. $49.8 \pm 2.5\%$ ($p = 0.02$) reduced DCP VD (51.2 ± 3.5 vs. $54.5 \pm 3.0\%$ ($p = 0.01$), increased choriocapillaris flow void density ($34.8 \pm 4.0\%$ vs. $28.2 \pm 3.5\%$ ($p < 0.001$), reduced CVI (0.61 ± 0.05 vs. 0.66 ± 0.04 ($p = 0.03$). ROC analysis showed: SCP VD (AUC = 0.74), DCP VD (AUC 0.86), FAZ area (AUC = 0.78), and CVI (AUC 0.80) were strong discriminators. Random Forest: AUC = 0.92, accuracy = 87%, sensitivity = 84%, specificity = 89%, SVM: AUC = 0.88, accuracy = 83%, Logistic Regression: AUC = 0.84, accuracy = 80 Feature importance analysis ranked CC FV density, FAZ area, SCP VD as top predictors.

Conclusions: Quantitative OCTA biomarkers reliably detect subclinical microvascular compromise in diabetes. Integrating these biomarkers into an ML model further improves predictive accuracy, supporting OCTA-based AI frameworks as a powerful, non-invasive tool for early DR risk stratification and screening.

Abstract No.: 201719

AIM-Net: A Deep Learning System for Detecting Myopia Onset and Predicting Myopia Progression in School-Aged Children

First Author: Mark WONG

Co-Author(s): Marcus ANG, Joey CHUNG, Gilbert LIM

Purpose: To develop and validate a deep learning system for the detection of myopia onset and prediction of 1-year myopia progression in school-aged children.

Methods: The Artificial Intelligence in Myopia in Singapore (AIM) study follows a prospective cohort of 1000 children aged 5-7 recruited from a national school health screening program. All participants underwent cycloplegic refraction and fundus photographs obtained using tabletop fundus camera, with a subset also having fundus photographs acquired using a handheld camera. 'Myopia onset' was defined as spherical equivalent (SE) $\leq -0.5D$ at baseline with no previous diagnosis or prescription. 'Myopia progression' was defined as an increment in SE $\leq -0.5D$ in 1 year. AIM-Net was trained on baseline fundus photographs with and without clinical meta-data using transfer learning from a DenseNet-121 model.

Results: For detection of myopia onset ($n=538$), AIM-Net achieved an AUC of 0.90 [0.86-0.93] compared to clinical demographics alone (AUC 0.60 [0.54-0.65]). For prediction of myopia progression ($n=790$), AIM-Net attained an AUC of 0.77 [0.72-0.82]. AIM-Net also performed comparably when using handheld-acquired retinal images for myopia detection (AUC 0.82 [0.72-0.90]). AIM-Net also achieved an AUC of 0.74 [0.72-0.76] for baseline myopia detection on an external cohort.

Conclusions: AIM-Net demonstrates potential in detecting myopia-onset and predicting myopia progression in children aged 5-7 who could benefit from early intervention. AIM-Net also performed robustly on handheld-acquired retinal images, supporting deployment in mobile screening settings.

Abstract No.: 209946

An Innovative Diagnostic Method for Myopia Using Blood-Based Biomemristor

First Author: Zhirong LIU

Purpose: To address the limitations of conventional myopia diagnostic methods (e.g., reliance on patient cooperation, unsuitability for young children, and challenges in large-scale screening), this study aims to develop a blood-based biomemristor for myopia diagnosis. We designed and fabricated an Ag/ZIF-8:PVP/FTO-structured biomemristor using ZIF-8 as the core functional material to detect and differentiate physiological states associated with high myopia. The memristor's resistive switching stability, multi-mechanism conduction behavior, and

sensitivity to subtle physiological changes in blood samples were verified, particularly its capability to distinguish phenotypic differences (rather than genetic consistency) via an identical twin family model. Ultimately, this work seeks to provide a novel solution for early myopia screening, phenotypic stratification, and minimally invasive monitoring in children and high-risk groups.

Methods: For the methods, peripheral venous blood was collected from healthy individuals and patients with high myopia, with plasma separated and stored. ZIF-8 nanoparticles were synthesized via a solution process. The Ag/ZIF-8:PVP/FTO memristor was fabricated using spin-coating, and its structure and properties were characterized by FE-SEM, XRD, XPS, FTIR, and electrical measurements. Key experiments included optimizing parameters (ZIF-8 concentration, voltage scan rate, maximum bias), conducting reliability tests through 100 consecutive I-V cycles, and clinically validating the device by comparing samples from healthy and myopic individuals, as well as identical twins.

Results: The results demonstrated that the memristor had a uniform layered structure and stable bipolar resistive switching. Optimal parameters were identified as 10 mg/mL ZIF-8, a 1 V/s scan rate, and a ± 2.0 V bias. The device exhibited mixed conduction mechanisms (Schottky emission, Ohmic conduction, and hopping transport) and could distinguish between blood samples from high myopia patients and healthy individuals: devices with patients' blood showed linear I-V curves without hysteresis, while those with healthy individuals' blood exhibited significant resistive switching. In the identical twin model, the memristor differentiated phenotypic differences despite genetic similarity.

Conclusions: In conclusion, this study realizes the first application of a ZIF-8-based memristor in myopia diagnosis. The Ag/ZIF-8:PVP/FTO memristor overcomes the shortcomings of traditional optical diagnostics (no requirement for patient cooperation, minimally invasive) and can distinguish between high myopia and healthy populations, even phenotypic differences in genetically identical individuals. However, limitations exist, such as a small sample size and unclear specific biochemical substances in blood that affect memristor signals. Future research will focus on elucidating the biochemical-electrical correlation, miniaturizing the device, and integrating machine learning to enable dynamic myopia monitoring and personalized ophthalmic care.

Abstract No.: 201416

Application of Artificial Intelligence in Uveal Malignant Melanoma

First Author: Yungang DING

Co-Author(s): Wei CHEN, Yongping LI, Ying WEN

Purpose: This study aims to explore the potential application of artificial intelligence (AI) in the diagnosis, treatment, and prognosis evaluation of uveal malignant melanoma, as well as to discuss its role in assisting clinical decision-making for ophthalmologists and pathologists.

Methods: A retrospective review of literature from PubMed and Web of Science was conducted to analyze the research findings on the application of machine learning and deep learning techniques in uveal malignant melanoma.

Results: Various models were used in the AI research on uveal malignant melanoma, with convolutional neural networks (CNNs) being the most commonly employed. The research mainly focused on differential diagnosis and prognosis evaluation. In terms of differential diagnosis, models based on color fundus photography, ocular ultrasound, and magnetic resonance imaging (MRI) were used to distinguish small choroidal malignant melanoma from pigmented nevi. In prognosis evaluation, models were primarily based on patient clinical characteristics and histopathological images. AI-driven prognostic evaluation using digital pathological images of biopsy cell smears can reach the level of gene expression profiling classification tests.

Conclusions: AI shows significant potential in optimizing the management of patients with uveal malignant melanoma. Convolutional neural network models are expected to play an essential role in clinical diagnosis and prognosis evaluation. However, challenges remain, including the limited sample size for this tumor, inconsistent image quality, and the interpretability of AI models. Future research should focus on addressing these issues to fully realize the application potential of AI technologies.

Abstract No.: 201846

Artificial Intelligence-Based Screening of Diabetic Retinopathy Using RetCAD Software: Results From a Mongolian Population

First Author: Tumenjargal ERDENEBAATAR

Co-Author(s): Bayasgalan PUREVDORI

Purpose: To evaluate the diagnostic accuracy of the AI-based RetCAD software for the early detection and staging of diabetic retinopathy.

Methods: A total of 359 patients aged 19–82 years were recruited using random sampling, including both diabetic and relatively healthy control groups. Sample size was calculated using standard epidemiological formulas (Fig. 1). All participants underwent a

comprehensive ophthalmic examination performed by an ophthalmologist, including staging of DR. Fundus photographs were processed with RetCAD, which applies convolutional neural networks (CNNs) to detect DR and age-related macular degeneration (AMD). The AI outputs were graded on a 0–5 scale (Table 1), corresponding to the International Council of Ophthalmology DR classification, ranging from no DR to proliferative DR. RetCAD's results were compared with ophthalmologists' clinical diagnoses to evaluate sensitivity, specificity, and diagnostic concordance (Figs. 2–3).

Results: • The mean age of participants was 39.41 ± 4.50 years. • Distribution of DR among diabetic patients: o Mild non-proliferative DR: 40% o Moderate non-proliferative DR: 20% o Severe non-proliferative DR: 30.9% o Proliferative DR: 9.1% • Diagnostic agreement between ophthalmologists and RetCAD: o Mild DR: 93.5% o Moderate DR: 87.5% o Severe DR: 95.0% o Proliferative DR: 100% • Overall performance of RetCAD in fundus image evaluation: o Sensitivity: 95.0% o Specificity: 96.8%

Conclusions: The AI-based RetCAD software provides rapid, reliable, and highly accurate early detection of diabetic retinopathy. Its integration into screening programs could significantly enhance the prevention of DR-related vision loss in Mongolia, reduce the burden on ophthalmic services, and lower treatment costs for patients.

Abstract No.: 202019

Automated Annotation in Iridocorneal Angle Imaging: AI-Driven Precision Mapping for Enhanced Glaucoma Diagnostics

First Author: Prasanna Vekatesh **RAMESH**

Purpose: This study explores an AI model developed for automated annotation of iridocorneal angle landmarks, providing precise measurements and classifying angles as open, narrow, or closed. Building on extensive research that underscores AI's transformative potential in ophthalmology, this study examines AI's role in enhancing diagnostic accuracy and streamlining efficiency in the management of glaucoma.

Methods: A total of 1,500 high-resolution Anterior images were analyzed, with 1,370 (91%) used for training and 130 (9%) for testing. Training was conducted in three sessions (Train-1, Train-2, Train-3), monitoring metrics such as train/box loss, precision, and recall. The AI identified key angle structures—scleral spur, trabecular meshwork, and angle apex—mapped the iridocorneal angle, and classified it as closed, narrow, open, or wide. Testing involved sequential evaluation of the 130 test images, split into three groups with each group assessed over five-day intervals. Predictions were refined through incremental training, enhancing angle status accuracy.

Results: The AI showed improved prediction in angle configuration annotation across testing phases. The percentage of images with fully correct predictions was 88% (Test 1), 91% (Test 2), and 96% (Test 3). Sensitivity scores improved from 82.61% to 95.24% across the tests, and specificity increased from 92.59% to 95.83%.

Conclusions: This AI system shows promising potential in automating iridocorneal angle analysis for glaucoma diagnostics, accurately categorizing angle configurations as closed, narrow, open, or wide. Its high sensitivity and specificity demonstrate potential as a precision diagnostic tool for AI-assisted glaucoma care.

Abstract No.: 200311

Automated Posterior Scleral Topography Assessment for Enhanced Staphyloma Visualization and Quantification With Improved Maculopathy Correlation

First Author: Xi **CHEN**

Purpose: Subjective assessment of posterior staphylomas based on morphology lacks reproducibility and scalability, and its association with myopic macular degeneration (MMD) remains unclear. This study aims to develop a precise, quantitative method to characterize posterior scleral shape.

Methods: Using deep learning, we automatically segmented surface points of the eyeball from MRI scans to reconstruct posterior scleral topography. In a three-dimensional Cartesian coordinate system, we calculated distances (D) from each point to a pre-elongation eye center and local curvatures (C). Derived parameters included Dmean, Cmean, Dmax, Cmax, Dvar, and a composite curvature-depth index (C-D). These were analyzed for concordance with traditional staphyloma classifications and their correlation with MMD grades. Staphylomas were categorized into three types: type-0 (symmetrical elongation without focal protrusion), type-1 (symmetrical elongation with conical protrusion), and type-2 (asymmetrical nasal/temporal protrusion).

Results: In 6528 eyes (6528 participants), segmentation achieved a Dice coefficient of 0.935. C-Dmax (AUC: 0.923) and Dvar (AUC: 0.981) were the most effective parameters in differentiating between staphyloma types. All key parameters showed strong discriminative power (AUC > 0.900). Dvar ($\beta = 0.75 \text{ mm}^{-2}$, $p = 0.02$) and C-Dmax ($\beta = 2.44$, $p = 0.02$) were significantly associated with MMD grade, independent of age and axial length.

Conclusions: This MRI-based automated analysis enables objective visualization and quantification of posterior staphyloma morphology, offering a scalable tool for classifying staphyloma subtypes and assessing their relationship to macular degeneration.

Abstract No.: 206741

Benchmarking Next-Generation Reasoning-Focused Large Language Models in Ophthalmology

First Author: Minjie Killian ZOU

Co-Author(s): Qingyu CHEN, Thaddaeus Wai Soon LO, Sahana SRINIVASAN, Yih Chung THAM

Purpose: Large language models (LLMs) with the advent of “reasoning-focused” show promise in healthcare yet remain understudied in specialized domains like ophthalmology. This study comprehensively evaluated the accuracy and reasoning capabilities of four reasoning-focused LLMs: DeepSeek-R1, OpenAI o1, OpenAI o3-mini, and Gemini 2.0 Flash-Thinking.

Methods: Each model was assessed via its respective APIs using 5,888 multiple-choice ophthalmology exam questions from the MedMCQA dataset. Accuracy, Macro-F1, text-generation metrics (METEOR, ROUGE-L, BERTScore, BARTScore, AlignScore) and inference time were assessed. Memorization test for exact token matches was conducted to address potential data leakage. Three ophthalmologists reviewed reasoning quality of LLMs’ outputs on 40 differential-diagnosis MCQs, rated on factuality, completeness, brevity, and safety using a five-point Likert scale.

Results: O1 (0.902) and DeepSeek-R1 (0.888) showed highest accuracy ($p < 0.001$). Meanwhile, inconsistencies across text-generation metrics were detected. O1 performed best on METEOR (0.232, $p < 0.001$), while o3-mini led on ROUGE-L (0.151) and AlignScore (0.181). DeepSeek-R1 (0.673) and o3-mini (0.673) tied for BERTScore; DeepSeek-R1 (-4.105) and Gemini 2.0 Flash-Thinking (-4.127) excelled on BARTScore. Inference time varied, with DeepSeek-R1 slowest (40.3s) and Gemini 2.0 Flash-Thinking fastest (6.7s). Memorization analysis found no exact matches, confirming models did not rely on memorized content. Models performed similarly well on factuality and safety, but o3-mini (12.925) scored lowest for completeness and Gemini 2.0 Flash-Thinking (10.500) in brevity.

Conclusions: Reasoning-focused LLMs show promise for ophthalmology, though trade-offs exist between accuracy, reasoning quality, and inference speed. The absence of a clear best-performing model underscores the need for multi-metric benchmarking before considering clinical deployment.

Abstract No.: 207281

Benchmarking Performance of an Agentic Pipeline in Conducting Meta-Analysis

First Author: Wai Chak CHOY

Co-Author(s): Oscar Hou In CHOU, Yam Cheuk Sing JASON, Hin Wah Lotus YU

Purpose: To investigate the accuracy and performance of a large language model-based agentic pipeline in performing steps of meta-analysis.

Methods: Three published meta-analyses were extracted from the JAMA Ophthalmology, covering pars-plana vitrectomy outcome, anti-vascular endothelial growth factor injection approach, and ocular adverse events for semaglutide. Abstracts and full-texts were retrieved manually from literature search engines following the specified search strategy and time frame from the original studies. We then tested the performance of the pipeline in abstract screening, full-text, screening, and extraction of study details. Manual labels were created and compared with pipeline outputs. Meta-analyses were repeated on the extracted dataset, with result compared to the original study.

Results: 712, 102, 3000 abstracts were retrieved. Across the 3 published meta-analyses, abstract screening achieved accuracy, precision, recall and AUC of 96.00 (95.13-96.87), 91.85 (90.68-93.02), 96.70 (94.76-98.64), and 92.22 (90.25-94.19) respectively. Full-text screening achieved accuracy, precision, recall and AUC of 96.00 (95.13-96.87), 95.95 (95.02-96.88), 96.70 (94.76-98.64) and 96.22 (94.25-98.19) respectively. Extraction of study parameters from full text achieved accuracy, precision, recall and AUC of 84.91 (82.41 – 87.41), 85.15 (82.62 – 87.68), 83.69 (78.02 – 89.36), and 86.26 (81.57 – 90.95) respectively. For the completed meta-analysis, the direction of conclusion aligns with the original study. Pooled estimate was found to have a mean difference of -0.1083 (-0.313-0.096). Paired t-test found no statistically significant differences ($P=0.2308$)

Conclusions: The advancement of language models may assist in literature review with careful design of the workflow. Human-in-the-loop approach may improve reliability with increased efficiency. Caution is still needed for model inaccuracy and hallucination.

Abstract No.: 207141

Beyond Grading: Non-Invasive Prediction of Angiographic Concepts From Fundus for Personalized Management and Treatment Planning in Diabetic Retinopathy

First Author: Hui TANG

Co-Author(s): Xiaomeng LI, Yanchun ZHANG

Purpose: Fundus Fluorescein angiography (FFA) provides critical information on retinal ischemia, vessel leakage for clinical managing diabetic retinopathy (DR)

but is invasive and resource-intensive. We aim to non-invasively predict these essential FFA concepts directly from fundus images to revolutionize DR management.

Methods: Current AI systems for fundus images perform grading or fundus lesion detection, but do not predict the FFA concepts required for personalized treatment planning. We introduce CURE (Cross-modality Understanding for Diabetic Retinopathy Evaluation), a pioneering model that uses cross-modality concept learning to predict FFA concepts from fundus images, enabling continuous, non-invasive monitoring.

Results: For DR grading, CURE achieves superior accuracy (78.0% vs. 62.0%), F1-score (76.4% vs. 58.6%), sensitivity (76.3% vs. 58.2%), and specificity (95.6% vs. 92.6%) compared to senior ophthalmologists. For predicting FFA concepts, CURE demonstrates a functional breakthrough, identifying five microvascular lesions undetectable by the naked eye. For three physician-detectable symptoms, it shows higher accuracy (90.0% vs. 87.3%), F1-score (72.9% vs. 71.2%), and sample-level accuracy (72.0% vs. 66.0%).

Conclusions: CURE non-invasively predicts crucial FFA concepts from fundus images, filling a critical gap in current AI systems. It enhances diagnostic performance, provides interpretable insights for risk stratification, and reduces the need for invasive FFA. This tool is poised to improve personalized treatment planning, guide timely referrals, and optimize patient outcomes in DR management.

Abstract No.: 200938

Can 'Deep Research' Agents and General Agentic System Autonomously Perform Systematic Review and Meta-Analysis?

First Author: Wan Ting **LOKE**

Co-Author(s): Pearse **KEANE**, Sahana **SRINIVASAN**, Yih-chung **THAM**, Gabriel Dawei **YANG**

Purpose: 'Deep Research' agents and general agentic systems have recently emerged, claiming to actively search and evaluate web content to generate insights. Their ability to conduct complete systematic reviews and meta-analyses, however, remains largely untested. We evaluated three 'Deep Research' agents (OpenAI, Google Gemini, Perplexity) and one agentic system (Manus AI) on performing these tasks autonomously.

Methods: Using a recently published review on screen time and myopia risk across 45 studies as a reference standard, we applied a structured two-part prompt and assessed outputs in five domains: sources cited, search term generation, study retrieval, figures and tables generation, and synthesis of findings. Three reviewers independently rated each domain as "Good," "Borderline," or "Poor," with ratings determined by majority consensus.

Results: For search term generation, Manus AI was rated "Good", while the other three agents were "Borderline." For study selection, Manus AI retrieved 10 papers, whereas the others retrieved the correct total count of 45 studies. In extracting key findings, OpenAI and Perplexity performed well, Manus AI was "Borderline," and Gemini performed poorly. None produced scientifically robust figures or tables (OpenAI being "Borderline", the rest being "Poor"). Manus AI uniquely provided detailed search steps and completed the meta-analysis autonomously but fabricated all its 10 selected studies and 5 of 40 citations.

Conclusions: While these agents may assist with early-stage literature exploration, their current capacity to execute rigorous systematic reviews and meta-analyses remains limited. Robust evaluation methods are needed before autonomous agents can be reliably integrated into routine research workflow.

Abstract No.: 207380

Can Corneal Epithelial Mapping Predict Postoperative Visual Quality and Patient Satisfaction in Cataract Surgery?

First Author: Gaurav **PANDE**

Co-Author(s): Abha **SHAH**, Rohit **SHETTY**, Vibha **SINGH**

Purpose: To evaluate how preoperative corneal epithelial mapping impacts postoperative visual quality and patient-reported quality of life (QoL) in cataract surgery patients, using Artificial Intelligence (AI) to identify predictive markers.

Methods: 250 patients underwent pre and postoperative evaluation, including epithelial mapping (Placido Ocular Coherence Tomography and Ray-tracing based system) and tear biomarker analysis using the BioM Pathfinder kit. Based on epithelial status, Group 1 (n=169) had regular epithelium and Group 2 (n=81) had irregular epithelium. Postoperative assessments included Uncorrected Visual Acuity (UCVA), Patient-Reported Outcomes with LASIK (PROWL) scores, Optical Quality Analysis System (OQAS), and epithelial/corneal Higher order aberrations (HOAs). AI algorithms were applied to identify predictors of visual and QoL outcomes.

Results: UCVA gains were comparable across groups. However, Group 1 had significantly better visual quality and QoL scores (PROWL<80 in 162/169 patients), while Group 2 had poorer outcomes (PROWL>120 in 48/81). Corneal HOAs and inflammatory biomarkers were markedly elevated in Group 2 (p<0.05). AI identified epithelial irregularity as a key predictor of both reduced visual quality and lower QoL.

Conclusions: Corneal epithelial mapping and tear biomarkers serve as effective surrogate markers for predicting both visual outcomes and postoperative quality of life following cataract surgery. Preoperative

epithelial mapping helps predict and optimize visual quality after cataract surgery.

Abstract No.: 202323

Community-Based External Validations of a Retinal Photo-Based Deep Learning Model for Disease-Related Visual Impairment Detection

First Author: Samantha YEW

Co-Author(s): Yibing CHEN, Jocelyn GOH, Xiaofeng LEI, Yih-chung THAM

Purpose: To externally validate deep learning (DL) models (foundation model, convolution neural network, vision transformers) in detecting disease-related visual impairment (VI) using retinal images, in a community screening setting.

Methods: Using 15,227 dilated retinal images from the Singapore Epidemiology of Eye Disease (SEED) population cohort, we developed four different models of different backbone architectures, namely foundation model RETFound, ResNet50+XGBoost, ViT-base, and SwinV2. We then retrospectively tested the four models externally on 519 undilated retinal images from 272 participants (age: >50 years old) collected from a community vision screening program. Disease-related VI was defined as pinhole visual acuity worse than 6/12 with an ophthalmologist-confirmed eye disease. Model performance was assessed using the area under the receiver operating characteristic curve (AUC), with statistical comparisons of traditional models against RETFound performed using DeLong's test.

Results: In this community-based external validation, RETFound recorded an AUC of 0.785 (95% CI: 0.735-0.832), followed by 0.789 (95% CI: 0.741-0.834) in ViT-base, 0.777 (95% CI: 0.721-0.823) in SwinV2, and 0.751 (95% CI: 0.691-0.805) in ResNet50+XGBoost. There were no significant differences between these models (all $P \geq 0.36$). At 80% sensitivity, RETFound showed marginally higher specificity (62.2%) compared to SwinV2 (60.3%), ViT-base (58.8%), and ResNet50+XGBoost (53.8%).

Conclusions: When tested externally on a non-dilated, community-based dataset, neither retinal-based foundation model, convolutional neural network, nor vision transformer model architectures achieved optimal performance. This underscores the persisting challenges of deploying DL models in real-world community settings. Future strategies in mitigating the domain gap and improving generalisability are needed.

Abstract No.: 204383

Comparative Analysis of Deep Learning Architectures for Cardiovascular Risk Classification in Fundus Imaging

First Author: Mujeeb Ur REHMAN

Co-Author(s): David MASIP RODÓ

Purpose: To compare five deep learning architectures for cardiovascular risk classification using retinal fundus images and establish optimal hyperparameter configurations for automated, non-invasive screening. Carotid intima-media thickness (CMT) was utilized as a surrogate marker for cardiovascular risk.

Methods: Five models (RetFound, ResNet18, ConvNeXt, DINOv2, EfficientNet) were evaluated on the China Fundus CMT dataset, comprising 5,806 images from 2,903 patients. A patient-wise data split (80/20) was used to prevent data leakage. Nine experimental setups varied learning rates, batch sizes, optimizers, and loss functions per model were performed. A CMT threshold of $\geq 0.9\text{mm}$ defined high cardiovascular risk. The primary performance metric was the area under the receiver operating characteristic curve (AUC-ROC), supplemented by accuracy, F1-score, precision, and recall.

Results: RetFound achieved the highest performance with an AUC of 0.849, 78.66% accuracy, and an F1-score of 0.838, using a low learning rate (1×10^{-5}), the AdamW optimizer, and weighted Cross-Entropy loss. Vision Transformer-based models, particularly RetFound, dominated the top results. ConvNeXt was the best-performing CNN (AUC = 0.844), and DINOv2 showed excellent recall (93.4%). Low learning rates and the AdamW optimizer were consistently linked to better performance, whereas high learning rates led to training instability.

Conclusions: Transformer-based architectures with domain-specific pretraining, like RetFound, represent the state-of-the-art for fundus-based cardiovascular risk assessment. This study highlights that meticulous hyperparameter optimization, especially using very low learning rates, can be crucial for clinical AI applications. These findings support the potential of automated retinal analysis for scalable, non-invasive cardiovascular screening.

Abstract No.: 200543

Construction of a Deep Learning-Based AS-OCT Image Analysis System and Its Application in Auxiliary Diagnosis of Corneal Diseases

First Author: Dongfang LI

Purpose: To develop an anterior segment optical coherence tomography (AS-OCT) image analysis system based on deep learning and evaluate its performance in the automatic recognition and localization of common corneal lesions and features.

Methods: A total of 4,026 patients (5,617 eyes) who visited our hospital were enrolled. Their AS-OCT images were used as the training set. Clinical physicians manually annotated 16 types of corneal features with their locations, as well as the tissue stratification of the corneal epithelium and stroma. The corneal feature pre-inspection model was evaluated using accuracy, sensitivity, and specificity, while the corneal stratification model was evaluated using the overlap rate (Dice coefficient) between model-annotated regions and manually annotated regions.

Results: In the 5,617 images of the training set, 1,472 cases of corneal epithelial defect, 2,416 cases of epithelial thickening, 2,001 cases of corneal thinning, 780 cases of corneal anterior protrusion, 2,064 cases of corneal thickening, 358 cases of subepithelial blisters, 486 cases of subepithelial opacity, 1,010 cases of corneal ulcer, 3,635 cases of stromal opacity. Compared with manual annotations, the corneal feature detection model showed an average sensitivity of 96.5% and an average specificity of 96.1% for the 16 features. There were 15 images with missed features, resulting in a missed detection rate of 0.93%.

Conclusions: This system can provide physicians with information on the types and locations of corneal features in AS-OCT images with high accuracy, which may help ophthalmologists improve diagnostic efficiency and accuracy.

Abstract No.: 206720

Deep Learning Prediction of Childhood Myopia Progression Using Fundus Image and Refraction Data

First Author: Mengtian **KANG**

Co-Author(s): Shi-ming **LI**

Purpose: To develop and validate a deep learning method for predicting myopia progression trajectory and high myopia risk in children using only fundus images and baseline refraction data.

Methods: Longitudinal school-based cohort study conducted from February 2012 to 2018 with 5 years of annual follow-up (analysis reported in 2025). Grade 1 students enrolled in the Anyang Childhood Eye Study (ACES). Myopia was defined as spherical equivalent refraction (SER) ≤ -0.5 D and high myopia as ≤ -6.0 D by cycloplegic autorefraction. Children who received myopia control treatments, had amblyopia, or underwent strabismus surgery were excluded. Area under the curve (AUC) for predicting myopia and high myopia risk and mean absolute error (MAE) for SER prediction using a deep learning model combining convolutional (ResNet34) and recurrent (LSTM) neural networks analyzing 16,211 fundus images.

Results: Among 3048 Chinese children (mean age 7.1 ± 0.4 years, 43.74% males), baseline prevalence of myopia and high myopia were 5.71% and 0.49%.

The deep learning model achieved AUC scores of 0.941 (95% CI, 0.936-0.946) for myopia risk prediction and 0.985 (95% CI, 0.982-0.988) for high myopia risk prediction, with an overall MAE of 0.322 D per year for SER prediction. External validation in Beijing ($n=130$, primarily Han Chinese) and Lhasa ($n=1039$, 96.9% Tibetan) cohorts demonstrated maintained cross-ethnic performance with MAE of 0.355 D and 0.261 D per year, respectively.

Conclusions: In this cohort study of Chinese children, deep learning accurately predicted myopia progression using minimal baseline data. This approach demonstrates promise for large-scale screening and early intervention in resource-limited settings.

Abstract No.: 202287

Deep Learning-Derived Retinal Aging Marker Reflects Multisystem Physiological Dysregulation: Findings From the UK Biobank

First Author: Krithi **PUSHPANATHAN**

Co-Author(s): Ching-yu **CHENG**, Yih-chung **THAM**, Can Can **XUE**, Gabriel Dawei **YANG**, Marco **YU**

Purpose: Retinal imaging-based markers are promising, non-invasive indicators of biological aging. RetiPhenoAge, a deep learning-derived estimate of phenotypic age from retinal photographs, has shown associations with multiple morbidities and mortality. However, its relationship with multisystem physiological dysregulation, a fundamental driver of aging-related health risks, remains unclear.

Methods: This cross-sectional study included 25,958 UK Biobank participants with complete data on RetiPhenoAge and relevant clinical measures. Biological Health Score (BHS), derived from 13 biomarkers across cardiovascular, metabolic, inflammatory, liver, and kidney systems, captured cumulative physiological dysregulation. Higher BHS indicate greater dysregulation. Associations between RetiPhenoAge and BHS were examined using multivariable linear regression adjusted for demographic, socioeconomic, lifestyle, and systemic health factors. Comparative analyses were performed between RetiPhenoAge and established aging markers, including telomere length, physical activity, handgrip strength.

Results: Higher RetiPhenoAge was associated with greater BHS (per SD increase, $\beta=0.01$, 95% CI: 0.01–0.02, $p<0.001$), independent of confounders. Highest RetiPhenoAge quartile showed 0.05 greater BHS (95% CI: 0.04–0.06, $p<0.001$) than the lowest. When BHS was segregated into system-specific measures, RetiPhenoAge showed strongest associations with immune- ($\beta=0.02$, $p<0.001$) and cardiovascular-specific BHS ($\beta=0.02$, $p<0.001$). Across the overall cohort and within demographic and clinical strata, RetiPhenoAge largely outperformed other aging biomarkers. Furthermore, significant interaction effects were observed between older RetiPhenoAge and

hypertension, as well as obesity ($\text{BMI} \geq 30$), in amplifying BHS (both $p < 0.001$).

Conclusions: Older RetiPhenoAge is associated with greater systemic physiological dysregulation, supporting its validity as a non-invasive retinal marker of systemic aging. Future longitudinal studies are warranted to evaluate the role of RetiPhenoAge in tracking BHS.

Abstract No.: 206177

Development and Validation of DeepOrient: A Deep Learning-Based System for Automatic Standard Orientation Recognition of Pediatric Fundus Images

First Author: Ping **LIU**

Co-Author(s): Zhenquan **WU**, Guoming **ZHANG**, Xinyu **ZHAO**

Purpose: To develop and validate DeepOrient, a deep learning system for automatic standard orientation recognition of pediatric fundus images, addressing the low efficiency and poor accuracy of manual interpretation, especially for conditions like retinopathy of prematurity (ROP).

Methods: Retrospective analysis was conducted on 19,166 RetCam fundus images (from 3,651 children, 2005–2023) from two hospitals, covering 10 standard and 1 non-standard orientations. Two models were compared: a cascaded Model 1 (using You Only Look Once version 8 [YOLOv8] for optic disc/macula detection, combined with Gaussian Mixture Model [GMM] and vascular features) and an end-to-end YOLOv8-based Model 2. Evaluation metrics included accuracy, F1-score, and area under the receiver operating characteristic curve (AUC).

Results: Model 2 outperformed Model 1 (internal/external AUC: 0.992/0.991 vs 0.924/0.874) with no performance decay, while Model 1 showed overfitting (external F1-score dropped to 0.730). Merging similar orientations further improved Model 2 (external F1-score: 0.917 vs 0.851).

Conclusions: DeepOrient fills the gap in automatic fundus orientation recognition, with strong generalization. It enhances the standardization of ROP/diabetic retinopathy (DR) screening, and prospective multi-center validation is needed.

Abstract No.: 206657

Development and Validation of a Foundation Model for ROP Screening Based on Self-Supervised Learning and Uncertainty Estimation

First Author: Kunliang **QIU**

Co-Author(s): Qianqian **HE**, Jianwei **LIN**, Mingzhi **ZHANG**

Purpose: To develop a self-supervised foundation model for ROP screening with an uncertainty-based referral strategy, and to validate its performance and generalizability across multiple datasets.

Methods: A ConvMAE-based self-supervised model was pretrained on 168,713 unlabeled infant fundus images from the Joint Shantou International Eye Center (JSIEC) ROP database (2010–2020). The model was fine-tuned on 48,540 annotated images from four institutions according to the International Classification of ROP. Uncertainty scores were computed by modeling the predicted probabilities with a beta distribution, and an optimal referral threshold was determined via the Youden Index to enable human–AI collaborative diagnosis.

Results: On the internal validation set (4,813 images), the model achieved an F1 score of 0.769 and an AUC of 0.9652; after uncertainty-based referral, the F1 score increased to 0.928 and AUC to 0.9687. On the internal test set (7,492 images), the F1 score improved from 0.810 to 0.954 and the AUC from 0.9844 to 0.9910. Robust performance was maintained in the SZEI (756 images) and HVDROPDB (185 images) external datasets, with further gains after referral. t-SNE visualizations confirmed class separability.

Conclusions: This ConvMAE-based self-supervised model, combined with uncertainty estimation, achieves high diagnostic accuracy and enhances reliability, offering a robust tool for real-world ROP screening.

Abstract No.: 200915

Development of an AI-Based Triage System for Myopic Tractional Maculopathy With a Focus on Maculoschisis

First Author: Anas **ABU SAID**

Co-Author(s): Shihao **CHEN**, Mingxin **DAI**, Yanfeng **SU**

Purpose: To develop and evaluate an artificial intelligence (AI)-based triage system for classifying maculoschisis stages in high myopia and providing consistent referral recommendations.

Methods: A retrospective study was conducted using 2,267 OCT images from 497 high myopia patients, each labeled for maculoschisis stage (0–4) by retina specialists. A DenseNet161 deep learning model was trained to classify stages, both with and without integration of patient metadata (age, axial length, visual acuity, gender). Model performance was

assessed by classification accuracy, Cohen's Kappa agreement with retina specialists, and comparison with non-retina specialists in staging and referral tasks.

Results: The DenseNet161 model achieved a classification accuracy of 92.97%, improving to 93.69% with metadata integration. Agreement with retina specialists was high (Cohen's Kappa = 0.867). The AI system outperformed non-retina specialists in both staging accuracy and referral decision-making, demonstrating particular value in non-specialist and resource-limited settings.

Conclusions: The AI-based triage system reliably classifies maculosis stages and improves referral consistency, matching retina specialist performance and surpassing non-specialist accuracy. This approach has the potential to enhance early detection and management of myopic tractional maculopathy in settings lacking subspecialty expertise.

Abstract No.: 201721

Diagnostic Accuracy of Artificial Intelligence in Detecting Diabetic Retinopathy in a Real-World Setting in Nepal

First Author: Arjun **SHRESTHA**

Co-Author(s): Bijay **KHATRI**

Purpose: Manual grading of retinal images for diabetic retinopathy (DR) is resource-intensive and time-consuming, particularly in low-resource settings. Artificial Intelligence (AI) offers a scalable alternative for DR screening. The purpose of this study is to evaluate the diagnostic performance of Cheers AI system, an AI-based screening tool, in detecting diabetic retinopathy compared to human graders in a clinical setting in Nepal.

Methods: Patients with diabetes underwent fundus imaging using a nonmydriatic portable camera. One macula-centered image per eye was analyzed by Cheers AI system which was based on deep learning model with Inception-v3 architecture. Retina image was independently graded by a retina specialist also. Sensitivity, specificity, positive prediction value, negative prediction value and accuracy of artificial intelligence in detecting diabetic retinopathy was compared with human grader (Retina Specialist) as standard. Computing was done using statistic test.

Results: A total of 281 eyes were assessed. Cheers AI demonstrated a sensitivity of 73.44%, specificity of 96.77%, PPV of 85.06%, NPV of 93.58%, and overall accuracy of 91.75%, all within acceptable confidence intervals.

Conclusions: Cheers AI achieved high specificity and accuracy in detecting diabetic retinopathy, meeting recommended thresholds for screening. Further algorithm training may enhance sensitivity, supporting its potential role in expanding DR screening in resource-limited settings.

Abstract No.: 200885

Domain Adaptation of Glaucomatous Optic Neuropathy (GON) Model Across OCT Vendors

First Author: Anni **LING**

Co-Author(s): Carol Y. **CHEUNG**, Anran **RAN**, Clement C. **THAM**, Bowen **XU**

Purpose: Glaucoma is the foremost cause of irreversible blindness worldwide. Detecting glaucomatous optic neuropathy(GON), which is a pivotal diagnostic marker, has been greatly advanced by artificial intelligence(AI) analysis of 3D optical coherence tomography(OCT) volumes. However, marked variation in imaging characteristics across OCT vendors produces a domain shift that undermines model performance outside the source-device. This study proposes and validates a robust domain-adaptation framework that transfers a high-performing GON-classification model to another OCT vendor.

Methods: A retrospective paired dataset built from a cohort of 256 participants encompassing patients with various types of glaucoma, and healthy controls. All participants underwent same-day imaging with Cirrus(Carl Zeiss Inc.) and Maestro 2(Topcon Inc.) OCT devices. Our framework included:(1) Automated pseudo-label transfer from Cirrus to paired Maestro 2 scans using an established GON classifier; (2) Adaptation via fine-tuning using pseudo-labelled Maestro 2 data only; (3) Validation on a non-overlapping test set from Maestro 2 and labelled by an experienced grader.

Results: The analysis included 498 eyes from 256 participants(age: 63.37 ± 15.18 years; female: male = 138:118), training: validation = 4:6. Before adaptation, the model achieved: accuracy 0.73, F1 score 0.71, sensitivity 0.71, specificity 0.76 and AUROC 0.78. After adaptation, the model achieved: accuracy 0.89, F1 score 0.88, sensitivity 0.87, specificity 0.90, and AUROC 0.95, effectively restoring diagnostic performance to near source-device level.

Conclusions: This domain adaptation markedly improves cross-device generalizability of OCT-based AI, potentially enabling future deployment on different OCT vendors without exhaustive retraining.

Abstract No.: 207839

Economic Outcomes of AI-Based Diabetic Retinopathy Screening: A Systematic Review and Meta-Analysis

First Author: Yue **WU**

Co-Author(s): Xiaotong **HAN**, Mingguang **HE**, Yueye **WANG**

Purpose: Artificial Intelligence (AI) has emerged as a promising tool to improve diabetic retinopathy (DR) screening efficiency, accessibility and cost-effectiveness. This study conducted a systematic

review of literature and meta-analysis on the economic outcomes of AI-based DR screening.

Methods: A systematic review of studies published before September 2024 was conducted across five databases. Eligible studies were included if they (1) were conducted among the adult diabetic population; (2) compared an AI-based DR screening strategy to a non-AI screening; and (3) performed a cost-effectiveness analysis. Meta-analysis was applied to pool incremental net benefit (INB) across studies stratified by country income and study perspective using a random-effects model. Statistical heterogeneity among studies was assessed using the I², Cochrane Q and meta regression.

Results: Nine studies were included in the analysis. From a healthcare system/payer perspective, AI-based DR screening was significantly cost-effective compared to non-AI-based screening. Subgroup analysis showed robust cost-effectiveness in high-income countries with low heterogeneity. From a societal perspective, AI-based DR screening was generally cost-effective, though the result lacked statistical significance and showed high heterogeneity. Besides, our meta-regression analysis showed that AI specificity was positively correlated with the INBs from a healthcare system perspective ($p=0.031$), in addition to status quo comparator type ($p=0.031$ and $p=0.011$ in societal and healthcare perspective, respectively).

Conclusions: AI-based DR screening is generally cost-effective from a healthcare system perspective, particularly in high income countries. Heterogeneity across different perspectives highlights the importance of contexts specific evaluations, to accurately evaluate the potential of AI-based DR screening in reducing global healthcare disparities.

Abstract No.: 201838

Evaluating the Utility of Multimodal ChatGPT-4 in Detecting Strabismus Using Anterior Segment Images

*First Author: Kirandeep KAUR
Co-Author(s): Bharat GURNANI*

Purpose: Strabismus is a common pediatric ocular disorder requiring timely diagnosis to prevent amblyopia and long-term visual impairment. Access to specialized care remains limited in many regions. This study aimed to evaluate the diagnostic accuracy of ChatGPT-4 in identifying strabismus using ocular imaging without prior training or fine-tuning.

Methods: The Ocular Imaging Strabismus Dataset (OISD), containing 300 test images, was used. ChatGPT-4 was tasked with classifying each image as “Likely Strabismus” or “Likely Non-Strabismus.” No domain-specific retraining or fine-tuning was performed, ensuring that diagnostic performance reflected baseline capacity. A confusion matrix was

constructed, and standard metrics, including accuracy, sensitivity, specificity, precision, and F1 score, were calculated with 95% confidence intervals.

Results: ChatGPT-4 correctly identified 87% of cases overall (accuracy: 87%, 95% CI: 83–91%). The model detected strabismus with a sensitivity of 65% (95% CI: 55–75%), capturing the majority of true positives, though missing some subtle presentations. Specificity was robust at 92% (95% CI: 87–97%), minimizing false positives and demonstrating strong reliability in confirming normal alignment. Precision was 60% (95% CI: 50–70%), indicating that 6 in 10 positive predictions were true strabismus cases, while the negative predictive value was 89%, highlighting the model’s ability to confidently exclude non-strabismus cases. The F1 score of 0.62 suggested a balanced though imperfect trade-off between sensitivity and precision.

Conclusions: ChatGPT-4 achieved high accuracy and specificity in detecting strabismus without fine-tuning, supporting its potential as a screening tool in resource-limited settings.

Abstract No.: 207250

Evaluation of a Scalable AI-Assisted Optometrist Model for Posterior Segment Conditions and Public Awareness of Diabetic Retinopathy Screening at the World’s Largest Religious Mass Gathering

*First Author: Kaushik MURALI
Co-Author(s): Jayamadhury GUDIMETLA, Ranjitha K, Payal NARESH, Anusha PURUSHOTHAM, Praveen REDDY*

Purpose: Across Asia-Pacific and Low- and Middle-Income Countries (LMIC), health systems face dual burden of rising diabetes and limited access to specialists. We evaluated whether an AI-assisted optometrist model using a smartphone-based fundus camera (Remidio Fundus on Phone, FOP NM10) could deliver accurate posterior segment screening at Mahakumbh 2025—the world’s largest religious gathering—and assessed whether such mass events can also raise public awareness of diabetic retinopathy (DR) screening.

Methods: Non-mydratic retinal images were collected from 4,329 participants using FOP NM10 with integrated offline MediosHI 3-in-1 AI (diabetic retinopathy, glaucoma, age-related macular degeneration). Subset of gradable images independently assessed by two ophthalmologists (reference standard) and compared with grading by two optometrists, one aided by AI and one unaided. 1,477 attendees completed survey on demographics, diabetes status, prior awareness of DR screening and knowledge gain post-exposure at Khumb.

Results: Referrable DR in 13.5% and glaucoma suspected in 8.5% screened. 736 participants graded

(1,472 eyes; mean age 52.6±14.4 years, 38% female), ophthalmologists found 98.1% gradable, with 2.4% showing pathology (DR 0.3%, AMD 1.35%, glaucoma 0.3%, BRVO 0.15%, choroiditis 0.15%, macular hole 0.15%). Inter-ophthalmologist agreement was 91.2%. AI-assisted optometrists achieved 95% agreement with the reference standard and AI reduced false positives by 28% (31 to 19 cases). 7% had prior DR awareness; 54% diabetics were unaware, but 68% reported improved awareness after the event.

Conclusions: Smartphone-based AI enables scalable, reliable screening in high-volume, resource-limited LMIC settings. Large mass gatherings can serve as effective public health platforms, providing opportunity to educate and offering a replicable model to reduce avoidable blindness.

Abstract No.: 204354

Exploration of Clinical Predictive Models for Rotational Stability After Toric Intraocular Lens Implantation

First Author: Ruihong JU

Purpose: This study aims to explore the clinical predictive models for rotational stability after toric IOL lens implantation.

Methods: A retrospective case series study was conducted. This study analyzed clinical data from patients who underwent Phaco combined with Toric IOLs implantation between 2018 and 2023, with complete follow-up examinations at 1 week and 1 month postoperatively. A large-scale clinical database was established to evaluate visual acuity, refractive status, residual astigmatism (RAS), and rotational stability following Toric IOL implantation. The construction and analysis of the predictive model included data set division and preprocessing, model training and validation, model explainable SHAP analysis, and model application with WeChat mini-program.

Results: Five machine learning (ML) models were constructed and evaluated, namely Random Forest (RF), XGBoost, LightGBM, Logistic Regression (LR), and Support Vector Machine (SVM). Among them, the RF model was determined as the optimal predictive model (AUC=0.740). According to SHAP values, the feature importance ranking from high to low was as follows: outpatient, ACP during surgery, age, IOL Loop design, Emery, axial length (AXL) and high intraocular pressure on the first day after surgery (Higher IOP, > 21 mmHg). Based on the results of the optimal predictive model, a WeChat mini-program titled "Postoperative Rotation Risk Prediction Calculator for Toric IOLs" was developed to apply the predictive model in clinical practice.

Conclusions: The primary clinical predictive factors identified were outpatient, ACP, age and IOL loop

design. The WeChat mini-program (Postoperative Rotation Risk Prediction Calculator for Toric IOLs) provided a convenient and practical risk prediction tool for ophthalmologists and patients.

Abstract No.: 206615

EyeDiff: Text-to-Image Generative Foundation Model Improves Rare Eye Disease Diagnosis

First Author: Ruoyu CHEN

Co-Author(s): Xiaolan CHEN, Mingguang HE, Bowen LIU, Shunming LIU, Danli SHI, Pusheng XU, Weiye ZHANG

Purpose: Data scarcity and imbalance persist in training robust diagnostic models, particularly for rare cases. This study aims to introduce a generative foundation model designed to synthesize lesion-preserving ophthalmic images from textual descriptions, namely EyeDiff.

Methods: EyeDiff was trained using a stable diffusion architecture with paired textual instructions and ophthalmic images across 14 modalities, including color fundus photography (CFP), fundus fluorescein angiography (FFA), optical coherence tomography (OCT), etc. Quantitative (VQAScore) and human evaluations were conducted to assess EyeDiff's ability to generate diagnostic lesions as guided by textual instructions. We utilized RETFound, an established foundation model, as the backbone and evaluated EyeDiff's generalizability across ten global datasets for minority class augmentation and disease diagnoses, encompassing various common and rare retinal diseases. The performance of retinal disease diagnosis was measured using the area under the receiver operating characteristic curve (AUROC) and the area under the precision-recall curve (AUPR).

Results: The average VQAScore for lesions diagnosed based on OCT, CFP, and multimodal imaging is 0.822, 0.776, and 0.670, respectively. Authenticity evaluations by two clinicians indicated that the synthetic images were difficult to distinguish from real ones (Turing test: 50.0%–54.5%). EyeDiff-generated images can augment minority classes across ten datasets and enhance the diagnostic accuracy of the state-of-the-art RETFound model. These improvements were supported by increased AUROC and AUPR for multiple common and rare diseases.

Conclusions: EyeDiff demonstrates potential as a generalist model, offering an effective solution for obtaining rare ophthalmic images from simple text cues, thereby boosting the performance of expert-level disease detection models.

Abstract No.: 201771

FFA Sora: Generating Fundus Fluorescein Angiography Videos for Healthcare Data Sharing

First Author: Xinyuan WU

Co-Author(s): Ruoyu CHEN, Mingguang HE, Danli SHI

Purpose: To address patient privacy concerns in cross-centre data sharing, we developed a text-to-video model that converted textual description into dynamic FFA videos, facilitating diverse visual representations of retinal vascular and structural abnormalities.

Methods: The text-to-video model named FFA Sora was trained on 3,625 anonymized paired FFA videos and text reports (train: validation: test = 8:1:1). The model integrated two key components: the Wavelet-Flow Variational Autoencoder (WF-VAE) and the diffusion transformer (DiT). Its performance was rigorously assessed through objective metrics and human evaluations. FFA domain-specific evaluation was measured using the Bidirectional Encoder Representations from Transformers Score (BERTScore), and privacy-preserving performance was evaluated through retrieval evaluations using Recall@K.

Results: The generated FFA videos demonstrated high authenticity, as validated by objective metrics: Fréchet Video Distance (FVD) = 2273, Learned Perceptual Image Patch Similarity (LPIPS) = 0.48 ± 0.04 , and Visual-question-answering Score (VQAScore) = 0.61 ± 0.08 . Domain-specific evaluations showed high alignment between generated videos and textual prompts, with BERTScore of 0.35 ± 0.09 . Human assessments indicated visual quality, with an average score of 1.57 ± 0.44 (1=best, 5=worst). Additionally, the model demonstrated privacy-preserving capabilities in retrieval evaluations, achieving an average Recall@K of 0.073.

Conclusions: This study demonstrated that AI-driven text-to-video generation could potentially improve privacy-preserving data sharing. The diverse synthetic generated videos might also serve as an interactive learning tool for clinical and educational applications.

Abstract No.: 207267

From Baseline to Fine-Tuned: Evaluating MedGemma, Gemma-3, and Gemini-2.5-Flash in Ophthalmology Knowledge and Reasoning

First Author: Sahana SRINIVASAN

Co-Author(s): Fares ANTAKI, Daniel MILAD, Yih Chung THAM

Purpose: We evaluated MedGemma-4B, Gemma-3-4B, and Gemini-2.5-Flash on ophthalmology-specific knowledge and reasoning tasks under zero-shot and fine-tuned conditions.

Methods: To prepare fine-tuning materials, we first converted 25 American Association of Ophthalmology Preferred Practice Patterns covering multiple ocular conditions and topics into 1,179 question-answer text-only (QA) pairs. Additional visual QA data were drawn from OphthalVQA (600 short-answer questions from 10 ophthalmological modalities) and EyeWiki (5,095 4-choice questions). These datasets were used to fine-tune all three VLMs. All baseline and fine-tuned VLMs were evaluated on BELO, an independent test set, consisting of 900 four-choice QA items. Accuracy was used to assess knowledge, while BERTScore (semantic similarity) and AlignScore (factual alignment) were used to evaluate reasoning. Statistical testing was performed using ANOVA with Tukey post hoc analysis.

Results: Baseline Gemini-2.5-Flash (0.86, 95% CI, 0.80-0.89) achieved the highest score in terms of accuracy ($p < 0.01$ compared with other models except for fine-tuned Gemini-2.5-Flash ($p = 0.89$)). Fine-tuned MedGemma achieved the highest BERTScore (0.71 95% CI, 0.71-0.71) ($p < 0.01$ compared with other models, except for baseline Gemma ($p = 0.16$)). Fine-tuned Gemma achieved the highest AlignScore (0.25 95% CI, 0.24-0.26; $p < 0.01$ compared with other models except for fine-tuned MedGemma ($p = 1.00$)).

Conclusions: Fine-tuning general-purpose VLMs with ophthalmology-specific data significantly improves reasoning performance, and may be sufficient without relying on medical-specific models. Further studies involving larger datasets will help to elucidate this aspect further.

Abstract No.: 206721

Global, Regional, and National Temporal Trends in Prevalence and Years Lived With Disability of Blindness and Vision Impairment, 1990–2021

First Author: Sihui ZHANG

Co-Author(s): Kaixuan CUI, Zhenquan WU, Guoming ZHANG, Xinyu ZHAO

Purpose: This study comprehensively assessed the burden of blindness and vision impairment from 1990 to 2021, analyzing temporal trends in disease burden and associations with age, period and birth cohort.

Methods: The prevalence and years lived with disability (YLDs) were calculated by the Global Burden of Disease (GBD) study from 1990 to 2021. These indicators were stratified by sex, age and socio-demographic index (SDI). We calculated the correlation between them and SDI. Age-period-cohort analysis evaluated the independent effects of age, period and cohort. The temporal trends were examined using the annual average percentage change (AAPC) and joinpoint regression.

Results: Between 1990 and 2021, the number or rate of prevalence and YLDs witnessed an overall upward

trend worldwide, with a notably higher burden in females compared to males. Blindness has a decreasing trend, while moderate to severe visual impairment and presbyopia have an increasing trend. Age-stratified analysis revealed a progressive increase in the burden of blindness and vision impairment with age. YLDs rate analysis further demonstrated distinct leading causes across age groups. The highest YLDs were observed in the middle and low-middle SDI regions, while the lowest were in the low and high SDI regions, with substantial differences across countries.

Conclusions: This analysis revealed the urgent need for targeted geriatric care, gender-sensitive approaches, and equitable health policies to address this evolving public health crisis.

Abstract No.: 203689

Large-Scale Primary Strabismus Screening Employing a Smartphone-Based Digital Ruler: A Prospective Real-World Study

First Author: Ruixin **WANG**

Co-Author(s): Shaowei **BI**, Zhangkai **LIAN**, Haotian **LIN**, Ruiwen **XU**, Xiping **YU**

Purpose: Strabismus can adversely affect visual development in children, highlighting the importance of early detection and screening. Yet systematic screening in primary care remains lacking. This study evaluates the performance of the smartphone-based Digital Ruler of Strabismus in large-scale, real-world screening in primary care.

Methods: We developed the Digital Ruler of Strabismus (DRS), an automated smartphone-based application for strabismus diagnosis. Primary care physicians (PCP) recorded standardized 15-second cover test videos at a distance of 33 cm for each participant. All videos were independently assessed by the DRS and by strabismus specialists remotely, and diagnostic performance was evaluated against expert judgment under real-world conditions. In addition, PCPs completed a questionnaire regarding their perceptions of the DRS.

Results: In May 2025, a total of 18,657 participants were screened (9,794 female and 8,863 male, 3-19 years) in Fengqing, Yunnan Province. The DRS demonstrated high diagnostic performance with a sensitivity of 91.1%(87.7%-94.6%), specificity of 92.7%(92.4%-93.2%), and overall accuracy of 92.7%(92.3%-93.1%) compared with remote specialists' diagnosis. The one-time video acquisition success rate of DRS was 99% and the entire screening program was completed within 22 consecutive working days. The questionnaire indicated that over 85% of PCPs considered DRS greatly facilitated their screening work.

Conclusions: The DRS provides a practical paradigm for strabismus screening, achieving specialist-level diagnostic accuracy with consumer-grade smartphones.

It demonstrates strong potential for large-scale implementation and future contributions to public eye health.

Abstract No.: 205519

Latent Retinal Archetypes as a Potential Platform for Screening Glaucoma

First Author: Kei **SANO**

Co-Author(s): Kota **FUKAI**, Tohru **NAKAGAWA**, Tadashi **NAKANO**, Shumpei **OGAWA**, Masayuki **TATEMACHI**

Purpose: To develop a method for quantifying individualized retinal characteristics from real-world optical coherence tomography (OCT) data, where multiple conditions coexist; to characterize normative aging changes in the retina; and to evaluate the utility of this approach for screening age-related diseases such as glaucoma.

Methods: We analyzed 189,387 OCT scans from 22,494 individuals. Latent retinal archetype modeling was applied to identify 36 archetypes describing spatial patterns in the macula and peripapillary regions. Associations between archetypes and age were examined, including subgroup analyses in myopic eyes. To assess clinical applicability, we evaluated whether archetypes reflecting macular ganglion cell-inner plexiform layer (mGCIPL) alterations, including temporal raphe sign-like patterns, improved glaucoma detection. Logistic regression models incorporating age and archetype features were validated with stratified 5-fold cross-validation.

Results: Age-related archetypes demonstrated diffuse or superior macular thinning, as well as inferior mGCIPL thinning in myopic individuals. In the peripapillary region, archetypes captured age-dependent vessel-trajectory-related changes. Archetypes resembling glaucomatous mGCIPL morphologies were strongly associated with glaucoma, and a parsimonious predictive model using age and selected archetypes achieved an AUC of 0.82.

Conclusions: This framework enables quantification of individualized retinal phenotypes from heterogeneous real-world OCT data. Latent retinal archetypes capture both physiological aging and disease-specific signatures, supporting their use as screening biomarkers for glaucoma and other age-related disorders.

Abstract No.: 201657

MM-Fundus-CLIP: A Multi-Modality Fundus Foundation Model Leveraging Large Language Model and Contrastive Language-Image Pre-Training

First Author: Richul OH

Co-Author(s): Seung Woo CHOI, Areum JEONG, Myeongkyun KANG, Yoojoong KIM, Eun Kyoung LEE, Kihwang LEE, Kyu Hyung PARK, Sang Hyun PARK, Un Chul PARK, Min SAGONG, Chang Ki YOON

Purpose: This study aimed to develop MM-Fundus-CLIP, a multi-modality fundus foundation model (FM) using contrastive language-image pre-training (CLIP). We investigated its generalizability and performance using open-source datasets (color-fundus photographs [CFP], ultra-widefield fundus photographs [UWF], and optical coherence tomography [OCT]) and compared it with previously reported multi-modality FMs, including FLAIR, Eye-CLIP, and RET-CLIP. Performance was evaluated using zero-shot inference and linear probing.

Methods: A total of 2.0 million fundus images across 11 imaging modalities and 0.8 million electronic medical records (EMRs) were collected from Seoul National University Hospital (SNUH). We generated synthetic summaries from the EMRs using Qwen 2.5. After matching the laterality of images and summarized texts, a total of 1.2 million image-text pairs were included for CLIP pre-training. Our final model, MM-Fundus-CLIP, was evaluated on 11 open-source datasets (6 CFP datasets, 3 UWF datasets, and 2 OCT datasets).

Results: MM-Fundus-CLIP consistently demonstrated good zero-shot performance. On UWF datasets, it achieved AUCs of 0.910 (OUWFD) and 0.841 (TOP). In OCT datasets, MM-Fundus-CLIP outperformed EyeCLIP, showing AUCs of 0.835 (OCTDL) and 0.944 (OCTID) compared to EyeCLIP (0.776 and 0.800, respectively). Across 6 CFP datasets, MM-Fundus-CLIP generally achieved the highest average AUCs (0.809) compared to FLAIR (0.670), EyeCLIP (0.714) and RET-CLIP (0.482). After linear probing, MM-Fundus-CLIP showed the highest average AUC on internal validation set (0.944) and external validation set (0.837) compared with FLAIR (internal: 0.887, external: 0.779), RET-CLIP (internal: 0.892, external: 0.766) and RETFound (internal: 0.785, external: 0.603).

Conclusions: MM-Fundus-CLIP, integrating 1.2 million image-text pairs, demonstrated superior performance to existing models across 11 open-source datasets.

Abstract No.: 203389

MRI-Based Radiomics and Deep Learning of Thyroid Eye Disease for Treatment Response Prediction: One-Slice Strategy

First Author: Huijie ZHANG

Co-Author(s): Duo Jin XIA, Haiyang ZHANG, Huifang ZHOU

Purpose: Magnetic resonance imaging (MRI)-based radiomics analysis demonstrates considerable potential in predicting the response to intravenous glucocorticoid (IVGC) treatment in thyroid eye disease (TED). Nevertheless, the conventional approach involving manual segmentation of the entire orbital region is characterized by a substantial investment of time and resources. Hence, our study explores the feasibility of leveraging single-slice MRI as an alternative avenue for the construction of prediction models.

Methods: In this retrospective cohort investigation, we enrolled a total of 127 patients diagnosed with TED who received 4.5 g of IVGC and underwent thorough follow-up assessments. Pre-treatment orbital T2-weighted imaging was acquired for all subjects. Two distinct segmentation approaches, including multi-slice segmentation and single-slice segmentation of the extraocular muscles, were employed. Subsequently, radiomics analysis, including three distinct machine learning algorithms, alongside deep learning (DL) algorithms, was applied to construct prediction models.

Results: Among the single-slice-based models, the model utilizing the third retrobulbar slice exhibited superior performance compared to the other three slices. Furthermore, it is noteworthy that single-slice-based models demonstrated comparable performance with multi-slice-based models. (radiomics: AUC = 0.850 vs. 0.863, respectively; DL: AUC = 0.900 vs. 0.908, respectively).

Conclusions: The study yielded favorable outcomes for models constructed utilizing both single-slice and multi-slice in the prediction of IVGC response among TED patients, with performance metrics showing comparability. This suggests that single-slice segmentation may serve as a cost-effective alternative strategy suitable for clinical implementation.

Abstract No.: 201151

MoEA-Net: Modality-Incremental Expert Aggregation Network for Retinal Prognostic Prediction

First Author: Jianing WANG

Co-Author(s): Hua WANG, Xiaobing YU, Xiaodan ZHANG, Yue ZHANG

Purpose: This study addresses challenges in automated retinal prognostic prediction using multi-modal temporal images: modality imbalance (uneven sample distribution) and heterogeneous visual patterns,

which hinder knowledge integration and perception of disease progression.

Methods: The proposed MoEA-Net unifies inter-modal integration and intra-modal perception. It employs Incremental LoRA (I-LoRA) layers on a Large Language Model (LLM) backbone to progressively incorporate new modalities without retraining, mitigating modality imbalance. Complementing this, a Spatiotemporal-aware Expert (SAE) module enhances intra-modal perception: its Spatial Context Aggregation (SCA) submodule captures anatomical structures via shared self-attention and diagnostic-aware pooling, while the Temporal Difference Aggregation (TDA) submodule identifies disease progression by highlighting lesion changes through patch-wise subtraction and confidence-weighted pooling. Extracted SAE features are projected into the LLM's embedding space and fused with textual prompts for joint prediction of subretinal fluid absorption and visual recovery.

Results: MoEA-Net achieved state-of-the-art performance on a longitudinal retinal dataset with 3,102 samples, attaining 90.1% accuracy for subretinal fluid absorption and 63.2% F1-score for visual recovery. It outperformed CNNs, multimodal fusion methods, and MLLM baselines by more than 5% in key metrics. Ablation studies confirmed the necessity of the SAE module, which increased the F1-score by approximately 5.8%, and demonstrated the effectiveness of integrating incremental modalities.

Conclusions: By dynamically integrating modalities via I-LoRA and enhancing spatiotemporal perception with SAE, MoEA-Net effectively addresses data bias in retinal prognosis, enabling continual learning and superior performance for clinical decision support.

Abstract No.: 207157

Novel Teleoptometry Using World's First Wearable, Wireless Subjective Refractor With Advanced Liquid Lens Technology in Community Eye Care

First Author: Disha AGARWAL

Co-Author(s): Namratha HEGDE, Kavita KUMAAR P K, Kaushik MURALI, Venkatakrishnan S, Kousar SIDIQ

Purpose: To validate the digital wearable subjective refractor and explore the feasibility of conducting remote subjective refraction in a remote setting for community eye care.

Methods: 3nethra Specto, equipped with liquid lenses that are controlled electronically, allowing fine regulation for subjective refraction, was validated on 540 eyes, comparing accuracy, agreement, and reliability of refractive measurements to conventional subjective refraction. Remote testing was conducted in a college, vision center and outreach camp. An optometrist operated the device remotely via teleoptometry with Real-time lens adjustments, guiding

on-site operators assisting patients. Results compared to standard refraction by an experienced optometrist at each site. Data from both eyes were included in the analysis.

Results: Mean spherical values were -0.97 ± 1.80 D (Specto) and -0.93 ± 1.77 D (subjective), with closely matching cylinder values (-0.52 D), axis variability clinically acceptable. Test-retest showed minimal deviation (-0.91 ± 1.82 D). Wilcoxon Signed-Rank testing revealed no significant difference in spherical equivalents ($p > 0.05$). Differences were noted in power vector components J0 and J45 ($p < 0.05$). Additionally, the percentage of measurements with agreement within ± 0.25 diopters was high, ranging from approximately 93.7% to 96.97%, and even higher within ± 0.50 diopters (97.4% to 98.5%), suggesting variation in cylindrical axis representation. Device performance depended on stable internet, with unstable connections limiting efficiency in some locations.

Conclusions: 3nethra Specto, with portability and teleoperated design demonstrates clinical accuracy in refractive assessment, validated through both controlled and remote community screening settings. Our approach validated across a variety of clinical settings demonstrates enhanced service efficiency by allowing expert oversight without physical presence, addressing resource constraints in community eye care.

Abstract No.: 203346

Predicting Visual Field Pattern Deviation Probability Maps From Volumetric OCT Scans

First Author: Deming WANG

Co-Author(s): Fei LI, Zefeng YANG, Xiulan ZHANG

Purpose: This study aims to develop a deep learning model that predicts visual field (VF) pattern deviation probability (PDP) maps from optical coherence tomography (OCT) scans, addressing the need for efficient glaucoma detection.

Methods: Using the EVA02 framework, the model was trained on 8,908 OCT-VF pairs from 5,604 participants. The focus was on OCT scans centered at the fovea and optic nerve head (ONH). Model performance was evaluated for accuracy on both macular and ONH scans.

Results: The model achieved accuracies of 0.84 for macular scans and 0.85 for ONH scans. Clinical validation with 200 samples demonstrated strong agreement in glaucoma diagnoses between senior and junior ophthalmologists, with Cohen's κ values of 0.86 and 0.73 when comparing OCT reports with clinically obtained or generated PDP maps.

Conclusions: The findings confirm that deep learning models utilizing OCT scans can effectively predict clinically useful PDP maps. This approach may enhance glaucoma diagnosis, particularly when traditional

VF data are unavailable, thereby facilitating timely intervention for patients.

Abstract No.: 204914

Real-World Evaluation of Online Visual Acuity Self-Testing and Remote Consultation: Three Years of Implementation Experience in a Paediatric Ophthalmology Service

First Author: Fengyi LIU

Co-Author(s): Raisa AHMED, Louise ALLEN, Bethany ELLIS, Deborah MULLINGER

Purpose: Our previous validation studies indicated that automated best corrected visual acuity (BCVA) testing using the DigiVis DVA web application is comparable to standard testing. Here, we evaluate real-world experience of digital BCVA self-testing (DVA) and remote consultation (RC) in a paediatric ophthalmology service.

Methods: Electronic records of children assigned follow up RC with home DVA testing for their routine clinical care between March 2021 and October 2024 were reviewed. Demographic and clinical features, test duration and usability scores were analysed. Serial clinician-tested BCVA and DVA results were compared using Bland-Altman statistical methods. Clinical outcomes and service adaptations were assessed.

Results: 205 RCs with DVA testing were scheduled for children (aged 4-14, median 6 years). DVA results were available for 192 (93.7%) RCs, with 166 (86.5%) tests undertaken asynchronously with telephonic consultation. The mean bias between serial clinician-tested BCVA and DVA was -0.005 logMAR ($p < 0.001$) with upper and lower limits of agreement of +0.182 (95%CI: 0.169 to 0.195) and -0.173 (-0.186 to -0.160) logMAR respectively. Expedited follow-up face-to-face consultations (f2fC) were arranged for 13 families unwilling or unable to self-test, 5 children with poor concentration and 9 with self-detected deterioration of BCVA. Informative DVA results were available for 187 (91.2%) encounters. 116 (81.7%) of 142 families voluntarily completing Likert scoring rated the application good/excellent.

Conclusions: In this real-world evaluation, 91.2% of offered DVA tests were informative and contributed to clinical decision-making. DVA correctly identified unexpected deterioration in 9 children supporting the utility of this innovative service model.

Abstract No.: 201623

Retinal Parameter Analysis for Cardiovascular and Cerebrovascular Diseases (CVDs) Risk Prediction in Diabetes: A Machine Learning Approach

First Author: Huanyan CHEN

Purpose: To evaluate the predictive potential for cardiovascular and cerebrovascular diseases (CVDs) risk stratification of retinal parameters extracted from fundus photos using automated image analysis, combined with clinical features.

Methods: Fundus images were processed using the Automorph to extract 64 quantitative retinal metrics, covering optic disc morphology, cup-to-disc ratios, vessel density, fractal dimensions, tortuosity indices, and arterial/venous measurements across global and zonal (B and C) regions. These were combined with 18 clinical and demographic variables, resulting in 84 tabular predictors. A range of machine learning classifiers were implemented—including Logistic Regression, Random Forest, CatBoost, LightGBM, XGBoost, Naïve Bayes and Decision Tree. Model performance was evaluated using the area under the receiver operating characteristic curve (AUROC), accuracy, recall, precision, and F1 score.

Results: Among the tested models, the top-performing one—Random Forest Classifier—achieved the AUC of 0.7678, surpassing traditional classifiers. Analysis of feature importance indicated that disc width, average vein width, tortuosity density, squared curvature tortuosity in zone C, and Knudtson-calculated AVR in zone B were the most influential predictors, outperforming most individual clinical risk factors. Moreover, combining retinal vascular metrics with demographic and biochemical variables further improved the AUROC compared with models based solely on clinical data.

Conclusions: AI-enabled quantitative retinal analysis combining with clinical features enhances prediction of CVDs risk in diabetes. This approach demonstrates that non-invasive, image-based risk stratification is feasible and holds potential for screening and precision medicine to facilitate earlier detection and intervention. .

Abstract No.: 202300

SCAR-AI: Smartphone-Based Community Assessment of Corneal Opacities and Referral for Keratoplasty Using Artificial Intelligence

First Author: Tavish GUPTA

Co-Author(s): Noopur GUPTA, Vivek GUPTA, Neiwete LOMI, Radhika TANDON, Jeewan Singh TITIYAL, M VANATHI, Praveen VASHIST

Purpose: There is a large burden of corneal blindness, most of which is avoidable. Our purpose was to create an Artificial Intelligence (AI) based smartphone

platform that can detect corneal opacities from smartphone images and identify patients requiring corneal transplantation, and to validate it in a community setting.

Methods: This was a population-based cross-sectional observational study to create the AI application, in which 2000 images of the cornea (1000 corneal opacities and 1000 normal) were used for training. The images were pre-processed and used to train an AI model. Once trained, the model was integrated into an Android application along with a questionnaire and tested in a population-based cross-sectional survey of 4954 participants to evaluate the applicability of the platform.

Results: The trained model achieved an accuracy of 92.25% with sensitivity, specificity, PPV and NPV above 90% during internal validation. In the field, the model demonstrated an accuracy of 94.59% in identifying corneal opacities, with a sensitivity and PPV of 72.4% (95% CI - 52.8% to 87.3%) and specificity and NPV of 97% (95% CI - 94.2% to 98.7%). Cohen's Kappa was determined to be 0.6942, indicating a significant agreement of the AI model diagnosis with that of the ophthalmologist. There was excellent correlation between the model and the ophthalmologist for determining the need for referral.

Conclusions: We developed a novel smartphone image-based AI system, which is widely accessible and scalable and can be used by healthcare workers at the community level to connect underserved populations to sight-restoring interventions.

Abstract No.: 200459

Smartphone Cataract Detection From a Selfie: Autonomous Eye Screening for Every Home

First Author: Pradipta **CHOWDHURY**

Co-Author(s): Prakash Kumar **CHOWDHURY**, Anureet **KAUR**

Purpose: To develop a clinical-grade Artificial Intelligence (AI) model which can detect and stage cataracts from selfies on smartphones.

Methods: This prospective study included 10,236 eyes clinically graded via slit-lamp as normal, immature and mature cataract. Anterior segment images were captured using front-facing smartphones under standardised lighting and preprocessed using CLAHE, HSV conversion, and red-channel extraction. YOLOv8 model was used to localise the pupil. A hybrid AI model combined Swin Transformer features with tabular metrics (brightness, red reflex percentage and entropy) for dual-output heads: categorical staging and continuous opacity scoring (0-5 scale). Adults ≥ 18 with clear, clinically graded selfies were included; blurry/obscured pupils or ocular pathology without cataract were excluded.

Results: The model produced an overall accuracy of 96.0%, achieving 97.1% sensitivity (detecting cataract images) and 94.3% specificity (ruling out non-cataract images). Stage-wise classification displayed a strong correlation with clinical grading ($r = 0.88$, $p < 0.001$). The mean absolute error (MAE) for continuous opacity scoring was 0.21 with R^2 of 0.85. A reliability score of 99.2% was achieved with YOLOv8 for pupil localisation.

Conclusions: This model allows accurate detection and staging of cataracts, simply from smartphone selfies - no slit-lamp, attachments, or training needed. The AI guides users to capture a selfie, detects cataracts instantly, and directs them to clinics. It enables accessible, offline cataract screening from homes to even the most remote locations.

Abstract No.: 201941

StrabNet-CQ: An Integrated Deep Learning Framework for Automated Strabismus Classification and Quantification Using Ocular Landmark Detection

First Author: Savleen **KAUR**

Co-Author(s): Akshat **ARYA**, Debabrata **GHOSH**, Jaspreet **SUKHIJA**

Purpose: Strabismus is a common ocular misalignment that can impair binocular vision if untreated.

Conventional diagnosis and treatment rely on clinical prism diopter (PD) readings, which quantify deviation along with base direction. However, these values are coarse, manual, and subject to inter-clinician variability. We present the development and results of StrabNet-CQ (Strabismus Network for Classification and Quantification), a newly developed deep learning-based framework for automated strabismus classification and quantification.

Methods: Six hundred eye images, with and without strabismus, were analyzed by the model. A YOLOv8 model performs classification into normal and abnormal as well as subsequent classification (normal, esotropia, exotropia, hypertropia, hypotropia), with refined classification via ResNet101 on segmented eye regions from the images. Ocular landmarks are detected using ResNet18, from which horizontal and vertical deviation indices and angular deviation are computed.

Results: The system achieved 94% accuracy in strabismus detection and 90% in strabismus classification, with high sensitivity for normal (0.91–1.00), esotropia (0.89), and hypotropia (0.90). The derived parameters show a good correlation with manual PD values ($r=0.733$) that can be utilized for the quantification of strabismus.

Conclusions: StrabNet-CQ supports objective diagnosis and holds promise for deployment in clinical settings for strabismus detection as well as quantification.

Abstract No.: 208282

The Application of Artificial Intelligence in Epiretinal Membrane From Detection to Prognosis Prediction

First Author: Muxin **XU**

Co-Author(s): Shirong **CHEN**, Yuqiang **HUANG**, Jianwei **LIN**

Purpose: Epiretinal membrane (ERM) is a prevalent vitreoretinal interface disorder characterized by fibro-cellular proliferation on the inner retinal surface. The prevalence increases markedly with age, and progressive membrane contraction distorts retinal architecture, producing metamorphopsia and irreversible visual impairment thereby significantly impairing patients' quality of life. This highlights the need for more accurate and efficient diagnostic and therapeutic strategies. Artificial intelligence (AI) has emerged as a promising tool to address such challenges. This review summarizes and evaluates recent studies on the applications of AI in ERM management, identifying current limitations and future research directions.

Methods: A comprehensive literature search was conducted in PubMed, Web of Science, Embase, and Cochrane Library databases, focusing on studies related to AI and ERM published over the past decade.

Results: The findings indicate that while research on treatment and prognosis prediction remains limited, and new technologies are expected in image processing, current AI models demonstrate substantial potential in the ERM management, especially in detection and diagnosis. Nonetheless, current evidence is constrained by challenges such as single-center design, limited external validation across devices or ethnicities, insufficient multimodal imaging, and a lack of health-economic or workflow integration data.

Conclusions: Future multicenter prospective studies, federated learning platforms, publicly annotated imaging dataset and cost-effectiveness analyses are warranted to develop robust, generalizable models that can be seamlessly integrated into clinical workflows, substantially optimizing ERM management and delivering tangible benefits to both patients and clinical practice.

Abstract No.: 207335

Validation of Anterior Curvature Metrics Measured by a Handheld Topography Device in Normal Eyes and Keratoconic Eyes

First Author: Neelima **BALAKRISHNAN**

Co-Author(s): Rashmi **DESHMUKH**, Mohit **PUSHPWAN**

Purpose: The purpose of this study was to evaluate the reliability of keratometric values measured by a handheld, placido-based topography device in healthy and keratoconic eyes by comparing it to the values

measured by Scheimpflug based device (Pentacam HR) for the same patients.

Methods: The InstaKC is a placido-disc-based, hand-held, portable, smart-phone-based, topography device which captures Sim K1, Sim K2, average K, axial and tangential maps. This prospective, observational study comprised of a cohort of 300 healthy eyes, who had presented to the refractive clinic for laser vision correction, and 298 eyes of patients with keratoconus, who had not undergone any previous ocular surgeries. All recruited subjects underwent imaging with the hand-held topography device and the topography of these eyes was repeated on the Pentacam HR device. The keratometry values of flat K, steep K, mean simulated keratometry and astigmatism power measured were compared to assess reliability.

Results: A total of 598 eyes of 299 patients with valid measurements for all parameters were available for analysis. In healthy eyes, there was no statistically significant difference noted in steep K, mean K and astigmatism between the hand-held topographer and Pentacam. In eyes with keratoconus, the mean k1 and k2 measured by the handheld device were 45.8 and 49.9, respectively, and those measured by Pentacam were 47.02 and 51.2, respectively. There was no significant difference in the astigmatism measured between both the devices in both normal and keratoconic eyes.

Conclusions: The handheld topography device provides reliable measurements for the metrics assessed in healthy and keratoconic eyes.

Abstract No.: 207087

A Prospective Study of Whole Genome Sequencing (WGS) Impacting Diagnostic Outcome of Genetic Eye Disorders

First Author: Tsz Ha Randa **LI**

Co-Author(s): Nicola **CRONBACH**, Mariya **MOOSAJEE**, Ana **RODRIGUEZ MARTINEZ**, Elena **SCHIFF**, Meei Fang **WONG**

Purpose: To review molecular diagnostic yields after the introduction of WGS into routine use in our Ocular Genetics Service including both children and adults seen at Moorfields Eye Hospital (MEH).

Methods: A total of 91 consecutive families who presented to our ocular genetics service over a 12-month period who underwent whole genome sequencing (WGS) with panels for (1) bilateral congenital or childhood onset cataract (R31) (2) retinal

disorders (R32) and (3) structural eye disease (R36) were recruited and followed up prospectively to review their genetic results. 49 of the probands were males and 42 were females.

Results: For the period from 1 October 2022 to 30 September 2023, the overall molecular diagnostic rate was 33.0%. The diagnostic yield for cataract was 14.2%, retinal disorders 45.7% and structural eye diseases 31.4%. The introduction of WGS has improved the overall rates of diagnosis however there remains a great gap between that for non-retinal developmental eye disorders compared with inherited retinal diseases.

Conclusions: To further improve overall diagnostic yields and narrow the difference for non-retinal developmental eye disorders, we need to improve our knowledge about the genes involved in eye development, raise awareness via training and widen access to appropriate genetic testing to all those involved in their management.

Abstract No.: 205321

Building a Framework for Public and Patient Involvement (PPI) in Dry Eye Disease Research

First Author: Helena Maria **PRIOR FILIPE**

Co-Author(s): Tess **AMES**, Laurence **FITZHENRY**, Evan **MATHEWS**, Alison **REYNOLDS**

Purpose: Patient and Public Involvement (PPI) remains limited in preclinical vision research, which may create a gap between laboratory outcomes and patient needs. Using Dry Eye Disease (DED) as a case study, this project aimed to strengthen collaboration between patients, caregivers, clinicians, researchers, and pharmaceutical stakeholders, and to develop a benchmark framework for integrating PPI in preclinical ocular therapeutics.

Methods: An international team (South East Technological University, University College Dublin, Instituto de Retina de Lisboa, Hospital de Egas Moniz, Egas Moniz Center for Interdisciplinary Research, and University of Warwick) conducted patient semi-structured interviews, surveys, social media listening, one “world-café” encounter (Lisbon) and semi-guided round-table discussions. These open, semi-structured conversations brought together patients, clinicians, pharmaceutical representatives, and preclinical researchers. Insights were analyzed to capture patient needs, research objectives, and clinical priorities, particularly regarding DED severity and impact on daily life.

Results: PPI activities highlighted the substantial burden of DED on quality of life and identified unmet treatment needs. Patient insights redirected researcher perspectives, encouraging alignment of laboratory work with outcomes meaningful to patients. Collaborative forums fostered mutual understanding

across diverse stakeholders and demonstrated the value of embedding PPI throughout the research process.

Conclusions: Our ongoing framework highlights how PPI can be meaningfully integrated into preclinical vision research. Aligning laboratory priorities with lived patient experiences can accelerate the development of patient-centred, longer-lasting treatments for DED and provide a transferable model for other ocular conditions.

Abstract No.: 202659

Correlation Between Expression of PPAR- γ M-RNA in Macrophages, With TGF- β 1 M-RNA and IL-1 β M-RNA in Hyperglycemic Model Rat Wounds

First Author: Riani **ERNA**

Co-Author(s): Shanti Fitrianti **BOESOERIE**, Wijana **HASANSULAMA**, Arief Sulaksan **KARTASASMITA**

Purpose: PPAR- γ expressed by macrophages is very important in the wound healing process and regulates the inflammatory phenotype. However, in conditions of acute or chronic hyperglycaemia, PPAR- γ activity may be inhibited, affecting TGF- β 1 and IL-1 β . This study aims to analyse the relationship between macrophage PPAR- γ mRNA expression and TGF- β 1 mRNA and IL-1 β mRNA, as well as blood glucose levels in skin wounds of hyperglycaemic rat models.

Methods: Experimental research using Wistar rats as test animals was conducted at the Central Laboratory and the Physiology Division Laboratory of the Department of Basic Medical Sciences, Faculty of Medicine, Padjadjaran University from May 2023 to October 2023. The research sample consisted of 30 rats, divided into 15 hyperglycemia model rats and 15 control rats.

Results: This study shows that there are significant differences in PPAR- γ mRNA expression between control rats and hyperglycemic rats on day 5 ($p = 0.011$) and day 7 ($p = 0.000$); IL-1 β mRNA expression on day 3 ($p = 0.015$), day 5 ($p = 0.015$) and day 7 ($p = 0.001$). However, there was no difference in TGF- β 1 mRNA expression ($p > 0.05$) and a difference in blood glucose levels was found on all days between control and hyperglycemic rats ($p < 0.000$). This study also found a strong negative correlation between PPAR- γ mRNA expression and TGF- β 1 on day 5 ($r = -0.728$; $p = 0.002$). A very strong negative correlation was found between PPAR- γ mRNA expression and blood glucose on day 7 ($r = -0.833$; $p = 0.000$); however, there was no correlation between PPAR- γ mRNA expression and IL-1 β on all days. The significant cutoff points for PPAR- γ mRNA expression to distinguish between control and hyperglycemic conditions were 23.11 (day 5) and 23.49 (day 7), with blood glucose levels capable of causing changes in PPAR γ mRNA expression being 314.6 mg/dL on day 5 and 329.3 mg/dL on day 7.

Conclusions: The blood glucose cut-off point that can cause changes in the cycling threshold of PPAR- γ mRNA expression is 314.6 mg/dL on day 5 and 329.3 mg/dL on day 7.

Abstract No.: 203740

Embedding Feedback Loops to Strengthen Ophthalmology Training: Insights From Five Years of Trainee and Supervisor Surveys in Australia and New Zealand

First Author: Santosh KHANAL

Co-Author(s): Victoria BAKER-SMITH, Justin MORA

Purpose: To evaluate how structured feedback drives systemic improvement in ophthalmology training in Australia and New Zealand, using five years of trainee and supervisor survey data.

Methods: Annual surveys (2020 to 2024) were administered to all trainees (N=158-185/year) and supervisors (~650/year) across eight training networks covering Australia and New Zealand, encompassing 68 sites and 178 training posts. Response rates were 45 to 60 percent. Surveys included Likert scale and free text questions across clinical and surgical supervision, examinations, workplace-based assessments, teaching, wellbeing, and workplace culture. Quantitative data were analysed longitudinally and qualitative responses underwent thematic analysis to identify systemic issues and guide reform.

Results: Overall satisfaction remained high, but declines were noted in adequacy of case discussion time (79.2% in 2021 to 52.3% in 2024), posting duration satisfaction (65.6% in 2020 to 40.8% in 2024), and one-to-one surgical supervision (49.1% in 2020 to 43.2% in 2024). Trainees and supervisors highlighted structured feedback as essential but inconsistently delivered. Survey-driven reforms included psychometric adjustment of examination pass marks, redesign of workplace-based assessments (40.0% in 2023 $\rightarrow$ 76.5% in 2024 approval), and redevelopment of the surgical logbook to support reflective learning. Free text insights highlighted bullying issues, inequities in training opportunities and exam misalignment, prompting targeted policy and curricula changes.

Conclusions: Embedding structured feedback across training networks enabled measurable reforms in ophthalmology training. Feedback shifted from monitoring to a strategic driver of change, improving supervision, assessment validity and equity. This framework offers a model for responsive and future-ready training programs internationally.

Abstract No.: 206432

Gut Dysbiosis Exacerbates Choroidal Neovascularization via the CYR61-FGF2 Angiogenic Pathway, Regulated by lncRNA NEAT1_2-Driven RBM14 Recruitment to Paraspeckles

First Author: Jia-qi PAN

Co-Author(s): Jian-huan CHEN

Purpose: Emerging evidence links gut dysbiosis to vascular dysfunction in eye diseases, with the role of long non-coding RNAs (lncRNAs) still unclear. Our study revealed how lncRNA NEAT1 and its long NEAT1_2 isoform were involved in gut dysbiosis-exacerbated CNV.

Methods: Comparative epitranscriptome and single-cell RNA sequencing analysis were performed on retinas from AMD patients and laser-induced CNV mice. Gut dysbiosis was induced in C57BL/6 mice with 2×10^8 CFU/day Escherichia coli via gavage for 1 week, plus laser-induced CNV on day 5, followed by subsequent in vivo and in vitro experiments.

Results: NEAT1 and its NEAT1_2 isoform were identified as the most upregulated retinal lncRNA in both AMD patients and CNV mice. Moreover, gut dysbiosis promoted CNV and retinal expression of NEAT1_2, cysteine-rich angiogenic inducer 61 (CYR61), and fibroblast growth factor 2 (FGF2), accompanied by a compromised intestinal barrier and elevated levels of systemic LPS and inflammation. NEAT1_2 was essential for CNV, as confirmed by intravitreal injection of antisense oligonucleotide in mice and siRNA knockdown in human retinal microvascular endothelial cells. Fluorescence in situ hybridization and chromatin immunoprecipitation showed that NEAT1_2 recruited RBM14 protein from the CYR61 promoter to paraspeckles, thereby relieving RBM14 transcriptional suppression and enhancing CYR61 expression and paracrine secretion, crucial for endothelial FGF2 production.

Conclusions: Our findings reveal a conserved role of NEAT1_2/paraspeckle-RBM14 in regulating the CYR61-FGF2 angiogenic pathway during gut dysbiosis.

Abstract No.: 209431

KLF10-IN-1 Attenuates Retinal Pigment Epithelial Cell Apoptosis and Experimental Diabetic Retinopathy via the KLF10/PERK/eIF2 α /ATF4/CHOP Pathway

First Author: Weiwen HU

Co-Author(s): Qiong ZHOU

Purpose: To investigate the role of Krüppel-like factor 10 (KLF10) and its inhibitor, KLF10-IN-1, in regulating high-glucose hypoxia-induced RPE cell apoptosis and to explore their potential implications in diabetic retinopathy (DR).

Methods: A DR mice model was established using a high-fat, high-glucose diet combined with streptozotocin. An RPE cell model of high-glucose hypoxia injury was created under high-glucose (30 mM) and cobalt chloride (200 μ M) conditions. KLF10 expression, apoptosis, and endoplasmic reticulum (ER) stress levels were assessed. KLF10 expression was regulated with small interfering RNA and overexpression plasmids. Dual luciferase reporter assays evaluated KLF10's regulation of PERK. The PERK pathway was activated with CCT020312 and inhibited with GSK2606414 in rescue experiments. The protective effects of KLF10-IN-1 were validated in vitro and in vivo.

Results: KLF10 was highly expressed in RPE cells of DR mice. After 48 hours of high-glucose hypoxia treatment, hypoxia, inflammation, ER stress, and apoptosis were significantly exacerbated, accompanied by upregulation of KLF10. KLF10 knockdown suppressed apoptosis and ER stress, while overexpression had the opposite effect. Western blotting confirmed KLF10's regulation of PERK phosphorylation, and dual luciferase assays showed KLF10 transcriptionally activates PERK. KLF10 mediated apoptosis through the PERK/eIF2 α /ATF4/CHOP pathway. Inhibition of this pathway with KLF10-IN-1 reduced high-glucose hypoxia-induced damage in RPE cells and improved retinal damage in diabetic mice.

Conclusions: KLF10 is upregulated in DR mice and high-glucose hypoxia RPE models. It modulates apoptosis and ER stress through the PERK/eIF2 α /ATF4/CHOP pathway. KLF10-IN-1 offers protective effects, suggesting its potential for early intervention in DR.

Abstract No.: 201707

Netarsudil 0.02% (Rho-Kinase Inhibitor) Administration in Preventing Retinal Ganglion Cell Death Caused by Ethambutol-Induced Toxic Optic Neuropathy Among Wistar Rats Model: An Animal Study

First Author: Raphael **GUMAFELIX**

Co-Author(s): Marianne **CARABEO**

Purpose: The purpose of the study was to evaluate the effect of Netarsudil 0.02% eye drops on damaged RGCs in an ETON-induced rat model by assessing RGC layer thickness and density.

Methods: This experimental study involved 15 male Wistar rats, randomized into three groups: negative control (sterile distilled water), positive control (ethambutol 35 mg/kg/day with normal saline eye drops daily), and the treatment arm (ethambutol 35 mg/kg/day with netarsudil 0.02% eye drops daily). After 30 days, all rats underwent bilateral enucleation for histopathologic analysis.

Results: Histopathology revealed that the treatment group exhibited significantly lower RGC layer thickness

and higher RGC density compared to the positive control group ($p < 0.001$). Ethambutol administration resulted in RGC damage, characterized by cytoplasmic vacuolization and structural disruption—changes that were notably attenuated in rats receiving topical Netarsudil. These findings suggest that ROCK inhibition via Netarsudil 0.02% eye drops may offer a protective effect against ethambutol-induced damage to retinal ganglion cells.

Conclusions: The reduction in histopathological abnormalities indicates its potential as an adjunctive therapy for ETON, although further studies are necessary to validate its efficacy and elucidate the underlying mechanisms.

Abstract No.: 210237

Professional Quality Training and Competency Enhancement of Ophthalmic Nurses Based on the ORBIS STEER Platform

First Author: Liu **CUIHONG**

Co-Author(s): Hu **BING**, Liu **XIN**

Purpose: To improve the professional quality and ability of ophthalmic nurses with scientific teaching methods, based on the ORBIS STEER project platform.

Methods: Through participating in ORBIS STEER project, we trained 29 ophthalmic nurses in county hospitals. We adopt the advanced teaching methods of ORBIS, such as PBL teaching method, problem list, failure model, hand-held teaching, etc. on the basis of completing the teaching syllabus, we have carried out targeted theoretical and skill training according to the needs of advanced nurses, improving the teaching quality and learning effect; At the same time, the above methods were applied to the eye standardized training of nurses in our hospital, and the special training of flipped classroom, integrated medical care teaching ward round, «clinical special disease knowledge + operation room cooperation + symptom care + nursing routine» was carried out. The medical treatment, nursing, and operation were integrated to improve the overall understanding of nurses on eye diseases, and the nursing specialty was cultivated for the development of an integrated medical care mode in the hospital talents.

Results: Through the development of the STEER project, the effect of “To-Teach-Is-To-Learn” has been significantly reflected. Our hospital has not only established a standardized management process for advanced nurses, with high satisfaction of advanced nurses, and successfully completed the STEER training task, but also significantly improved the teaching level and professional quality of nurses, the comprehensive ability, and academic influence of the nursing team. The integration mode of nursing and medical team has been successfully carried out, and the sense of gain and achievement of nurses has been significantly improved,

and the patient satisfaction is clear significantly improved.

Conclusions: The STEER project has an advanced training concept, scientific teaching methods, and is suitable for adults' learning and education. It can promote the standardization of ophthalmic nurses' training, the establishment of nurses' clinical comprehensive thinking ability, the improvement of nurses' comprehensive quality and specialized nursing ability, and establish standards and criteria for the cultivation of ophthalmic specialized nurses.

Abstract No.: 206398

Protective Role of SIRT1 Activation Against Retinal Injury Caused by Polystyrene Micro/Nanoplastics Exposure

First Author: Junfeng **PIAO**

Co-Author(s): Yujiao **JIN**, Woojin **KIM**, Ria **KANG**, Dong Hyun **KIM**, Jong Suk **SONG**

Purpose: Plastic particles are persistent environmental pollutants that can accumulate in ocular tissues and potentially contribute to retinal damage. Sirtuin 1 (SIRT1), a key regulator of oxidative stress and cellular senescence, may play a protective role against plastic-induced retinal injury, but its role remains unclear.

Methods: In this study, human retinal pigment epithelial (RPE) cells and rat retinas were directly exposed to polystyrene microplastics (PS-MPs, 2 µm) and nanoplastics (PS-NPs, 50 nm). Cell viability, intracellular reactive oxygen species (ROS), SIRT1 expression, antioxidant enzyme levels (SOD1, SOD2, catalase), and senescence were assessed. In vivo, rats received intravitreal injections of plastic particles, with or without the SIRT1 activator SRT1720.

Results: Results showed that PS-MPs and PS-NPs reduced RPE cell viability in a dose- and time-dependent manner, suppressed SIRT1 and antioxidant enzymes, and increased ROS and senescence. PS-NPs induced stronger ROS and senescence than PS-MPs in vitro. Co-treatment with SRT1720 restored SIRT1 expression, improved antioxidant responses, and attenuated ROS and senescence. In vivo, both particle types induced retinal changes similar to those observed in cell experiments. However, there was no significant toxicity differences between MPs and NPs.

Conclusions: In conclusion, PS-MPs/NPs promote oxidative stress and senescence in RPE cells and retinal tissue via downregulation of SIRT1 and antioxidant defenses, while SRT1720 provides protective effects. These findings SIRT1 as a potential therapeutic target for plastic-induced retinal injury.

Abstract No.: 206379

Sema4D Knockout Attenuates Choroidal Neovascularization by Inhibiting M2 Macrophage Polarization via Regulation of the RhoA/ROCK Pathway

First Author: Kaixuan **CUI**

Co-Author(s): Guoming **ZHANG**

Purpose: The aim of this study was to elucidate the role of Sema4D in the pathogenesis of senescence-associated choroidal neovascularization (CNV) and to explore its underlying mechanisms.

Methods: In this study, we utilized a model of laser-induced CNV in both young (3 months old) and old (18 months old) mice, including those with or without Sema4D knockout. The expression and localization of Sema4D in CNV were assessed using PCR, Western blot and immunostaining. Subsequently, the morphological and imaging examinations were employed to evaluate the size of CNV and vascular leakage. Finally, the expression of M2 markers, senescence-related markers, and molecules involved in the RhoA/ROCK pathway was detected.

Results: We found that Sema4D was predominantly expressed in macrophages within CNV lesions, and both the mRNA and protein levels of Sema4D progressively increased following laser photocoagulation, a trend more pronounced in old mice. Moreover, Sema4D knockout markedly inhibited M2 polarization in senescent macrophages and reduced the size and leakage of CNV, particularly in aged mice. Mechanistically, aging was found to upregulate RhoA/ROCK signaling, and knockout of Sema4D effectively suppressed the activation of this pathway, with more significant effects observed in aged mice.

Conclusions: Our findings revealed that the deletion of Sema4D markedly inhibited M2 macrophage polarization through the suppression of the RhoA/ROCK pathway, ultimately leading to the attenuation of senescence-associated CNV. These data indicate that targeting Sema4D could offer a promising approach for gene editing therapy in patients with neovascular age-related macular degeneration.

Abstract No.: 206250

Six Sigma Quality Analysis of 1,500 Cataract Surgeries Using a 33-Point Surgical Safety Checklist

First Author: Amod **NAYAK**

Purpose: Surgical safety checklists enhance consistency and reduce preventable errors in ophthalmic surgery. This study evaluates compliance and quality in a high-volume cataract surgery setting using Six Sigma methodology.

Methods: A retrospective audit of 1,500 consecutive cataract surgeries was conducted over 9 months.

Each surgery was evaluated across 33 checklist steps covering preoperative (sign-in), intraoperative (time-out), and postoperative (sign-out) processes. A total of 49,500 opportunities for error (1,500 surgeries × 33 steps) were analysed. Errors were documented, categorized, and analysed to calculate the Defects Per Million Opportunities (DPMO) and Sigma level

Results: 109 errors were identified (DPMO ≈ 2,202), corresponding to a process performance of ~4.35 Sigma. Most errors involved documentation or process delays, with no critical adverse events or wrong-site surgeries reported.

Conclusions: High compliance with the 33-step checklist resulted in a high-reliability process, with Six Sigma analysis confirming a 4+ Sigma performance level. Focused training and monitoring can drive further improvement toward 5 Sigma and enhance surgical safety.

Abstract No.: 203251

Study on the Molecular Mechanism of MAMs-Mediated Dysfunction in Trabecular Meshwork Cells in Primary Open-Angle Glaucoma

First Author: Fang **CHAI**

Co-Author(s): Xiquan **ZHAO**

Purpose: To investigate the structural and functional alterations of Mitochondria-Associated ER Membranes (MAMs) in trabecular meshwork (TM) cells under pathological conditions, elucidate the key signaling pathways involved in MAMs dysfunction in TM cells, and evaluate the regulatory effects of targeted inhibitors on MAMs function in TM cells.

Methods: An endoplasmic reticulum (ER) stress model in human trabecular meshwork (HTM) cells (induced by tunicamycin) was established, with pre-treatment intervention using the inhibitor 4-PBA. The following analyses were conducted: (1) Transmission electron microscopy (TEM) to analyze MAMs structural characteristics; (2) qRT-PCR/Western blot to detect the expression of key molecules in the GRP78, IP3R-VDAC1, and PERK-eIF2 α -ATF4 pathways; (3) Confocal microscopy combined with flow cytometry to monitor intracellular Ca²⁺ oscillations and ROS generation.

Results: In the HTM ER stress injury model, the length of MAMs domains increased and the distance between the ER and mitochondria decreased post-injury. The expression of GRP78-IP3R-VDAC1 and PERK-eIF2 α -ATF4 was elevated, intracellular Ca²⁺ concentration increased, and ROS expression enhanced. Intervention with 4-PBA effectively reversed these abnormalities. Compared to HTM cells, GTM3 cells showed basal high expression of PERK and IP3R-VDAC1. Under stress stimulation, the expression levels of this signaling axis were synergistically upregulated, accompanied by a significant increase in ROS generation and

higher cell apoptosis rates. PERK overexpression led to upregulated expression of GRP78-IP3R-VDAC1, increased intracellular Ca²⁺ concentration, decreased mitochondrial membrane potential, and increased cell apoptosis.

Conclusions: Oxidative/ER stress disrupts the stability of the IP3R-VDAC1 complex, leading to an imbalance in MAMs calcium homeostasis, thereby inducing apoptosis in trabecular meshwork cells.

Abstract No.: 202696

Transcriptional Responses in a Mouse Model of Silicone Wire Embolization Induced Acute Retinal Artery Ischemia and Reperfusion

First Author: Xuan **XIAO**

Co-Author(s): Ting **CHEN**, Jiaqing **FENG**, Ying **LI**, Yuwei **WAN**, Chuansen **WANG**, Yuedan **WANG**, Anhuai **YANG**

Purpose: To develop a novel mouse model that accurately mimics acute retinal artery occlusion (RAO) and to investigate the transcriptional and cellular changes during ischemia and reperfusion.

Methods: A unilateral pterygopalatine ophthalmic artery occlusion (UPOAO) model was established using silicone wire embolization and carotid artery ligation. Retinal structure, function, and cellular changes were assessed via immunofluorescence, OCT, ERG, and transcriptomic analysis at various ischemia (30/60 min) and reperfusion (0/3/7 days) time points.

Results: Sixty minutes of ischemia caused significant loss of retinal ganglion cells, inner retinal thinning, and reduced ERG b-wave and oscillatory potentials. Transcriptome analysis revealed distinct phases: immune cell migration during ischemia, oxidative stress at 3 days reperfusion, and immune inflammation at 7 days. Increased microglial activation and leukocyte infiltration were observed. UPOAO showed unique lipid and steroid metabolism pathways compared to other models.

Conclusions: The UPOAO model effectively simulates RAO and highlights key pathophysiological mechanisms, offering a valuable tool for studying ischemic retinopathy and screening neuroprotective therapies.

Abstract No.: 202181

Validation of SiEyeVR: Virtual Reality for Physical Examination Training in Ophthalmology

First Author: Kiatthida **HOKIERTI**

Co-Author(s): Sutasinee **BOONSOPON**, Pitipol **CHOOPONG**, Somkiat **FAKMEE**, Sarayoot **PANGARM**, Piangporn **SAKSIRIWUTTHO**, Wasawat **SERMSRIPONG**, Sophita **SUWUTTHO**

Purpose: To validate SiEyeVR, a Virtual Reality (VR) prototype designed to train ophthalmic examination

skills, specifically the detection of Relative Afferent Pupillary Defect (RAPD) and measurement of visual acuity (VA).

Methods: This randomized prospective study was conducted in two phases following the development of SiEyeVR. In Phase 1, a structured rubric was created to assess performance both on real patients and in VR. Twenty participants (10 experts and 10 novice medical students) were video-recorded performing RAPD and VA assessments. Experts provided Likert-scale ratings, converted into Content Validity Index (CVI) scores, while three blinded ophthalmologists independently scored performance for validity and reliability analyses. In Phase 2, the finalized rubric was applied to 70 participants (10 experts and 60 novices). Novices were randomized to either a non-VR group, which received traditional instruction and peer practice, or a VR group trained with SiEyeVR. All novices completed pretests on real patients, followed by posttests on real patients (both groups) and in VR (VR group).

Results: In Phase 1, expert Likert-scale ratings indicated strong content validity, with mean CVI values of 0.94 (SD 0.08). Inter-rater reliability of the rubric was high, with intraclass correlation coefficients (ICC) ranging from 0.87 to 0.99. Experts scored significantly higher than novices across most tasks.

Conclusions: Phase 1 findings demonstrate that SiEyeVR possesses strong content validity and reliable inter-rater agreement in rubric, supporting its use as a valid and reliable assessment tool. Phase 2 analyses will further evaluate its effectiveness for training novices and the potential of VR as an alternative to traditional methods.

Abstract No.: 206376

miR-15a-5p Inhibits Angiogenesis and Suppresses Inflammation and Fibrosis via Targeting VEGF and smad2 in Ocular Neovascularization

First Author: Hui **ZHANG**

Co-Author(s): Xiaorong **LI**, Xinyue **YU**, Xiaomin **ZHANG**

Purpose: We aim to determine the therapeutic role of miR-15a-5p on fundus neovascularization and reveal its advantages in comparison to anti-VEGF therapy.

Methods: Elevated miR-15a-5p was found in plasma, plasma sEVs, and vitreous of diabetic (DM, NPDR, PDR) patients. In OIR and CNV models, intravitreal miR-15a-5p potentially inhibited pathological neovascularization, with efficacy comparable to anti-VEGF. It also improved retinal structure (OCT) and function (ERG), and reduced inflammatory and pro-fibrotic markers. Systemic safety was confirmed. Mir-15a-5p KO mice exhibited exacerbated neovascularization. In vitro, miR-15a-5p inhibited HRMEC tube formation, TGF- β -induced EndMT in RPE cells, and inflammatory activation in

rMC-1 cells. It directly targeted smad2 and VEGF, as shown by dual-luciferase assays, WB, and PCR.

Results: MiR-15a-5p was elevated in NPDR and PDR patients' plasma sEVs and vitreous, but not in plasma. In OIR and CNV models, miR-15a-5p inhibited neovascularization similarly to anti-VEGF treatment, but improved retinal non-perfusion area recovery better. Compared to anti-VEGF, miR-15a-5p reduced Müller cell activation, decreased retinal inflammation, promoted vascular attachment to astrocytes, and facilitated reconstruction. MiR-15a-5p knockout mice showed enhanced neovascularization, which could be reversed by miR-15a-5p injection. Additionally, miR-15a-5p improved retinal structure/function and was safer than anti-VEGF in growing mice. MiR-15a-5p inhibited TGF β -induced endothelial cell proliferation/transition and suppressed Müller cell activation and VEGF secretion. Dual-luciferase assays confirmed miR-15a-5p directly down-regulated VEGF and smad2.

Conclusions: MiR-15a-5p decreases retinal neovascularization, supports normal vascular growth, reduces inflammation/fibrosis, and is safer than anti-VEGF for mouse body development and lipid metabolism. MiR-15a-5p may be a potential treatment for pathological neovascularization.

Abstract No.: 202995

5-Year Trifocal IOL Outcomes in Chinese Cataract Patients: Visual Performance, Stability, and Satisfaction

First Author: Lulu **CHEN**

Co-Author(s): Lu **SUN**, Shunhua **ZHANG**, Xia **ZHANG**

Purpose: To evaluate the 5-year visual outcomes, refractive stability, IOL centration, patient satisfaction, and complications following trifocal intraocular lens (IOL) implantation in a Chinese cohort.

Methods: This study included 33 patients (66 eyes) with bilateral implantation of trifocal IOL. Postoperative assessments at 5 years included uncorrected and corrected distance, intermediate and near visual acuity, refractive outcomes, contrast sensitivity (CS), defocus curves, reading speed, and patient-reported outcomes (VFQ-25 questionnaire). IOL tilt/decentration and aberrometry were analyzed using anterior segment optical coherence tomography (AS-OCT) and iTrace visual function analyzer.

Results: At 5 years, mean UDVA, UIVA, and UNVA were 0.06 ± 0.16 , 0.10 ± 0.14 , and 0.09 ± 0.12 logMAR, respectively. 92.4% of eyes achieved a postoperative spherical equivalent within ± 1.0 D. Over 87.9% of patients achieved spectacle independence. Mean IOL tilt was $4.19 \pm 1.46^\circ$ and mean IOL decentration was

0.21 ± 0.11 mm. Contrast sensitivity declined under glare, particularly at mesopic conditions. Moderate-to-severe halos were reported by 21.2% of patients, correlating significantly with IOL tilt ($4.79 \pm 1.16^\circ$ vs. $3.75 \pm 1.45^\circ$ in mild cases, $p=0.021$). Posterior capsule opacification necessitated Nd:YAG capsulotomy in 63.6% of eyes (mean intervention time: 22.0 ± 9.9 months), with no complications post-procedure. Patient satisfaction remained high (VFQ-25 score: 93.9 ± 13.7), despite persistent dysphotopsias.

Conclusions: Trifocal IOLs provided long-term efficacy in visual acuity, refractive stability, and exceptional patient satisfaction among Chinese populations. However, PCO remains a prevalent late complication, requiring timely Nd:YAG intervention. IOL tilt significantly influences halo severity.

Abstract No.: 203611

A Multi-Center Clinical Observational Study: Cataract Surgery Patients With Binocular Full-Range Intraocular Lens (Synergy) Implantation in Northwest China

First Author: Kaiyun **ZHANG**

Co-Author(s): Ting **MA**, Cheng **PEI**, Yuecong **REN**, Changrui **WU**, Hong **YAN**, Jiejing **YAN**

Purpose: To evaluate the postoperative visual performance of age-related cataract (ARC) patients who have undergone binocular implantation of the new full-range intraocular lens (TECNIS Synergy™, Johnson & Johnson Surgical Vision) in northwest China.

Methods: This is a multi-center, single-arm, prospective observational study. ARC patients who underwent binocular phacoemulsification with Synergy implantation were enrolled at three hospitals. The study analyzed the distance, intermediate, and near visual acuity of both eyes postoperatively, as well as the defocus curve and subjective visual quality assessment (VF-14 questionnaire and patient-reported measure assessing spectacle independence questionnaire (PRSIQ)) postoperatively.

Results: A total of 40 participants have been included in this study. One month postoperatively, 95% of right eyes and 85% of left eyes had UCDVA ≥ 0.8 . Three months postoperatively, 100% of right eyes and 95% of left eyes had UCDVA ≥ 0.8 . Compared to one month post-operation, UCDVA of most patients' eyes remained stable or improved at three months. The defocus curve shows full-range visual acuity of single or both eyes was ≥ 0.6 , and distant and near visual acuity was better than intermediate vision. Based on VF-14 and PRSIQ, most patients were satisfied with visual quality and achieved glasses-free life and work.

Conclusions: This study is the first to evaluate the postoperative visual outcomes of ARC patients who received Synergy implantation binocularly in northwest China. The findings indicate that Synergy provides

patients with excellent postoperative visual acuity at all distances, superior visual quality, and a high rate of spectacle independence, particularly at a near distance of 33-40 cm.

Abstract No.: 205320

A Multicenter Time-and-Motion Study Assessing the Efficiency Impact of the Next Generation of Phacoemulsification System on Cataract Surgery

First Author: Neda **SHAMIE**

Co-Author(s): Nicole **FRAM**, Carine **HSIAO**, Arjan **HURA**, Li-chen **PAN**, Lawrence **WOODARD**

Purpose: To evaluate the workflow efficiency impact of UNITY VCS (UVCS) when compared to CENTURION™ Vision System with ACTIVE SENTRY™ (CAS) during cataract surgery.

Methods: Prospective, observational, multi-center comparative time-and-motion study assessing patients with non-complicated, age-related cataracts were recruited from two US ambulatory surgical centers (Georgia, California) and surgeries were performed by one of four surgeons. The study received IRB-approval and patients consented to participate. Primary and secondary endpoints were captured through videographic analysis, while exploratory endpoints were obtained from the console metrics. Study outcomes included comparisons of console set-up time (primary endpoint), surgery turnover time (secondary endpoints), CDE, ultrasound time, and BSS fluid use (exploratory endpoints).

Results: A total of 303 patients underwent cataract surgery ($n=161$ CAS; $n=142$ UVCS), with the majority of patients in both arms having $\leq 2+$ grade cataract density. In a multivariate regression analysis for the primary and secondary endpoints, adjusting for technician factors (e.g., technician years of experience), use of UVCS was associated with a significant reduction in console set-up time (adjusted mean difference: -229 seconds, $p<0.001$) and surgery turnover time (adjusted mean difference: -52.81 seconds, $p<0.016$) compared with CAS. For the exploratory endpoint, after adjusting for patient factors (e.g., age, cataract density), CDE and ultrasound time was reduced by 34.5% ($p<0.001$) and 7.5% ($p=0.028$), respectively.

Conclusions: This study's results provide real-world evidence that UNITY VCS improves operating room workflow efficiency in cataract surgery across surgeons and sites.

Abstract No.: 205960

A Novel Nomogram Based on the Total Corneal Astigmatism for Paired Anterior Penetrating Femtosecond Laser Arcuate Keratotomy

First Author: Zhe ZHANG

Co-Author(s): Suhua ZHANG

Purpose: To develop a nomogram for paired anterior penetrating femtosecond laser arcuate keratotomy (FLAK) based on the total corneal refractive power (TCRP) astigmatism (CATot) during femtosecond laser-assisted cataract surgery (FLACS).

Methods: Retrospective case series designed. Paired anterior penetrating FLAKs were created at an 8.0 mm optical zone with a depth of 90% by LenSx laser. CATot measurements were obtained preoperatively and after 1 year with Scheimpflug tomography (Pentacam HR; Oculus, Wetzlar, Germany) for 3- and 5-mm diameter zones, respectively. Vector analysis using the Alpins method to describe the surgically induced astigmatism (SIA) and correction index (CI). The Holladay-Cravy-Koch formula was used to calculate the corneal net changes in a 3-mm diameter zone caused by the FLAKs. Multiple regression analysis with generalized estimating equations was used to develop the nomogram.

Results: The study included 64 eyes of 64 patients. The mean preoperative CATot (3-mm: 1.50 ± 0.59 D; 5-mm: 1.45 ± 0.52 D) were significantly reduced to 0.73 ± 0.46 D and 0.76 ± 0.49 D, respectively, at a 1-year follow-up period (both $P < 0.05$). The 3-mm and 5-mm SIA were 1.16 ± 0.61 D and 1.03 ± 0.56 D, respectively ($P < 0.01$). The 3-mm and 5-mm CI were 0.72 and 0.64 ($P > 0.05$). The mean corneal net changes were -0.97 D in the 3-mm zone, -0.85 D in the 5-mm zone, respectively. A nomogram is established based on age, length, and location of the FLAKs.

Conclusions: Paired anterior penetrating FLAKs showed efficient and stable corneal astigmatism reduction 1 year postoperatively. The nomogram is proposed according to the CATot, which considers the effect of posterior astigmatism of the cornea, and may further improve correction accuracy.

Abstract No.: 203445

A Safety Study on Different Intraocular Pressure Settings During Surgery for High Myopia Combined With Cataract

First Author: Kaili TANG

Co-Author(s): Liwei MA, Jing WANG, Jinsong ZHANG

Purpose: Compare the safety of different intraocular pressure Settings during the operation for high myopia combined with cataract surgery.

Methods: A total of 100 patients with high myopia who underwent cataract surgery in our hospital from May 2023 to January 2025 were included. The safety

and prognosis of different IOP settings—the low IOP group & the high IOP group—during the operation for high myopia combined with cataract surgery were compared. Including intraoperative parameters, such as the total case time, total CDE, total U/S time, aspiration time, the number of ASM, EFU and the occurrence of intraoperative complications, as well as changes in corneal thickness and corneal endothelial cell parameters before and after the operation.

Results: The intraoperative parameters only showed statistical differences in ASM ($P = 0.013$). One case of PCR occurred during the operation in the high IOP group. There was a statistically significant difference in the changes of central and vertical corneal thickness before and after the operation between the two groups ($P < 0.05$). There was no significant difference in the absolute values of ECD changes in all directions before and 1 day after surgery between the two groups ($P > 0.05$). There was no statistically significant difference in the changes of CD, CV and 6A in the central cornea between the two groups before the operation and 6 months after the operation ($P > 0.05$).

Conclusions: For patients with high myopia and cataract undergoing phacoemulsification surgery for cataract, a lower intraoperative IOP setting can significantly reduce the occurrence of intraoperative surges, and it did not increase the side effects on corneal thickness in the early postoperative period or on corneal endothelial cells in the long term.

Abstract No.: 201556

A Single-Cell Transcriptomic Atlas of Human Lens Epithelium: Identification and Functional Insights Into Lens Stem/Progenitor Cells

First Author: Qiuli FU

Co-Author(s): Lu CHEN, Yuzhou GU, Ke YAO

Purpose: The existence of stem/progenitor cells in the lens epithelium has been demonstrated, but their identification remains challenging.

Methods: Eight pairs of human donor lens epithelium samples were collected for single-cell RNA sequencing (scRNA-seq). Subsequent analyses involved cell (sub) type characterization, trajectory inference, and cell-cell communication and validated using many models.

Results: Six groups were identified via UMAP mapping of scRNA-seq data. One of the four LEC clusters exhibited a distinct gene expression profile and was identified as transient amplifying cells (TACs). TACs specifically express TOP2A and are localized at the lens equator. CytoTRACE analysis to the LEC and LFC data sets provided a differentiation trajectory. The TAC group was determined as stage 2 in the trajectory and LFCs last. The 3 sub groups were labelled early, mid and late LECs and corresponded to stage 1, 3 and 4 in the path. While cell population demographics remained stable with age, transcriptomic changes in LECs were

observed, including weaker intercellular crosstalk and adhesion, and fewer TACs in S phase. Lens progenitor-like cells (LPLCs) were identified as a sub-population in early LECs and express ID1. In addition, pleiotrophin (PTN) signaling was prevalent at all differentiation stages, with a notable weakening of PTN signaling in aged LPLCs.

Conclusions: This study identified four subclasses of LECs within the human lens epithelium that follow a progressive staged development pathway from progenitor cells to mature LECs. TOP2A can serve as a biomarker for TAC in the lens, and LPLCs sustain their dedifferentiated state by expressing ID1.

Abstract No.: 200165

AI-Enabled Smartphone Cataract Screening: A Low-Cost Solution for Community Eye Care

First Author: Siddharam **JANTI**

Co-Author(s): Raghavendra Rao, Kalpana **MALI**, Hari Kumar S

Purpose: The aim of this study was to assess the clinical performance of a smartphone-based cataract screening application that uses an AI module to identify cataracts in photos taken with the device's camera. The study compared the application's results with diagnoses made by ophthalmologists using a slit lamp.

Methods: A total of 495 patients participated in a prospective clinical trial at the Institute of National Importance, India. The AI-based screening solution examined smartphone images that were taken in accordance with a set protocol to identify whether cataracts were present. The results of the application were then compared with the diagnoses made by ophthalmologists based on slit-lamp tests.

Results: The study included 990 eye images. The AI screening application demonstrated an overall accuracy of 90.01% for cataract detection. Specific metrics include a sensitivity of 89.50%, specificity of 89.73%, precision of 91.43%, and an F1 score of 90.36%. The positive predictive value (PPV) was approximately 91.3%, based on 485 true positives and 46 false positives. The negative predictive value (NPV) was approximately 87.6%, based on 402 true negatives and 57 false negatives.

Conclusions: The smartphone-based cataract screening application proves to be an effective tool for community-level cataract screening in remote areas where access to expensive equipment and specialized ophthalmic care is limited. Its high accuracy and efficiency make it a valuable option for low-resource settings and suitable for home screening, particularly in the post-COVID era.

Abstract No.: 202729

AMD IOL – a Visual Oasis in Old Dry Desert – a Case Report

First Author: Mamta **KUMARI**

Co-Author(s): Bhavin **DHARANI**, Anjali **ISRANI**, Uma **THAKUR**

Purpose: Detailing the use of eyemax mono IOL as Low Vision Aid in a centre involving macular scar and cataract.

Methods: A 75 years female presented with poor vision both eyes since few years. On Examination -Her right eye best-corrected distance visual acuity (BCDVA) was 20/400 and best-corrected near visual acuity (BCNVA) was N36. In left eye BCDVA was 20/200 and BCNVA was N24. She had nuclear sclerosis grade 2 in both eyes. Fundus showed both eyes center involving macular scar approximately 1DD. Rest examination was within normal limits. Intervention - Standard topical phacoemulsification was performed in both eyes with capsular bag implantation of EyeMax Mono , a single-piece, hydrophobic, acrylic IOL designed to optimize image quality across the macula. The surgery was uneventful and Standard follow-up protocols were applied.

Results: Visual acuity progressively improved following surgery and was stable by 6 months. Postoperative BCVA OD - 20/200, OS - 20/60. Binocular near vision was N12. The patient reported subjective improvement immediately after surgery for distance vision. With near vision, incremental improvements were reported, consistent with a neuro-adaptive component that may occur with such types of IOL.

Conclusions: This is the first case undertaken at our center, where cataract extraction and EyeMax Mono implantation were done as an LVA. The subjective and objective outcomes were good. Present available LVAs are usually cumbersome to use. Our case report indicates that this extended macular vision IOL has a safety profile comparable with standard IOLs, with the additional benefit of providing magnified vision in patients with such macular disorders undergoing cataract surgery.

Abstract No.: 203763

Accuracy of AI-Based and PK-Enhanced IOL Power Calculation Formulas in Post-Refractive Surgery Eyes With Long Axial Lengths

First Author: Qian **TAN**

Purpose: To evaluate the accuracy of artificial intelligence (AI)-based and posterior keratometry (PK)-enhanced intraocular lens (IOL) power calculation formulas in post-refractive surgery eyes with long axial length (AL $\geq$ 26.0 mm).

Methods: This retrospective study analyzed 197 eyes from 138 post-LASIK/PRK patients undergoing cataract

surgery. Thirteen no-history formulas were compared: regression-based (Haigis-L, Haigis-E, Haigis-K, Shammas-PL, Triple-S, Potvin-Hill), AI-based (EVO 2.0, DGS, HQST), the non-AI no-history Barrett True K, and PK-enhanced formulas (Barrett TKPK, EVOPK, HQSTPK). Refractive prediction error (RPE) was calculated using the implanted IOL power. Accuracy metrics included mean prediction error (MPE), median absolute error (MedAE), mean absolute error (MAE), root mean square absolute error (RMSAE), and the percentage of eyes within ± 0.25 D, ± 0.50 D, ± 0.75 D, and ± 1.00 D. Subgroup analyses were performed according to AL, posterior/anterior corneal radius ratio (P/A), and keratometry (Km).

Results: In the overall cohort, MPE ranged from -0.44 to $+0.33$ D. Only EVOPK, EVO 2.0, DGS, and Triple-S showed no significant deviation from emmetropia ($P > 0.05$). Barrett TKPK achieved the lowest MedAE (0.38 D) and RMSAE (0.59 D), significantly outperforming Haigis-K ($P \leq 0.025$). EVO 2.0 yielded the highest proportion of eyes within ± 0.50 D (64.0% , $P < 0.05$ vs. DGS and Haigis-K) and maintained consistent accuracy across AL and P/A subgroups. In eyes with $AL \geq 28.0$ mm, Barrett TKPK and EVOPK provided the lowest RMSAE, while EVO 2.0 showed superior robustness in eyes with higher P/A ratios. GEE analysis confirmed that AL, Km, and P/A significantly influenced prediction errors, with P/A strongly impacting AI- and PK-based formulas.

Conclusions: AI-based and PK-enhanced formulas demonstrated superior refractive prediction accuracy compared with traditional no-history methods in long AL post-refractive eyes. EVO 2.0 showed the most consistent performance across subgroups, while Barrett TKPK achieved the lowest absolute errors. These results support the clinical adoption of AI-driven and PK-enhanced approaches to reduce refractive surprises and improve outcomes in challenging post-refractive cataract cases.

Abstract No.: 201585

Advantages of Femtosecond Laser Assistance in Refractive Lens Exchange: A Comparative Analysis

First Author: Maiia **NEMSITSVERIDZE**

Co-Author(s): Ernest **BOIKO**, Ekaterina **SIMAK**

Purpose: To evaluate the benefits of femtosecond laser-assisted phacoemulsification (FLACS) in refractive lens exchange with implantation of advanced technology intraocular lenses (ATIOLs).

Methods: The study included 200 patients with various degrees of ametropia after conventional phacoemulsification (CPS) or in combination with FLACS, followed by implantation of different ATIOLs models. Exclusion criteria comprised extreme degrees of ametropia, corneal astigmatism, concomitant ocular pathology potentially limiting best-corrected visual

acuity (BCVA), and background of keratorefractive surgery. In all cases, the intended postoperative refraction was emmetropia. The primary outcome measure was the postoperative spherical equivalent (SE).

Results: The study groups did not differ significantly in demographic characteristics. In the 2nd group, we made a 5.0-5.5mm femtosecond capsulotomy, and the lens was pre-fragmented into four parts. The groups were also comparable with biometric parameters and visual acuity ($p > 0.05$). All patients demonstrated excellent functional outcomes postoperatively. However, the FLACS group showed a significantly lower residual SE (0.07 ± 0.43 D) compared to the CPS group (-0.13 ± 0.40 D; $p < 0.05$).

Conclusions: Femtosecond laser assistance in refractive lens exchange offers superior refractive precision, resulting in a smaller postoperative spherical error and potentially enhanced visual performance. We believe that, the ideal shape and size of the capsulotomy makes us expect symmetrical contraction of the capsular bag in the postoperative period that results in minimal lens decentration and an effective lens position close to the calculated one.

Abstract No.: 208135

Alpha and Kappa Angle on Postoperative Visual Quality in Cataract Surgery

First Author: Jia **WEI**

Co-Author(s): Xiaona **CHEN**, Yali **GAO**, Yingshi **ZOU**

Purpose: To explore the effect of Alpha and Kappa angles before multifocal intraocular lenses (MIOLs) implantation on the postoperative visual quality of patients.

Methods: Before and 3 months after cataract surgery, Alpha and Kappa angles were measured via IOL Master 700, iTrace, and Pentacam. Postoperatively, iTrace was used to collect visual quality indicators (high-order aberrations [HOA], modulation transfer function [MTF], point spread function [PSF]). Multiple linear regression analyzed correlations of Kappa/Alpha angles with age, axial length (AL), anterior chamber depth (ACD), keratometry (K), lens thickness (LT), and corneal white-to-white distance (WTW). Pearson correlation coefficient assessed the Alpha-Kappa angle correlation, while Bland-Altman analysis evaluated consistency of pairwise measurements across the three devices.

Results: $\text{Alpha} = 2.230 + 0.003 \times \text{age} - 0.036 \times \text{AL} - 0.025 \times \text{K} - 0.058 \times \text{WTW}$, and the Kappa angle model was $\text{Kappa} = 0.685 + 0.003 \times \text{age} - 0.013 \times \text{K} - 0.061 \times \text{WTW}$. The total Alpha and Kappa angles of the three instruments showed weak positive correlation ($r = 0.291$, $P = 0.000$). Among the three instruments, only IOL Master 700 and iTrace had good consistency in Kappa angle measurement ($P = 0.4254$). At 3 months post-surgery, Alpha and Kappa angles decreased significantly

($P=0.011$, 0.018 ; $P=0.008$, 0.036). $\square$ Kappa=1.136-0.021 $\times$ AL-0.013 $\times$ K. Kappa angle positively predicted HOA ($\beta=0.18$, $P=0.000$), MTF ($\beta=0.171$, $P=0.000$) and PSF ($\beta=0.088$, $P=0.000$), while Alpha angle did not ($P>0.05$).

Conclusions: Patients with older age, flatter K, and shorter WTW should be alert to larger Alpha and Kappa angles; AL should also be considered for Alpha angle. For MIOL implantation candidates, Kappa angle requires careful evaluation. The preoperative <0.5 mm standard for Kappa angle can refer to $\square$ Kappa=1.136-0.021 $\times$ AL-0.013 $\times$ K and be appropriately relaxed.

Abstract No.: 203861

Analysis of Retinal Defocus in Pseudophakic Eyes Based on VPR System

First Author: Jing **WANG**

Co-Author(s): Luan **LI**, Lang **WEI**, Jinsong **ZHANG**

Purpose: To explore the variation patterns in retinal defocus topographic distribution in pseudophakic eyes.

Methods: A cross-sectional study. Patients who underwent phacoemulsification combined with monofocal IOL implantation for more than 3 months were enrolled. Inclusion criteria are uncorrected distance visual acuity (UCVA, LogMAR) ≤ 0.1 , postoperative MRSE $\leq 0.5D$, and the morphology of the macula was normal. All enrolled patients underwent data collection and recording of VPR measurement (fast whole-field peripheral refraction, Earth 100, China). Refraction Difference Value at 5° from the fovea (RDV 0°-5°), refraction difference value at 12.5° from the fovea (RDV 5°-12.5°), refraction difference value at 25° from the fovea (RDV 12.5°-25°), and refraction Difference Value at $\square 25^\circ$ from the fovea (RDV $>25^\circ$) were collected. Also with RDV in the Superior Quadrant (RDV-S), Inferior Quadrant (RDV-I), Nasal Quadrant $\square$ RDV-N $\square$ and Temporal Quadrant (RDV-T).

Results: A total of 126 subjects were enrolled. RDV (0°-5°) was $0.081\pm 0.108(D)$, RDV (5°-12.5°) was $-0.149\pm 0.248(D)$, RDV(12.5°-25°) was $-0.708\pm 0.692(D)$ and RDV $>25^\circ$ was $-1.377\pm 1.196(D)$. Except for the 5-degree area centered on the fovea, the retina in other areas showed myopic defocus changes. As the distance from the fovea increases, the retinal myopic defocus shows an increasing trend. The superior, inferior, nasal, and temporal retinal quadrants all showed myopic defocus changes (RDV was -0.338 ± 0.491 , -0.621 ± 0.767 , -0.318 ± 0.711 , and -0.704 ± 0.735 , respectively). The myopic defocus amount was smaller in the superior and nasal quadrants, while it was larger in the temporal and inferior quadrants.

Conclusions: Analysis of eyes implanted with monofocal IOLs based on VPR revealed a trend of retinal myopic defocus.

Abstract No.: 203172

Angle-to-Angle Depth Thresholds for Accurate Prediction of Effective Lens Position

First Author: Sunee **CHANSANGPETCH**

Co-Author(s): Mantapond **ITTARAT**, Shan **LIN**

Purpose: Although newer intraocular lens (IOL) formulas are generally more accurate, SRK/T remains useful when the measured anterior chamber depth (ACD) does not reflect the true anatomical depth. We compared SRK/T-predicted effective lens position (ELP) with postoperative anterior segment optical coherence tomography (AS-OCT) measurements and identified conditions in which SRK/T predictions may be unreliable.

Methods: This prospective observational study included eyes undergoing uncomplicated cataract surgery. Preoperative biometry was obtained and postoperative lens position was measured by AS-OCT. The SRK/T-predicted ELP was subtracted from the measured value to calculate prediction error (Δ ELP). Nine AS-OCT parameters representing anterior segment and lens dimensions were tested for association with the Δ ELP, with significant factors entered into a mixed-effect regression model. Thresholds associated with an absolute Δ ELP >0.25 mm were estimated.

Results: A total of 125 eyes were analyzed. The mean Δ ELP was 0.05 ± 0.39 mm (range -1.12 to 1.35 mm). Angle-to-angle depth (AAD), and anterior chamber width were included in the multivariable model (all $p<0.05$). In the multivariable model, only AAD was significantly associated with Δ ELP (B 1.22, 95%CI 0.38 to 2.06, $p=0.005$). The cut-off value for Δ ELP >0.25 mm (underestimate ELP) was AAD >3.1 mm, while the cut-off value for Δ ELP <-0.25 mm (overestimate ELP) was AAD <2.6 mm.

Conclusions: In SRK/T, ELP was underestimated in eyes with deeper AAD and overestimated in those with shallower AAD. These findings suggest that AAD, rather than ACD, should be considered, especially for values that exceed the proposed cut-offs, when evaluating the suitability of SRK/T for IOL power calculation.

Abstract No.: 200457

Anterior Capsulotomy Fixation Reduces PCO: A Systematic Comparison of FEMTIS vs. In-the-Bag IOLs With Identical Optic Design

First Author: David **BECKERS**

Purpose: To assess whether the fixation site of an intraocular lens (IOL) independently affects the rate of posterior capsular opacification (PCO), by comparing Nd:YAG capsulotomy rates of the capsulotomy-fixated FEMTIS IOL to conventional in-the-bag IOLs of identical material and edge design.

Methods: A systematic literature review was conducted using PubMed and Embase (through April 2025) to

identify clinical studies reporting Nd:YAG capsulotomy rates for hydrophilic acrylic IOLs with square-edge profiles. Included studies had ≥ 3 months of follow-up and specified fixation type. Capsulotomy rates were extracted for FEMTIS IOLs and comparable in-the-bag LENTIS models and synthesized descriptively.

Results: The FEMTIS IOL showed a lower 12-month YAG rate (3.1%) than the in-the-bag hydrophilic LENTIS IOL (4.7%), despite identical optic design and material. Multifocal in-the-bag IOLs demonstrated even higher early capsulotomy rates ($\geq 10.3\%$). The findings suggest that anterior capsulotomy fixation reduces the potential space for lens epithelial cell migration by promoting optic-posterior capsule apposition, possibly mitigating early PCO formation.

Conclusions: Fixation site appears to be an independent factor influencing PCO risk. Capsulotomy-fixed IOLs such as FEMTIS may provide enhanced early capsular clarity through closer anatomical contact with the posterior capsule. These findings support further prospective trials to evaluate fixation design as a modifiable factor in PCO prevention.

Abstract No.: 200611

Artificial Intelligence-Based Formulas in the Calculation of Intraocular Lens Power

First Author: Chau DINH NGOC BAO

Co-Author(s): Huong BUI THI THU

Purpose: To compare the accuracy of artificial intelligence-based formulas in the calculation of intraocular lens power, such as Barrett Universal II, Kane, Hill-RBF, and Hoffer Q.

Methods: In this retrospective series, 123 eyes of patients who had undergone phacoemulsification surgery with intraocular implantation from January 2025 to February 2025 at Vietnam-Russia International Eye Hospital-HCMC were investigated. Mean numerical error (MNE) and mean absolute error (MAE) were recorded at 4 weeks postoperatively.

Results: Kane formula demonstrated the lowest MAE (0,21; SD=0,19D), MedAE (0,14D) and highest percentages of eyes with prediction errors $< 0,25D$ and $< 0,5D$ although there was no statistically significant difference between Barrett Universal II, Hill-RBF and Kane. In the short-eye subgroup, Kane also demonstrated the lowest MAE, while Hill-RBF took this placement in the long-eye subgroup. There was statistically significant difference between formulas in eyes which had multifocal lens implantation where Kane exhibited the lowest MAE (0,19; SD=0,15D), MedAE (0,14D).

Conclusions: Kane was proved the most accurate formula in terms of MAE and MedAE, especially in multifocal implantation.

Abstract No.: 207610

Association Between Retinal Vascular Morphology and Incident Treatment for Sight-Threatening Diabetic Retinopathy

First Author: Paul NDERITU

Co-Author(s): Mark CHIA, Asterios DIAFAS, Urvi KARAMCHANDANI, Pearse KEANE, Christine KIIRE, Sarah MATTA, Yukun ZHOU

Purpose: Retinal vascular morphology (RVM) has been linked to diabetic retinopathy (DR), yet large longitudinal data connecting RVM with the first treatment for sight-threatening DR (STDR) are scarce.

Methods: We conducted a retrospective analysis of the Moorfields Diabetic imAge dataSet Study (MIDAS, 2000–2022) and included 20,858 patients (33,865 unique eyes) with graded macula-centered fundus images. We extracted arterial and venous macula RVM metrics of fractal dimension (FD), vessel density (VD), and average width (AW) using the AUTOMORPH deep learning tool. Eligible eyes were treatment-naïve at baseline with no to severe non-proliferative DR and no or mild diabetic macular oedema. Outcomes included initiation of treatment for proliferative DR (PDR) or clinically significant macula oedema (CSMO). Cox proportional hazards regression, adjusted for age, sex, ethnicity, baseline DR, and inter-eye dependence, was applied.

Results: Compared with the lowest quartile (Q1), eyes in the highest FD quartile (Q4) had markedly reduced risk of incident PDR/CSMO treatment: arterial FD HR = 0.52 (95% CI 0.45–0.59), venous FD HR = 0.66 (95% CI 0.57–0.75). Higher arterial VD conferred protection to incident PDR/CSMO treatment (Q4 vs Q1 HR = 0.47, 95% CI 0.41–0.54); higher venous VD was protective for incident PDR treatment alone (HR = 0.66, 95% CI 0.57–0.75). Wider venules increased the risk of PDR/CSMO treatment (HR = 2.53, 95% CI 2.24–2.86), while narrower arterioles raised incident PDR treatment risk alone (HR = 0.62, 95% CI 0.52–0.75). Associations were consistently stronger for PDR treatment vs CSMO treatment.

Conclusions: AUTOMORPH-derived macula RVM metrics demonstrate robust associations with incident STDR treatment and are promising biomarkers for DR progression.

Abstract No.: 203526

Association of Accelerometer-Monitored Physical Activity With Incident Cataracts: Epidemiologic and Genetic Evidence

First Author: Chenxiao SHEN

Co-Author(s): Jiahui CAO, Zijiang DU, Ting SU, Qiaowei WU, Honghua YU, Xiayin ZHANG

Purpose: To investigate the association and potential causal relationship between accelerometer-assessed physical activity (PA) and the risk of senile cataract (SC).

Methods: The study population was derived from the UK Biobank database. Triaxial accelerometer data from wearable devices were utilized to define domains of PA at specific intensities: light, moderate, and vigorous. Multivariable Cox proportional hazard models explored the association between PA and SC incidence. Furthermore, Two-sample Mendelian randomization analyses were conducted using genome-wide association data from multiple large-scale prospective study cohorts (UK Biobank for PA and FinnGen for SC) to elucidate potential causal links between them.

Results: The study ultimately enrolled 77,123 participants with a mean age of 55.67 ± 7.8 years. Among them, 1,194 subjects were diagnosed with SC during a mean follow-up period of 6.3 years (interquartile range [IQR]: 5.3-7.3 years). The findings indicated that engaging in 150-600 minutes of moderate to vigorous-intensity PA (MVPA) per week was associated with a significant 21% reduction in the risk of SC, with a clear dose-response relationship observed. Additionally, a robust and significant causal association was demonstrated between MVPA and SC risk (OR=0.56, 95% CI: 0.38-0.83, P=0.004).

Conclusions: Adhering to the PA guidelines established by the World Health Organization emerges as a novel and modifiable protective measure to slow the progression of SC.

Abstract No.: 200907

Biocompatibility and the Effect of Glistening on the Optical Quality in Four Different Hydrophobic-Acrylic Intraocular Lenses

First Author: Xiaomin LIU

Purpose: To study the biocompatibility at the level of tissue fibrosis and the impact of glistening on the optical quality of four hydrophobic acrylic intraocular lenses (IOLs).

Methods: Four hydrophobic acrylic IOLs were evaluated: i-Sert XY1 with ultraviolet-ozone treatments (Hoya, Japan); i-Sert 251 with no-special treatments (Hoya, Japan); ZCB00 with no-special treatments (Johnson & Johnson, USA); SN60WF with argon-plasma treatment (Alcon, USA). Twelve New Zealand rabbits were divided into four groups based on the implanted IOL type. Slit lamp and histopathology examinations were conducted to assess the posterior capsular opacification (PCO) postoperatively. Simulating aging test to evaluate glistening by light microscopy and image analysis. Optical performance, including modulation transfer function (MTF), IOL power and United States Air Force Target test, was measured using an OptiSpheric IOL PRO 2 optical bench.

Results: The mean PCO score of i-Sert XY1 was significantly lower than that of the others (P<0.05). SN60WF showed the highest glistening density, followed by i-Sert 251 and i-Sert XY1, with ZCB00 being

the lowest. After the aging test, all four IOLs showed a declining trend MTF curve, but only SN60WF had a significant difference (P<0.05), while i-Sert XY1, i-Sert 251 and ZCB00 did not. All four IOLs exhibited increased power after aging, with the greatest change in SN60WF and the smallest in ZCB00.

Conclusions: Ultraviolet-ozone-treated IOL surfaces effectively improve biocompatibility and reduce PCO. Among the tested IOLs, i-Sert XY1, i-Sert 251 and ZCB00 show high glistening resistance with little impact on optical performance, while SN60WF induces more glistening and impairs optical quality.

Abstract No.: 204472

Capsular Bag Defects and the Intraocular Lens in Dead Bag Syndrome

First Author: Shu Wen Nicole CHAN

Co-Author(s): Soon-phaik CHEE, Jia Xu LIM

Purpose: To describe the characteristics of the intraocular lens (IOL) and capsular bag defects in eyes with dead bag syndrome.

Methods: Retrospective review of a single-surgeon series of eyes with out-of-the-bag IOL dislocation. Data collected included patient demographics; history of ocular trauma/eye rubbing; IOL model and placement; location and size of the capsular bag rip and defect, respectively.

Results: Eye rubbing, the only form of trauma, was reported in 34 (68.0%) of 50 eyes (45 patients). The average posterior capsule (PC) defect size was $53.8 \pm 15.5\%$. The PC defect was most commonly nasal (25 eyes; 50.0%), followed by central (13 eyes), then temporal (10 eyes). The PC rip originated across the PC in 34 eyes (68.0%). The haptic was partially attached to the bag in 27 of these eyes; the rip location (obliquely nasal (20 eyes), obliquely temporal rip (7 eyes)) coincided with the optic edge of obliquely- (17 eyes) or vertically- (10 eyes) aligned IOLs. The other 7 eyes had single-piece hydrophobic acrylic IOLs with square anterior and posterior edges that dislocated into the vitreous through oblique PC rips. Circumferential equatorial rips seen in the remaining 16 eyes (32.0%) were mostly nasal (13 eyes), coinciding with the previous haptic location.

Conclusions: The predominantly nasal location of capsular bag rips in dead bag syndrome may be accounted for by eye rubbing. Rips across the PC may be related to the square edge of the optic, while equatorial rips may be related to the haptic.

Abstract No.: 201239

Capsular Tension Ring Implantation Improves Intraocular Lens Power Prediction Accuracy in Cataract With Retinitis Pigmentosa

First Author: Siyan LI

Co-Author(s): Yun-e ZHAO

Purpose: To evaluate the impact of capsular tension ring (CTR) implantation on the predictive accuracy of 12 intraocular lens (IOL) power calculation formulas in patients with retinitis pigmentosa (RP) receiving cataract surgery.

Methods: The predictive accuracy of 12 IOL formulas was assessed using refractive prediction error (PE), mean absolute error (MAE), root-mean-square absolute error (RMSAE), and the percentage of eyes achieving target refraction within ± 0.25 D to ± 1.00 D. These metrics were compared between eyes with (n=23) and without (n=30) CTR implantation. The influence of lens thickness (LT) on formula accuracy was also evaluated.

Results: In the overall cohort of 53 eyes from 38 RP patients, the BUII formula yielded the lowest numerical MAE (0.45 D) and RMSAE (0.56 D), though no formula was statistically superior in RMSAE. In the CTR group, significantly lower MAE was observed for Cooke K6 (P=0.016), EVO 2.0 (P=0.021), Kane (P=0.024), and PEARL-DGS (P=0.040) compared to the non-CTR group. The CTR group also exhibited a significantly higher percentage of eyes within ± 0.50 D (P = 0.016), ± 0.75 D (P < 0.001), and ± 1.00 D (P < 0.001) of target refraction. Increasing LT correlated with a hyperopic shift for all formulas; however, BUII demonstrated relatively stable MAE across LT quartiles.

Conclusions: Implantation of a CTR significantly improved the predictive accuracy of several IOL formulas in RP patients. The BUII formula demonstrated the best overall calculation accuracy.

Abstract No.: 206730

Carbon-Foot Print and Day Surgeries: Building a Platform for Ongoing Review

First Author: Tim ROBERTS

Co-Author(s): Kylie BENNETT, Chris HODGE

Purpose: Climate change represents a significant ongoing concern to society. Understanding the estimated carbon footprint of day surgery operations represents an important step to evaluating both best practice and opportunities for improvement.

Methods: Based on readily available metrics, we developed a basic calculation to derive the cataract-based carbon footprint of both a single practice and group-wide surgical procedures performed in Vision Hospital Group facilities (Australia-wide privately owned ophthalmic day surgeries), analysing surgery time, mean number of surgical procedures, estimated staff and patient travel.

Results: Eleven-day surgeries were included. Mean number of cataract surgeries ranged from 10 to 254 per month (median 132). The number of pre- and post-operative patient visits ranged from 1 to 4 per eye in total. Staff surveyed included administration, surgeon, nursing, and sterilising staff. The mean total procedure time was considered as 15 minutes. The estimated inclusive monthly CO2 emissions overall were 90,355kg for all sites. Staff travel represented 59% to 84% of emissions.

Conclusions: Staff and patient travel are responsible for the majority of total procedure-related emissions. Consideration of the number of pre- and post-op visits may represent a simple opportunity with reference to ongoing patient safety. Further analysis of equipment usage and prioritisation of bookings may be a further avenue.

Abstract No.: 203889

Characterization of Mechanical Stress in the Occurrence of Cortical Opacification in Age-Related Cataracts Using Three-Dimensional Finite Element Model of the Human Lens and RNA-Seq

First Author: Lu CHEN

Co-Author(s): Zhe CHEN, Qiuli FU, Ke YAO

Purpose: Cataract is the leading cause of blindness worldwide, with age-related cataract (ARC) being the most common type. The lens, as the only adjustable refractive medium of the eye, undergoes lifelong deformation during accommodation. However, the contribution of mechanical stress to ARC pathogenesis remains unclear. This study aimed to characterize dynamic stress distribution in the human lens and its potential role in cortical opacification using finite element modeling and experimental validation.

Methods: A three-dimensional finite element model (3D-FEM) of the human lens was constructed based on anatomical and biomechanical parameters to simulate stress distribution under physiological loading. In parallel, human lens epithelial cells (HLECs) were exposed to cyclic mechanical stretch. Senescence markers, PIEZO1 expression, and mechano-responsive pathways were assessed using qPCR, western blot, and RNA-seq followed by pathway enrichment analysis.

Results: 3D-FEM simulations revealed asymmetric stress distribution, with highest concentration in cortical regions corresponding to typical sites of cortical opacity. In stretched HLECs, senescence-related markers were significantly upregulated, indicating sensitivity to mechanical stimulation. Notably, PIEZO1 mRNA expression increased in a stretch duration-dependent manner, peaking at 9 hours. Transcriptomic profiling further identified enrichment of mechanosensing and mechanotransduction pathways, suggesting downstream signaling of PIEZO1 under mechanical stress.

Conclusions: This study demonstrates that accommodation-induced mechanical stress predominantly affects the lens cortex, aligning with cortical ARC localization. Mechanical stretch promotes senescence in HLECs and upregulates PIEZO1, implicating PIEZO1-mediated mechano-transduction as a potential biomechanical driver of cortical ARC formation.

Abstract No.: 202129

Chopper Assisted Positioning Hook for Intraocular Lens Exchange in Patients With Intraocular Lens Opacification

First Author: Yani WANG

Purpose: To report the surgical technique of intraocular lens (IOLs) exchange and outcomes of IOLs exchange in patients with IOLs opacification after cataract surgery.

Methods: The medical data from 111 eyes of 111 patients who were diagnosed with IOLs opacification after cataract surgery undergoing IOLs exchange were retrospectively reviewed between May 2019 and May 2024 in Qingdao Eye Hospital. Complications, the rate of IOLs implantation in the bag, postoperative best corrected visual acuity (BCVA) are analyzed.

Results: Patients with average age of 70.7 ± 10.8 years presenting IOLs opacification occurred at an average time of 4.6 ± 2.3 years after cataract surgery. All extracted IOLs were identified as hydrophilic single-piece, which were extracted successfully without other complications in 96.4% of patients; only 1.8% and 1.8% of cases requiring capsular tension ring implantation and vitrectomy. As result, the percentage of IOLs implantation in the bag successfully was 78.4%. Patients with LogMar < 0.3 after surgery accounted for 70.3%, and BCVA at postoperative 1 month was 0.3 ± 0.3 LogMar, which improved significantly than 1.4 ± 1.0 LogMar before surgery ($P < 0.001$).

Conclusions: Chopper assisted positioning hook for intraocular lens exchange is an effective method for increasing the success rate of intraocular lens replacement in the bag and reducing the complications.

Abstract No.: 206459

Clinical Efficiency and IOL Stability Following Novel 8-Point Quadrilateral Looping Scleral Fixation in Dislocated Loop-Haptic IOLs

First Author: Shravanthi NAGARAJ

Co-Author(s): Nagesha Chokkahalli KRISHNAPPA, Rohitha NAYAK, Naren SHETTY

Purpose: This study aims to describe quadrilateral 8-exit 4-knot fixation of dislocated loop haptic design IOLs. To analyse IOL positioning by imaging and postoperative visual outcomes.

Methods: Consecutive patients with posteriorly dislocated loop haptic design IOLs following capsular

bag loss underwent internal scleral refixation. The 2 farthest points in the haptic loops on either side of IOL are looped using 9-0 polypropylene or Gore-Tex suture in ab externo manner. The radial orientation of the thread holds the IOL at 1.5 mm to 3.5 mm from the limbus, aiming for the positioning of the IOL with good iris clearance. Postoperative tilt, decentration were measured using anterior segment optical coherence tomography. Visual outcomes and frequency of immediate and late complications were analyzed.

Results: A total of 11 eyes underwent scleral fixation, among which 8 were loop haptic design monofocals, 2 AcrySof A60, and 1 Zeiss Sphere lens. All underwent complete vitrectomy, and 6 eyes had polypropylene, and 5 had Gore-Tex sutured. Mean tilt was 3 degrees, and decentration was 236 microns. Mean best corrected visual acuity improved from 0.2 logMAR to 0.1 logMAR units. One transient vitreous haemorrhage, one postoperative CME were reported. Lately, one eye developed a macular hole, which required gas tamponade. IOL positioning was stable over a mean follow-up of 6 months.

Conclusions: Quadrilateral loop scleral fixation of loop haptic-design lenses generates equivocal torque in 4 directions thereby maximising stability, centration and minimising tilt. This technique can be extended to toric and multifocal IOLs in eyes with capsular bag loss.

Abstract No.: 200375

Clinical Outcomes of Cataract Surgery Using New-Generation Monofocal Intraocular Lenses With Enhanced Intermediate Vision

First Author: Altangerel

Co-Author(s): Jiwon JEONG, Sohyeon KIM, Tae-im KIM

Purpose: In our study, we conducted a retrospective case series to compare the clinical outcomes of two new-generation monofocal intraocular lenses (IOLs) designed to enhance intermediate vision.

Methods: The study included cataract surgery patients with either TECNIS Eyhance ICB00 or Precizon Go 580 IOLs between May 2020 and December 2024. We evaluated various visual acuity measures, including uncorrected distance visual acuity (UDVA), uncorrected intermediate visual acuity (UIVA), uncorrected near visual acuity (UNVA), as well as corrected distance visual acuity, defocus curves were evaluated at week 2, week 3 and at 3 months, contrast sensitivity, and ocular aberrations at 1 month and 3 months postoperatively. All 207 eyes underwent phacoemulsification with IOL implantation, and no complications occurred during or after the surgery.

Results: Our findings showed that three months after surgery, the Precizon Go group had significantly better postoperative CDVA. Precizon GO demonstrated superior outcomes in both monocular and binocular photopic UIVA and UNVA when compared to the

Eyhance ICB00 group. Specifically, the Precizon Go group exhibited better outcomes in the binocular and monocular defocus curve within the range of -2.00 to -3.50 D compared to the Eyhance ICB00 group.

Conclusions: At one month, the Eyhance ICB00 group showed superior internal spherical aberration results. Overall, the results indicated that the Precizon Go group showed superior performance in both intermediate and near vision.

Abstract No.: 201068

Color Discrimination in Cataract Patients Under Day and Night Conditions: Assessment and Correlation With Lens Opacity

First Author: Yuchen **WANG**

Co-Author(s): Anqi **GUO**, Xuemin **LI**

Purpose: To investigate color discrimination performance and its relationship with lens opacity in cataract patients under daytime and nighttime conditions.

Methods: Color discrimination of 7 hues (red, orange, yellow, green, cyan, blue, and purple) was assessed in 68 cataract patients using a dedicated software tool. Pairwise Spearman correlation analyses were conducted to examine relationships between color discrimination thresholds under daytime and nighttime conditions. Lens opacity was quantified and correlated with color resolution thresholds, defined as the minimal distinguishable wavelength difference within each color range.

Results: All 68 patients successfully completed the color vision assessment. In cataract patients, scores for red and green were the lowest ($p < 0.05$). Under daytime condition, orange and blue scores showed a negative correlation ($r = -0.57$, $p < 0.05$). At nighttime, purple and green ($r = 0.59$, $p < 0.05$), purple and blue ($r = 0.52$, $p < 0.05$), and blue and green ($r = 0.46$, $p < 0.05$) scores were positively correlated. Analysis of lens density and fine color discrimination revealed negative correlations between lens density and cyan and purple scores during daytime ($p < 0.05$), and between lens density and purple scores at nighttime ($p < 0.05$).

Conclusions: Cataract-related lens opacity impairs color discrimination. Due to protein aggregation, increased lens scattering, and alterations in the refractive index of the central region, cataractous lenses lead to declines in red and green visual function, alter inter-color relationship, and reduce resolution of short-wavelength light. These findings underscore the importance of comprehensive color vision assessment in cataract and highlight potential targets for preserving visual function in aging populations.

Abstract No.: 200250

Combination of Panel-Based Next-Generation Sequencing and Clinical Findings in Congenital Ectopia Lentis Diagnosis in Chinese Patients

First Author: Tianhui **CHEN**

Co-Author(s): Yongxiang **JIANG**

Purpose: To evaluate the diagnostic yield of congenital ectopia lentis (EL) in a Chinese cohort combined panel-based next-generation sequencing with clinical findings.

Methods: In total, 175 patients with congenital EL and their available family members ($n = 338$) were enrolled. All congenital EL patients underwent genetic testing. Genotype-phenotype analyses were conducted to assess the biometric and structural ocular manifestations of congenital EL.

Results: In total, 175 patients with congenital EL and 338 of their relatives were included in this study. In these patients, 92.57% (162/175) of disease-related variants were detected in FBN1 (83.43%), CPAMD8 (1.71%), COL4A5 (0.57%), ADAMTSL4 (3.43%), LTBP2 (1.71%), and CBS (2.29%). Based on the genetic and clinical findings, the primary diagnostic rate was elevated to 40.57% from 19.43% except for the 91 diagnoses of potential MFS, though a new diagnostic strategy of congenital ectopia lentis was developed. Within this group of patients harboring FBN1 mutations, 16.44% (19/141) probands were re-diagnosed with ectopia lentis syndrome (ELS) and 2.13% (3/141) were re-diagnosed with Marfan syndrome (MFS).

Conclusions: The results of this cohort study expand the genomic landscape associated with congenital EL in Chinese cohorts. FBN1 mutations represent the most common cause of congenital EL in this population, and we developed a new diagnostic strategy of congenital EL subtypes via a well-designed panel-based next-Generation Sequencing (NGS) which can be used to efficiently and precisely diagnose patients with congenital EL in a cost-effective manner.

Abstract No.: 201138

Comparison of Intracameral Injection of Mydriatics and Anaesthetic Combination Versus Topical Tropicamide + Phenylephrine Drops in Cataract Surgery

First Author: Ezhilvendhan **KALAIMAMANI**

Co-Author(s): Jeyaprakash **BALASUBRAMANIAN**

Purpose: To compare the safety and efficacy of intracameral injection of tropicamide + phenylephrine + lidocaine versus topical tropicamide+phenylephrine. To evaluate if intracameral injection has a positive influence on the pupil size, which could

minimize complications due to a small pupil during phacoemulsification.

Methods: In this comparative study, 100 eyes of 50 patients with bilateral senile cataract who underwent phacoemulsification were studied. Each patient's eyes were randomly assigned to two groups. One eye was operated on after instillation of a topical mydriatic (1 drop every 10 mins for 40 mins). The fellow eye was operated on only with intracameral injection of mydriatic and anaesthetic (injected after entering the anterior chamber). Pupil size is assessed during capsulorhexis, hydro-dissection, phacoemulsification, cortex wash, and IOL implantation. Blood pressure and pulse rate were also monitored.

Results: Patients with topical mydriatics had better dilatation than intracameral mydriatics, but pupil size was consistent throughout the procedure with intracameral injection. Surgeon's comfort was better with intracameral injection. Intra and postoperative complications were significantly less in the intracameral group.

Conclusions: Intracameral injection of mydriatics and anaesthetic is safe as it has no effect on the blood pressure, pulse rate and it is effective in phacoemulsification as it has significantly reduced the complications due to small pupil. It is extremely beneficial in patients undergoing toric IOL implantation.

Abstract No.: 201482

Comparative Analysis of 0.3% Nepafenac Once Daily, 0.1% Nepafenac Thrice Daily, and 0.5% Loteprednol Thrice Daily for Postoperative Inflammation Control After Uneventful Phacoemulsification

First Author: Ayushi **BANSAL**

Co-Author(s): Sahleen **AHMAD KHAN**

Purpose: To evaluate and compare the efficacy and safety of 0.3% Nepafenac once daily, 0.1% Nepafenac thrice daily, and 0.5% Loteprednol thrice daily in controlling postoperative inflammation and preventing cystoid macular edema (CME) following uneventful phacoemulsification cataract surgery.

Methods: A prospective comparative study was conducted on 600 patients undergoing phacoemulsification cataract surgery at Rajshree Hospital, Bareilly, between December 2023 and December 2024. Patients were equally randomized into three groups: 0.3% Nepafenac once daily, 0.1% Nepafenac thrice daily, and 0.5% Loteprednol thrice daily. Postoperative assessments were performed at baseline, week 1, and week 6. Parameters evaluated included anterior chamber (AC) cells, pain scores, conjunctival hyperemia, central macular thickness (CMT), and intraocular pressure (IOP). Data were analyzed using ANOVA and Chi-square tests.

Results: All groups demonstrated significant reduction in AC cells, pain, and hyperemia by week 6. The 0.3% Nepafenac group showed the least increase in CMT, indicating superior CME prevention. IOP profiles and safety outcomes were comparable across groups.

Conclusions: All regimens effectively controlled postoperative inflammation. However, 0.3% Nepafenac once daily provided comparable efficacy to 0.1% Nepafenac thrice daily and 0.5% Loteprednol thrice daily, with the added advantages of simplified dosing, better compliance, and enhanced CME prevention.

Abstract No.: 202802

Comparative Analysis of Iris Blood Flow After First and Second Cataract Surgeries: Insights Into Increased Pain Perception in the Second Eye

First Author: Jitong **ZHOU**

Co-Author(s): Yuxi **CHEN**, Wenwen **HE**, Yi **LU**, Jiaqi **MENG**, Xiangjia **ZHU**

Purpose: To investigate quantitative changes in iris blood flow after first and second cataract surgeries and its correlation with increased pain in the second eye.

Methods: In this prospective study, 88 eyes of 44 participants who underwent uneventful cataract surgery were followed up at enrollment, 1 day before, and 1 day, 1 week, and 1 month after each eye surgery. Iris blood flow was quantified by swept optical coherence tomography angiography, and intraoperative pain was evaluated. Participants were divided into 3 groups according to time intervals between two eye surgeries: ≥ 1 to < 2 weeks (short), ≥ 2 to ≤ 4 weeks (medium), and greater than 4 weeks (long).

Results: The second eye experienced two significant increases in iris blood flow following cataract surgery: one after the first eye and the other after its own, with the latter being significantly higher than the increase observed in the operated eye after the first surgery ($P < .05$). Additionally, the second eye showed higher iris blood flow density in the short interval group compared to the long and medium at specific time points ($P < .05$). The bilateral pain index difference positively correlated with second eye iris blood flow density ($P < .05$) and was significantly greater in the short interval group than the long interval group ($P < .05$).

Conclusions: Iris blood flow increased in the second operated eye post-surgery compared to the first eye, which may correlate with second-eye pain. However, due to the variability in individual pain perception, a larger sample size is needed to prospectively validate our findings to improve their generalizability.

Abstract No.: 203696

Comparative Analysis of Surgical Efficiency and Postoperative Corneal Clarity With Circumferential Sequential Nucleotomy vs Deep Vertical Nucleotomy in Dense Cataract

First Author: Bharti **KASHYAP**

Co-Author(s): Nidhi **GAJENDRAGADKAR**, Nilendu Dutta **MISHRA**, Nagendra **PRASAD**

Purpose: To compare intraoperative parameters CDE, Aspiration volume and time with circumferential sequential nucleotomy (Gr1) vs deep vertical nucleotomy (Gr2) in dense cataract and its effect on 1st and 7th day postop endothelial cell count, central corneal thickness, uncorrected distance visual acuity and 1month postop uncorrected distance visual acuity.

Methods: Prospective comparative study between circumferential sequential nucleotomy (Gr1) vs deep vertical nucleotomy (Gr2) in dense cataract for Intraoperative outcomes measure were CDE, Aspiration vol and time. 1&7 day postop outcomes measure were Endothelial Cell Count, Central Corneal Thickness, UCDVA & 1month postop outcome measures UCDVA. 100eyes each group, Single surgeon. Preop data comparable. Inclusion criteria: 4+ nuclear sclerosis on LOC III scale, sequential cataract surgery, Age 50-75yrs, ECD>2000 cells/mm², No Astigmatism & ocular morbidity, same viscoelastic and phaco machine with similar parameters in each group, Axial eye length variations upto 0.4mm. No zonular laxity, 5.5mm dilatation.

Results: Intra op CDE values & Asp.Time significantly less in Gr1 p=.0001, 95% CI (7.81,9.96) & p=0.03, 95% CI (1.49,34.5). Postop day 1 CCT significantly more in Gr2 p=.04, 95% CI (0.018,25.94), Preop ECC comparable. P=0.097, 95% CI (-2.60,30.64). Postop Day1 ECC is significantly higher in Gr1, Mean diff.=-119, p=.0001, 95% CI (-141.26,-96.74), Mean reduction in ECC significantly higher in Gr2, P<.0001, 95% CI (121.05,145.15). Post op day 1 Photopic UCDVA significantly better in Gr1 p=.0001, 95% CI (0.278,0.282). Post op day7 CCT & ECC and Post op 1month UCDVA comparable.

Conclusions: Intra op significantly less CDE and Asp by circumferential sequential nucleotomy results in sig. less Central Corneal Thickness, sig. better Endothelial cell count in early post op period which results in significantly better Uncorrected visual acuity on post op day 1.

Abstract No.: 200607

Comparative Evaluation of Corneal Endothelial Cell Loss in Grade 3 Cataract Following Femtosecond Laser-Assisted Cataract Surgery, Four Quadrant Versus Full Softening

First Author: Arnav **SINGHAL**

Co-Author(s): Rishi **SETHI**

Purpose: The primary objective is to compare the mean corneal endothelial cell loss by analyzing the decrease in endothelial count (in absolute numbers per mm²) using a specular microscope preoperatively and postoperatively in both groups. The secondary objectives are to compare central corneal thickness by analyzing changes in corneal thickness (in microns) using a specular microscope preoperatively and postoperatively in both groups, and to compare visual acuity in postoperative patients of both groups using Snellen's chart.

Methods: This was a single-center randomized controlled trial evaluating femtosecond laser-assisted cataract surgery (FLACS) with two nucleus softening techniques: four-quadrant fragmentation and full softening. Cataract patients reporting to the Ophthalmology Department who met the inclusion and exclusion criteria were considered for the study. Sample Size At 95% confidence level and 90% power, taking mean reduction in endothelial count in four quadrant nucleus fragmentation group as 1.66±0.50 and mean reduction in endothelial cell count in full softening nucleus fragmentation group as 0.58±0.75, sample size was calculated as 20 per group. Patients were recruited after being advised for cataract surgery and intraocular lens (IOL) implantation by a consultant ophthalmologist. Informed written consent was obtained from each patient after explaining the study objectives, methodology, and follow-up requirements. Patients were randomized into two groups using a concealed allocation method.

Results: Full softening method resulted in lower endothelial cell loss and better visual acuity and less edema.

Conclusions: Full softening technique in FLACS surgery is highly efficient and better prognosis than four quadrant.

Abstract No.: 207451

Comparative Evaluation of Preoperative Bromfenac and Nepafenac Eye Drops in Sustaining Intraoperative Mydriasis During Small Incision Cataract Surgery

First Author: Asam **NAVEENA**

Co-Author(s): Megha **VARNIKA**, Bhavishya

Purpose: To compare the effectiveness of preoperative topical Bromfenac Nepafenac in maintaining

intraoperative mydriasis during small incision cataract surgery, and to assess their efficacy in relation to the duration of surgery.

Methods: This prospective, comparative study was done on 102 patients undergoing cataract surgery. Patients were equally divided into two groups by simple randomization and received either Bromfenac or Nepafenac eye drops preoperatively. Pupillary diameter was measured before entering the anterior chamber and at the end of surgery, and the mean difference in pupillary diameter is calculated. The data were analyzed to compare the percentage loss of pupillary diameter between groups and to correlate maintenance of mydriasis with the duration of the surgical procedure.

Results: Both the Bromfenac and Nepafenac groups showed minimal and statistically insignificant reduction in mean pupillary diameter overall. However, when the duration of surgery was prolonged, Bromfenac demonstrated a superior ability to maintain pupillary dilation compared to Nepafenac.

Conclusions: Preoperative administration of both Bromfenac and Nepafenac effectively sustains intraoperative mydriasis during cataract surgery. Notably, Bromfenac offers a significant advantage in maintaining dilation during longer surgical procedures, making it the preferred Non steroidal anti inflammatory drug of choice for extended operations, especially while trainee surgeons are operating.

Abstract No.: 206069

Comparative Evaluation of Traditional and AI-Based Intraocular Lens Power Calculation Formulas in Highly Myopic Eyes

First Author: Xiaopeng **JIANG**

Co-Author(s): Jiangjie **WANG**, Fei **XIA**

Purpose: To assess the accuracy of artificial intelligence (AI)-based intraocular lens (IOL) power calculation formulas compared with traditional methods in highly myopic eyes, and to evaluate their performance across varying axial lengths and corneal curvatures.

Methods: This retrospective case series included 115 highly myopic eyes that underwent phacoemulsification with IOL implantation. IOL power was calculated using four conventional formulas (SRK/T, Haigis, Holladay 2, Barrett Universal II) and seven AI-based formulas (Hill-RBF 3.0, Karmona, Hoffer QST, PEARL-DGS, Ladas Super Formula, Kane, HM-ZL). The outcomes were evaluated using standard deviation (SD), assessed with the Heteroscedastic test; root-mean-square absolute error (RMSAE), assessed with the bootstrap-t method; mean absolute error (MAE), assessed with the Friedman test; and the percentage of eyes within ± 0.25 D to ± 1.00 D of prediction error, assessed with Cochran's Q test. Subgroup analyses were performed based on axial length (AL) and corneal curvature (Kmean).

Results: Most AI-based formulas—especially Hill-RBF 3.0, PEARL-DGS, and Kane—demonstrated higher accuracy than traditional formulas. Overall, the MAEs of Hill-RBF 3.0, PEARL-DGS, and Kane were significantly lower than those of Holladay 2 ($P < 0.05$). The SD of PEARL-DGS also differed significantly from Holladay 2 ($P < 0.05$). In the long axial length group, Hill-RBF 3.0, PEARL-DGS, and Kane showed significantly lower MAEs than Holladay 2 ($P < 0.05$). In the moderate corneal curvature group, Hill-RBF 3.0, Hoffer QST, PEARL-DGS, and Kane had significantly lower MAEs than Holladay 2, and the SDs of Hill-RBF 3.0 and PEARL-DGS differed significantly from both Holladay 2 and SRK/T ($P < 0.05$). Trend lines showed that AI-based formulas exhibited more consistent and stable performance across different AL and Kmean.

Conclusions: AI-based formulas provide superior refractive prediction in highly myopic eyes compared with traditional methods. Tailored formula selection based on biometric profiles may enhance refractive outcomes in cataract surgery.

Abstract No.: 201088

Comparative Outcomes of Femtosecond Laser-Assisted Arcuate Keratotomy (FSAK) With Multifocal IOL Implantation Versus Multifocal Toric IOL Implantation in Cataract Patients With Varying Astigmatism Patterns

First Author: Zunxia **HU**

Co-Author(s): Li **LI**, Jing **SIMA**

Purpose: Comparison of FSAK and Multifocal Toric IOLs in Correcting Corneal Astigmatism in Different Types of Cataract Patients

Methods: Prospective Cohort Study on FLACS with Low-to-Moderate Corneal Astigmatism. A total of 91 eyes received FSAK combined with ZMB00 IOL implantation (37 WTR, 44 ATR, and 10 OBL), while 89 eyes were implanted with ZMT150/ZMT225 (32 WTR, 45 ATR, and 11 oblique). Postoperative outcomes at 3 months were compared, including UDVA, UNVA, BCDVA, Residual total astigmatism, Defocus curves, Astigmatic correction efficacy using Alpíns vector analysis.

Results: There was no statistically significant difference in best-corrected distance visual acuity (BCDVA) between the two groups. However, the ZMT group demonstrated superior uncorrected distance and near visual acuity (UDVA: 0.08 ± 0.09 vs 0.12 ± 0.12 , $P = 0.027$; UNVA: 0.14 ± 0.08 vs 0.21 ± 0.11 , $P = 0.002$). The ZMT group showed significantly less residual total ocular astigmatism (-0.51 ± 0.49 D) compared to the FSAK group (-0.84 ± 0.51 D, $P = 0.012$). Defocus curves revealed comparable visual performance across all distances. The FSAK group exhibited significantly lower overall CI values (0.73 ± 0.43 vs 1.07 ± 0.44 , $P < 0.001$) and particularly for with-the-rule astigmatism (0.61 ± 0.47 vs 1.30 ± 0.37 , $P < 0.001$). No significant differences were

observed in CI values for against-the-rule (0.75 ± 0.40 vs 0.89 ± 0.42 , $P=0.270$) or oblique astigmatism (0.75 ± 0.39 vs 1.20 ± 0.37 , $P=0.058$).

Conclusions: Multifocal TIOLs provide better astigmatic correction than FSAK combined with MIOLs. However, overcorrection was observed in WTR and OBL cases with toric IOLs.

Abstract No.: 200458

Comparative Patient Study: Lentis Quantum vs. Acunex Quantum – Is There a Difference in Visual Performance and Subjective Quality of Vision?

First Author: Lena **BECKERS**

Co-Author(s): David **BECKERS**, Florian **KRETZ**

Purpose: To compare the clinical and subjective visual performance of the Lentis Quantum (hydrophilic, clear) and the Acunex Quantum (hydrophobic, blue-light filtering) intraocular lenses (IOLs) in a paired-eye patient study.

Methods: Ten patients (20 eyes) undergoing bilateral cataract surgery received the Lentis Quantum in one eye and the Acunex Quantum in the fellow eye. At 3 months postoperatively, patients were evaluated monocularly and binocularly. Objective assessments included corrected distance visual acuity (CDVA), corrected intermediate visual acuity (CIVA), corrected near visual acuity (CNVA), defocus curves (mono- and binocular), and contrast sensitivity testing. Subjective evaluation addressed perceived differences in visual quality, specifically color perception and contrast, when comparing the two eyes.

Results: Both IOLs provided excellent visual acuity across all tested distances. Defocus curves revealed comparable depth of focus in both groups. Contrast sensitivity was slightly reduced in the eye with the blue-light filtering IOL in some patients. Subjectively, several patients reported subtle differences in color and contrast perception between the two eyes, with a tendency to notice a warmer hue or reduced brightness in the Acunex Quantum eye. However, these differences were minimal under binocular conditions and did not affect overall satisfaction.

Conclusions: This intraindividual comparison highlights the clinical equivalence of the Lentis Quantum and Acunex Quantum in terms of visual acuity and defocus performance. However, differences in material and chromophore design may lead to slight subjective variations in color and contrast perception. These findings underscore the value of tailored IOL selection based on patient-specific visual preferences and sensitivities.

Abstract No.: 205841

Comparison Among Topical 2% Rebamipide, 3% Diquafosol, and 0.1% Hyaluronic Acid in Post-Cataract Surgery Dry Eye Patients

First Author: Jae Yong **KIM**

Co-Author(s): Ho-seok **CHUNG**, Tae Hun **KIM**, Hun **LEE**

Purpose: To compare preoperative and postoperative changes at 1 and 3 months in post-cataract surgery dry eye patients treated with topical 2% rebamipide (G1), 3% diquafosol (G2), and 0.1% hyaluronic acid (G3).

Methods: This was a single-center prospective study. Ocular Surface Disease Index (OSDI), tear break-up time (TBUT), NEI corneal/conjunctival staining score, Schirmer test, tear osmolarity, and MMP-9 levels were measured in G1, G2, and G3 at baseline and 1 and 3 months after surgery. Between-group comparisons were performed using ANOVA on the changes (Δ = 1 month or 3 months – baseline), while within-group changes were assessed with paired t-tests.

Results: For OSDI, intergroup differences in change were significant at both 1 and 3 months ($p < 0.05$). All three groups showed significant reductions at 1 month (G1: $35.07 \pm 19.65 \rightarrow 16.95 \pm 11.24$, $p < 0.001$; G2: $38.78 \pm 21.81 \rightarrow 22.98 \pm 16.31$, $p = 0.018$; G3: $45.34 \pm 23.27 \rightarrow 12.28 \pm 12.55$, $p < 0.001$). At 3 months, significant reductions persisted in the diquafosol and hyaluronic acid groups (G2: $38.78 \pm 21.81 \rightarrow 20.79 \pm 10.85$, $p = 0.018$; G3: $45.34 \pm 23.27 \rightarrow 13.41 \pm 20.07$, $p < 0.001$). In the Schirmer test, the hyaluronic acid group showed a significant increase at 3 months (G3: $9.29 \pm 5.42 \rightarrow 12.06 \pm 5.74$, $p = 0.026$). For NEI corneal staining, intergroup differences at 1 month were significant ($p < 0.05$), with hyaluronic acid showing a significant reduction (G3: $4.88 \pm 2.42 \rightarrow 2.35 \pm 1.66$, $p < 0.001$).

Conclusions: After cataract surgery, rebamipide improved symptoms in the early postoperative period, diquafosol contributed to sustained improvement up to 3 months, and hyaluronic acid showed significant benefits not only in symptoms but also in tear secretion and corneal status.

Abstract No.: 202981

Comparison and Evaluation of New Artificial Intelligence-Based Formulas With Regression Formulas for Intraocular Lens Power Calculations

First Author: Abhishek A T M

Co-Author(s): Harish **ARAVINDABABU**, Amod **HANSDAK**, Hannah **RANJEE WILLIAMS**

Purpose: Accurate IOL power calculation is critical for optimal postoperative refractive outcomes after cataract surgery. Traditional regression formulas (SRK II, Haigis, Hoffer Q, Holladay I) may falter in eyes with atypical biometry. AI-driven formulas—Hill RBF and the Ladas Super Formula (LSF)—offer enhanced

adaptability across diverse biometric profiles. This study compares the predictive accuracy of Hill RBF and LSF versus four regression methods in routine cataract patients and evaluates performance across axial length (AL) and keratometric values.

Methods: In this analytical cross-sectional study (Nov 2022–May 2024), 222 eyes who underwent uneventful cataract surgery were enrolled and had IOL power calculated by six formulas; actual postoperative spherical equivalents were recorded. Prediction errors (MNE, MAE, MeAE) were computed. Subgroup analyses addressed axial lengths (short, average, long) and keratometry ranges (flat, normal, steep).

Results: SRK II achieved the lowest MAE, followed by Holladay I; Haigis showed the greatest error spread. AI-based formulas maintained stable error metrics across axial length extremes, unlike regression formulas, which were sensitive to biometric outliers. Bland–Altman analysis revealed Holladay I's bias and agreement limits closely matched SRK II, while AI models exhibited minimal systematic bias relative to target refraction.

Conclusions: Regression formulas, SRK II and Holladay I, remain reliable for refractive predictions. AI-driven formulas excel in eyes with atypical axial lengths, offering consistent accuracy without bias. Combining conventional and AI-based approaches tailored to biometric profiles may improve outcomes. Future multicenter trials with larger cohorts and extended follow-up are needed to validate and refine AI formula performance.

Abstract No.: 204260

Comparison of Axial Length and Predictive Error Using Swept-Source Optical Coherence Tomography (SS-Oct) Based Biometer and Scheimpflug-cum- Partial Coherence Interferometry (PCI) Based Biometer Post Phacoemulsification

First Author: Pankhudi **VERMA**

Co-Author(s): Amit **RAJ**, Devkant

Purpose: To compare biometric measurements and postoperative refractive outcomes between Pentacam AXL (PCI with Scheimpflug) and IOLMaster 700 (SS-OCT) in cataract surgery patients.

Methods: This prospective observational study included 102 eyes undergoing phacoemulsification at a tertiary care hospital. Biometric parameters, including axial length (AL), anterior chamber depth (ACD), central corneal thickness (CCT), keratometry (K1, K2, ΔK), and white-to-white (WTW), were recorded on both Pentacam AXL and IOL Master 700. Then, patients were randomly allocated to Group A (Pentacam AXL–based IOL calculation) or Group B (IOLMaster 700–based calculation). Postoperative uncorrected visual acuity (UCVA), best corrected visual acuity(BCVA), and

predictive error (PE) were assessed at 6 weeks and 3 months.

Results: AL measurements showed no significant difference ($p > 0.05$). K1 values demonstrated strong agreement (CCC = 0.972), while K2 and ΔK showed poor concordance. ACD values were comparable, though IOLMaster 700 recorded slightly higher means. Significant differences were observed in CCT and WTW ($p < 0.001$). At 6 weeks, mean PE was -0.280 ± 0.290 D with Pentacam AXL and -0.411 ± 0.295 D with IOLMaster 700 ($p = 0.039$). At 3 months, differences were not significant ($p = 0.239$). At both follow-ups, >85% of eyes achieved refraction within ± 0.50 D, with Group B slightly higher at 3 months (90.20% vs. 86.27%).

Conclusions: Both devices showed reliable biometric accuracy and high refractive predictability. Pentacam AXL is a clinically viable alternative to IOLMaster 700 for IOL power calculation.

Abstract No.: 200684

Comparison of Clinical Outcomes in Cataract Surgery at Near Physiologic Intraocular Pressure Using the Active Fluidics System Versus Higher IOP

First Author: Kun **ZENG**

Co-Author(s): Lishi **LUO**, Yuanjiao **QIAO**, Ye **YE**

Purpose: This study aims to compare the need for additional topical anesthetic due to breakthrough discomfort during cataract surgery at a low intraocular pressure (IOP) of 30 mmHg using the Centurion active fluidics system with Active Sentry (AS) versus the traditional (higher) IOP (≈ 80 mmHg at 110 cm bottle height) using the Stellaris system.

Methods: Conducted at Shenzhen Eye Hospital, this prospective, randomized, comparative study enrolled 80 eyes scheduled for phacoemulsification surgery. Participants were randomly assigned to two groups: Group A underwent cataract surgery at near physiologic IOP (30 mmHg) using Centurion with AS while the control group underwent cataract surgery at traditional IOP at 110 cm bottle height (≈ 80 mmHg) using Stellaris. Preoperative evaluation was performed, including ophthalmologic exams, IOP measurement, central corneal thickness (CCT), and corneal endothelial count. Breakthrough pain was managed with additional topical anesthetic and recorded. Patients rated their intraoperative pain on a visual analog scale (VAS), in which 0 was 'no pain' and 10 was 'unbearable pain'. Visual acuity, IOP, and CCT were recorded on the first day post-surgery and one week later.

Results: The study found a significant difference in the primary outcome, with only 2.5% of patients (1 of 40 eyes) in Group A needing additional anesthetic compared to 12.5% (5 of 40 eyes) in Group B ($p < 0.05$). Phacoemulsification times were similar, though Group

A had a slight, non-significant reduction. Group A also reported lower mean VAS scores (1.17) than Group B (2.5) ($p < 0.01$). Post-surgery, both groups showed no statistically significant differences in visual acuity and IOP. However, Group B experienced a greater increase in central corneal thickness (CCT) on the first day ((9.04% vs. 5.85%, respectively) ($p < 0.05$)). After one week, both changes in CCT and corneal endothelial cell count were not significantly different between the groups.

Conclusions: Near Physiologic Intraocular pressure cataract surgery using the Centurion system reduces intraoperative discomfort and early postoperative corneal edema compared to the Stellaris system, offering potential benefits for patient comfort and recovery without compromising visual outcomes.

Abstract No.: 203698

Comparison of Visual Performance and Astigmatism Tolerance Between Five Presbyopia-Correcting Intraocular Lenses

First Author: Xiaofei HU

Co-Author(s): Lixia LUO, Xuhua TAN, Jiaqing ZHANG, Yu ZHANG

Purpose: To compare the impact of astigmatism on the visual performance of five presbyopia-correcting IOLs in patients following cataract surgery.

Methods: This prospective, observational study enrolled cataract patients who underwent uncomplicated phacoemulsification with implantation of ZXR00, ZMB00, ZFR00V, Vivity or TFNT00. Uncorrected distance visual acuity (UDVA), corrected distance visual acuity (CDVA), uncorrected intermediate visual acuity (UINA), uncorrected near visual acuity (UNVA), and refractive outcomes 3 months postoperatively were collected. Astigmatism was induced with a negative cylinder from -0.25 to -2.00 diopters (D) in 0.25-D steps for different astigmatic orientations, and the corresponding distance visual acuity was recorded.

Results: A total of 214 patients (214 eyes) were included. For the ZMB00, TFNT00, and ZFR00V, -0.50D of astigmatism significantly affects UDVA, UIVA and UNVA. In contrast, for the Vivity and ZXR00, -0.75D astigmatism primarily impacts UDVA (all $P < 0.05$). Regarding the ZMB00, TFNT00, and ZFR00V, when with-the-rule (WTR) astigmatism is $\leq 1.00D$, against-the-rule (ATR) astigmatism is $\leq 0.75D$, and oblique astigmatism is $\leq 0.75D$, UDVA remains better than 0.2 logMAR. For the Vivity and ZXR00 IOLs, when WTR astigmatism is $\leq 1.50D$, ATR astigmatism is $\leq 1.25D$, and oblique astigmatism is $\leq 1.00D$, UDVA exceeds 0.2 logMAR. Across all five PC-IOLs, WTR astigmatism demonstrates the least impact on visual acuity in all types of astigmatism (all $P < 0.05$).

Conclusions: Extended depth-of-focus (EDOF) IOLs demonstrated greater tolerance to astigmatism compared to multifocal and full visual range IOLs.

Abstract No.: 202734

Comprehensive Analysis of Ocular Biometry in Cataract Patients: A Large-Cohort Retrospective Study at a Tertiary Eye Hospital in Hong Kong

First Author: Wai Ting CHAN

Co-Author(s): Julia Yan Yu CHAN, Chung Chai CHI, Vanessa Wing-see CHOW, Nai Man LAM, Ke LIU, Rachel Wing Yan TSUI

Purpose: To evaluate the accuracy of ocular biometry and refractive outcomes in patients undergoing cataract surgery at a regional tertiary eye referral center in Hong Kong.

Methods: This was a cross-sectional, retrospective study of patients ($n = 1133$) who underwent uneventful phacoemulsification with intraocular lens (IOL) implantation at Hong Kong Eye Hospital between April and August 2024. Data collected included demographics, preoperative parameters (axial length, anterior chamber depth, target spherical equivalent, biometry machine and formula), and postoperative outcomes (IOL model, IOL power, postoperative SE). Exclusion criteria included ECCE or ICCE, combined procedures and complicated surgeries involving AV or PCR.

Results: A total of 1133 eyes from 1133 patients were analyzed (614 female [52.4%], 519 male [45.8%], mean age: 75.6 ± 8.5 years, range: 36–96 years). Biometry was performed by qualified personnel using the IOLMaster 700 (1103 eyes, 97.4%, Barrett Universal II formula) or Nidek biometer (30 eyes, 2.6%, SRK/T formula). Overall, 95.7% (1084/1133) achieved postoperative SE within $\pm 1.0 D$ of the target refraction (mean absolute difference: $0.37 \pm 0.32 D$, range: 0–2.49 D). Subgroup analysis demonstrated high accuracy across IOL models: ZCB00 (96.2%, 428/445), ICB00 (95.6%, 644/677), and SN60WF (81.8%, 9/11). Stratified by AL, outcomes were within $\pm 1.0 D$ in 90.0% (28/31) with AL < 22 mm, 95.0% (927/972) with AL 22–26 mm, and 99.0% (129/130) with AL > 26 mm.

Conclusions: Cataract surgery at our centre achieved excellent biometry accuracy, with 95.7% of patients within $\pm 1.0 D$ of target refraction which is well above the 85% benchmark set by the RCO Cataract Surgery Guidelines. These underscore the need to consider advanced formulas (e.g., EVO, Kane formula) for nanophthalmic eyes.

Abstract No.: 204356**Decoding Toric IOL Performances in Real-World: A Study on Postoperative Rotational Stability and Influencing Factors***First Author: Ruihong JU*

Purpose: This study aims to investigate the rotational stability of Toric IOLs in real-world clinical settings and to identify independent risk factors that may influence their rotational stability.

Methods: This retrospective case series study included 732 patients with 913 eyes who underwent phacoemulsification and implantation with Toric IOLs for cataracts with astigmatism at our hospital between 2018 and 2023. Postoperative uncorrected distance visual acuity (UDVA), best-corrected visual acuity (BCVA), residual astigmatism (RAS), and Toric IOL rotation were evaluated at 1 week and 1 month postoperatively.

Results: Postoperative UDVA was 0.22 ± 0.15 on the 1st day, 0.13 ± 0.13 at 1st week, and 0.11 ± 0.12 at 1st month. BCVA was 0.04 ± 0.08 at 1st week and 0.03 ± 0.09 at 1st month postoperatively ($P > 0.05$). The proportion of eyes with equivalent spherical refraction (SE) within $\pm 0.5D$ was 85.9% at 1st week and 85.29% at 1st month ($P > 0.05$). The mean preoperative astigmatism was $1.81 \pm 0.67D$, and the expected RAS was $0.14 \pm 0.09D$, with a statistically significant difference ($P < 0.001$). Postoperative RAS was $0.45 \pm 0.32D$ at 1st week and $0.40 \pm 0.32D$ at 1st month, significantly reduced comparing to the preoperative values ($P < 0.001$). The mean rotation of Toric IOLs was $3.26^\circ \pm 0.82^\circ$ at 1st week and $3.36^\circ \pm 2.80^\circ$ at 1st month, with no statistically significant difference ($P = 0.137$). Using the rotation of Toric IOLs $\geq 5^\circ$ at 1st month as the observation indicator, four independent risk factors were identified after univariate regression analysis, multicollinearity testing, interaction term verification, and multivariate regression analysis: mean keratometry (K), anterior segment length (ASL), anterior capsule polishing (ACP), and postoperative hospital observation ($P < 0.05$).

Conclusions: Patients with cataracts and corneal astigmatism who underwent Toric IOL implantations mostly achieved good astigmatic correction, postoperative visual acuity, and rotational stability. Furthermore, ASL, K, intraoperative ACP and 1-day postoperative hospital observation were identified as independent predictive factors influencing the rotational stability of Toric IOLs.

Abstract No.: 203869**Early Real-World Experience With a Full Visual Range, Non-Toric Intraocular Lens***First Author: Chameen SAMARAWICKRAMA*

Purpose: To present a case series documenting real-world outcomes following implantation with the

enVista ENVY (EN) non-toric intraocular lens (IOL) in patients undergoing cataract surgery.

Methods: EN is a full visual range IOL that provides up to 4 D of continuous vision with enhanced tolerance to dysphotopsia. In this interim case series, five eyes of five patients were implanted with the EN IOL by one ophthalmologist at one center in Australia from January to March 2025. Additional cases will be collected (~20 patients), and all patient cases with adequate follow-up will be presented. Key outcomes include uncorrected distance visual acuity (UDVA), uncorrected near visual acuity (UNVA), and mean refractive spherical equivalent (MRSE).

Results: In the interim case collection, the mean $\pm$ SE target spherical equivalent (SEQ) was $0.13 \pm 0.05 D$ ($n=5$). A monocular UDVA of 6/6 or better was achieved in three of five eyes; one eye achieved 6/9, and one achieved 6/12. A monocular UNVA of J4 or better was achieved in three of five eyes; one eye achieved J6, and one achieved J8. The mean $\pm$ SE MRSE was 0.15 ± 0.22 ($n=5$), and the mean $\pm$ SD delta SEQ was 0.02 ± 0.21 ($n=5$).

Conclusions: In this real-world case series, most patients implanted with the FVR IOL achieved good distance vision and functional near vision.

Abstract No.: 203365**Effect of Angle Kappa on the Refractive Prediction Accuracy in Cataract Patients After Myopic LASIK/PRK***First Author: Xuhua TAN**Co-Author(s): Haorui YUAN*

Purpose: To evaluate the impact of angle kappa on prediction accuracy in patients after myopic laser-assisted in-situ keratomileusis (LASIK)/photorefractive keratectomy (PRK).

Methods: This retrospective, consecutive case-series study included 127 post-myopic-LASIK/PRK cataract patients (176 eyes). Three different keratometry (K) values measured by 2 devices were assessed, including simulated keratometry (SimK) obtained by IOLMaster 700 at 2.5-mm ring centered on corneal vertex and SimK derived from Pentacam AXL in 3-mm zone centered on corneal vertex (Pentacam [CV]) and pupil center (Pentacam [PC]). The performance of the Barrett True-K formula based on vertex-centered K values (IOLMaster 700; Pentacam [CV]) and pupil-centered K values (Pentacam [PC]) was compared. The polynomial regression curve was the best-fit curve to illustrate the variation in arithmetic prediction error (PE) with angle kappa. Subgroup analysis was performed based on the inflection point suggested by curves (angle kappa < 0.4 mm; angle kappa ≥ 0.4 mm).

Results: The hyperopic PE of the IOLMaster 700 and Pentacam (CV) modes increased with larger angle kappa. Both in total and in eyes with angle kappa < 0.4 mm, compared with other modes, the IOLMaster

700 mode showed no systematic bias and relatively lower absolute PE. For eyes with angle kappa ≥ 0.4 mm, IOLMaster 700 and Pentacam (CV) modes demonstrated hyperopic PE (0.43 to 0.46 D, $P < 0.05$), while the Pentacam (PC) mode displayed no systematic bias, relatively lower mean absolute PE (0.70 D vs 0.90-0.96 D) and the highest percentage of eyes with PE within ± 0.5 D (51.22% vs 36.59%-41.46%).

Conclusions: In post-myopic-LASIK/PRK patients, the prediction accuracy decreased with greater angle kappa when using the corneal vertex-centered K values. The pupil-centered K values were preferred for these patients with angle kappa ≥ 0.4 mm.

Abstract No.: 206458

Effect of Capsular Tension Ring on Toric IOL Stability and Visual Outcomes: A Cohort Study Stratified by Axial Length

First Author: Jian **DENG**

Co-Author(s): Hui **GUO**, Liduo **PAN**, Xi **SONG**, Xiaoyi **YU**

Purpose: Rotational stability of toric intraocular lenses (IOLs) is key to effective astigmatism correction, particularly in long eyes at higher risk of mispositioning. This study compares toric IOL rotational stability and visual outcomes with and without a capsular tension ring (CTR), to define the optimal axial length for CTR use.

Methods: A prospective cohort study enrolled eyes receiving toric IOL (ZMT) with or without CTR. All affected eyes underwent phacoemulsification and toric IOL implantation, with CTRs implanted in the eyes of the CTR group. Eyes were stratified by axial length (AL): non-myopic (AL:22-24.5mm), mild-moderate myopic (AL:24.5-26mm), and highly myopic (AL ≥ 26 mm). Patients were followed up at 1 day, 1 week, 1 month, and 3 months. Key outcome measures included TIOL rotation, tilt, decentration, residual astigmatism, refractive error, and objective visual quality.

Results: Of 116 eyes (93 patients) analyzed, the CTR group showed significantly less IOL rotation than controls at 1 week (2° vs 3° , $p < 0.05$). CTR implantation also reduced residual astigmatism and improved rotational stability in both mild-to-moderate and highly myopic eyes. Additionally, the CTR group had significantly lower total tilt (4° vs 5° , $p < 0.05$), horizontal tilt (3.7° vs 4.6° , $p < 0.05$). The CTR group demonstrated significantly lower coma (0.07 vs 0.08, $p < 0.05$), with highly myopic eyes also exhibiting significantly lower coma compared to controls ($p < 0.05$). A significant correlation was found between IOL rotation and residual astigmatism ($R=0.38$, $p < 0.001$). Multivariable analysis confirmed CTR implantation as an independent factor for reduced rotation.

Conclusions: CTR implantation significantly improves stability and visual outcomes of toric IOL in eyes with axial length ≥ 24.5 mm, but provides no benefit in non-

myopic eyes. These findings support the selective use of CTR in longer eyes to optimize surgical outcomes. Further validation with a larger sample size and longer-term follow-up is warranted.

Abstract No.: 203851

Effect of Neodymium:Yttrium-Aluminum-Garnet Laser on Capsular Convexity and Capsulorrhexis in Intumescent Cataracts: Anterior Segment Optical Coherence Tomography Assessment

First Author: Vaibhav **VISHAL**

Co-Author(s): Rohitha **NAYAK**, Naren **SHETTY**

Purpose: To evaluate anterior segment changes and intraoperative challenges following Neodymium:Yttrium-Aluminum-Garnet (Nd:YAG) laser pretreatment in different types of intumescent cataracts, as classified by anterior segment optical coherence tomography (AS-OCT).

Methods: This prospective study included 90 eyes with intumescent mature cataracts diagnosed on slit-lamp examination and categorized using AS-OCT. Biometry was performed with immersion ultrasonography, intraocular lens (IOL) Master, and Argos devices. A single Nd:YAG laser shot was applied 30 minutes before surgery. CASIA-2 AS-OCT scans were obtained before and after treatment. Parameters analyzed included lens biometry, circumferential lens rise, and anterior chamber depth. Intraoperative complications were recorded.

Results: Nd:YAG laser was most effective in type II and type III intumescent cataracts. Following treatment, anterior capsule convexity and circumferential lens rise decreased, while anterior chamber depth increased. No intraoperative complications such as Argentinian flag sign, capsulorrhexis extension, or posterior capsule rupture were observed.

Conclusions: Nd:YAG laser pretreatment reduces anterior capsule convexity and deepens the anterior chamber, thereby preventing intraoperative complications in intumescent cataracts. AS-OCT is a valuable tool for classifying cataract morphology, predicting Nd:YAG laser effects, and selecting suitable cases to improve surgical safety.

Abstract No.: 201647

Efficacy and Safety of a Selective Laser Device to Create Centered Capsulotomies in White Intumescent Cataracts: A International Multicenter Study (LC – WIC Study)

First Author: Jai **KELKAR**

Co-Author(s): Aditya **KELKAR**, Richard **PACKARD**, Sathish **SRINIVASAN**

Purpose: To evaluate the efficacy and safety of a centered anterior capsulotomy creation with a new

selective laser device in eyes with white intumescent cataracts.

Methods: Prospective multicentre interventional study across five clinical sites in United Kingdom, Bulgaria, India and Saudi Arabia. A total of 84 eyes of – subjects with white intumescent cataracts were recruited after anterior segment OCT (AS-OCT) established the presence of intralenticular fluid pockets indicative of raised intralenticular pressure. In all cases, prior to phacoemulsification, selective laser capsulotomy (SLC) was performed by staining the anterior capsule with a customised 0.4 % trypan blue. Capsulotomies were created with a diameter of 5.5 mm. Subjects were followed up at one day, one week, one and three months postoperatively.

Results: In all cases, the capsulotomy was successfully created as planned. No intraoperative complications were observed. At 3 months postoperatively the mean capsulotomy diameter measured 5.3 mm (range: 5.2 to 5.5 mm). No cases of capsular phimosis were observed during the three-month follow-up period. In all cases, visual acuity improved from preoperative light perception to mean postoperative uncorrected distance visual acuity (UDVA) of 0.28 LogMAR (range: 0.0 to 1.0).

Conclusions: The use of SLC in this series of eyes with white intumescent cataracts achieved consistently sized, continuous and well-centred capsular openings. There were no complications such as the Argentine flag sign or anterior capsular tears. These results highlight the precision and safety of using selective laser capsulotomy for creating anterior capsulotomies in white intumescent cataracts.

Abstract No.: 205070

Endothelium's BFF: Miloop to the Rescue in Tough Cataracts

First Author: Sneha G V

Co-Author(s): Sriganesh, Sadhwini HARISH, Supriya SRIGANESH

Purpose: To compare intra-operative phaco energy and post-operative endothelial cell density(ECD) with and without a nuclear fragmentation device.

Methods: Patients aged more than 45 years with NS grade ≥ 3 were included. Total of 64 eyes were included, 32 in control group and 32 in miLOOP group. Single surgeon, using the same phaco machine (Centurion Vision System, Alcon Surgicals) performed all surgeries. Phaco energy parameters, day 1 post-operative corneal edema and ECD on day 15 & 3 months were noted.

Results: Mean Cumulative Dissipated Energy (CDE) was 15.21 ± 3.28 units in miLoop group and 21.73 ± 10.27 units in the other. Mean total ultrasound time was $01:05.19 \pm 00:15.77$ minutes in miLOOP group and $01:29.95 \pm 00:34.42$ minutes in control group. On

post-op day 1, grade 3 corneal edema was seen in 6.3% of miLOOP group eyes and 21.9% of control group eyes. Mean post-operative ECD at 3 months was 1898.52 ± 455.52 cells/mm² in miLOOP group and 1361.53 ± 408.12 cells/mm² in the other. The comparisons were statistically significant.

Conclusions: miLOOP is a useful tool in managing hard cataracts. Phaco power, time & endothelial cell loss at 3 months is significantly lower compared to routine phacoemulsification, with low incidence of corneal edema on day 1.

Abstract No.: 200988

Enhanced Wet Lab Training With the Microwave-Induced Nucleus Cataract Model Eye

First Author: Kosei TOMITA

Co-Author(s): Takenori INOMATA, Ken NAGINO, Shintaro NAKAO

Purpose: This study is to develop reproducible cataract model eyes in porcine eyes using a microwave surgical device, aiming to simulate key steps of cataract surgery and enhance the effectiveness of wet lab training.

Methods: Fresh porcine eye was used to create the nucleus cataract model eye. A pencil-type electrode was inserted 4 mm posterior to the limbus and activated at 50 mW for 30 seconds at the lens center to create the nucleus cataract model eye. The nucleus cataract model eyes (n=23) were evaluated using cumulative dissipated energy (CDE) during phacoemulsification.

Results: Microwave thermal coagulation successfully created hardened nucleus cataract models without affecting corneal transparency. Trypan blue staining simulated a poor red reflex, allowing capsulorhexis practice. The hardened nucleus enabled training in divide-and-conquer and phaco-chop techniques with tactile feedback similar to actual cataract surgery. The mean CDE value of the 23 nucleus cataract model eyes was 8.25 ± 2.68 (mean $\pm$ SD).

Conclusions: Microwave-induced thermal denaturation in porcine eyes provides a reproducible method for simulating the nucleus cataract. The nucleus cataract model eye offers realistic wet lab conditions for surgical training, particularly in capsulorhexis under low visibility and advanced phacoemulsification techniques.

Abstract No.: 204608

Epidemiological Characteristics, Distribution of Axial Length, and Prevalence of Ocular Abnormalities Associated With Congenital Cataract in Northwest China

First Author: Xu HOU

Co-Author(s): Guorui DOU, Min GONG, Mengmei HE, Jian ZHOU

Purpose: We aimed to identify epidemiological characteristics, distribution of axial length and ocular abnormalities associated with congenital cataract in Northwest China.

Methods: This observational cross-sectional study evaluated patients with congenital cataracts who underwent surgery between 2008 and 2023. Patient characteristics were compared among different age groups and hospitalization years.

Results: A total of 527 patients (527 eyes) underwent cataract surgeries. Of these, 323 patients (61.29%) resided in rural areas and 204 (38.71%) in urban regions. Rural patients exhibited a higher median age at surgery [36[6,72] months) compared to urban counterparts [23.5[4,64] months), with a significant difference between them ($Z = -2.543$, $p = 0.011$). Median surgical age differs significantly across hospitalization year subgroups ($\chi^2 = 40.636$, $p < 0.001$). Axial length demonstrated accelerated growth prior to 2 years of age, with statistically significant interocular differences in unilateral cases below 24 months ($p < 0.05$). Congenital cataract cases were predominantly diagnosed between 2 and 6 years (32.26%). Age distribution patterns significantly varied across hospitalization periods ($\chi^2 = 70.394$, $p < 0.001$). Ocular abnormalities alone were present in 293 cases (55.60%), while 40 patients (7.59%) exhibited concurrent systemic abnormalities. Amblyopia emerged as the most frequent ocular comorbidity (23.34%).

Conclusions: Rural patients constituted a higher proportion of congenital cataract. The median surgical age demonstrated a significant difference across hospitalization year subgroups. Axial growth patterns showed significant correlations with surgical timing, sex, and laterality. These findings indicate enhanced parental awareness of pediatric ocular health and provide an evidence-based rationale for early intervention strategies in congenital cataracts in Northwest China.

Abstract No.: 203589

Establishment and Validation of Evaluation Model for Zonula Stability Before Cataract Surgery Based on Multimodal Imaging

First Author: Hao YUAN

Co-Author(s): Xuemin LI

Purpose: To establish the evaluation model for zonula stability before cataract surgery based on multimodal

images by artificial neural network and other algorithms, and verify their diagnostic efficiency.

Methods: A total of 182 patients who would undergo cataract surgery in Peking University Third Hospital were included. They were divided into the zonula abnormality group (58 patients) and the control group (124 patients). Anterior segment optical coherence tomography (AS-OCT) and ultrasound biomicroscope (UBM) were performed to measure the anterior segment structural parameters before and after cycloplegia. Three diagnostic prediction models were established respectively: binary logistic model based on logistic regression (LR) algorithm, artificial neural network model based on multilayer perceptron (MLP) algorithm and decision tree (DT) model based on Chi square automatic interaction detector (CHAID) algorithm. The subjects were randomly divided into training groups at the ratio of 7 to 3.

Results: In the logistic diagnostic model, the curvature radius of anterior surface of the lens ($\beta = -0.664$, $P = 0.018$), the change of lens diameter before and after cycloplegia ($\beta = 1.437$, $P = 0.008$), and ciliary process-equatorial lens distance ($\beta = 1.437$, $P < 0.001$) were essential, and the fitting degree of the regression model was significantly high ($P = 0.088$). In the ANN model, ciliary process-equatorial lens distance (100.0%; 0.230), the curvature radius of anterior surface of the lens (63.0%; 0.145), and the change of lens diameter before and after cycloplegia (55.4%; 0.128) were important. In the decision tree model, ciliary process-equatorial lens distance, the curvature radius of anterior surface of the lens and lens decentration were remarkable. The AUC of different models were compared by Delong test: ANN model was significantly better than the preoperative suspicious signs ($P < 0.001$), the logistic regression model ($P = 0.010$) and the decision tree model ($P = 0.003$).

Conclusions: The Logistic, ANN and DT diagnostic models based on multimodal imaging that combined the data of AS-OCT and UBM were superior to subjective signs in the diagnosis of zonula abnormality before cataract surgery, and ANN model showed the best comprehensive diagnostic performance, which was of great significance in evaluating preoperative zonula stability.

Abstract No.: 204379

Evaluation and Decision Making in Cataractous Eyes of Coloboma

First Author: Nishi SATISH

Co-Author(s): Sangeeta ABROL

Purpose: To evaluate the preoperative and intraoperative difficulties in the management of patients with coloboma who present with cataract.

Methods: This observational case series was done on 35 patients with colobomas who presented to us with

cataract. Different intraocular lenses were implanted according to the technical difficulties faced during surgery. Analysis of preoperative and intraoperative findings was clubbed with postoperative findings of each patient.

Results: No patient was left aphakic. All patients with coexisting fundal colobomas were first given barrage laser sessions before surgery for scleral fixated IOL, and after surgery for in-the-bag PCIOL. No patient developed retinal or choroidal detachment. Among secondary IOLs, 3-piece PMMA IOLs performed the best; iris claw IOL was implanted in 4 patients, and all 4 patients had an anterior chamber reaction. Hydrophilic acrylic single-piece IOLs inserted as SFIOL also experienced mild anterior chamber reaction but good postoperative vision gain.

Conclusions: The best option we documented is to stabilise the bag with a lack of zonules by use of a capsular tension ring or segment and place a posterior chamber IOL; however, when a secondary IOL is needed, the best outcome was seen with a 3-piece PMMA optic SFIOL with Hoffmann pockets.

Abstract No.: 201091

Evaluation of Femtosecond Laser-Assisted Arcuate Keratotomy (FSAK) With Multifocal IOL Implantation for the Correction of Against-the-Rule Astigmatism in Cataract Surgery

First Author: Zunxia HU

Co-Author(s): Li LI, Jing SIMA

Purpose: Compare the efficacy of FSAK combined with MIOL versus toric multifocal IOL for cataract patients with against-the-rule corneal astigmatism.

Methods: The FSAK group (45 eyes) received ZMB00 IOL implantation, while the toric group (41 eyes) received ZMT150/ZMT225 IOLs. Patients were followed up at 1 week, 1 month, and 3 months postoperatively. UDVA, UNVA, BCDVA, residual total astigmatism, defocus curves, and objective visual quality were compared at 3 months postoperatively.

Results: There were no significant differences in UNVA and BCDVA between the two groups. However, the ZMT showed better UDVA compared to the FSAK. The residual total astigmatism was -0.79 ± 0.45 D in the FSAK and -0.64 ± 0.47 D in the ZMT ($P = 0.165$). The defocus curve indicated that the ZMT group had better distance visual acuity than the FSAK group. The surgically induced astigmatism (SIA) and correction index (CI) were 1.00 ± 0.58 and 0.76 ± 0.45 in the FSAK group, respectively, compared to 0.88 ± 0.46 and 0.76 ± 0.33 in the ZMT group, with no statistically significant differences between the two groups. iTrace analysis showed that PSF and MTF in the FSAK were 0.17 ± 0.16 and 0.37 ± 0.11 , respectively, while in the ZMT, they were 0.09 ± 0.09 and 0.27 ± 0.09 . FSAK demonstrated

better corneal optical quality. There were no statistically significant differences in total ocular PSF and MTF between the two groups.

Conclusions: Cataract patients with low-to-moderate ATR, there was no significant difference in postoperative visual function between those treated with FSAK and those implanted with multifocal toric intraocular lenses (IOLs).

Abstract No.: 201069

Evaluation of the Protective Effect of Mannitol-Containing Ophthalmic Viscosurgical Devices on Corneal Endothelial Cells During Phacoemulsification in Patients With Low Endothelial Cell Density

First Author: Huynh Phuc NGUYEN

Co-Author(s): Van Nam PHAN

Purpose: To assess the safety and efficacy of mannitol-containing OVDs in protecting corneal endothelial cells during phacoemulsification in patients with low preoperative ECD ($1000\text{--}2000$ cells/ mm^2).

Methods: In this randomized trial, patients were assigned to receive one of three OVDs: (A) SH 2.0% + mannitol 0.5%, (B) SH 1.4%, or (C) HPMC 2.4%. ECD and corneal thickness were measured preoperatively and at 1 week, 1 month, and 3 months post-surgery.

Results: Group A had significantly lower ECD loss (11.2% at 1 week, 14.7% at 3 months), less corneal edema, and better early visual acuity than groups B and C ($p < 0.001$).

Conclusions: OVDs with 2% SH and 0.5% mannitol offer better endothelial protection in low ECD patients, reducing corneal edema and aiding early visual recovery. This formulation is a suitable option for high-risk cases, such as glaucoma, to enhance surgical safety and visual outcomes.

Abstract No.: 200752

Factors Affecting the Efficacy of pFSAK in Correcting Corneal Astigmatism in Chinese Cataract Patients

First Author: Zunxia HU

Co-Author(s): Li LI, Jing SIMA

Purpose: To analyze the factors influencing the efficacy of symmetric FSAK in correcting corneal astigmatism in Chinese cataract patients.

Methods: A total of 123 patients (157 eyes) undergoing symmetrical FSAK were consecutively enrolled and followed up for 6 months postoperatively. The arcuate incision diameter was set at 8 mm with a depth of 85%, and the DONO algorithm was applied. The correction index was calculated using the Alpíns method. Multiple linear regression analysis was performed to assess the relationship between the correction index

and factors including age, axial length, intraocular pressure (IOP), mean keratometry (Km), central corneal thickness (CCT), and peripheral corneal thickness (PCT). Additionally, the corrective effects were compared among different types of astigmatism.

Results: TIA 1.22 ± 0.40 D, SIA 0.76 ± 0.49 D, DV 0.76 ± 0.43 D, CI 0.62 ± 0.33 . The CI values for WTR, ATR, and OBL were 0.51 ± 0.28 , 0.76 ± 0.33 , and 0.71 ± 0.31 , respectively. The correction effect was significantly better in ATR than in WTR ($P = 0.000$), and oblique astigmatism also demonstrated superior correction compared to WTR astigmatism ($P = 0.049$). However, there was no statistically significant difference in correction efficacy between ATR and oblique astigmatism ($P = 0.648$). Axial length, IOP, Km, CCT, and PCT showed no correlation with the CI. Age is a positive correlation—older age was associated with better correction outcomes. The derived regression equation was: $CI = 0.407 + (Age \times 0.008)$.

Conclusions: pFSAK demonstrated the optimal corrective effect for ATR. Age was identified as a factor influencing CI. $CI \approx 1$ was observed at 74 years.

Abstract No.: 204208

Femtosecond Laser-Assisted Cataract Surgery for Morgagnian Cataract: A Case Report

First Author: Shiqi DONG

Purpose: The fully developed Morgagnian kind of cataract is incredibly uncommon in this day and age of readily available medical facilities. Few clinical trials have been conducted on this highly rare kind of cataract, despite the fact that femtosecond laser-assisted cataract surgery (FLACS) offers considerable benefits in a variety of complicated cataract operations.

Methods: This paper reports successful femtosecond laser-assisted cataract surgery with implantation of a Toric IOL in the capsular bag for a case of unilateral Morgagnian cataract.

Results: During surgery, anterior capsulotomy was performed with the LenSx femtosecond LASER (Alcon, USA), setting the truncated anterior lens capsule diameter at 5.2 mm. Upon capsule rupture, a large amount of chylous fluid filled the anterior chamber, releasing like a smoke bomb. After laser completion, the anterior chamber was irrigated to remove the fluid. The anterior lens capsule was then stained with 0.5% indocyanine green dilution, and a secondary continuous curvilinear capsulorhexis was done with forceps along the laser path. The lens nucleus was fragmented and aspirated using a Centurion phacoemulsification machine (Alcon, USA). An intraocular lens (IOL; SN6AT4, +11D, Alcon, USA) was implanted into the capsular bag and axially aligned at 95° , with no intraoperative complications. On postoperative day 1, the left eye's uncorrected visual acuity (UCVA) was 20/20.

Conclusions: FLACS combined with functional intraocular lens implantation can maximize the safety of surgery and improve the visual quality of patients with Morgagnian Cataract.

Abstract No.: 203549

Follow-Up Analysis of 4-Haptic Bitoric Intraocular Lens Implantation in Chinese Patients With Cataract and Regular Astigmatism: A Multicenter Study

First Author: Jing WANG

Co-Author(s): Jinsong ZHANG

Purpose: To evaluate the visual and refractive outcomes of 4-haptic bitoric intraocular lens (IOL) implantation in Chinese patients with cataract and astigmatism.

Methods: A post-market, prospective, multicenter, single-arm study was conducted. 709M IOLs were implanted in 318 subjects and evaluated at 1-day, 1-week, 1-month and 3 to 6 months postoperatively. An objective photographic method was used to determine postoperative IOL rotation and postoperative 1 day IOL axis was set as the baseline. Uncorrected distance visual acuity (UDVA), postoperative residual astigmatism, subjective refraction, visual quality, and patient satisfaction were assessed. Safety assessment of surgical complications and adverse side events was recorded.

Results: A total of 318 subjects from 23 centers were enrolled. Uncorrected distance visual acuity improved significantly after surgery, from 0.85 ± 0.42 preoperatively to 0.24 ± 0.28 (1-day), 0.17 ± 0.20 (1-week), 0.14 ± 0.18 (1-month) and 0.13 ± 0.17 (3 to 6 months) postoperatively. Mean refractive cylinders also decreased significantly, from -1.72 ± 1.25 to -0.62 ± 0.52 (1-day), -0.55 ± 0.45 (1-week), -0.49 ± 0.48 (1-month) and -0.46 ± 0.42 (3 to 6 months). The mean magnitude of the SIA vector (1.74 diopters [D]) was almost the same as the mean magnitude of the TIA vector (1.75 D) at the last follow-up. The mean difference vector was 0.46 D, and the mean correction index was 1.03 , all indicating an effective astigmatism correction effect that remained stable during the follow-up. The mean absolute IOL rotation was 0.92 ± 2.68 (1-week), 0.80 ± 2.70 (1-month) and $0.55 \pm 2.2^\circ$ (3 to 6 months) postoperatively, showing good stability. Patients were very satisfied or satisfied with overall visual outcomes.

Conclusions: Implantation of 4-haptic bitoric IOL proved effective for correcting regular astigmatism in Chinese eyes.

Abstract No.: 204526**Ganglion Cell Intracellular Edema as a Reason of Early Visual Quality Decline After Cataract Surgery: An OCT-Based Clinical Study***First Author: Li LI*

Purpose: To investigate the mechanism of macular ganglion cell intracellular edema (GCIE) in early postoperative visual quality decline after cataract surgery.

Methods: We identified 18 patients (21 eyes) who developed subjective visual quality decline within the early postoperative period after cataract surgery and demonstrated OCT findings consistent with GCIE. All patients underwent comprehensive evaluation including comprehensive medical history, visual quality assessment, slit-lamp examination, and macular OCT scans. All patients received periocular injections of Triamcinolone Acetonide (20mg); 21 eyes received one injection, 4 eyes received a second injection after 3 weeks due to incomplete response.

Results: Visual decline manifested as: 1-2 lines of visual acuity loss (12 eyes; associated with subtle corneal Descemet's membrane wrinkles and faint anterior chamber Tyndall effect) or blurred vision without acuity loss (9 eyes; no significant anterior chamber reaction). OCT findings uniformly demonstrated GCIE characterized by: increased GCL reflectivity (width/color), indistinct GCL boundaries. The central macular thickness (CMT) values of 259.19 ± 21.08 μ m preoperatively, 280.33 ± 27.91 μ m at the time of macular edema onset, and 281.0 ± 16.42 μ m two weeks after intravitreal triamcinolone acetonide (IVTA) injection ($P \leq .001$). The macular volume thicknesses were 273.95 ± 12.15 μ m, 286.24 ± 16.63 μ m, and 289.0 ± 10.03 μ m ($P \leq .001$), while average ganglion cell layer (GCL) thicknesses were 84.48 ± 10.4 μ m, 85.0 ± 16.10 μ m, and 85.55 ± 8.57 μ m ($P = 0.65$).

Conclusions: Macular GCIE may be one of the mechanisms underlying early postoperative visual quality decline after cataract surgery.

Abstract No.: 207406**Hidden Macular Threats: Preoperative OCT As the Game-Changer for Cataract Surgery Outcomes***First Author: Harshitha C**Co-Author(s): Nishitha NARUKULLA*

Purpose: To determine the prevalence of occult macular pathology detectable only by preoperative optical coherence tomography (OCT) and evaluate its impact on postoperative visual outcomes in eyes scheduled for routine cataract surgery.

Methods: This prospective observational study included consecutive eyes undergoing routine cataract surgery with no clinically evident macular disease

on dilated fundus examination. All eyes underwent preoperative spectral-domain macular OCT. Detected abnormalities were categorized as epiretinal membrane, macular edema, vitreomacular interface disorders, or early age-related macular degeneration. Postoperative best-corrected visual acuity (BCVA) was measured at 1 month. Visual outcomes were compared between eyes with and without OCT-detected pathology, and multivariate logistic regression identified predictors of suboptimal visual gain.

Results: Of 200 eyes evaluated, 38 (19%) harbored previously unsuspected macular pathology. Epiretinal membrane (10%) and early AMD (5%) were the most frequent. Mean postoperative BCVA was significantly worse in eyes with OCT-detected pathology (0.52 ± 0.08 logMAR) compared with normal maculae (0.18 ± 0.04 logMAR, $p < 0.001$). OCT findings independently predicted suboptimal postoperative vision (OR 4.2; 95% CI 2.1–8.3). Early detection allowed modification of surgical planning and optimized patient counseling, preventing unrealistic expectations.

Conclusions: Nearly one in five cataract surgery candidates harbors a hidden macular lesion detectable only by OCT. Routine preoperative macular OCT is a game-changer—it unmasks silent threats, predicts postoperative visual outcomes, guides surgical decision-making, and elevates patient satisfaction. These results strongly support the adoption of preoperative macular OCT as a global standard of care in cataract surgery work-up.

Abstract No.: 202925**Impact of Tear Film Stability on Visual Outcomes After Trifocal Intraocular Lens Implantation***First Author: Lan WANG**Co-Author(s): Kaiwen CHENG, Wenwen HE, Yi LU, Jiaqi MENG, Xiangjia ZHU*

Purpose: To investigate the impact of tear film stability on visual outcomes in patients undergoing trifocal intraocular lens (IOL) implantation.

Methods: Patients scheduled for cataract surgery with trifocal IOL implantation were enrolled in this prospective study. Postoperative follow-up was conducted at 3 months after surgery. Patients were categorized into four groups according to postoperative tear breakup time (TBUT): normal (≥ 10 s), mild (≥ 5 s but < 10 s), moderate (≥ 2 s but < 5 s), and severe (< 2 s) tear film instability groups. Postoperative visual outcomes encompassing visual acuity, defocus curves, contrast sensitivity (CS), objective visual quality metrics such as the corneal performance index (CPI), higher-order aberrations (HOA), modulation transfer function (MTF), and subjective visual quality questionnaires were evaluated. Totally, 97 eyes of 97 patients were analyzed.

Results: The severe group showed significantly worse uncorrected near visual acuity compared to the normal and mild groups, and significantly worse intermediate visual acuity compared to the normal group. The defocus curve of the severe group was also significantly poorer at near or intermediate distances. Relative to the normal group, both moderate and severe groups exhibited a significantly reduced CS at low-to-mid spatial frequencies, as well as worse corneal visual quality metrics, including lower CPI, higher corneal HOAs and coma, and reduced corneal MTF. The severe group was more likely to report severe glare, blurred vision and hazy vision, with significantly lower VF-14 scores and higher ocular surface disease index (OSDI) scores.

Conclusions: Tear film instability may adversely affect visual outcomes following trifocal IOL implantation.

Abstract No.: 203354

Implantation of Trifocal Intraocular Lens in Mild Pathologic Myopia: Visual Outcomes and Influence of Fundus Structures

First Author: Meiyi ZHU

Co-Author(s): Guangbin ZHANG

Purpose: To compare the visual outcomes of simple high myopia (HM) and mild pathologic myopia (PM) following implantation of a trifocal intraocular lens (IOL), and investigate the influence of fundus structures.

Methods: We retrospectively studied 63 high myopic eyes of 63 patients underwent femtosecond laser-assisted cataract surgery with implantation of AT LISA tri 839MP IOL (Carl Zeiss Meditec AG, Germany) between July 2020 and September 2024. 34 eyes in the HM group and 29 eyes in the PM group. Main visual outcomes including monocular corrected distance (4 m, CDVA), distance-corrected intermediate (80 cm, DCIVA), distance-corrected near (40 cm, DCNVA) visual acuity, defocus curves, and subjective refraction. Optical coherence tomograph was employed to evaluate macular tilt degree (MTD), central foveal thickness, and subfoveal choroidal thickness (SFCT). Multiple linear regression analysis was used to evaluate the independent predictors of visual acuity in the PM group.

Results: The CDVA, DCIVA, and DCNVA were 0.00 ± 0.00 , 0.08 ± 0.05 , and 0.09 ± 0.07 logarithm of the minimum angle of resolution (logMAR) in the HM group, 0.02 ± 0.05 , 0.15 ± 0.09 , and 0.17 ± 0.09 logMAR in the PM group, respectively. In the PM group, mean MTD was $17.13 \pm 6.79^\circ$. The MTD demonstrated a significant predictive effect on CDVA (regression coefficient: 0.005; $P = 0.026$) and DCNVA (regression coefficient: 0.015; $P = 0.003$), and the SFCT was associated with DCIVA (regression coefficient: -0.001; $P = 0.05$).

Conclusions: Trifocal IOL implantation yielded favorable visual outcomes in simple high myopic eyes, though results were comparatively poorer in PM cases. MTD was associated with the expected visual outcomes.

Abstract No.: 206500

Inflammation Factors Mediate Association of Dietary Habits and Senile Cataract: Insights From a Mendelian Randomization Study

First Author: Jian DENG

Co-Author(s): Yonghao LI, Liduo PAN, Meng WANG, Tao WANG

Purpose: Senile cataract (SC), a leading cause of global blindness, poses a major public health challenge. This study employed Mendelian randomization (MR) to assess the causal effects of 83 dietary habits on SC.

Methods: Initially, we employed bidirectional and replication sample MR to identify dietary habits associated with SC. Multivariable MR(MVMR) was then applied to adjust for confounders and assess their independent causal effects. Two-step MR also examined mediating mechanisms related to inflammatory biomarkers. Finally, to validate the core findings, additional analyses employed independent datasets for the overall cataract phenotype and the cataract surgical endpoint.

Results: The bidirectional MR initially identified 13 dietary habits potentially associated with SC risk. After false discovery rate correction, four associations remained significant. Validation in an independent cohort indicated that current drinkers consuming alcohol exclusively with meals, unlike those drinking apart from meals, demonstrated a substantial and robust protective causal effect against SC (OR = 0.67; 95% CI: 0.55–0.82; $P = 5.86 \times 10^{-5}$). MVMR sustained this independent protective effect after adjusting for 15 outcome-related confounders. Mediation analysis supported partial mediation by inflammation, of which IL-6 explained 11% of the effect and CRP 6%. Further analyses also linked this drinking pattern to a reduced likelihood of undergoing cataract surgery (OR=0.99; 95%CI: 0.98-0.99; $P=2.34 \times 10^{-6}$) and a lower risk of overall cataract (OR=0.83; 95%CI: 0.76–0.91; $P=5.26 \times 10^{-5}$).

Conclusions: The study illustrates that drinking with meals significantly reduces SC risk compared to drinking alone. CRP and IL-6 are emphasized as mediating biomarkers in this protective correlation, providing essential insights for clinical preventative and public health measures addressing SC.

Abstract No.: 204798**Influence of Anterior Capsule Polishing on Capsular Bag and Intraocular Lens After Phacoemulsification**

First Author: Jeyaprakash **BALASUBRAMANIAN**
Co-Author(s): Ezhilvendhan **KALAIMAMANI**

Purpose: To evaluate if anterior capsule polishing could minimize the chance of posterior capsular opacification which needs Nd-Yag capsulotomy and anterior capsular opacification / anterior capsular contraction syndrome which influences the effective lens position (ELP).

Methods: In this prospective study, 120 eyes of 60 consecutive patients with bilateral age-related cataract who underwent phacoemulsification were evaluated. Each patient's eyes were randomly assigned to two groups. One eye received 360-degree anterior capsule polishing (Group-A: Cases) and the fellow eye without anterior capsule polishing (Group-B: Controls). In this study, capsulorrhexis size is uniform as we used a corneal capsulorrhexis marker (5mm at the anterior capsule). All eyes were implanted with a similar type of intraocular lens. Eyes were evaluated at 1st week, 1st, 3rd, 6th month and 1st year.

Results: All eyes were evaluated with slit lamp biomicroscope, A-SCAN ultrasonography and anterior segment OCT. Significant reduction in the formation of posterior capsular opacification, anterior capsular opacification, and anterior capsular contraction syndrome was noted in Group-A (eyes which received 360 degrees of anterior capsule polishing).

Conclusions: Anterior capsule polishing had a positive influence by reducing the formation of PCO which minimized the need for Yag capsulotomy (which has its own complications such as Cystoid macular oedema, post Yag uveitis, raise in IOP and retinal detachment), reducing post operative refractive error (due to ACCS).

Abstract No.: 203102**Interferometric Optical Metrology of Diffractive Multifocal Intraocular Lenses: A Comparative Bench Study**

First Author: Seung Pil **BANG**

Purpose: To quantitatively characterize the optical performance of commercially available diffractive multifocal intraocular lenses (IOLs) and assess their functional behavior under varying pupil sizes.

Methods: Eight +20.0 D diffractive multifocal IOLs—PanOptix (Alcon), Odyssey and Synergy (Johnson & Johnson), Envy (Bausch & Lomb), Elana (Zeiss), Gemetric and Gemetric Plus (HOYA), and Intensity (Hanita)—were evaluated using a Mach-Zehnder interferometer (NIMO TEMPO) in accordance with ISO 11979-2 standards. Optical path difference maps were converted into wavefront profiles, point spread

functions, and modulation transfer functions (MTFs). Diffractive step structures and through-focus MTFs at 50 lp/mm were compared across pupil diameters of 2.0, 3.0, and 4.5 mm.

Results: All IOLs except Envy exhibited uniform diffractive step heights. Odyssey and Synergy employed higher-order diffractive designs that introduced primary and secondary spherical aberrations, extending the depth of focus and enhancing near vision. At a 3.0 mm pupil, all IOLs except Gemetric Plus showed far-dominant energy distribution. At 2.0 mm, Elana and Gemetric maintained far dominance, whereas other lenses shifted toward intermediate or near foci. At 4.5 mm, Elana and Intensity demonstrated balanced energy distributions, while the remaining lenses stayed far-dominant.

Conclusions: Interferometric optical metrology provides detailed, quantitative profiling of multifocal IOLs. Combining such optical data with patient-specific ocular parameters may enable more personalized IOL selection and improve postoperative visual outcomes.

Abstract No.: 201590**Intermediate Task Performance and Predictors of Difficulty After Bilateral Vivity EDOF IOL Implantation: A Patient Perspective**

First Author: Muskan **MANGAL**

Co-Author(s): Aditya **KELKAR**, Jai **KELKAR**, Sabyasachi **SENGUPTA**

Purpose: To evaluate visual outcomes, task-specific intermediate vision, and patient satisfaction following bilateral implantation of the AcrySof IQ Vivity Extended Depth of Focus (EDOF) intraocular lens (IOL).

Methods: This prospective single-centre study included patients who underwent bilateral phacoemulsification with Vivity EDOF IOL. Postoperative assessments at one month included uncorrected distance (UCDVA), intermediate (UIVA), and near visual acuity (UNVA), as well as responses to a modified Catquest-9SF questionnaire. Two additional items were included to assess difficulty in computer use and reading large-font text on mobile phones, tasks relevant to Vivity's intended optical benefits. Multivariable logistic regression was used to identify predictors of reported difficulty.

Results: A total of 170 patients (340 eyes) were enrolled. At one month, all patients achieved UCDVA and UIVA of 6/6, and 87% achieved UNVA of N8 or better. However, 26.3% of patients reported "Some Difficulty" with computer use or reading mobile phone text. Multivariable analysis identified shorter axial length (<23.3 mm) and worse preoperative visual acuity (<0.35 logMAR) as independent predictors of this difficulty. Visual disturbances were infrequent (occurring in ≤2% of patients), and 98.4% of patients reported overall satisfaction with their vision.

Conclusions: While the Vivity EDOF IOL delivers excellent distance and intermediate visual acuity with high patient satisfaction, a notable proportion of patients may experience difficulty with intermediate digital tasks, though this requires confirmation with longer follow-up. These findings highlight the importance of tailored patient selection and task-specific outcome assessment in evaluating EDOF lens performance.

Abstract No.: 201589

Interocular Axial Length Asymmetry: Developing a Better Understanding of Red Flag Presentations

First Author: Christopher GO

Co-Author(s): Uday BHATT, Christopher HODGE, Michael LAWLESS, Christolyn RAJ

Purpose: Accurate biometry is critical for optimal refractive outcomes post-cataract surgery. While inter-eye axial length differences are often flagged as pathological, they may reflect stable anatomical variation. This study aims to improve characterisation of biometric asymmetry and develop a metric to identify true outliers.

Methods: A retrospective cohort analysis of biometric data from 15,245 patients (Vision Eye Institute) was conducted. Predictor variables included anterior chamber depth (ACD) difference, lens thickness (LT) difference, posterior segment difference, and derived anatomical ratios. Stepwise linear regression identified significant contributors to axial length asymmetry. A composite metric was developed using z-scores of key predictors to quantify anatomical disproportion. Outliers were flagged based on the top 5% of composite scores.

Results: Mean interocular axial length difference was 0.24 ± 0.44 mm. ACD and LT differences were statistically significant predictors. LT/ACD ratio difference showed weaker association but was retained for proportional context. The composite metric effectively highlighted cases with multi-dimensional anatomical deviation.

Conclusions: Most interocular axial length differences reflect proportional anatomical variation. The development of a composite metric offers a novel, objective tool to identify eyes with disproportionate biometry, potentially reflecting patients at risk of reduced refractive accuracy post-IOL implantation and representing a true "red flag". This approach may enhance preoperative surgery planning and patient counselling.

Abstract No.: 206627

Intraocular Lens Calculation Formula Selection for Short Eyes: Based on Axial Length and Anterior Chamber Depth

First Author: Ruoxi GAO

Co-Author(s): Lixia LUO, Xuhua TAN, Jiaqing ZHANG

Purpose: To evaluate the predictive accuracy of 11 intraocular lens (IOL) calculation formulas in eyes with an axial length (AL) less than 22.00 mm.

Methods: New-generation formulas (Barrett Universal II [BUII], Emmetropia Verifying Optical [EVO] 2.0, Hill-Radial Basis Function [Hill-RBF] 3.0, Hoffer QST, K6, Kane, Pearl-DGS) and traditional formulas (Haigis, Hoffer Q, Holladay 1 and SRK/T) were evaluated for predictive accuracy. Subgroup analyses were performed based on AL and anterior chamber depth (ACD).

Results: The study enrolled a total of 184 eyes of 184 patients. The BUII, Hoffer QST, Hoffer Q, Holladay 1, and SRK/T showed myopic shifts (-0.49 to -0.18 diopters [D], $P < 0.05$), whereas K6 displayed a hyperopic shift (0.11 D, $P = 0.03$). The Kane exhibited no systematic bias (-0.07 D), and yielded lower mean absolute error (MAE) (0.48 D, $P < 0.05$) and root mean square absolute error (RMSAE) (0.65 D, $P < 0.01$). For eyes with an $AL \leq 21.5$ mm and an $ACD > 2.5$ mm, the Pearl-DGS displayed the smallest MAE (0.43 D) and lowest RMSAE (0.57 D), while other new-generation formulas showed relatively worse performance (MAE: 0.46 to 0.67 D; RMSAE: 0.60 to 0.84 D).

Conclusions: The Kane formula showed the highest accuracy in short eyes, whereas the Pearl-DGS had superior performance in eyes with a relatively shorter AL and deeper ACD.

Abstract No.: 206820

Intraocular Lens Power Calculation in Post-Myopic-LASIK Eyes: Comparison of Two Different Corneal Refractive Power Measurements by Pentacam

First Author: Qingying YANG

Co-Author(s): Wenwen HE, Xiangjia ZHU

Purpose: To compare the accuracy of corneal refractive power measurements centered on corneal apex (K_{apex}) and pupil center (K_{pupil}) by Pentacam in intraocular lens (IOL) power calculation in post-myopic-LASIK eyes, and to help with improving visual outcomes after cataract surgery.

Methods: Post-myopic-LASIK patients scheduled for cataract surgery were enrolled. Corneal refractive power centered on the corneal apex (K_{apex}) and pupil center (K_{pupil}), decentration of the ablation zone, and Kappa angle were measured by Pentacam. Predicted postoperative spherical equivalence (SE) was calculated with K_{apex} and K_{pupil} using the Barrett True-K (no history) formula, respectively. Prediction error was

calculated as actual SE minus predicted SE. Mean error (ME), mean absolute error (MAE), and median absolute error (MedAE) were compared between Kapex and Kpupil groups, with subgroup analysis in terms of decentered ablation and Kappa angle. The backward stepwise multiple linear regression analysis was also performed to identify the factors influencing prediction errors with each K value.

Results: Totally 92 eyes from 92 patients were analyzed. Fewer eyes had a prediction error of more myopic than -1.00 D with Kapex than with Kpupil (17/92 vs. 29/92, $P = 0.041$). ME, MAE, and MedAE with Kapex were all lower than those with Kpupil (-0.42 ± 1.06 vs. -0.64 ± 1.21 D, 0.89 ± 0.71 vs. 1.01 ± 0.92 D, 0.69 vs. 0.76 D, respectively; $P < 0.05$ for ME and MedAE). In both subgroups of larger decentration of ablation zone and larger Kappa angle, ME with Kapex was lower than that with Kpupil to a higher degree (both $P < 0.05$). Average Kapex was higher than average Kpupil ($P < 0.001$), and the difference between them was higher with larger decentration of ablation zone or larger Kappa angle. Multivariate analysis demonstrated that prediction error with Kpupil was associated with decentration of ablation zone ($\beta = -0.264$, $P = 0.019$), while no such association was found in prediction error with Kapex.

Conclusions: The Kapex achieved better accuracy in IOL power calculation than Kpupil in post-myopic-LASIK eyes, especially in eyes with large decentration of the ablation zone or large Kappa angle.

Abstract No.: 204436

Investigating the Protective Effect and Mechanism of Ellagic Acid on Cataract by Network Pharmacology, Molecular Docking, and Experimental Validation

First Author: Li **TANG**

Purpose: Ellagic acid (EA) is a natural polyphenol with well-documented antioxidant and anti-inflammatory activities; however, its precise mechanism against cataract remains unclear. This study aimed to identify the bioactive components of EA and elucidate its mode of action in cataract prevention.

Methods: Putative targets of EA were retrieved from TargetNet, TCMSP, TargetPrediction, PharmMapper and SEA. Cataract-related genes were collected from multiple databases. The common targets were imported into String to construct a protein-protein interaction (PPI) network. The “drug-component-target-disease” network was visualised with Cytoscape. KEGG and GO enrichment analyses were performed in R. Molecular docking was carried out using MOE. The therapeutic efficacy of EA was further evaluated in a sodium-selenite-induced cataract model in rat pups.

Results: A total of 43 common targets shared by ellagic acid and cataract were identified. PPI network analysis

revealed TP53, SIRT1, NFE2L2, AKT1, BCL2, CASP3, TNF, IL6 and TGFB1 as hub genes, with TP53 showing the lowest binding energy to ALB. Experimentally, EA markedly reduced ROS and MDA levels, elevated GSH content, and enhanced the activities of the antioxidant enzymes GST, SOD, GPx and CAT. After EA treatment, TNF- α and IL-6 concentrations were significantly decreased, Bcl-2 mRNA was up-regulated, p38 and JNK phosphorylation was suppressed, while caspase-3 and Bax mRNA expression were down-regulated.

Conclusions: EA protects against cataract by attenuating oxidative stress and inflammation, inhibiting p38/JNK phosphorylation, decreasing ROS/MDA generation, maintaining GSH/GSSG homeostasis, and ultimately lessening oxidative damage and lens opacification in experimental models.

Abstract No.: 204824

Is Astigmatism Correction Necessary for Patients With Cataract Who Have Corneal Astigmatism of Less Than 0.75 D?

First Author: Xiaohang **XIE**

Purpose: To investigate the proportion of patients with predicted refractive astigmatism (PRA) of 0.75 diopters (D) or greater and associated risk factors among cataract surgery candidates with low corneal astigmatism.

Methods: A retrospective cross-sectional study was conducted in Zhongshan Ophthalmic Center, Guangzhou, China. Patients with cataract who had preoperative simulated keratometric astigmatism of less than 0.75 D were recruited. The PRA was calculated by Barrett toric calculator using posterior corneal astigmatism (PCA) measured by the IOLMaster 700 (Carl Zeiss Meditec AG) and corneal surgically induced astigmatism (SIA). Two corneal incision locations (temporal $[0^\circ/180^\circ]$, 135° incision) and varying magnitudes (0.10 to 0.60 D) were considered for SIA. Multiple logistic regression analysis was used to explore risk factors associated with PRA of 0.75 D or greater and build a predictive model. Sensitivity analysis was performed using PRA threshold of 0.50 D.

Results: A total of 1,750 eyes from 1,750 patients were included (mean age: 60.14 ± 13.24 years, 42.91% male, 1,010 right eyes and 740 left eyes). The 135° incision (odds ratio [OR]: 17.86) and against-the-rule (ATR) astigmatism (OR: 37.55) are the major risk factors for PRA of 0.75 D or greater. Higher simulated keratometric astigmatism (OR: 2.03), larger PCA (OR: 1.64), and surgically induced astigmatism (OR: 1.29) also significantly increased the risk of PRA of 0.75 D or greater. Nomogram model were constructed with an area under curve of 0.90.

Conclusions: For patients with corneal astigmatism ≤ 0.75 D, temporal incision and measured PCA is

preferred. Patients with ATR and 135° incision should consider astigmatism correction.

Abstract No.: 203839

Is Preoperative Mydriasis Indicative of Intraoperative Floppy Iris Syndrome? A Multivariate Analysis

First Author: Argyrios TZAMALIS

Co-Author(s): Chrysanthos CHRISTOU, Ioannis TSINOPOULOS, Nikolaos ZIAKAS

Purpose: The study's objective was to examine how dilated pupil diameter (PD) may serve as a risk factor for the development of Intraoperative Floppy Iris Syndrome (IFIS) and its relationship with complications during and after cataract surgery.

Methods: A total of 1178 cataract patients were identified and included in a multivariate cross-sectional analysis at a tertiary care ophthalmic center. Each case had a thorough preoperative documentation of potential predisposing risk factors for the occurrence of IFIS, and pupil size was assessed one week before surgery, after maximum pharmacologic dilation.

Results: In a study of 1,294 eyes undergoing cataract surgery, IFIS was noted in 44 cases, amounting to 3.4%. The preoperative pupil diameter (PD) was significantly lower in patients who developed IFIS (PDIFIS=6.23±1.4mm compared to PDNON-IFIS=7.38±0.9mm, $p<0.001$), and this significant difference persisted among patients using α -blockers for benign prostatic hyperplasia (PD IFIS=5.86±1.5mm vs PD NON-IFIS=6.78±0.9mm, $p=0.01$). Pupil diameter was found to have a negative correlation with rates of posterior capsular rupture and iris trauma ($p=0.03$ and $P<0.001$, respectively). A cut-off value of 6.8mm in all patients and 6mm in patients taking α 1 blockers was found indicative of predicting the appearance of IFIS with high sensitivity and specificity.

Conclusions: The degree of pupillary dilation before surgery appears to play a crucial role in the appearance of floppy iris and may serve as a predictive indicator for surgeons to help reduce the possible severe outcomes of unexpected IFIS.

Abstract No.: 203424

Lens Morphology in Cataract Patients With Zonula Dialysis by Anterior Segment Optical Coherence Tomography

First Author: Hao YUAN

Co-Author(s): Xuemin LI, Ziyuan LIU

Purpose: To investigate the morphologic characteristics of the lens in cataract patients with zonula dialysis (ZD) before and after cycloplegia by anterior segment optical coherence tomography (AS-OCT).

Methods: A total of 56 eyes from 56 participants who would undergo cataract operations were included,

with 29 eyes of normal controls and 27 eyes of zonula dialysis patients. Lens morphologic parameters were then evaluated by AS-OCT, including anterior chamber depth (ACD), lens thickness (LT), lens diameter, lens vault, anterior curvature radius, posterior curvature radius, decentration and tilt of lens. After participants were treated with three-time tropicamide solution, AS-OCT was repeated to acquire the post-cycloplegia results. SPSS Software 22.0 was used for statistical analysis.

Results: The comparison of basic lens morphologic parameters without cycloplegia found only anterior curvature ($P=0.039$) showed significant differences between normal and ZD groups. AS-OCT measured after 30-min cycloplegia treatment showed significantly increased ACD, lens diameter, posterior curvature and decreased vault in both groups, decreased lens thickness in normal group, increased anterior curvature and decreased lens decentration in ZD group (all $P<0.05$). The logistic regression model showed ZD group had greater alterations of ACD ($P=0.014$), anterior curvature ($P=0.009$) and decentration ($P=0.031$) after cycloplegia treatment when compared with the normal group.

Conclusions: Lens in ZD patients was characterized by steeper anterior curvature, and greater alterations of ACD, anterior curvature and decentration after cycloplegia. The comparison of lens morphologic parameters before and after cycloplegia might be the potential method to evaluate the stability of zonula.

Abstract No.: 200527

Lens Position Change Following Cataract Surgery in Eyes With Thick Lenses: An SS-OCT-Based Study

First Author: Xiangjia ZHU

Purpose: To evaluate the impact of intraocular lens (IOL) positional change following cataract surgery by swept-source optical coherence tomography (SS-OCT) in eyes with different lens thicknesses (LTs), and its influence on the accuracy of IOL power calculation.

Methods: This prospective cohort study enrolled patients who planned to undertake phacoemulsification and monofocal IOL implantation, and were divided into three groups according to the LT ($LT<4\text{mm}$, $4\text{mm}\leq LT<5\text{mm}$, $LT\geq 5\text{mm}$). Lens position change (δLP), measured by the anterior segment SS-OCT, was defined as the difference between the position of postoperative IOL and the equatorial plane of preoperative lens. The prediction errors (PEs) of Barrett Universal II (BUII), Kane, Emmetropia Verifying Optical and Pearl-DGS formulas were evaluated at least one year postoperatively.

Results: Totally 90 eyes of 90 patients were analysed. The overall average δLP was $-0.12\pm 0.60\text{mm}$. Eyes with $LT\geq 5\text{mm}$ had more negative δLP (-0.44 ± 0.65 vs

0.02±0.65 and 0.04±0.49mm) and myopic PE of all four formulas than the LT<4mm and 4mm≤LT<5mm groups, respectively ($p<0.05$). δ LP was negatively correlated with LT ($r=-0.264$, $p=0.012$) and positively correlated with anterior chamber depth (ACD) ($r=0.263$, $p=0.012$). Multiple linear regression analyses further revealed LT was the only independent influencing factor of δ LP ($p<0.05$). ACD and δ LP were the independent influencing factors of the PE with the BUII formula, while LT and δ LP were the independent influencing factors of the PE with the other formulas ($p<0.05$).

Conclusions: Postoperative forward IOL movement contributes to myopic PEs of eyes with thick lenses.

Abstract No.: 206103

Leveraging Generative AI-Based Chatbot to Complement Cataract Surgery Consultation

First Author: Dayna **YONG**

Co-Author(s): Ziyou David **CHEN**, Naimah Binte **ISMAL**, How Sheng Rubin **YONG**

Purpose: To evaluate the accuracy and patient acceptance of a novel Generative AI-based (GenAI) chatbot designed to complement cataract surgery consultation and identify suitable patients for surgery.

Methods: A study was conducted at a tertiary institute's ophthalmology clinic from December 2024 to August 2025. Patients who attended the consultation for only cataract review were recruited. The ophthalmologist's recommendation for cataract surgery was recorded. Patients also engaged with the chatbot to generate recommendations for the cataract condition. The agreement between the chatbot and the ophthalmologist's recommendation was analysed. Patients' acceptance of the chatbot was evaluated using a modified Website User Survey.

Results: 149 eligible responses were analysed. 72 patients who were reviewed in the cataract clinic were offered cataract surgery by the ophthalmologist. Our chatbot recommended 77 patients for cataract clinic review. Sensitivity of the chatbot was 84.7% whilst specificity was 79.2%. Concordance was 81.9%. Patient feedback was positive, with 139 (92.6%) agreeing it is user-friendly, and 53 (35.6%) were willing to use the chatbot to replace their routine cataract clinic visits with this format of consultation.

Conclusions: Our GenAI chatbot demonstrated good agreement with the clinician's assessment of suitability for surgery. Its utility could be more as an adjunct to identify patients who might require surgery before consultation.

Abstract No.: 206969

Long-Term Clinical Outcomes of Bilateral Implantation of a Non-Diffractive Spherical Aberration-Based Increased Range of Focus Toric Intraocular Lens in Filipino Eyes

First Author: Keshia Lourdes **DUYONGCO-LENON**

Co-Author(s): Victor Jose **CAPARAS**, Isabel Mara **CAPARROS**, Maria Isabela **DE GUIA**, Maureen Anne **REYES**

Purpose: To evaluate the long-term astigmatic correction, rotational stability, and visual performance of the non-diffractive spherical aberration-based Increased Range of Focus RayOne EMV® Toric intraocular lens (IOL) [Rayner, Worthing, UK] in Filipino patients up to 6-12 months after cataract surgery.

Methods: Adults above 18 years old with corneal astigmatism ≥ 0.75 D underwent bilateral phacoemulsification with implantation of the RayOne EMV® Toric IOL targeted at emmetropia. Exams at 7-14 days, 30-45 days, and 6-12 months were manifest refraction(MR), monocular and binocular uncorrected/corrected visual acuity (UDVA/CDVA) at distance(4m), intermediate(UIVA/DCIVA 80cm and UIVA/DCIVA 63cm), and near(UNVA/DCNVA 40cm). Rotational stability, defocus curve, contrast sensitivity(CS), photic phenomena (Halo/Glare Simulator, ViSU-L GmbH), and quality of vision(QOV) using the McAlinden questionnaire were evaluated.

Results: Fourteen patients ($n=28$ eyes) were included. At 6-12 months, mean refractive spherical equivalent was $-0.19(\pm 0.30)$ D. Binocular uncorrected visual acuities(logMAR) were UDVA $-0.19(\pm 0.08)$, UIVA 80cm $0.37(\pm 0.07)$, UIVA 63cm $0.30(\pm 0.08)$, and UNVA 40cm $0.26(\pm 0.11)$. Binocular corrected visual acuities(logMAR) were CDVA $-0.19(\pm 0.08)$, DCIVA 80cm $0.40(\pm 0.08)$, DCIVA 63cm $0.32(\pm 0.10)$, and DCNVA 40cm $0.27(\pm 0.12)$. Mean rotation was $5^\circ \pm 4^\circ$ with 89% of eyes rotating $\leq 10^\circ$. Post-op mean refractive cylinder was $0.20(\pm 0.57)$ D. Binocular defocus curve showed CDVA ≤ 0.20 logMAR from +2.0D to -2.5D. Mean halo size/intensity were 25/100 and 27/100; glare 23/100 and 27/100. CS(logCS) 1m and 40cm were $1.53(\pm 0.14)$ and $1.58(\pm 0.11)$. Mean QOV was 91.4/100.

Conclusions: The RayOne EMV® Toric IOL effectively provides long-term astigmatic correction with good rotational stability, increased range of vision from distance to functional near when targeted at emmetropia, minimal photic phenomena, good contrast sensitivity and high quality of vision in Filipino patients.

Abstract No.: 203010

Mechanistic Study of the Novel Peroxidase Mimetic DhHP-6 in Metabolic Cataracts

First Author: Zhuoya LI

Co-Author(s): Hui ZHANG

Purpose: Metabolic disorders such as diabetes and hypergalactosemia often induce oxidative damage and mitochondrial dysfunction in the lens, leading to metabolic cataracts. Although surgical intervention remains the primary treatment, its associated risks and complications underscore the demand for pharmacological alternatives with multifaceted protective effects. This study aims to further elucidate the underlying mechanisms of the novel microperoxidase mimetic Deuteroheemin- β Ala-His-Thr-Val-Glu-Lys (DhHP-6) in attenuating the progression of metabolic cataracts.

Methods: To investigate the mechanisms, galactose-induced rat cataract models and high-galactose-treated lens epithelial cells were established. Lens opacity and ocular toxicity were assessed via slit-lamp examination. In both models, activities of antioxidant enzymes superoxide dismutase (SOD) and catalase (CAT), as well as levels of malondialdehyde (MDA), glutathione (GSH), and adenosine triphosphate (ATP) were measured. Western blot was used to analyze the Nrf2/Keap1/HO-1 pathway and apoptosis-related proteins (Bax, Bcl-2, cleaved caspase-3). Further in vitro assays included mitochondrial membrane potential, Mito-SOX fluorescence, Nrf2 nuclear translocation by immunofluorescence, and mitochondrial dynamics proteins. The role of Nrf2 was verified using a specific inhibitor to evaluate downstream effects.

Results: The results revealed that DhHP-6 significantly alleviated lens opacity by activating the NRF2/KEAP1/HO-1 pathway, thereby boosting antioxidant enzyme activity, restoring ATP levels, and inhibiting apoptotic signaling. Crucially, in vitro analyses confirmed DhHP-6's ability to maintain mitochondrial structural integrity and functional homeostasis through this pathway, thereby preventing the initiation of apoptosis cascades.

Conclusions: These findings demonstrate that DhHP-6 attenuates metabolic cataract progression through multi-target mechanisms orchestrated by the NRF2/KEAP1/HO-1 pathway, integrating antioxidative defense, mitochondrial homeostasis restoration, and apoptosis inhibition into a unified therapeutic strategy.

Abstract No.: 201523

Not All Monofocals Are Equal: Defocus Curve Analysis of Clarion, Magnifient, Tecnis Eyhance, and Vivinex Impress Advanced Monofocal Intraocular Lenses

First Author: Ayushi BANSAL

Co-Author(s): Sahleen AHMAD KHAN

Purpose: To compare visual performance across distance, intermediate, and near ranges of four advanced monofocal intraocular lenses (IOLs)—Clarion, Magnifient, Tecnis Eyhance, and Vivinex Impress—using standardized defocus curve analysis.

Methods: This prospective observational study included pseudophakic patients aged 50–75 years, 1–3 months after uncomplicated phacoemulsification with in-the-bag implantation of one of the four IOLs. Monocular best-corrected visual acuity (logMAR) was measured under standardized photopic conditions at defocus levels from +1.50 D to –3.00 D in 0.50 D steps, starting from best distance correction. Defocus curves were plotted, and the area under the curve (AUC) and visual acuity at key defocus points (0.00 D, –1.50 D, –2.00 D) were compared. Statistical analysis was performed using one-way ANOVA with post-hoc testing ($p < 0.05$).

Results: All IOLs provided excellent distance vision (mean logMAR ≤ 0.05 at 0.00 D). Tecnis Eyhance and Clarion demonstrated superior intermediate vision, with significantly better acuity at –1.50 D (mean logMAR 0.12 ± 0.05) compared with Magnifient and Vivinex Impress ($p = 0.02$). Magnifient achieved peak performance at –1.00 D (mean logMAR 0.10 ± 0.04) but showed reduced near performance beyond –2.00 D. Vivinex Impress provided balanced intermediate and near outcomes with moderate decline at higher defocus levels. AUC ranking was: Tecnis Eyhance (1.85), Clarion (1.78), Vivinex Impress (1.70), Magnifient (1.60; $p = 0.03$).

Conclusions: All advanced monofocal IOLs achieved excellent distance vision, but defocus curve profiles differed. Tecnis Eyhance and Clarion enhanced intermediate vision, Magnifient excelled midrange, and Vivinex Impress provided balanced performance, underscoring individualized IOL selection.

Abstract No.: 203565

Novel Tear Biomarkers as Predictors of Postoperative Discomfort After Cataract Surgery

First Author: Naren SHETTY

Co-Author(s): Ravi Krishna KANARADI, Swaminathan SETHU

Purpose: To investigate the relationship between inflammatory tear film biomarkers and postoperative discomfort, specifically pricking sensation, in patients undergoing cataract surgery, and to explore the

potential of preoperative biomarker profiling in predicting and managing such symptoms.

Methods: This prospective observational study was conducted on 100 eyes of 100 patients undergoing cataract surgery. Pre-operatively steroids and NSAIDs were deferred. Tear samples were collected at two time points: pre-operatively on the day of surgery and postoperatively on day 1 using Whatman Filter Paper 41 strips and inflammatory biomarkers were analyzed. On postoperative day 1, patients were divided into two groups based on symptoms: Group 1 (n = 50): no pricking sensation and Group 2 (n = 50): pricking sensation present. Patients with ocular surface disease, uveitis and systemic conditions affecting tear production, or surgical complications were excluded.

Results: Patients with postoperative pricking sensation demonstrated elevated levels of IL-17A and TNF α compared to asymptomatic patients, indicating an underlying inflammatory state of the ocular surface. The findings suggest that these biomarkers may serve as predictors for postoperative discomfort

Conclusions: IL-17A and TNF α are potential inflammatory markers linked to postoperative discomfort following cataract surgery. Preoperative biomarker screening could identify at-risk patients, enabling targeted anti-inflammatory therapy to improve postoperative comfort and satisfaction. This biomarker-driven approach may enhance personalized care in cataract surgery.

Abstract No.: 200545

One Surgery, Two Worlds: The First Cross-Continental Carbon Footprint Study of Cataract Surgery Between the UK NHS and South Asia

First Author: Pradipta **CHOWDHURY**

Co-Author(s): Mandeep Singh **BINDRA**, Prakash Kumar **CHOWDHURY**, Anureet **KAUR**

Purpose: This study evaluates the environmental footprint of phacoemulsification within the UK National Health Service (NHS). It benchmarks this against a high-volume South Asian eye hospital to uncover how resource-lean surgical systems achieve comparable outcomes with dramatically lower carbon emissions.

Methods: This prospective study analyzed 1,000 standalone phacoemulsification surgeries, comprising 500 surgeries at Stoke Mandeville Hospital NHS Trust (UK) and 500 surgeries at the Bangladesh Eye Hospital (BEH, Bangladesh). Surgical waste was measured bin by bin, and energy data were collected from hospital records. Travel emissions were survey-based. CO₂e was calculated using the EPA's TRACI 2.1. Post-op infection rates and patient satisfaction were also assessed.

Results: Each NHS phacoemulsification generates 128.3 kg CO₂e (primarily from disposable procurement) and 3.7 kg of solid waste. Averaging 12 cases/day, per-

surgery energy use reaches 33.8 kWh (HVAC 30.4 kWh; autoclave 2.18 kWh) due to constant climate control and underfilled sterilisers. In contrast, Bangladesh Eye Hospital averages 37 cases/day, using just 8.4 kWh/case (HVAC 2.8 kWh; autoclave 0.093 kWh). BEH generates 17.1 kg CO₂e and 0.45 kg waste per case - reductions of 86% and 87.84% respectively, compared to the NHS. This is achieved through reusable tools, batch sterilization, and multi-use medications. No endophthalmitis occurred. Patient satisfaction was 95.1% in the UK and 90.9% in BEH.

Conclusions: This study demonstrates that sustainability is a reproducible strategy for high-quality, low-carbon surgery rather than a compromise. Ophthalmology can now adapt.

Abstract No.: 201940

Optimizing Post-Phacoemulsification Protection: The Role of Intracameral Levofloxacin

First Author: Kristo Hadi Audric **SUGIAMAN**

Co-Author(s): Stefenie, Gede **PARDIANTO**, Diyah **PURWORINI**

Purpose: To evaluate the efficacy of intracameral levofloxacin 0.5% in preventing postoperative infection following phacoemulsification cataract surgery.

Methods: A total of 2864 eyes from 2032 patients underwent phacoemulsification and intraocular lens (IOL) implantation at SMEC, Medan, Indonesia, performed by a single surgeon. At the end of each procedure, 0.5% levofloxacin was administered intracamerally. Observations included signs of inflammation or infection (uveitis, conjunctivitis, keratitis, endophthalmitis), and measurements of uncorrected visual acuity (UCVA), best corrected visual acuity (BCVA), and intraocular pressure (IOP) preoperatively and one month postoperatively. Data were analyzed using SPSS v29.0 with a paired t-test; p<0.05 was considered statistically significant.

Results: No cases of postoperative infection or inflammation were observed. Significant improvements were noted in UCVA (from 0.16 to 0.84), BCVA (from 0.23 to 0.94), and IOP (from 19.06 mmHg to 12.10 mmHg), all with p<0.001.

Conclusions: Intracameral levofloxacin 0.5% appears to be highly effective in preventing post-phacoemulsification infections. Improved UCVA, BCVA, and reduced IOP further support the safety and clinical benefits of this prophylactic approach in cataract surgery.

Abstract No.: 201413

Outcomes of Toric Intraocular Lenses for High Astigmatism Post-Penetrating Keratoplasty

First Author: Yunhai **DAI**

Co-Author(s): Fanqian **SONG**

Purpose: To evaluate the efficacy and predictability of cataract extraction and bi-toric intraocular lens (IOL) implantation in patients with high corneal astigmatism after penetrating keratoplasty (PKP).

Methods: Prospective, non-randomized cohort study. Eighteen eyes in 18 patients were included and divided into the Toric (n = 9) and Non-Toric (n = 9) groups. The main outcomes included uncorrected distance visual acuity (UDVA), corrected distance visual acuity (CDVA), manifest refraction, refractive prediction errors, intraocular pressure (IOP), and endothelial cell counts for 3 months postoperatively.

Results: At postoperative month 3, UDVA and CDVA were significantly improved in all patients. UDVA and CDVA were significantly better in the Toric group compared with the Non-Toric group ($P = 0.004$, $P = 0.003$). UDVA and CDVA reached $\geq 20/30$ in 56% and 89% of the Toric group, respectively, versus 0% and 33% in the Non-Toric group. Astigmatism was significantly decreased from 9.89 ± 3.55 D diopters (D) to 2.89 ± 0.82 D ($P < 0.001$) in the Toric group. The mean errors of spherical power, astigmatism, and spherical equivalent were all under 1 D in the Toric group. IOP and corneal endothelial cell counts had no significant changes from preoperative values ($P = 0.5$ and $P = 0.9$, respectively) in both groups.

Conclusions: Toric IOLs can be safe and effective in PKP patients with high regular astigmatism, improving UDVA and CDVA and reducing the manifest refraction cylinder to predictable low values.

Abstract No.: 200196

PERK Regulates Epithelial–Mesenchymal Transition Through Autophagy and Lipid Metabolism in Lens Epithelial Cells

First Author: Xiaoran **WANG**

Purpose: Pathological epithelial–mesenchymal transition (EMT) of lens epithelial cells (LECs) plays a crucial role in the formation of lens fibrosis, particularly in fibrotic posterior capsular opacification and anterior subcapsular cataract (ASC). Here, we investigated the potential roles of endoplasmic reticulum (ER) stress in the development of lens fibrosis.

Methods: RNA sequencing analyzed gene expression in ASC patients, TGF β 2-treated human lens explants, and rabbit LECs. Rabbit LECs were treated with TGF β 2 $\pm$ PERK inhibitor ISRIB or autophagy modulators. A mouse fibrosis model assessed ISRIB's effects. Techniques included lipidomics, TEM, immunostaining, qPCR, and Western blot.

Results: ER stress genes were upregulated in patients with ASC, TGF β 2-stimulated human explants and primary LECs. Pharmacologic ER stress induction promoted EMT, while its inhibition reduced TGF β 2-induced mesenchymal gene levels. Blocking the PERK axis of ER stress with ISRIB or targeting downstream factor ATF4 suppressed EMT, whereas the IRE1 axis showed no effect. Consistent with these in vitro observations, anterior chamber injection of ISRIB also reduced subcapsular plaque formation in a mouse model of lens fibrosis by suppressing SMAD2/3 activation. Mechanistically, ISRIB suppressed LC3-II conversion and P62 degradation, indicating autophagy suppression. Lipidomics revealed phosphatidylethanolamine (PE), essential for autophagosome formation, was downregulated in TGF β 2-treated LECs and upregulated with ISRIB cotreatment. Inducing autophagy with rapamycin significantly rescued the mesenchymal gene suppression by ISRIB, whereas autophagy inhibitor CQ produced opposite effects.

Conclusions: ER stress, particularly the PERK axis, promotes LECs' EMT through autophagy and PE metabolism, offering potential therapeutic targets for the treatment of lens fibrosis.

Abstract No.: 207542

Partial Resection of Iris Cysts by a Fluid-Jet ("Water-Knife") Surgical Technique During Cataract Surgery

First Author: Wenjie **LIU**

Co-Author(s): Yin **CHANG**, Zeqi **FAN**, Jiewei **LIU**, Lichun **YANG**

Purpose: To evaluate the feasibility and clinical outcomes of a new fluid-jet "water-knife" technique for partial excision of iris cysts complicating cataract surgery.

Methods: A prospective interventional case series included three patients (five eyes) with iris cysts interfering with cataract surgery. A 5-mL syringe with a bent cannula was used to deliver targeted fluid-jet impulses onto the cyst surface. Initial jets ruptured the cyst wall and decompressed its contents, followed by stepwise jets directed approximately 1 mm from the rupture edge to detach adjacent cyst wall segments. Irrigation/aspiration was performed to clear residual material. Standard phacoemulsification and intraocular lens implantation were subsequently completed. Postoperative follow-up included slit-lamp examination and ultrasound biomicroscopy (UBM).

Results: All five surgeries were successfully completed in a single session. Intraoperatively, the fluid-jet technique removed the majority of the cyst wall, effectively clearing the pupillary axis and facilitating safe phacoemulsification. No intraoperative complications occurred. On postoperative day 1, no visible cyst was observed under natural or dilated pupil examination.

At 1 month, UBM demonstrated only minimal residual wall tissue or small cyst remnants. During 3–4 months of follow-up, no recurrence or secondary complications were observed.

Conclusions: The fluid-jet “water-knife” technique provides a simple, minimally invasive, and effective approach for managing iris cysts encountered during cataract surgery. By enabling substantial cyst wall removal while preserving iris architecture, this method improves surgical visualization, minimizes intraoperative risks, and avoids staged interventions. Preliminary outcomes suggest strong clinical applicability and potential for broader adoption, warranting further multicenter validation.

Abstract No.: 202374

Patient Reported Experience Measures (PREM) Tool for Enhancing Cataract Surgery Safety in Indian Hospitals

First Author: Samina **ZAMINDAR**

Purpose: This study aimed to develop and validate a PREM tool to assess patient experiences related to cataract surgery safety across Indian hospitals.

Methods: A multiphase study was conducted across 16 Indian hospitals. Phase 1 involved tool development via expert panel discussions (n=31), literature review, and content validation (Content Validity Index [CVI] ≥ 0.8). Phase 2 piloted the 14-item tool with 240 patients (KR-20=0.801). Phase 3 implemented the tool in a baseline study (n=582 patients) to evaluate reliability and domain-specific performance (e.g., communication, safety). Data were analysed using descriptive statistics and validity indices.

Results: The tool demonstrated high validity (mean CVI=0.982) and reliability (KR-20=0.801). Over 95% of patients reported adherence to hand hygiene (97.6%), identity verification (99.7%), and post-operative guidance (99.0%). Gaps were noted in anaesthesia understanding (92.1%) and financial counselling (95.7%). Domain-wise, Patient Communication scored highest (M=3.90, SD=0.33), followed by Clinical Care (M=1.96, SD=0.19).

Conclusions: The validated PREM tool effectively captures patient experiences in cataract surgery, identifying strengths (e.g., safety protocols) and areas for improvement (e.g., preoperative counselling). Its integration into routine practice can enhance patient-centred care and surgical safety in resource-limited settings.

Abstract No.: 206057

Planned vs Intraoperative Aberrometry Guided IOL Power Calculation in Post-Corneal Transplant Cataract Surgery

First Author: Lekha **CHANDEL**

Co-Author(s): Shivam **GARG**, Amit **GUPTA**, Deeksha **SHARMA**, Vipasha **SHARMA**

Purpose: To evaluate whether the use of intraoperative biometry (Optiwave Refractive Analysis, ORA) improves visual and refractive outcomes compared to planned IOL power calculations in eyes with clear corneal grafts undergoing cataract surgery.

Methods: This retrospective series reviewed 10 post-keratoplasty eyes from 9 patients who underwent cataract surgery. Preoperative IOL power calculations based on standard optical biometry were compared against intraoperative aphakic refractive measurements using the ORA system. The primary outcome was the refractive prediction error, with analysis of the percentage of eyes achieving a spherical equivalent (SE) refraction within ± 0.50 D and ± 1.00 D of the target for both methods.

Results: Intraoperative biometry demonstrated superior predictive accuracy. With ORA, 50% and 90% of eyes were within ± 0.5 D and ± 1.0 D of target refraction, respectively, compared to 40% and 80% with the planned preoperative biometry. The mean refractive spherical equivalent (MRSE) improved significantly from -6.09 ± 5.28 D preoperatively to -0.25 ± 0.395 D postoperatively. All eyes achieved a final best-corrected visual acuity (BCVA) of 20/70 or better.

Conclusions: Intraoperative wavefront aberrometry is a valuable tool for IOL power calculation in challenging post-keratoplasty eyes. The use of ORA demonstrated improved refractive prediction accuracy over standard preoperative biometry, contributing to better postoperative refractive outcomes in this complex patient population.

Abstract No.: 200701

Post-Operative Outcome Comparison Between Phacoemulsification and Manual Small-Incision Cataract Surgery in Patients With Posterior Polymorphous Corneal Dystrophy

First Author: Md Dedarul **HASSAN**

Co-Author(s): Zaman **SAKIB**

Purpose: Posterior polymorphous corneal dystrophy (PPCD) is a rare, typically bilateral endothelial dystrophy that can complicate cataract surgery due to altered corneal morphology and endothelial fragility. This study aims to compare the postoperative outcomes of phacoemulsification and manual small incision cataract

surgery (MSICS) in PPCD patients to determine the safer and more effective surgical approach.

Methods: A retrospective cohort study was conducted, analyzing 60 eyes of 45 patients with PPCD who underwent cataract surgery between January 2020 and June 2025. Patients were divided into two groups: 30 eyes treated with phacoemulsification and 30 eyes with MSICS. Outcome measures included BCVA, endothelial cell density, corneal thickness, and postoperative corneal decompensation at one week, one month and three months follow-up.

Results: Both groups demonstrated significant improvement in BCVA postoperatively. However, the phacoemulsification group exhibited a statistically higher rate of endothelial cell loss compared to the MSICS group ($p < 0.05$). Corneal edema was more frequent and persistent in the phaco group during the early postoperative period. In contrast, MSICS, though associated with a slightly larger incision and slower visual recovery in the first week, showed better corneal clarity and endothelial preservation at three months.

Conclusions: Phacoemulsification appears to be safer and more effective than MSICS, but in patients with PPCD, MSICS offers a safer profile with less endothelial trauma and better post-operative corneal clarity. Surgical choice should be made individualized, considering the extent of corneal involvement and surgeon experience but MSICS is preferred in cases with advanced endothelial compromise.

Abstract No.: 204340

Precision Perfected: Advancing Toric IOL Axis Planning With IOL Master 700 Total Keratometry

First Author: Ankita **SANJAY KULKARNI**

Co-Author(s): Sri **GANESH**, Sushmitha **SAMAK SRIGANESH**

Purpose: To compare the accuracy of IOL Master 700 vs online calculators for toric IOL axis planning.

Methods: A retrospective analysis of 145 eyes undergoing toric IOL implantation with Tecnis Eyhance or Hoya Vivinex lenses was performed. Preoperative planning used the IOL Master 700 with total keratometry, incorporating anterior and posterior corneal astigmatism, and was compared to standard online calculators based on anterior measurements. Axis prediction from the IOL Master and toric calculator was evaluated. Postoperative UCVA, BCVA, spherical equivalent, cylinder, and astigmatic axis were assessed on days 7 and 15.

Results: The IOL Master 700 demonstrated superior precision in axis prediction, achieving $\leq 5^\circ$ axis deviation from postoperative alignment in 64.4% of eyes, outperforming online calculator estimations. Both Tecnis Eyhance and Hoya Vivinex groups exhibited robust visual acuity gains postoperatively (mean UCVA

LogMAR improved from 0.652 ± 0.343 preoperatively to 0.042 ± 0.081 at day 15, $p < 0.001$; BCVA improved from 0.354 ± 0.325 to 0.010 ± 0.039 , $p < 0.001$). Importantly, the significant discrepancy between preoperative online calculator axis and postoperative IOL position ($p < 0.001$) underscores the advantage of total corneal astigmatism incorporation. Although spherical and cylindrical refractive components showed trends towards improvement, axis alignment accuracy correlated strongly with better refractive outcomes and patient visual satisfaction.

Conclusions: Incorporation of total keratometry with the IOL Master 700 significantly improves toric IOL axis alignment and refractive predictability compared to anterior surface-based calculations. This refinement enhances the precision of toric IOL performance and supports personalized refractive cataract surgery. Comparative evaluation of Tecnis Eyhance and Hoya Vivinex toric lenses demonstrates consistent efficacy across platforms, reinforcing the clinical relevance of this approach. Integration of posterior corneal curvature into online calculators is expected to further improve axis predictability and refractive outcomes.

Abstract No.: 204508

Predictors of Surgically Induced Astigmatism: A Step Towards Customizing the Toric IOL Calculation

First Author: Nilesh **KUMAR**

Purpose: To identify predictors of the direction and magnitude of surgically induced astigmatism (SIA) after phacoemulsification and to quantify their impact using odds ratios.

Methods: Retrospective analytical study from the clinical records of a single surgeon where the data from 618 eyes were analyzed. Variables included preoperative astigmatism (ΔK), incision size, and the angular distance between incision axis and steep meridian. SIA direction (positive or negative) was modeled using multivariate logistic regression.

Results: Mean SIA was $+0.015$ D (SD 0.38). Pre-op ΔK significantly predicted SIA polarity (OR 0.636, $p=0.0012$), with each diopter reducing the odds of positive SIA by $\sim 36\%$. Axis distance was also significant (OR 1.009, $p=0.0052$), increasing the odds of positive SIA by $\sim 0.9\%$ per degree of misalignment.

Conclusions: Both pre-op astigmatism and incision-axis alignment are significant and independent predictors of SIA direction after cataract surgery.

Abstract No.: 200888**Preoperative Diquafosol vs Intense Pulsed Light With Gland Expression for MGD: Effects on Refractive Accuracy and Tear Film Stability in Cataract Surgery***First Author: Takeshi TESHIGAWARA**Co-Author(s): Tatsukata KAWAGOE, Akira MEGURO, Nobuhisa MIZUKI, Yuki MIZUKI*

Purpose: To compare the effects of two preoperative dry eye treatments—3% diquafosol sodium (DQS) and intense pulsed light with meibomian gland expression (IPL-MGX)—on refractive accuracy in cataract surgery, and to identify tear break-up time (TBUT) thresholds predictive of refractive success.

Methods: In this prospective, paired-eye study, 62 patients (124 eyes) with meibomian gland dysfunction underwent bilateral cataract surgery with the same trifocal IOL. One eye received DQS, and the fellow eye underwent four IPL-MGX sessions before biometry. Postoperative absolute prediction error (P-SE) was compared. TBUT and higher-order aberrations (HOAs) were evaluated. Logistic regression identified predictors of refractive accuracy, and ROC analysis assessed the predictive value of TBUT for P-SE thresholds of <0.25 D and <0.50 D.

Results: P-SE was significantly lower in IPL-MGX-treated eyes than in DQS eyes (mean paired difference -0.11 D, $p < 0.001$). Success rates within <0.25 D and <0.50 D were higher with IPL-MGX ($p < 0.01$). TBUT and HOAs were predictors in univariate models, but only TBUT remained significant in multivariable analysis (OR 4.90 per 1-s increase, 95% CI 1.92–12.51, $p < 0.001$). ROC analysis supported TBUT cutoffs of 7 s (<0.25 D) and 6 s (<0.50 D).

Conclusions: IPL-MGX may improve refractive accuracy compared to DQS. TBUT appeared to be the most consistent predictor, and achieving ≥ 6 s was associated with a higher likelihood of refractive success.

Abstract No.: 203576**Prophylactic Topical Steroids in Cataract Patients and Its Impact on Postoperative Tear Inflammatory Biomarkers***First Author: Naren SHETTY**Co-Author(s): Arkasubhra GHOSH, Tejal S J, Swaminathan SETHU*

Purpose: To evaluate the impact of pre-operative topical steroids on ocular surface immune cell subsets and tear fluid inflammatory cytokines in cataract surgery patients.

Methods: A prospective study was conducted on 40 cataract patients (ages 45–65), divided into a control group ($n=20$) without pre-operative steroids and a case group ($n=20$) receiving prednisolone acetate 1% eye drops (4x/day for 3 days pre-operatively, continuing

post-operatively per standard tapering). Patients with retinal, glaucoma, or corneal pathologies, steroid use, or complicated cataracts were excluded. Tear fluid biomarkers (Schirmer's test) were assessed pre-surgery, at 1 and 3 months post-op, with additional pre-op assessments in the case group. Statistical analysis included the Shapiro-Wilks test for data distribution and two-way repeated measures ANOVA ($P < 0.05$).

Results: Patients in the case group who received pre-operative steroids exhibited a significant reduction in key inflammatory biomarkers, including TNF- α , IL-6, IL-17A, VEGF-A, and ICAM-1, at both 1-month and 3-month post-operative time points which was not noticed in the control group. The findings suggest that pre-operative steroid use helps regulate the ocular surface immune response, potentially reducing post-surgical inflammation and improving recovery outcomes.

Conclusions: Pre-operative topical steroid use effectively modulates inflammatory cytokines, contributing to better ocular surface stability and reduced inflammatory response following cataract surgery. These findings support the potential benefits of pre-operative steroid administration in optimizing post-operative healing.

Abstract No.: 203706**Prospective Study on Efficacy and Safety Profile of Topical Pilocarpine in Management of Presbyopia***First Author: Nishi SATISH**Co-Author(s): Harinder Singh SETHI, Ritu SINGH*

Purpose: To study the efficacy and safety profile of topical Pilocarpine in the management of presbyopia.

Methods: Phakic patients of age >40 years were included. Exclusion criteria were uveitis, history of ocular surgery, concomitant systemic morbidity, known allergy to the concerned drug, and media opacity. The patients were followed up monthly for repeat evaluation of near vision and the onset of any adverse effects. Results- 153 patients were recruited with a mean age of 46 ± 4.03 years. The majority of the patients were homemakers, followed by working professionals with near-range work, such as software engineers, etc.

Results: A total of 153 patients were recruited with a mean age of 46 ± 4.03 years. The majority of the patients were homemakers, followed by working professionals with near-range work, such as software engineers, etc. The results showed a significant reduction in refraction after 2 weeks. The patients complained of minimal side effects like hyperemia ($n=82$) and brow ache ($n=59$). Conclusion- Topical 1% Pilocarpine nitrate aids in better near-vision within 2 weeks with no serious side effects.

Conclusions: The study revealed significant improvement in near vision after use of topical Pilocarpine nitrate 1% OD. It proves to be a safe alternative to glasses for the presbyopic age group. Although it is a temporary option, one can enjoy spectacle independence for near with minimal side effects.

Abstract No.: 203942

Pumping Up the Performance: A Comparative Analysis of Triple-Pump vs Quattro-Pump Phacoemulsification System on Corneal Endothelial Health

First Author: Grace SETIAWAN

Co-Author(s): Budiman, Mayasari KUNTORINI, Emmy SUGIHARTI

Purpose: To compare the safety of the triple-pump and quattro-pump phacoemulsification systems in regard to endothelial cell changes.

Methods: This is an experimental study with a double-blind randomized clinical trial method. The sample was selected using randomization with permutation blocks and was conducted at Cicendo Eye Hospital National Eye Center. There were a total of 23 subjects, of which 11 subjects underwent phacoemulsification with a triple-pump system and 12 subjects with a quattro-pump system. All subjects underwent specular biomicroscopy examinations preoperatively, 1-week, and 1-month postoperatively.

Results: The mean endothelial cell density (ECD) change in the triple-pump group was higher than in the quattro-pump group both at 1 week postoperatively (464.27 ± 319.58 vs 163.42 ± 131.85 , $p=0.007$) and 1 month postoperatively (456.55 ± 458.78 vs 88.50 ± 90.74 , $p = 0.001$). The mean coefficient of variation (CV) change was significantly higher in the triple-pump group (5.27 ± 7.79 , 16.3%) compared to the quattro-pump group (0.67 ± 2.30 , 2.07%) with $p = 0.011$. Changes in hexagonality (HEX) and central corneal thickness (CCT) were greater in the triple-pump group than the quattro-pump group at both 1 week and 1 month postoperatively, although these differences were not statistically significant.

Conclusions: The quattro-pump phacoemulsification system resulted in more minimal changes in ECD one month postoperatively compared to the triple-pump system.

Abstract No.: 201560

Rescue of a Dislocated Intraocular Lens With Silicone Tip Aspiration: A Novel Technique

First Author: Haibo LI

Co-Author(s): Xiaoxi LI

Purpose: To evaluate the clinical efficacy of a novel surgical technique using a 25-gauge active aspiration of

flute needle for treating posterior intraocular lens (IOL) dislocation.

Methods: This retrospective study included 12 eyes in 12 patients with posterior dislocated IOL. All patients underwent comprehensive ophthalmic evaluations before surgery. Surgery was performed with three-port pars plana vitrectomy, the dislocated IOL was aspirated to the anterior vitreous by 25-gauge flute needle, and then managed by different surgical corrections. Comprehensive ophthalmologic evaluations were performed preoperatively and postoperatively, including best-corrected visual acuity (BCVA), intraocular pressure (IOP), slit-lamp biomicroscopy and fundus examination. Postoperative assessments were conducted at 1 week, 1 month, and 3 months.

Results: Twelve eyes were treated. All surgeries were successfully completed using a 25-gauge silicone tip with active aspiration. IOL repositioning without sutures in 1 case (8.3%), IOL repositioning with scleral sutures in 4 cases (33.3%), IOL exchanged with Yamane technique in 4 cases (33.3%) and IOL exchange with scleral sutures in 3 cases (25.0%). The mean BCVA preoperatively was log MAR 0.48 ± 0.33 (range 0.2-1.3), decreasing to log MAR 0.34 ± 0.22 (range 0.2-0.7) at three-month postoperatively. IOP remained stable except for one patient who developed transient high IOP, but well controlled by medications.

Conclusions: The use of an active aspiration of flute needle with silicon tip provides a simplified, efficient and safe method for IOL dislocation, minimizing the need for perfluorocarbon liquids and forceps.

Abstract No.: 202553

Retropupillary Iris Claw Lens Implantation in Pediatric Subluxated Lenses: A Clinical Study

First Author: Pravalika PAMULAPATI

Co-Author(s): Jagadheesh Kumar Reddy, Vandhana SUNDARAM

Purpose: To evaluate the visual and anatomical outcomes, as well as the safety profile, of lensectomy followed by retropupillary iris-claw intraocular lens (IOL) implantation in children under 18 years with subluxated crystalline lenses of various etiologies.

Methods: A retrospective analysis was conducted on pediatric patients (≤ 18 years) who underwent anterior segment lensectomy with retropupillary iris-claw IOL implantation for subluxated lenses between 2011 and 2024 at a tertiary eye care center. Data collected included demographic details, preoperative and postoperative best corrected visual acuity (BCVA), intraocular pressure, endothelial cell count, intraoperative and postoperative complications, and follow-up outcomes over a period of 2 years.

Results: A total of 34 eyes from 24 patients were included, with a mean age of 8.5 years. Significant improvement in BCVA was noted postoperatively

(mean pre-op LogMAR BCVA: 0.85 ± 0.30 , mean post-op LogMAR BCVA at 12 months: 0.38 ± 0.20 , $p < 0.0001$). Mean postoperative intraocular pressure was 15.5 mm Hg. The mean endothelial cell density reduced from 2907.35 ± 387.07 cells/mm² to 2612.02 ± 435.90 cells/mm² post-surgery. No cases of endophthalmitis or retinal detachment were observed. IOLs remained well-centered in >90% of cases.

Conclusions: Lensectomy combined with retropupillary iris-claw IOL implantation is a safe and effective surgical option for visual rehabilitation in children with subluxated lenses. It offers good visual outcomes with an acceptable complication profile, making it a viable alternative in cases where capsular support is inadequate.

Abstract No.: 206076

Risk Factors for Late Presentation With Advanced Cataract in the Hong Kong Adult Population

First Author: Yan Yin **LO**

Co-Author(s): John **BUCHAN**, Catey **BUNCE**, Jonathan Cheuk Hung **CHAN**, Hon Chi Angie **FONG**

Purpose: Cataract is the main cause of blindness and impaired best-corrected visual acuity (BCVA) in Hong Kong. This study aims to analyse the risk factors for late presentation of patients with advanced cataract, while also investigating the motivation factors for eye screening programme attendance.

Methods: The study is a case-control study. Participants in the Southern District Eye Examination Scheme were classified into cases and controls by their BCVA at primary diagnosis. BCVA and demographic data were collected from the database, and information on other risk factors was collected by questionnaire.

Results: 175 participants (99 females) were recruited for this study, mean (SD) age 69 (8) years old, with 86 cases. Univariate analysis shows that low socioeconomic status is associated with late presentation of advanced cataract, as measured by monthly household income, housing type, education level, and occupation. Other significant factors include increasing age, lack of social support, diabetes, hypertension, heart disease, no primary family history of cataract and lowered mobility. Presence of symptoms and recommendations from friends or family were the common reasons for attending screening programme. The general level of knowledge about cataract was low; word-of-mouth and healthcare providers were the most frequently reported channels for receiving cataract information by patients.

Conclusions: Identification of risk factors for late presentation with cataract in Hong Kong provides useful information to guide policy. Targeted interventions to improve access for those of lower socioeconomic status, increasing age, lack of social

support and medical co-morbidities could be expected to be most impactful in reducing late presentation.

Abstract No.: 201035

Rotational Stability of Three Toric Intraocular Lens Platforms in Patients Undergoing Repositioning Surgery

First Author: Honglei **LI**

Co-Author(s): Xiaoming **WU**

Purpose: To evaluate the rotational stability of three toric intraocular lens (TIOL) platforms in patients undergoing repositioning surgery.

Methods: This comparative retrospective study enrolled eyes that underwent cataract surgery and were implanted with an AcrySof, AT TORBI/LISA, or TECNIS TIOL. Patients who experienced TIOL misalignment $\geq 10^\circ$ postoperatively and underwent repositioning surgery were included. The incidence of repositioning surgery after cataract surgery and the misalignment degree before and after repositioning surgery of the three TIOL platforms were mainly compared.

Results: Of the 2598 eyes implanted TIOLs, 56 eyes (2.156%) undergoing repositioning. The repositioning rates for the AcrySof, AT TORBI/LISA, and TECNIS platforms were 0.848% (10/1179), 2.935% (28/954), and 3.871% (18/465), respectively, showing significant differences ($P < 0.001$). Misalignment degrees before repositioning surgery for the AcrySof, AT TORBI/LISA, and TECNIS TIOLs were $27.90 \pm 15.74^\circ$, $60.79 \pm 18.79^\circ$, and $31.61 \pm 20.84^\circ$, respectively ($P < 0.001$). AT TORBI/LISA platform had a significantly greater misalignment degree compared to AcrySof (Difference: 32.89° , $P < 0.001$) and TECNIS platforms (Difference: 29.18° , $P < 0.001$). There was no significant difference between AcrySof and TECNIS (Difference: 3.71° , $P = 0.629$). After repositioning, the AT TORBI/LISA platform showed significantly higher misalignment degrees compared to AcrySof and TECNIS (Difference: 6.63° ; 5.49° , $P = 0.009$).

Conclusions: AcrySof TIOLs had a lower incidence of repositioning surgery compared with AT TORBI/LISA and TECNIS, while AT TORBI/LISA TIOLs exhibited a higher degree of axis misalignment both before and after repositioning.

Abstract No.: 201501

Safety and Efficacy of Intracameral Steroids in Controlling Post-Operative Inflammation in Phacoemulsification: A Meta-Analysis

First Author: Lorenz Jacob **MANGAHAS**

Co-Author(s): Ian Ben **BATCAGAN**, Richmond **SIAZON**

Purpose: This study aimed to compare intracameral steroid use, a recent innovation, with traditional topical corticosteroid application to understand their efficacy and safety.

Methods: The meta-analysis design and method were reported in line with Preferred Reporting Items for Systemic Reviews and Meta-Analyses (PRISMA) guidelines. We included all randomized control clinical trials (RCT) with completed manuscripts or abstracts published online regardless of publication date or publication status.

Results: Four studies were included in this meta-analysis. The pooled mean difference showed no significant difference in the reduction of inflammation scores in anterior chamber cells (MD=-0.11, 95%CI=-0.22 to 0.01, p=0.07), anterior chamber flare between (MD=0.04, 95%CI=-0.04 to 0.13, p=0.29), and in IOP (MD=-0.06, 95%CI=-0.54 to 0.42, p=0.81) between the two groups. Two studies reported on adverse events which observed the absence of serious adverse events in the topic group and one case in intracameral group.

Conclusions: There is evidence that supports the equivalence of intracameral steroid injections and topical steroids in reducing postoperative inflammation after phacoemulsification. There are also minimal adverse events, including ocular surface toxicity, in both intracameral steroid injections and topical steroids. Postoperative intraocular pressure is also comparative in both treatments. It is recommended that intracameral steroid injections be used as a safe and effective alternative to topical steroids for managing postoperative inflammation after phacoemulsification. Additionally, intracameral steroid injections may offer the added benefit of improved patient compliance due to their convenience and reduced frequency of administration.

Abstract No.: 201819

Safety of Immediate Sequential Bilateral Cataract Surgery (ISBCS) Enhanced With Patient Selection and High Standard Protocols in a Tropical Region

First Author: Givenchy Angela **WINARJO**

Co-Author(s): Ruth **ANASTASIA**, Clarissa **LISTER**, Gede **PARDIANTO**, Diyah **PURWORINI**

Purpose: Given the heightened risk of dual-eye infection in tropical climates, the purpose of this study was to determine if strict patient selection and maintained surgical standards could successfully improve the safety and efficacy of Immediate Sequential Bilateral Cataract Surgery (ISBCS) in a hot and humid climate.

Methods: Thirty-nine patients (78 eyes) meeting stringent inclusion criteria underwent ISBCS. The stricter criteria included absence of systemic disease, absence of ocular abnormalities, and presence of physiological cataract (no traumatic cataract, complicated cataract, pseudoexfoliation, etc). ISBCS was performed using the phaco-chop technique with a venturi phaco machine, bimanual irrigation/aspiration, and hydro-implantation of the intraocular

lens (IOL). Intra-operative complications (posterior capsule rupture (PCR), and vitreous loss) and post-operative outcomes (corneal edema, toxic anterior segment syndrome (TASS), and endophthalmitis) were monitored. Uncorrected visual acuity (UCVA), best corrected visual acuity (BCVA), and intraocular pressure (IOP) were measured and compared pre- and post-operatively. Statistical analysis was performed, with $p < 0.05$ considered significant.

Results: Zero intra-operative complications (PCR, vitreous loss) or major post-operative complications (TASS, endophthalmitis, visual-disturbing corneal edema) were observed. Minimal corneal edema occurred but did not affect vision. Significant improvements were seen in UCVA and BCVA ($p < 0.001$), along with a significant reduction in IOP ($p < 0.001$).

Conclusions: Strict patient selection and standards may improve ISBCS safety in tropical regions, preventing complications, offering rapid visual recovery, corneal stability, and reduced intraocular pressure. Further studies with a larger sample size are needed to establish this as a healthcare policy reference.

Abstract No.: 201649

Scaling Up Cataract Surgery in the Community: A Decade of Experience From Malaysia's Cataract Satellite Centre

First Author: Wan Radziah **WAN NAWANG**

Co-Author(s): Norasyikin **MUSTAFA**, Mohamad Aziz **SALOWI**, Siti Nurhuda **SHARUDIN**

Purpose: To describe the establishment, objectives, and outcomes of a community-based cataract centre, created through strategic partnerships to expand access, increase surgical coverage, and deliver high-quality eye care.

Methods: The cataract satellite centre was detailed based on its design, partnerships, and service model. Patient and surgical outcomes were obtained from the Cataract Surgery Registry within the National Eye Database and analyzed descriptively.

Results: Established in 2012 under Malaysia's National Blue Ocean Strategy through a partnership between the Ministry of Health and a statutory religious council, the cataract satellite centre was located in a commercial shop lot and functioned as a static outreach facility and one-stop centre for pre-operative, operative, and post-operative care. It catered to low-risk patients, operating five days per week with a capacity of 20-30 surgeries daily. Since commencing services in January 2013, the centre has served over 100,000 patients and performed more than 30,000 cataract operations. Among patients without ocular comorbidities, 96% achieved good visual outcomes (6/12 or better), while the posterior capsule rupture rate was 1.5%. The centre also accepted referrals nationwide, reduced waiting times, and helped decongest operating theatres in

nearby hospitals. It further set benchmarks for cataract pathways, surgical outcomes, training, and community engagement.

Conclusions: This cataract satellite centre demonstrates that high-quality cataract surgery can be effectively delivered through a community-based, partnership-driven model. By expanding access, increasing coverage, and defining national standards, it offers a scalable framework for cataract care in resource-limited settings.

Abstract No.: 202434

Spectacle Independence and Near Task Performance in Eyes Implanted With a Small Aperture IOL Following Corneal Inlay Removal

First Author: Robert ANG

Purpose: Evaluate spectacle independence and near task performance in patients undergoing cataract surgery with monocular implantation of a small-aperture IOL following removal of a corneal inlay.

Methods: In this prospective study, 13 patients with cataracts who had previously had a Kamra inlay implanted in one eye were enrolled. The inlay was removed, and the eye was monitored for stability prior to implantation of the IC-8 Aphera IOL. Visual outcomes, defocus curves and subjective questionnaire data were collected at 1, 3, 6, and 12 months (M) following IOL implantation.

Results: Mean monocular uncorrected distance, intermediate, and near visual acuity were 0.10 logMAR (20/25), 0.05 logMAR (20/22), and 0.05 logMAR (20/22), respectively, 12M after Aphera IOL implantation. Monocular defocus curves show a depth of focus of approximately 4.0 D at 0.2 logMAR or better, with a negative intercept of -2.33 D. Spectacle independence increased for tasks at all distances and there was a mean improvement of 1 to 2 rating levels for near vision tasks and minimal change in distance vision task performance from the screening visit to 12M.

Conclusions: The Aphera IOL provides an extended range of vision from distance to near with improved spectacle independence and near visual function in patients with prior Kamra inlay.

Abstract No.: 203922

Study on the Clinical Effect of Aligning Astigmatic Lens Axis With Corneal Steep Axis

First Author: Fanqian SONG

Co-Author(s): Yunhai DAI

Purpose: This study aims to investigate the clinical efficacy of aligning the axis of toric intraocular lenses (IOLs) with the corneal steep axis in patients undergoing cataract surgery.

Methods: This is a prospective randomized controlled trial included seventy cataract patients with regular corneal astigmatism of more than 1 diopters (D), who underwent phacoemulsification combined with implantation of a Tecnis Toric IOL. Patients were randomly divided into two groups, each group enrolled 35 patients. In the control group, SIA was set as 0.5 D, alignment axis were set according to the Tecnis Toric Aspheric IOL Calculator. In the experimental group, SIA was set as 0 D and the alignment axis was the same as the steep axis of corneal astigmatism. Main outcome measurements, including visual acuity, expected residual astigmatism (PRA), residual astigmatism, and toric IOLS alignment axis, were detected at 3 months postoperatively. SIA and error of refractive astigmatism (ERA) were analyzed by vector analysis.

Results: Measurements of postoperative uncorrected and corrected distance visual acuity (UDVA and CDVA), toric IOL rotation(°), total and vector analysis of SIA showed no differences between the two groups ($P > 0.05$). The ERA of the experimental group (0.15 ± 0.32 D) was significantly smaller than the control group (0.58 ± 0.48 D) ($P < 0.001$). Vector analysis of total error vector (EV) was smaller in the experimental group (0.30 ± 0.24 D) than the control group (0.60 ± 0.46 D) ($P = 0.001$), mainly in the vertical/horizontal direction (XEV) (0.0 ± 0.26 D in the experimental group and 0.24 ± 0.66 D in the control group) ($P < 0.05$). The experimental group showed lower postoperative cylinder (0.49 ± 0.23 D) than the control group (0.71 ± 0.49 D), although had no significant differences ($P = 0.055$).

Conclusions: This study suggests that aligning the toric IOL axis with the corneal steep axis shows better predictability of corneal astigmatism correction and provides a reliable therapeutic strategy for correcting corneal astigmatism during cataract surgeries.

Abstract No.: 202127

Surgical Outcomes of Cataract Surgery Following Rapid Glycemic Correction During the Preoperative Period

First Author: Yani WANG

Purpose: To evaluate the effects of rapid glycemic control during preoperative period on outcomes of cataract surgery for type 2 diabetes patients with high HbA1c levels.

Methods: The medical data of patients with type 2 diabetes who underwent cataract surgery were respectively reviewed between January 2023 and May 2024. The rapid control group consisted of 152 patients (222 eyes) with HbA1c $> 9.0\%$ following rapid glycemic correction (average duration: 17.3 ± 6.6 days), and the good control group consisted of 111 patients (162 eyes) with HbA1c $< 7.0\%$. Complications and visual outcomes were analyzed between the two groups during the 6-month postoperative follow-up.

Results: Macular edema and vitreous hemorrhage were the main postoperative complications in rapid control group (11.7%) and good control group (4.9%) ($P = 0.005$). Multivariate analysis showed that rapid glycemic correction and moderate to severe non-proliferative diabetic retinopathy were the main risk factors of complications ($P = 0.004$, $P = 0.003$). However, only 3.8% of patients with timely intervention for diabetic retinopathy developed severe complications in rapid control group ($P = 0.019$). At the final follow-up, the average best correction visual acuity in rapid control group was 0.30 ± 0.32 logMAR, with significant improvement compared with 1.26 ± 0.74 logMAR before surgery ($P < 0.0001$).

Conclusions: It seems to be unnecessary to prolong the duration of glycemic control before cataract surgery. Timely intervention may prevent the severe complications of diabetic retinopathy after cataract surgery following rapid glycemic control.

Abstract No.: 202395

Sutureless Intrasceral IOL Fixation: Outcomes and Efficacy of the Modified Yamane Technique

First Author: Purendra **BHASIN**

Co-Author(s): Priyamvada **BHASIN**

Purpose: To evaluate the postoperative outcomes, visual acuity, and intraocular lens (IOL) stability following the Modified Yamane technique for intrasceral fixation of three-piece IOLS.

Methods: This retrospective observational study included 33 eyes from 31 patients who underwent secondary IOL implantation using the Modified Yamane technique. The study included patients with dislocated/subluxated IOLs or crystalline lenses, poor capsular support/weak zonules, or spherophakia who underwent scleral-fixated IOL surgery using the Modified Yamane technique, with a minimum follow-up period of 3 months postoperatively. Patients were excluded if they underwent SFIOL surgery using other techniques, had a postoperative follow-up of less than 3 months, or did not consent to using their clinical data for research purposes.

Results: The study included 33 eyes from 31 patients, of whom 20 were male and 11 were female. Postoperative best-corrected visual acuity (BCVA) ranged from 6/6 to 6/9 in 12 eyes (39.3%), 6/12 to 6/18 in 10 eyes (30.3%), 6/24 to 6/36 in 4 eyes (12.1%), and 6/60 or worse in 5 eyes (15.1%). Pre-existing ocular comorbidities were present in 11 patients. Corneal edema and iritis were observed in 5 eyes on postoperative days 1-4, resolving within one week with conservative management. Postoperative complications included hypotony in 1 eye, vitreous hemorrhage in 1 eye, and conjunctival erosion due to haptic protrusion in 1 eye, which was managed by haptic trimming.

Conclusions: The Modified Yamane technique appears to be simple, safe, and time-efficient.

Abstract No.: 203852

Tear Metabolomics for Differentiating Bacterial, Viral, and Fungal Endophthalmitis

First Author: Vaibhav **VISHAL**

Co-Author(s): Vrushali **DESHPANDE**, Arkasubhra **GHOSH**, Padmamalini **MAHENDRADAS**, Naren **SHETTY**

Purpose: This prospective case-control study aimed to identify metabolite biomarkers in ocular fluids that distinguish bacterial, viral, and fungal endophthalmitis, enabling accurate diagnosis and risk stratification.

Methods: Tear and aqueous humor samples were analyzed using ultra-performance liquid chromatography-mass spectrometry (UPLC-MS) and multivariate statistical models. Patients were stratified by infection type and severity, and differentially expressed metabolites were compared across etiologies.

Results: Distinct metabolic profiles were observed. Bacterial endophthalmitis was associated with elevated methyl linolenate, palmitoleamide, and myristoleoyl carnitine. Viral cases showed alterations in cholesterol- and triglyceride-related metabolites. Fungal infections demonstrated changes in sterol and ergosterol pathways.

Conclusions: Metabolomic analysis of ocular fluids can differentiate bacterial, viral, and fungal endophthalmitis. The identified biomarkers may facilitate early diagnosis, guide targeted therapy, and support personalized clinical management, ultimately improving visual outcomes and reducing complications.

Abstract No.: 203716

The Art of Minimalist Correction: Low Astigmatism Strategies in Cataract Operations

First Author: Ankita **SANJAY KULKARNI**

Co-Author(s): Sri **GANESH**, Supriya **SAMAK SRI GANESH**

Purpose: To compare the effectiveness of manual limbal relaxing incisions (LRI), femtosecond laser arcuate keratotomy (FLAK), and toric intraocular lenses (IOL) against conventional non-toric IOL implantation in correcting low corneal astigmatism during cataract surgery.

Methods: In this prospective study, 200 eyes from patients over 50 years with cataracts and 0.75–1.5 diopters of regular corneal astigmatism were assigned to one of four groups: conventional phacoemulsification with non-toric IOL (control), manual LRI, FLAK, or toric IOL implantation. Surgeries were performed via a 2.8 mm clear corneal incision under topical anesthesia. Postoperative assessments included visual acuity, refraction, keratometry, and

vector analysis of astigmatism (Alpins method) at day 1, 15, and 3 months.

Results: At 3 months, toric IOLs showed remarkable superiority, with 92% of eyes achieving residual cylinder <0.5 D and excellent uncorrected visual acuity (0.046 logMAR). FLAK outperformed manual LRI by providing more predictable correction with lower residual astigmatism vectors (DV 0.77 D vs ~ 1.2 D, $p < 0.001$) and better visual outcomes. Manual LRI, while less precise, remains an important technique when laser technology is unavailable. Differences in surgically induced astigmatism were minimal among groups

Conclusions: Our data highlight toric IOL implantation as the leading choice for managing low corneal astigmatism in cataract patients, delivering precise, consistent visual improvement. FLAK offers a cutting-edge, laser-based alternative with superior accuracy compared to manual methods. These results mark a pivotal step toward refined, personalized cataract surgery—guiding surgeons to optimize outcomes based on available resources and patient needs

Abstract No.: 203864

The Effect of Exosomes Derived From Human Umbilical Cord Mesenchymal Stem Cells on Lens Regeneration

First Author: Jing **WANG**

Co-Author(s): Xiaotong **LI**, Wei **ZHANG**

Purpose: To investigate the effect of exosomes derived from human umbilical cord mesenchymal stem cells on lens regeneration.

Methods: We co cultured human umbilical cord mesenchymal stem cells and human lens epithelial cells using a transwell chamber, and then investigated the changes in LEC proliferation and migration through CCK-8 and cell scratch assays. Exosomes were isolated from hucMSC using ultracentrifugation and identified by transmission electron microscopy and nanoparticle tracking. Co culture the extracted exosomes with LEC and verify the expression of LEC related markers through PCR and immunofluorescence. Exosomes were injected into the eyes of adult Wistar rats that underwent extracapsular resection, and the regeneration of intraocular lenses was evaluated by OCTA.

Results: Compared with the control group, the proliferation and migration of LECs increased after co culture of the two types of cells (both $P < 0.05$), while treatment with HucMSC Exo exacerbated this phenomenon. The PCR results showed that the relative mRNA expression levels of PAX6, BMI-1, SOX2, and Nanog in LECs treated with HucMSC Exo were 1.52 ± 0.27 , 1.87 ± 0.40 , 1.71 ± 0.45 , and 2.12 ± 0.51 , respectively. Compared with the control group, the expression levels of PAX6 ($P < 0.01$), BMI-1 ($P < 0.01$), SOX2 ($P < 0.001$), and Nanog ($P < 0.01$)

were significantly increased, which was confirmed by immunofluorescence results. Meanwhile, OCTA results showed that the lens regeneration in Wistar rats treated with HucMSC Exo was significantly better than that in the untreated group.

Conclusions: This study indicates that the stem cell characteristics of LECs are enhanced and their proliferation and migration abilities are promoted after treatment with HucMSC Exo. The regeneration of the lens is improved after treatment with HucMSC Exo.

Abstract No.: 200685

The Effect of Pupil Dilation on Pre-Operative Optical Biometry Results for Phacoemulsification: A Meta-Analysis

First Author: David **CHEN**

Co-Author(s): Krystal **KHOO**, Angeline **LAI**, Shen **LIANG**, Jocelyn **YEO**

Purpose: Modern cataract surgery blends sight restoration and refractive correction through the implantation of intraocular lenses, with modern formulas utilizing seven or more parameters from optical biometers. Dilation affects these measurements, in turn compromising post-operative refractive outcomes. The effect of cycloplegia on ocular parameters is therefore of increasing interest for pre-surgical planning. This systematic review and meta-analysis summarizes the effects of pupil dilation on optical biometry results, and its impact on intraocular lens power calculations.

Methods: The study protocol was pre-registered in the PROSPERO registry (CRD42021248502). Eligible articles from inception to 5 December 2024 from three databases (PubMed, Embase, Cochrane) were independently screened and quality assessed by two reviewers.

Results: Pupil dilation was associated with significantly increased ACD by 0.08 mm (95% confidence interval [CI], 0.06 – 0.09 mm; $I^2 = 97.40\%$), reduced LT by 0.02 mm (95% CI, 0.01 – 0.03 mm; $I^2 = 97.57\%$), and increased WTW by 0.12 mm (95% CI, 0.04 – 0.19 mm; $I^2 = 97.59\%$). The increase in ACD was dependent on the type of dilating agent used; when compared to using tropicamide, cyclopentolate resulted in a significantly greater increase in ACD by 0.03 mm (95% CI, 0.00 – 0.07 mm) and decrease in LT by 0.04 mm (95% CI, 0.00 – 0.06), while phenylephrine significantly less by 0.06 mm (95% CI, 0.02 mm – 0.10 mm).

Conclusions: Pupil dilation significantly affects calculations from the later generation IOL calculation formulas. It would be prudent to consider performing biometry in a non-dilated state to avoid impacting on IOL calculation and subsequently final refractive outcome.

Abstract No.: 205089

The Environmental Impact of Phacoemulsification in a Private Tertiary Hospital in Metro Manila, Philippines

First Author: Isabella BONDOC

Co-Author(s): Victor Jose CAPARAS

Purpose: Phacoemulsification is one of the most frequently performed surgical procedures worldwide, yet little is known about its environmental impact in developing nations. This study quantified the carbon footprint of phacoemulsification in a Philippine tertiary hospital to identify opportunities for improving efficiency and sustainability.

Methods: All phacoemulsification cases performed over 1 month were included. Data collected included (1) energy consumption, (2) disposable waste, (3) pharmaceuticals, and (4) surgical duration. The EyeEfficiency application (eyeEfficiency.org) and life cycle assessment (LCA) methodology were used to estimate greenhouse gas emissions (CO₂ equivalents, CO₂e) per case.

Results: A total of 240 cases were recorded with a mean surgical time of 17 minutes. Waste and consumables converted to CO₂e were: Electricity (8–14 kW per case): 2.24–3.92 kg/case Disposable items (drapes, gowns, gloves): 1.7 kg, ~4.25 kg/case Phaco machine Fluid Management System (cassette/tubing): 0.25 kg, ~0.63 kg/case Pharmaceuticals: ~0.2–0.6 kg/case The average carbon footprint per surgery was 7.3–9.4 kg CO₂e, equivalent to burning 3–4 liters of fuel. This is lower compared to the global average and well within the recommended carbon footprint levels.

Conclusions: Given the global volume of cataract surgery, improving the environmental efficiency of phacoemulsification is imperative. This study provides valuable baseline data for operational and financial planning and supports efforts to reduce the carbon footprint of cataract surgery in the local setting. On a broader scale, benchmarking against international best practices can guide strategies to lower costs and minimize emissions in ophthalmic care.

Abstract No.: 200904

The Impact of Corneal Spherical Aberration on the Optical Performance of Extended Depth of Focus Intraocular Lenses

First Author: Xiaomin LIU

Purpose: To assess the optical performance of four extended depth of focus (EDOF) intraocular lenses (IOLs) with different designs under varying corneal spherical aberrations (SAs).

Methods: Three refractive EDOF IOLs (ES60, EDA601, AcrySof IQ Vivify), one diffractive hybrid EDOF IOL (ZFR00), and a monofocal IOL (SY60WF, control) (all 20.0D) were tested using OptiSpheric® IOL PRO 2. USAF

resolution, modulation transfer function (MTF), and MTF area (MTFa) with defocus were measured under three SA conditions (0 μ m, +0.13 μ m, +0.28 μ m) and 3.0 mm/4.5 mm apertures.

Results: At SA was 0 μ m, refractive EDOF IOLs showed better far-focus quality with larger apertures (opposite for diffractive hybrid/monofocal IOLs). Intermediate focus quality declined with larger apertures, but diffractive hybrid IOLs had better near focus. With 3.0 mm aperture, far-focus MTF was stable across SAs. With 4.5 mm aperture, all EDOF IOLs performed better than with 3.0 mm; diffractive hybrid/monofocal IOLs improved with higher SA, while refractive EDOF IOLs were less affected. MTFa showed diffractive hybrid IOLs covered far/intermediate/near foci, refractive ones covered far/intermediate foci, with varying depth of focus.

Conclusions: EDOF IOLs differ in depth of focus but are little affected by SAs, with better performance at 4.5 mm aperture. This aids clinical selection based on patient needs.

Abstract No.: 204648

The LISA-PPV Formula: An Ensemble Artificial Intelligence-Based Thick Intraocular Lens Calculation Formula for Vitrectomized Eyes

First Author: Jiaqing ZHANG

Co-Author(s): Lixia LUO, Xuhua TAN

Purpose: To investigate the relationship between effective lens position (ELP) and patient characteristics, and to further develop a new intraocular lens (IOL) calculation formula for cataract patients with previous pars plana vitrectomy (PPV).

Methods: A total of 2793 age-related cataract patients (group 1) and 915 post-PPV cataract patients (group 2) who underwent phacoemulsification with IOL implantation were included. The ELP of two groups was compared and the association between ELP and patient characteristics was further evaluated using standardized multivariate regression coefficients. An ensemble artificial intelligence-based ELP prediction model was developed using a training set of 810 vitrectomized eyes, and a thick-lens IOL formula (LISA-PPV) was constructed and compared with seven existing formulas on an external multi-center testing set of 105 eyes.

Results: Compared to eyes with age-related cataract, vitrectomized eyes showed a similar ELP distribution ($P = 0.19$), but different standardized coefficients of preoperative biometry for ELP. The standardized coefficients also varied with the type of vitreous tamponade, history of scleral buckling, and ciliary sulcus IOL implantation. The LISA-PPV formula showed the lowest mean and median absolute prediction error (MAE: 0.63 D; MedAE: 0.44 D), and the highest

percentages of eyes within ± 0.5 D of prediction error (57.14%) in the testing dataset.

Conclusions: The ELP prediction required optimization specifically for vitrectomized eyes based on their biometric and surgical characteristics. The LISA-PPV formula is a useful and accurate tool for determining IOL power in cataract patients with previous PPV.

Abstract No.: 200329

The Relationship Between Age at Secondary Intraocular Lens Implantation and Visual Outcomes & Complications in Bilateral Congenital Cataract

First Author: Kun **HU**

Co-Author(s): Weirong **CHENG**, Qiwei **WANG**

Purpose: To Report the Visual Acuity and Complications in Children With Bilateral Aphakia After Lensectomy for Pediatric Cataracts, Undergoing Secondary IOL Implantation at Different Ages

Methods: This single-center prospective observational cohort study, conducted from 2014 to 2023, is a 7-year follow-up study. The 158 children (316 eyes) underwent lensectomy before the age of 2 years, followed by secondary IOL implantation between the ages of 2 and younger than 6 years in bilateral pediatric cataracts. The main outcome was Best-corrected VA (BCVA) outcomes at age 7 years after secondary IOL implantation in children with bilateral pediatric cataracts.

Results: At age 7 years, the mean (SD) BCVA for children who underwent secondary IOL implantation was 0.49 (0.35) logMAR (Snellen equivalent, 20/62) at 2 to younger than 3 years, 0.59 (0.36) logMAR (Snellen equivalent, 20/78) at 3 to younger than 4 years, 0.60 (0.30) logMAR (Snellen equivalent, 20/80) at 4 to younger than 5 years, and 0.65 (0.34) logMAR (Snellen equivalent, 20/89) at 5 to younger than 6 years ($P = .20$). Glaucoma-related adverse events occurred in 47 eyes in total: 6 eyes (8.8%), 7 eyes (9.0%), 10 eyes (15.6%), and 24 eyes (22.6%) across the groups, respectively, with a statistical difference among the groups ($P = .03$).

Conclusions: These findings suggest that secondary IOL implantation performed between the ages of 2 and younger than 6 years following bilateral pediatric cataract lensectomy can achieve comparable visual outcomes; however, the risk of glaucoma increases with older implantation age.

Abstract No.: 203574

Tolerance to IOL Decentration and Tilt in Five Presbyopia-Correcting IOLs: A SS-AS-OCT-Based Study

First Author: Xuhua **TAN**

Co-Author(s): Xiaofei **HU**, Lixia **LUO**, Jiaqing **ZHANG**, Yu **ZHANG**

Purpose: To compare the impact of intraocular lens (IOL) decentration and tilt on the visual performance of five presbyopia-correcting IOLs in patients following cataract surgery.

Methods: This is a prospective observational study. Cataract patients who underwent uncomplicated phacoemulsification with implantation of ZXR00, ZMB00, ZFR00V, Vivity or TFNT00 were enrolled. Each IOL group was stratified based on the third quartile (Q3) of IOL tilt and decentration measured by CASIA2. Intraocular higher-order aberrations (HOAs), contrast sensitivity (CS), modulation transfer function (MTF), Strehl ratio and patient-reported outcomes 3 month postoperatively were compared between subgroups.

Results: A total of 260 patients (260 eyes) were included. Based on the Q3 values, eyes were categorized into tilt subgroups T1 ($<5.63^\circ$) and T2 ($\geq 5.63^\circ$), and decentration subgroups D1 (<0.24 mm) and D2 (≥ 0.24 mm). No significant differences in visual quality were observed between Vivity and ZXR00 subgroups. In contrast, T2 subgroups of TFNT00, ZMB00 and ZFR00V exhibited significantly higher HOAs and coma, along with decreased CS, compared to their respective T1 subgroups (all $P < 0.05$). The D2 subgroup of ZFR00V showed increased HOAs and coma, and reduced CS under photopic conditions and mesopic conditions with glare (all $P < 0.05$). The D2 subgroup of ZMB00 demonstrated higher HOAs and coma, as well as lower MTF (all $P < 0.05$). The D2 subgroup of TFNT00 reported significantly lower patient satisfaction (3.25 ± 0.46 vs 3.83 ± 0.38 , $P = 0.008$).

Conclusions: Extended depth-of-focus (EDOF) IOLs demonstrated greater tolerance to tilt and decentration compared to multifocal and full visual range IOLs.

Abstract No.: 201587

Total Versus Standard Keratometry in a Large Australian Cohort

First Author: Christopher **GO**

Co-Author(s): Uday **BHATT**, Christopher **HODGE**

Purpose: Accurate biometry is essential to achieving accurate postoperative outcomes in cataract surgery. Utilising both anterior and posterior surfaces in deriving an overall value (total keratometry or TK) should provide for greater accuracy; however, despite availability, TK use is not universal. Analysing differences between standard and total keratometry values may help improve general clinician

understanding of this new value and drive greater utility.

Methods: Retrospective audit of TK and standard keratometry (K) in a large multicentre cohort utilising Swept-Source OCT imaging (IOLMaster 700). Linear regression was undertaken to assess contributing factors, identifying differences between standard and total keratometry values.

Results: A total of 14,889 eyes were included. Mean difference in corneal cylinder between K and TK values was $0.03 \pm 0.21D$ with K value representing a higher value in 63.3% of eyes. Axis orientation matched in 89.3% of eyes. Against-the-rule orientation was dominant in TK eyes (26.2% vs. 21.1%). Age, flat keratometry, posterior keratometry and corneal cylinder magnitude were significant contributors to the difference between K and TK values.

Conclusions: Although differences between standard and total keratometry values may not reflect clinical significance, changes across demographic and biometric characteristics still warrant consideration prior to surgical intervention and may impact particular scenarios. This analysis represents the largest current analysis globally, with further surgical implications discussed.

Abstract No.: 207901

Uncovering the Metabolic Landscape of Aqueous Humor in Posterior Subcapsular Cataract Associated With Hyperuricemia

First Author: Yang SUN

Co-Author(s): Ling LI, Yongjie QIN, Hongyang ZHANG

Purpose: To investigate the metabolic alterations underlying posterior subcapsular cataract (PSC) associated with hyperuricemia and to identify key metabolic pathways contributing to disease progression.

Methods: Untargeted metabolomic profiling was conducted on aqueous humor samples obtained from twelve cataract patients classified into four groups based on PSC status and serum uric acid levels. Comparative analyses among hyperuricemic PSC (HP), normouricemic PSC (NP), hyperuricemic non-PSC (HC), and normouricemic non-PSC (NC) groups were performed. Pathway enrichment analysis identified key dysregulated pathways. Targeted amino acid profiling and $^{13}C5$ -glutamine metabolic flux analysis were conducted in uric acid-treated lens epithelial cells (LECs). Experimental validation of glutathione metabolism was carried out via immunofluorescence and western blot in both LECs and capsular specimens.

Results: Untargeted metabolomics identified 46 differentially expressed metabolites (DEMs) between HP and NP groups, with enrichment in pathways related to glutathione metabolism and amino acid biosynthesis. Comparative profiling showed that

PSC under hyperuricemia exhibits distinct metabolic features beyond those observed in hyperuricemic non-PSC patients, especially in glutaminolysis and redox regulation. Targeted analysis confirmed glutamine accumulation in LECs treated with uric acid. Metabolic flux tracing demonstrated increased incorporation of labeled glutamine into tricarboxylic acid cycle intermediates and glutathione. Despite increased glutamine utilization, redox balance was impaired. At the protein level, GPX4 was downregulated, while GLS1 and GLS2 was upregulated in response to elevated uric acid levels.

Conclusions: Disruption of glutaminolysis and glutathione metabolism is identified as the potential hallmark of PSC associated with hyperuricemia, indicating the role of glutamine-dependent redox regulation in linking systemic metabolic disturbance to PSC development.

Abstract No.: 206630

Vision on Waves: A Mobile Ophthalmology Unit Framework for Small Island Nations

First Author: Saraa YOOSUF

Purpose: To propose an innovative mobile ophthalmology service model tailored for small island nations, where geographic fragmentation creates significant barriers to equitable eye care access.

Methods: Using principles of clinical service operations and health systems design, we developed the "Vision on Waves" framework. Core components include: 1. Mobile Surgical Unit — a retrofitted vessel or mobile van equipped for cataract and minor ophthalmic procedures. 2. Teleophthalmology Integration — remote screening and triage using portable fundus cameras and cloud-based image transfer. 3. Rotational Staffing Model — scheduled deployments of ophthalmologists, optometrists, and nurses across island communities. 4. Community Partnership — local health workers trained to provide follow-up and patient recall between visits. Feasibility was assessed through resource mapping, workflow simulations, and alignment with existing Maldivian healthcare logistics.

Results: The model addresses three major challenges: • Accessibility: reduces travel costs and time for patients from remote atolls. • Continuity: teleophthalmology enables between-visit monitoring and early referrals. • Efficiency: rotational deployment optimizes scarce specialist workforce distribution. (Conceptual)

Conclusions: "Vision on Waves" offers a pragmatic, scalable framework for expanding ophthalmic services in geographically fragmented nations. By combining mobile surgical capacity with teleophthalmology and community partnerships, this model can reduce inequities in access, improve early disease detection, and strengthen surgical coverage in small island states.

Abstract No.: 203258

Visual Performance After Bilateral Implantation of a Nondiffractive Extended Depth-of-Focus Intraocular Lenses Targeted for Mini-Monovision in a Chinese Population

First Author: Yijing **WANG**

Co-Author(s): Xiteng **CHEN**, Fang **TIAN**

Purpose: To evaluate the visual outcomes, patient satisfaction, spectacle independence, and photic phenomena after bilateral implantation of a new non-diffractive extended depth-of-focus intraocular lens using a mini-monovision approach in the Chinese cataract population.

Methods: This is a single-center prospective study including 50 patients who underwent bilateral cataract surgery. To achieve mini-monovision, the spherical equivalent was calculated between -0.25 and +0.25 D for the dominant eye, and between -0.5 and -0.75 D for the non-dominant eye. The main outcomes were uncorrected and corrected distance visual acuity (UDVA, CDVA), uncorrected and distance-corrected near visual acuity, and intermediate visual acuity at 40 cm, 66 cm (UNVA, CNVA, UIVA, CIVA) 3 months postoperatively. Secondary outcome parameters were the binocular defocus curve, patient satisfaction, including spectacle independence and photic phenomena.

Results: A total of 17 patients are currently enrolled. Binocular UDVA and CDVA were $0.02 \pm 0.05 \log \text{MAR}$ and $0.01 \pm 0.03 \log \text{MAR}$, respectively, three months after surgery. Meanwhile binocular UNVA and CNVA achieved $0.18 \pm 0.05 \log \text{MAR}$, $0.16 \pm 0.08 \log \text{MAR}$ respectively, while, UIVA and CIVA was $0.09 \pm 0.06 \log \text{MAR}$, $0.08 \pm 0.04 \log \text{MAR}$ respectively. The defocus curve showed that when the diopter ranged from -2.0D to -3.0D, the average binocular visual acuity was less than 0.22 logMAR, indicating a better intermediate to near visual performance than monocular visual acuity. All patients experienced spectacle independence for distance and intermediate vision tasks after surgery, and were quite satisfied with their vision. No visual disturbances were reported in this study.

Conclusions: Patients implanted with EDOF IOL using mini-monovision technique showed improved distance and intermediate visual acuity, reduced need for glasses, and expressed a high degree of satisfaction.

Abstract No.: 203868

Visual Performance of Small-Aperture IOL in Cataract Patients With Preexisting Corneal Comorbidities

First Author: Chameen **SAMARAWICKRAMA**

Purpose: To evaluate the outcomes of small-aperture IC-8 IOL in cataract patients with significant preexisting corneal comorbidities.

Methods: Case records of patients with preexisting corneal comorbidities who underwent cataract surgery and IC-8 IOL implantation were retrospectively reviewed. Outcome measures included uncorrected distance visual acuity (UDVA), spherical equivalent refraction (SER), and spherical equivalent refractive prediction accuracy of various IOL formulas (Barrett Universal 2, EVO, Kane, Hill RBF, Pearl DGS) using biometry measurements from IOLMaster 700 and Pentacam.

Results: Of the 67 eyes analyzed, 56 underwent implantation of IC-8 IOL only, and 11 required piggyback IOL as a secondary procedure. Mean postoperative UDVA in IC-8 only eyes was $0.24 \pm 0.30 \log \text{MAR}$, and 61.1% eyes achieved UDVA of 6/9 or better. Mean postoperative SER in IC-8 eyes was $-0.17 \pm 1.27 \text{ D}$, with 54.2% and 81.3% of eyes achieving postoperative SER within 0.50 and 1.00 D, respectively. IOL formulas showed similar refractive prediction accuracy with no significant differences in the precision and accuracy of IOL formulas and biometry measurements evaluated. Eyes that underwent piggyback implantation had a mean UDVA of $0.42 \pm 0.39 \log \text{MAR}$, with 36.4% of eyes achieving UDVA of 6/9 or better postoperatively.

Conclusions: IC-8 IOL implantation in patients with preexisting corneal comorbidities was safe and effective, yielding good visual and refractive outcomes in this niche population, who typically have suboptimal outcomes.

Abstract No.: 205621

Visual Performance of the RayOne Galaxy Spiral Full-Range of Vision IOL in Filipino Eyes

First Author: Victor **CAPARAS**

Co-Author(s): Maria Isabella **CAPARROS**, Maria Isabela **DE GUIA-MAYUGA**, Keshia **DUYONGCO**, Maureen **NAGUIT-REYES**

Purpose: To evaluate visual outcomes after bilateral implantation of the full-range of focus RayOne Galaxy Spiral intraocular lens (Rayner, Worthing, UK).

Methods: Fifteen patients (30 eyes) underwent phacoemulsification with bilateral RayOne Galaxy implantation, targeting emmetropia. Post-op visits were at 7–14 days (V1), 30–45 days (V2), 90–105 days (V3). Monocular/binocular and uncorrected/corrected visual acuity (VA) at 4m, intermediate VA at 63cm, and near VA at 40 and 33cm were measured. Defocus curve, contrast sensitivity (CS), photic phenomena (Halo and Glare Simulator, ViSU-L GmbH), and quality of vision (McAlinden QOV questionnaire) were also assessed.

Results: At V2, mean spherical refraction was $-0.36 (\pm 0.75 \text{ std dev}) \text{ diopter (D)}$. Mean monocular uncorrected distance, intermediate, near 40cm, and 33m VA were: $0.05 (\pm 0.23)$, $0.35 (\pm 0.10)$, $0.25 (\pm 0.09)$

and 0.22 (± 0.09) logMAR, respectively. Binocular uncorrected distance, intermediate, near 40cm, and 33cm VA were: -0.08 (± 0.16), 0.27 (± 0.09), 0.14 (± 0.04), and 0.10 (± 0.04) logMAR, respectively. Binocular defocus curve showed corrected distance VA ≤ 0.2 logMAR from +2.0D to -3.25D. Binocular mean halo size/intensity were 13/100 and 17/100; glare size/intensity 16/100 and 20/100. Far (1m) and near (40cm) binocular CS were 1.59 (± 0.08) and 1.62 (± 0.10) logCS, respectively. Mean QOV was 89/100. Additional follow-up results (V3) will be presented at the Congress.

Conclusions: Bilateral RayOne Galaxy implantation provided a full range of clear distance to near vision with excellent contrast sensitivity, minimal photic disturbance, high spectacle independence, and excellent patient-reported quality of vision.

Abstract No.: 204131

Visual and Refractive Outcomes After Bilateral Implantation of a Low-Addition Segmental Varifocal Intraocular Lens

First Author: Hao **ZHANG**

Co-Author(s): Jorge L. **ALIÓ**, Jorge L. **ALIÓ DEL BARRIO**, Mario **CANTÓ-CERDÁN**, Antonio **MARTÍNEZ ABAD**, Pilar **YEBANA-RUBIO**

Purpose: To evaluate the clinical outcomes of cataract patients undergoing implantation of a novel low-addition hydrophobic segmental refractive varifocal intraocular lens (Acunex Vario, Teleon Surgical).

Methods: This prospective study enrolled 25 patients (50 eyes) who underwent bilateral implantation of the Acunex Vario lens. Examinations were performed preoperatively and at 1, 3, and 6 months, including uncorrected and corrected distance (UDVA, CDVA), intermediate (UIVA, DCIVA), and near (UNVA, CNVA, DCNVA) visual acuities, manifest refraction, defocus curves, contrast sensitivity, and aberrometry. Patient-reported outcomes were assessed using the Quality of Vision (QoV) and Near Activity Visual Questionnaires (NAVQ).

Results: Significant postoperative improvements were observed in UDVA, CDVA, UNVA, CNVA, Sphere, and Cylinder (0.08 ± 0.09 , 0.03 ± 0.06 , 0.23 ± 0.11 , 0.10 ± 0.07 logMAR; -0.01 ± 0.25 D, -0.51 ± 0.49 D; $p < 0.05$). CNVA (0.10 ± 0.07 logMAR) and Spherical Equivalent (-0.26 ± 0.35 D) showed no significant change ($p > 0.5$). UIVA, DCIVA, and DCNVA remained stable postoperatively (0.14 ± 0.13 , 0.14 ± 0.09 , and 0.30 ± 0.13 logMAR, respectively). Defocus curve analysis demonstrated excellent distance vision (0.02 ± 0.06 logMAR at 0.0D), with a gradual decline at intermediate (-1.5 D: 0.16 ± 0.09 logMAR) and near (-2.5 D: 0.31 ± 0.11 logMAR) distances. Defocus curve demonstrated excellent distance vision (0 D: 0.02 ± 0.06 logMAR with a gradual decline at intermediate (-1.5 D: 0.16 ± 0.09) and near (-2.5 D: 0.31 ± 0.11) foci. Contrast sensitivity and ocular aberrometry remained

stable. Patient-reported outcomes showed minimal halo disturbances (64.7% never, 35.3% occasional, none significant). and high satisfaction with daily near activities.

Conclusions: The low-addition varifocal IOL provides excellent distance and intermediate visual outcomes, functional near acuity, high refractive accuracy, and strong patient-reported satisfaction with minimal dysphotopsias.

Abstract No.: 203621

WOcular Manifestations of a Family With Marfan Syndrome and Osteogenesis Imperfecta

First Author: Nikolai Thadeus **MAPPATAO**

Co-Author(s): Pia Regina **GALVANTE**

Purpose: To report a case series of a Filipino family with ocular manifestations of Marfan syndrome and Osteogenesis Imperfecta.

Methods: Comprehensive ophthalmologic evaluation was performed on all patients. Fundus photography was conducted for each individual, and two patients received 360-degree retinal barrier laser treatment. Corneal tomography was performed on one patient to assess corneal structure. All patients were monitored for progression of ocular manifestations related to Marfan syndrome and Osteogenesis Imperfecta.

Results: The three sons (ages 30, 27, and 22) exhibited blue sclerae, superior ectopia lentis, and lattice degeneration. The second son had lens coloboma in both eyes, pathologic myopia, and lenticular astigmatism. The third son showed lenticular astigmatism and keratoconus in the right eye. Corneal tomography revealed corneal thinning without keratoconus in the second son. No surgical interventions have been performed to date; however, special considerations for scleral-fixated intraocular lens implantation are ongoing due to the integrity of the bluish sclera.

Conclusions: This case series highlights the diverse ocular manifestations of Marfan syndrome and osteogenesis imperfecta, especially in a family with multiple affected members. The presence of vision-threatening features emphasizes the need for early diagnosis and personalized management. Ongoing monitoring is essential to track progression, especially regarding lens subluxation and retinal detachment. Careful attention to scleral integrity is critical for planning potential surgical interventions, such as scleral-fixated intraocular lens implantation.

Abstract No.: 202945**Yap1 Is Essential for Lens Development and Exhibits Dose-Dependent Effects***First Author: Jingyu MA**Co-Author(s): Fei CHEN, Lixia LUO, Qihang SUN*

Purpose: The Hippo-YAP pathway, which is crucial for regulating organ size, has been shown to play critical roles in lens development and homeostasis. However, Yap1's specific role in early lens morphogenesis is unclear. This study aims to investigate lens defects in Yap1 conditional knockout mice and explore the underlying mechanisms.

Methods: Lens-specific Yap1 deletion was induced using P0-3.9GFP-Cre in both Yap1^{fl/fl} and Yap1^{fl/+} mice. Slit-lamp and brightfield imaging were used to observe the ocular phenotype. Lens histology was examined by H&E staining, while marker expression was analyzed using immunofluorescence and Western blot. Cellular proliferation and apoptosis were assessed via BrdU and TUNEL assays, respectively.

Results: Yap1 was consistently expressed throughout lens development. Deletion of Yap1 resulted in a range of phenotypes, from no visible abnormalities to microphakia, and in severe cases, aphakia. The severity of these phenotypes correlated with Yap1 expression levels, demonstrating a dose-dependent effect. The reduced lens size was primarily attributed to decreased proliferation and a modest increase in apoptosis in lens epithelial cells (LECs). Additionally, some Yap1-deficient lenses exhibited defects in the separation of the lens vesicle from the surface ectoderm, accompanied by downregulation of key transcription factors such as FoxE3 and Ap2α.

Conclusions: Yap1 is essential for early lens development, regulating lens size, cell proliferation, and the separation of the lens vesicle from the surface ectoderm, with its effects being dose-dependent.

Abstract No.: 200890**miR-497-5p/FGF7 Axis Promotes the Formation of m6A Methyltransferase Complex WTAP by Activating Autophagy to Inhibit Posterior Capsule Opacification***First Author: Jinfei WEI**Co-Author(s): Yingyan MAO, Xiuhua WAN*

Purpose: Pathological epithelial-mesenchymal transition (EMT) of lens epithelial cells (LECs) is key to posterior capsule opacification (PCO), with autophagy inhibited. This study explored how the miR-497-5p/FGF7 axis regulates LEC autophagy via m6A methylation to affect PCO-associated EMT, revealing new pathogenesis.

Methods: TNFα induced EMT in HLEB3 cells (with/without siFGF7 transfection). CCK8, EDU staining and flow cytometry assessed cytotoxicity/proliferation.

Western blot, immunofluorescence and q-RT-PCR detected autophagy, EMT markers and m6A levels. CO-IP and RNA pull-down verified target interactions. RNA-seq, meRIP-seq and meRIP-qPCR confirmed FGF7-m6A correlation. Microfluidics packaged PLGA nanoparticles (METTL3 inhibitor) to modify intraocular lenses (IOLs) for PCO efficacy evaluation.

Results: In the TNFα-induced EMT model, FGF7 gene was significantly upregulated, while miR-497-5p expression was markedly decreased, with impaired autophagy. Transfection of si-FGF7 significantly activated autophagy to inhibit EMT, which was alleviated by transfection of miR-497-5p inhibitor. m6A RNA dot blot and WB showed that m6A modification was significantly activated during TNFα-induced EMT. On this basis, knockdown of methyltransferase WTAP attenuated m6A modification and reduced EMT markers, which was reversed by FGF7 overexpression. The correlation between FGF7 and m6A methylation was verified by RNA-seq, MeRIP-seq and MeRIP QPCR. After phacoemulsification, rabbit eyes were grouped for intraocular lens (IOL) implantation. Slit-lamp photography at 1–4 weeks postoperatively showed that IOLs loaded with METTL3 inhibitor significantly suppressed the occurrence of PCO.

Conclusions: The miR-497-5p/FGF7 axis influences PCO-associated EMT via regulating LEC autophagy and m6A methylation, offering potential therapeutic targets and highlighting m6A as a PCO treatment entry point.

Cornea, Dry Eyes, External Eye Diseases and Eye Banking**Abstract No.: 206234****A Case Series of Overnight Orthokeratology-Related Acanthamoeba Keratitis in Northwest China: Clinical Presentation, Management, and Outcomes***First Author: Yan CHENG*

Purpose: To report a series of cases of overnight orthokeratology-related Acanthamoeba Keratitis (OK-AK) at a tertiary transfer care eye hospital in China from January 1, 2021, to February 29, 2024, and to provide a reference for its treatment.

Methods: This was a single-center, retrospective case study. Records of patients with a history of OK lens use who were diagnosed with AK were analyzed. Data on clinical presentation, management, and outcomes were analyzed. We also preliminarily investigated behaviors associated with the risk of OK-AK.

Results: A total of 11 patients were included. Topical anti-amoebic agents (a combination of topical polyhexamethylene biguanide [PHMB], metronidazole, and voriconazole) were used in all infected eyes once the AK diagnosis was made. Systemic metronidazole and/or voriconazole were added in stromal keratitis. Eight eyes (57.1%) were cured by medication. The remaining eyes (6/14, 42.9%) underwent therapeutic keratoplasty surgery because of poor response or rapid progression of the disease. The surgeries included two lamellar keratoplasty (ALK), one deep lamellar keratoplasty (DALK), and three therapeutic penetrating keratoplasty (TPK). Recurrence occurred in two cases (2/6, 33.3%), one after 1 year following DALK and the other 3 months after TPK. All patients had improved visual acuity after treatment.

Conclusions: These findings indicate that OK-AK is a serious problem in Northwest China. The medication cure rate in OK-AK was 57.1%. The early keratoplasty surgery rate was 42.9%, and the risk of post-operation recurrence should be a concern.

Abstract No.: 205553

A New Approach to Assessing Pterygium Progression and Volume Using SII and Anterior Segment OCT

First Author: Rui NIU

Co-Author(s): Zhe DU, Wei HE, Chen XING, Zhongyang YAN

Purpose: To compare the clinical manifestations and prognosis of 90 patients with pterygium. The occurrence and progression of pterygium are associated with the systemic immune inflammatory index (SII) and clinical characteristics. The size of pterygium was assessed by anterior segment phase and anterior segment OCT.

Methods: According to the pterygium score, the patients were divided into group A, group B, and group C. The evaluation parameters included gender, age, onset time, signs and symptoms of underlying diseases, anterior segment OCT, NLR, PLR, MLR, and SII values. The postoperative pterygium tissue was weighed. The clinical characteristics of each group were analysed by a nonparametric test and a chi-square test. Ordered logistic regression analysis evaluated the parameters related to pterygium area and volume.

Results: Compared with the control group, the SII, NLR, and MLR values of pterygium patients were significantly increased. The incidence of both eyes, NLR, MLR, SII values and other markers in group C were significantly higher than those in groups A and B. The incidence of both eyes and SII value would affect the severity of pterygium. The SII value was significantly correlated with the area of pterygium progression and weighing volume. The combination of anterior segment phase and anterior segment OCT can effectively evaluate the volume of pterygium.

Conclusions: SII can be used as a biomarker to predict the severity and prognosis of pterygium. Compared with traditional methods, imaging data can better evaluate the progression of pterygium by calculating the volume of pterygium.

Abstract No.: 206901

A Smartphone-Based Blink Training Application for Alleviating Dry Eye Signs and Symptoms

First Author: Liang HU

Purpose: In this prospective, randomized study, we assessed whether a smartphonebased blinktraining application alleviates the signs and symptoms of Dry eye disease (DED).

Methods: This prospective, randomized study was conducted in young adult daily smartphone users. Forty participants were randomly assigned to either an intervention group that used the application or a control group without intervention, and they were followed for 30 days. Primary outcomes were Ocular Surface Disease Index (OSDI) score, blink rate (BR), percentage of incomplete blinks (IB), Ocular Protection Index (OPI), fluorescein/noninvasive breakup time (FTBUT/NIBUT) and tear meniscus height (TMH). An exploratory post-cessation visit occurred at Day 60 in the training arm.

Results: After 30 days, the intervention group showed significant improvements in blink behavior and ocular surface parameters, whereas the control group showed no meaningful changes. Between-group comparisons at Day 30 favored the intervention for OSDI, IB (both eyes), FTBUT (OS), and OPI (OS). Generalized estimating equations indicated that time on intervention (Day 30), training duration, OPI, BR, and sex were independently associated with changes in the OSDI scores. OPI was inversely related to symptoms, whereas BR showed a modest positive association. Gains partially regressed by Day 60 yet remained improved from baseline in the training arm, and no adverse events were reported.

Conclusions: These findings suggested that a simple, app-based behavioral intervention yields measurable benefits for DED management and provided a scalable, cost-effective strategy for ocular health preservation in digital environments.

Abstract No.: 203824

A Study on the Influencing Factors and Efficacy of Insular Infraorbital Neurovascular Pedicle Labial Salivary Gland Transplantation for the Treatment of Severe Dry Eye Disease

First Author: Yinghui WANG

Co-Author(s): Ying JIE

Purpose: To study the effect of labial salivary gland flow rate (LSGFR) and infraorbital artery hemodynamics

(IOAH) on the postoperative outcomes of insular infraorbital neurovascular pedicle labial salivary gland transplantation (IINPLSGT) for the treatment of severe dry eye disease (DED).

Methods: This was a prospective, observational, self-controlled before-and-after study. From July 2022 to June 2024, 11 eyes of 10 severe DED patients underwent IINPLSGT, with follow-up at least 6 months. The changes in ocular symptoms and signs were analyzed, and factors influencing surgical efficacy were explored.

Results: With a mean follow-up of 17.56 ± 11.72 months. BCVA improved in 5 eyes and stabilized in 6. Ocular Surface Disease Index score decreased from 59.33 ± 14.37 to 26.27 ± 10.14 ($P < 0.001$). Schirmer I test (SIT) improved from 0.00 ± 0.00 mm to 5.44 ± 2.01 mm ($P < 0.0001$). Tear break-up time increased from 0.23 ± 0.48 s to 5.48 ± 4.67 s ($P = 0.008$). Corneal fluorescence staining scores decreased from 12.56 ± 2.65 to 7.56 ± 3.09 ($P < 0.001$). IOAH did not change pre- and postoperatively ($p > 0.05$). Preoperative peak systolic velocity of the infraorbital artery positively affects LSGFR ($B = 0.034$, $P = 0.042$), while end-diastolic velocity had a negative effect ($B = -0.070$, $P = 0.039$). LSGFR was positively associated with improvement in SIT post-op ($P < 0.05$). ROC analysis showed an AUC of 0.714, with an optimal LSGFR cutoff at $0.41 \mu\text{L}/\text{min}/\text{cm}^2$. IOAH did not correlate with ophthalmology results ($P > 0.05$).

Conclusions: IINPLSGT has shown a positive effect in the treatment of severe DED. LSGFR reflected postoperative lubrication, while IOAH monitored graft blood flow and helped prevent adverse events.

Abstract No.: 202876

A Superoxide Anion-Responsive Persulfide Prodrug for Remedying Dry Eye Diseases via Scavenging ROS and Inhibiting Apoptosis

First Author: Panpan YE

Co-Author(s): Mingzhi SU, Weixin ZHENG

Purpose: Dry eye disease (DED) is a prevalent ocular disorder in which excessive reactive oxygen species (ROS) drive oxidative stress, inflammation, and apoptosis. This study aimed to design a superoxide anion ($\text{O}_2^{\cdot-}$)-responsive persulfide prodrug (Ac-SOPD) capable of sustained hydrogen sulfide (H_2S) release to alleviate oxidative stress and interrupt the vicious cycle of DED.

Methods: Ac-SOPD was synthesized as a peptide-persulfide conjugate and characterized for its morphology, self-assembly, and $\text{O}_2^{\cdot-}$ -triggered H_2S release. Its biocompatibility, antioxidant, and anti-apoptotic effects were evaluated in human corneal epithelial cells using cell viability assays, fluorescence probes, flow cytometry, and transcriptomic analysis. Therapeutic efficacy was validated in benzalkonium

chloride (BAC)-induced DED mouse model. Clinical assessments, histological analyses, and immunofluorescence staining were performed to evaluate corneal repair, tear stability, inflammation, and apoptosis.

Results: Ac-SOPD exhibited excellent cytocompatibility and controlled H_2S release under oxidative stress conditions. It significantly reduced intracellular ROS, enhanced antioxidant enzyme expression, preserved mitochondrial function, and suppressed apoptosis. Transcriptomic analyses and molecular experiments together confirmed enrichment of oxidative phosphorylation and downregulation of Hippo signaling. In vivo, Ac-SOPD markedly promoted corneal epithelial repair, improved tear secretion and tear film stability, reduced IL-1 β and MMP-9 expression, and decreased apoptosis in BAC-induced DED model. No ocular toxicity was observed in safety evaluations.

Conclusions: With its dual functions of ROS scavenging and sustained H_2S release, Ac-SOPD effectively alleviates oxidative stress, inflammation, and apoptosis both in vitro and in vivo. Collectively, Ac-SOPD represents a promising therapeutic candidate for DED and other oxidative stress-related diseases.

Abstract No.: 202870

AAV-Mediated Corneal Gene Therapy for Prevention and Treatment of Neurotrophic Keratopathy

First Author: Lin CONG

Co-Author(s): Benxiang QI, Lixin XIE, Bi Ning ZHANG

Purpose: Neurotrophic keratopathy (NK) is a degenerative disease caused by corneal nerve damage. Clinical management primarily relies on symptomatic treatments, which yield suboptimal outcomes in some patients and may eventually require tarsorrhaphy to reduce exposure and secondary infection risks. AAV-mediated gene therapy represents a safe, innovative, and etiologically targeted approach. This study aimed to develop a novel, simple, and efficient gene therapy for preventing and treating NK.

Methods: The high-efficiency AAV.rh10 serotype was selected, followed by a 1-year long-term observation. Multiple assays were performed to evaluate corneal immune responses post-AAV treatment for safety assessment. Three-dimensional imaging of GFP (self-expressed) co-immunofluorescence with ZO-1 and tubulin via corneal whole mounts was used to observe AAV transfection, anterograde, and retrograde transport. The preventive and therapeutic effects of single stromal injection of AAV-Ngf on NK of varying severity were evaluated in murine models, including capsaicin-induced, herpes simplex keratitis, two diabetic models, and alkali burn models.

Results: Stromal injection of AAV.rh10 efficiently transfected corneal stromal cells, with anterograde

transport to the subepithelial nerve plexus and retrograde transport to the trigeminal ganglion, exerting therapeutic effects at both corneal stroma and trigeminal ganglion. Single AAV-Ngf injection significantly promoted corneal nerve regeneration, accelerated epithelial repair, reduced stromal edema, and improved corneal sensitivity across NK models of varying severity. Its therapeutic efficacy was comparable to long-term, continuous rhNGF eye drop administration.

Conclusions: This proof-of-concept study demonstrates that AAV.rh10-Ngf gene therapy holds promising potential for NK prevention and treatment. The safety and efficacy findings strongly support its clinical translation prospects.

Abstract No.: 201899

Adjunct Topical Recombinant Deoxyribonuclease Therapy in Dry Eye Disease

First Author: Khatheeya **SALWA**

Co-Author(s): Sandeep **JAIN**, Maroof A **KHAN**, Radhika **TANDON**, Murugesan **VANATHI**, Thirumurthy **VELPANDIAN**

Purpose: Recent evidence points to the role of extracellular DNA and neutrophil extracellular traps (NETs) in the pathogenesis of dry eye disease (DED). The aim of this study is to evaluate adjunct topical recombinant deoxyribonuclease (r-DNase) in moderate to severe refractory Dry Eye Disease.

Methods: This longitudinal double blinded Randomized Control Trial enrolled 80 patients with moderate to severe DED into two groups: standard treatment and standard treatment plus topical r-DNase (0.02% QID for 3 months) group. Assessments at baseline, week-2, Month-1,3 and 6 included Ocular Surface Disease Index (OSDI), conjunctival hyperemia (CH), tear break-up time (TBUT), non-invasive TBUT (NIBUT), Schirmer's test, conjunctival and corneal staining score (SS); lipid layer thickness (LLT), tear meniscus height (TMH), meibography for meibomian gland loss (MGL) and treatment grading scores for steroids and lubricants.

Results: In 40 patients (80 eyes) [mean age 46.375 ± 12.45 yrs] in r-DNase group and 40 patients (79 eyes) [mean age 38.75 ± 13.95 yrs] in standard treatment group, significant improvement was noted in the adjunctive DNase group at Month-3 and 6 [CH ($p < 0.0001$), TBUT ($p = 0.0002$), NIBUT ($p = 0.0027$), Schirmer's ($p < 0.0001$), conjunctival SS ($p < 0.0001$), NEI corneal SS ($p = 0.0175$), and TMH ($p < 0.0001$) along with greater OSDI reduction with significant within-group change ($p < 0.0001$) and decrease in need for topical steroids ($p = 0.0060$) and lubricants ($p = 0.0224$) at M-6 follow-up]. No significant changes were noted in LLT or MGL. Topical r-Dnase was well tolerated with no adverse events.

Conclusions: Adjunct Topical r-DNase 0.02% for 3 months provides significant improvement in both subjective and objective clinical parameters in moderate to severe refractory Dry Eye Disease, suggesting it to be a novel therapeutic option.

Abstract No.: 207276

Advanced Imaging of Conjunctival Collagen in Cicatrizing Conjunctivitis using Second Harmonic Generation and its Correlation with Clinical Severity

First Author: Hon Shing **ONG**

Co-Author(s): Jodhbir **MEHTA**, Andri **RIAU**, Ralene **SIM**

Purpose: Cicatrizing conjunctivitis (CC) is a major cause of visual morbidity. Differentiating progressive from non-progressive disease is critical, as progressive CC often requires timely immunosuppression. Current clinical assessment of conjunctival scarring may lack sensitivity for early progression. This study used two-photon excitation with second harmonic generation (SHG) imaging to quantitatively assess conjunctival collagen in CC and explore associations with clinical severity, aiming to identify sensitive biomarkers of progression.

Methods: Conjunctival tissues from patients with chronic CC due to Stevens-Johnson Syndrome were imaged with SHG microscopy. Severity was graded using a validated CC clinical tool incorporating inflammation, scarring, and morbidity. Collagen morphometry in regions of interest was quantified with FibroIndex software (HistoIndex, Singapore), including collagen fiber density (CFD), collagen area ratio (CAR), and collagen fiber number (CFN) per mm².

Results: Eighteen participants were analyzed (7 CC, 11 controls; mean age 60.7 ± 14.4 years, $p = 0.89$). CC patients showed lower CAR ($p < 0.01$) and CFN ($p < 0.01$) but higher CFD ($p = 0.03$) versus controls. In CC, CAR correlated with inflammation ($R = -0.55$, $p = 0.011$), scarring ($R = 0.61$, $p = 0.0034$), morbidity ($R = 0.46$, $p = 0.035$), and composite score ($R = 0.52$, $p = 0.017$). Across all participants, CFN inversely associated with inflammation ($R = -0.50$, $p < 0.01$), morbidity ($R = -0.37$, $p < 0.01$), and composite score ($R = -0.33$, $p = 0.02$).

Conclusions: This study highlights distinct collagen remodeling patterns in CC. CAR correlated strongly with all clinical severity domains, supporting its potential as a reliable diagnostic marker. CFN, uniquely demonstrating consistent negative associations with severity measures, may serve as a promising predictor of disease progression.

Abstract No.: 206696**Amorphous Layered Double Hydroxide-Based Nano-Enzyme Eye Drops Against Dry Eye Disease by Inhibiting Mitochondrial Damage and Pyroptosis***First Author: Dandan CHU**Co-Author(s): Tingting HU, Jingguo LI, Zhanrong LI, Chaoliang TAN*

Purpose: Dry eye disease (DED) is a prevalent ocular disorder characterized by chronic inflammation and oxidative stress. Reactive oxygen species (ROS) and downstream NLRP3 inflammasome activation trigger pyroptosis, exacerbating inflammation. This study aims to develop amorphous layered double hydroxide (a-LDH)-based nano-enzyme eye drops (Needs) to treat DED by targeting mitochondrial damage and pyroptosis.

Methods: a-LDH nanoparticles were synthesized via acid etching-mediated crystalline-to-amorphous phase engineering. The ROS scavenging capacity was assessed using methylene blue, 3,3',5,5'-tetramethylbenzidine, dihydroethidium, and electron spin resonance assays. In vitro models of hyperosmotic stress in human corneal epithelial cells and in vivo DED mouse models were used to evaluate antioxidative, anti-pyrototic, and therapeutic effects. RNA sequencing, immunofluorescence, and western blotting were employed to investigate underlying mechanisms.

Results: a-LDH exhibited superior ROS scavenging ability, with $\cdot\text{OH}$ and $\cdot\text{O}_2^-$ elimination capacities 1.77- and 1.20-fold higher than crystalline LDH, and 3.38- and 1.43-fold higher than CeO_2 , respectively. This enhancement was attributed to $\text{Cu}^+/\text{Cu}^{2+}$ redox cycling and oxygen vacancies. a-LDH significantly reduced intracellular and mitochondrial ROS, suppressed the NLRP3/Caspase-1/GSDMD-mediated pyroptosis pathway, and inhibited N-GSDMD-induced mitochondrial damage. In DED mice, Needs promoted corneal epithelial repair, restored goblet cell density, enhanced tear secretion, and downregulated inflammatory cytokines without toxicity.

Conclusions: a-LDH-based nano-enzyme eye drops represent a safe and effective therapeutic strategy for DED by mitigating oxidative stress, inhibiting pyroptosis, and preserving mitochondrial function. This study provides a novel insight into LDH-based nano-enzyme applications for DED treatment.

Abstract No.: 203034**Anti-Swelling Properties of XTRA4 Maintain the Thickness of Pre-Loaded DSAEK Grafts for Up to Six Days***First Author: Jameson CLOVER**Co-Author(s): Braedon BRADDY, Mark ELLISON, Megan STRAIKO, Khoa TRAN*

Purpose: To compare the graft thickness and cell viability of preloaded DSAEK grafts in a new cold storage solution XTRA4, using Optisol-GS as a reference.

Methods: Cornea pairs were prepared as preloaded DSAEK grafts, with one stored in Optisol-GS and the mate in XTRA4. Two carriers were tested (Weiss Glass Cannula and Endoglide Ultrathin, N=5 pairs each). OCT was performed after pre-cutting, after pre-loading, and on subsequent storage days at the same location. Endothelial cell loss (ECL) was assessed by Calcein-AM vital dye staining and fluorescence microscopy.

Results: In the glass cannula group, grafts cut to $105 \pm 27 \mu\text{m}$ and stored in XTRA4 swelled 28% after pre-loading but remained stable for 6 days ($P=0.97$), whereas Optisol-GS grafts (cut to $101 \pm 1 \mu\text{m}$) swelled 32% after pre-loading and increased by 70% over 6 days. In the Endoglide group, grafts cut to $105 \pm 17 \mu\text{m}$ and stored in XTRA4 swelled 18% after pre-loading and remained stable ($P=0.71$), while Optisol-GS grafts swelled 14% initially and thickened 48% over 6 days. ECL was 21% vs. 23% in the glass cannula ($P=0.73$) and 11% vs. 14% in the Endoglide ($P=0.08$). Greater cell loss was associated with graft overlap in the narrower glass cannula ($P<0.01$).

Conclusions: XTRA4 preserves graft thickness during hypothermic storage and minimizes swelling in pre-cut, preloaded DSAEK grafts. These properties enhance logistics and the feasibility of long-distance shipping, including transcontinental transport.

Abstract No.: 209405**Antibiotic Nanozyme Hydrogel Depot for Single-Injection MDR Bacterial Keratitis Therapy via Localized Antibacterial, Pro-Healing and Corneal Reinforcement***First Author: Hongwei WANG*

Purpose: Bacterial keratitis (BK), a severe ocular infection caused by pathogenic bacterial invasion, requires urgent therapeutic development due to the limitations of conventional antibiotics, such as drug resistance and systemic toxicity caused by frequent dosing.

Methods: To address these challenges, we developed an injectable antibiotic nanozyme hydrogel depot (ANHD) for single-dose therapy of BK. The ANHD was prepared by synthesizing the Ce-gatifloxacin nanozyme through metal-organic coordination between cerium

nitrate and gatifloxacin, followed by co-precipitation, and subsequently incorporating CGN into an injectable xanthan-PEG hydrogel constructed via Schiff base linkages. The antibacterial activity of the nanozyme-composite hydrogel was assessed in vitro, along with its scavenging capacity against reactive oxygen species ($O_2^-/H_2O_2/\cdot OH$), its ability to promote corneal wound healing, and its effect on enhancing corneal mechanical strength. Finally, a mouse model of multidrug-resistant *Staphylococcus epidermidis* keratitis was established, and a single intrastromal injection of ANHD was administered as the treatment intervention.

Results: The resulting hierarchical composite exhibited multiple functional synergistic effects, including antibacterial activity, scavenging of reactive oxygen species ($O_2^-/H_2O_2/\cdot OH$), promotion of corneal wound healing, and reinforcement of corneal mechanical strength. Furthermore, nanozymes and hydrogels were ubiquitous in the corneal stroma and can exert their functions without penetration across the corneal surface, which distinguishes them from the eye drop formulations. In a murine model, a single injection of ANHD into the corneal stroma effectively treated multidrug-resistant *Staphylococcus epidermidis* keratitis, with complete bacterial eradication, significant inflammation reduction, and accelerated epithelial repair.

Conclusions: These results demonstrated the potential of ANHD in the treatment of ocular infectious diseases.

Abstract No.: 206953

Assessing the Impact of Losartan on Visual Rehabilitation in a Tertiary Care Centre

First Author: Shweta **DEV**

Co-Author(s): Gairik **KUNDU**, Swaminathan **SETHU**, Rohit **SHETTY**

Purpose: To assess clinical and imaging outcomes of corneal scars treated with topical losartan (0.8 mg/mL) for 6 months, targeting TGF- β -mediated fibrosis.

Methods: In this prospective study, 45 eyes were evaluated (mean age: 32.6 ± 4.6 years) with etiologies mainly scars post-fungal keratitis, post-corneal tear, and post-refractive surgery. Losartan stock was aseptically prepared, 0.2 μm filter-sterilized, labelled, and sterility-verified before use at our lab. Patients received losartan drops 6 times daily for 6 months. Drop comfort and side effects were recorded.

Results: At 3 months, mean BCVA improved from 0.25 ± 0.17 to 0.17 ± 0.09 logMAR ($p=0.12$). Visual acuity improved in 35 eyes, stable in 10. OCT showed reduced scar depth and densitometry in 35 eyes. No significant side effects were noted.

Conclusions: Topical losartan may reduce corneal fibrosis by inhibiting TGF- β pathways, improving clarity and scar depth.

Abstract No.: 207455

Assessment of Intraocular Pressure After Pterygium Excision Using Goldmann Applanation Tonometry and Non-Contact Tonometry, Adjusted for Corneal Structural Abnormalities

First Author: Inchara **NAGARAJ**

Co-Author(s): Karan **SINGH**

Purpose: To evaluate the effect of pterygium and its surgical excision on intraocular pressure (IOP) measurements and to compare Goldmann applanation tonometry (GAT) with non-contact tonometry (NCT), accounting for corneal structural alterations.

Methods: A prospective observational study included 40 patients with primary nasal pterygium undergoing excision with conjunctival autograft. IOP was measured preoperatively and postoperatively using GAT and NCT. Central corneal thickness (CCT) and corneal curvature (K values) were recorded with pachymetry and keratometry. Statistical analysis included paired t-tests and correlation studies.

Results: Preoperative mean anterior curvature was 41.09 ± 3.38 D / 44.33 ± 2.29 D, which changed postoperatively to 43.13 ± 1.79 D / 43.98 ± 2.17 D. NCT readings decreased by approximately 5–6 mmHg, while GAT values showed reductions of about 2 mmHg. Both changes correlated with alterations in corneal curvature, indicating biomechanical effects of pterygium and its removal on IOP measurement.

Conclusions: Pterygium excision modifies corneal biomechanics, resulting in falsely elevated preoperative IOP values and apparent postoperative reductions with both GAT and NCT. Adjusting IOP readings for corneal thickness and curvature is essential to avoid misinterpretation in glaucoma evaluation and management.

Abstract No.: 206691

Association of Work Productivity and Activity With Dry Eye Outcomes in Mild to Moderate Dry Eye Disease Patients: A Study of a Hong Kong Cohort

First Author: Yiu Man **WONG**

Co-Author(s): Kam Lung Kelvin **CHONG**, Zhichao **HU**, Chi Pui Calvin **PANG**, Chee Yung Clement **THAM**

Purpose: To investigate the association of work productivity and activity level with dry eye parameters in mild to moderate dry eye disease (DED) subjects.

Methods: Work productivity and activity level are assessed via the Work Productivity and Activity Impairment (WPAI:GH) questionnaire, a 6-item instrument that yields absenteeism (work time missed), presenteeism (reduced on-the-job effectiveness), work productivity loss (overall work impairment), and activity impairment. Associations between WPAI:GH

scores and DED outcomes, including Tear Break Up Time (TBUT) and Ocular Surface Disease Index (OSDI), are analyzed using Spearman's correlation in SPSS Version 29. (ClinicalTrials.gov ID: NCT06089317)

Results: For 198 included subjects (153 females, 76.9%) aged 54.69 ± 14.58 years, their 4 WPAI:GH mean scores of absenteeism, presenteeism, work productivity loss, and activity impairment are 1.54 ± 10.73 , 30.78 ± 22.25 , 31.07 ± 22.26 and 28.59 ± 20.00 respectively, while the mean of OSDI and TBUT are 22.99 ± 11.92 and 3.65 ± 2.36 . Significant positive correlations with OSDI score are observed for presenteeism ($r = 0.318$, $P = 0.002$), work productivity loss ($r = 0.326$, $P = 0.002$), and activity impairment ($r = 0.374$, $P < 0.001$), while interestingly TBUT also has positive correlations with presenteeism ($r = 0.223$, $P = 0.036$) and work productivity loss ($r = 0.222$, $P = 0.038$) only.

Conclusions: The patient-reported symptom severity (OSDI) has a significant positive association with DED-affected Work Productivity and Activity Impairment.

Abstract No.: 208279

Associations of Warm Compression, Eyelid Massage and Lid Hygiene With Ocular Surface Changes in Cocaine and Methamphetamine Users: A Longitudinal Study

First Author: Stephany Wing Lam **TAI**

Co-Author(s): Kelvin Kl **CHONG**, Kenneth Ka Hei **LAI**, Calvin Cp **PANG**, Clement Cy **THAM**

Purpose: To evaluate longitudinal changes in ocular surface parameters over six months following warm compression, eyelid massage, and cleaning intervention in cocaine and methamphetamine users.

Methods: A longitudinal study was conducted in Hong Kong (Jan 2024 - Sep 2025). Primary users of cocaine and/or methamphetamine, averaging 24 intakes within 6 months over the past 2 years, were included. Those with significant medical comorbidities or mental retardation were excluded. Between visits separated by 6 months, subjects received standardized instructions for daily warm compression, eyelid massage, and cleaning. Ocular surface evaluations included lipid layer thickness and meibography (LipiView® II), tear meniscus height and non-invasive keratography break-up time (NIKBUT) (Keratograph® 5M), Schirmer Test, slit-lamp examination conducted by ophthalmologists, and Ocular Surface Disease Index (OSDI). Meibomian glands were graded 0-3 by consistent graders.

Results: Paired data from twenty-nine subjects (15 males, age 39.1 ± 11.4 years) were analyzed. First NIKBUT improved (left: $+4.75$ seconds, $P=0.008$), as did average NIKBUT (left: $+3.63$ seconds, $P=0.016$). Meibomian gland distortion decreased: upper lid distortion (right: -0.31 , $P=0.009$; left: -0.38 , $P=0.002$), lower lid distortion (left: -0.32 , $P=0.008$). Papillae grading improved (left: -0.38 , $P=0.039$). Conversely,

under the National Eye Institute (NEI) scheme, increased corneal and conjunctival staining were observed in multiple regions at both eyes (all $P < 0.05$). Foaming increased at left eyes ($+0.38$, $P=0.025$).

Conclusions: Warm compression, eyelid massage, and cleaning yield mixed effects in drug abusers: improving tear film stability and meibomian gland morphology but increasing ocular surface staining and inflammation. Longer-term, controlled trials are warranted to fully evaluate their effectiveness on drug abusers.

Abstract No.: 206360

Asymmetric Intracorneal Ring Segments Implantation for Management of Keratoconus – 3-Year Follow-Up

First Author: Marta **SARTORI**

Co-Author(s): Armando **BRITO**, Carlos **ARCE**, Sandra **BEER**, Claudia **FRANCESCONI**, Walton **NOSE**

Purpose: To evaluate the clinical and tomographical outcomes in patients submitted to asymmetric corneal rings (AS-ICRS) implantation to treat keratoconus.

Methods: Prospective observational study, AS-ICRS were implanted asymmetric topographic patterns of keratoconus assigned to four groups: A-160 arc length with thicker clockwise or counterclockwise tips (like a "smoking pipe"). B – 180 arc length with thicker midbody (like a "moustache"). C – 330 arc length with thicker sites at 6h (midbody) (like a "goatee"). D – 320 arc length with 3 and 9 h location thicker than the tips and the midbody – (like a "sideburn"). Patients with the "duck" or "snowman" phenotype received one or two "smoking pipe" AS-ICRS (A), patients with the "DMP-like" phenotype received one "moustache" AS-ICRS (B) and "nipple" phenotype received "goatee" (C) or "sunburd" (D) AS-ICRS depending in quantitative amount of topographic astigmatism, less than or greater of 3 Dioptries. The visual, refractive, astigmatism, keratometric, and corneal aberrometry changes were evaluated over a three-year follow-up period.

Results: Forty-four eyes were analyzed. Significant differences were observed between pre and post operative outcomes in uncorrected logmar vision, (1.02 to 0.53 ± 0.21), corrected (0.37 to 0.14 ± 0.13) (maximum keratometric (KM) values (57.96 D to 52.13 D ± 4.43 D), spherical equivalent (-7.81 D to -3.67 D ± 2.30), anterior toric elevation (KCA index) (56.32 to 26.31 ± 14.14) and HOA coma (1.70 D to 1.29 D ± 0.70) on the 4 AS – ICRS types analyzed ($p < 0.05$). There were significant differences in surgery outcomes between AS-ICRS types, specially in Spherical Equivalent values ($p < 0.01$) and refractive ($p < 0.02$) and topographical ($p < 0.01$) cylinder. Goatee" and "Sunburn" ring models show a difference in Anterior KCA index when comparing "to" "pipe" or "moustache" ($p < 0.05$). No difference between "goatee"

and “sunburn” in decreasing cylinder($p,0,x$), ($p < 0.01$). Anterior KCA index was the most important index analyzed, showing significant differences, in all follow-up periods of time (3,6,12,24,36 mo) ($p < 0.01$) and in 4 AS – ISCR types individually.

Conclusions: Asymmetric ICRS did improve the outcomes. The “sunburn” and “goatee” are better at flattening and correcting corneal anterior asymmetries.

Abstract No.: 204510

BOT-Graft (Botropase) vs. Conventional Fixation: Comparative Outcomes in Primary Pterygium Surgery

First Author: Nilesh KUMAR

Purpose: To evaluate the outcomes of various conjunctival autograft fixation techniques in primary nasal pterygium surgery, and to assess the safety, efficiency, and cost-effectiveness of the novel Botropase-Optimized Conjunctival Tissue Grafting (BOT-Graft) technique.

Methods: A total of 104 primary nasal pterygium surgeries performed by the same surgeon were analyzed. Patients were divided into four groups based on graft fixation technique: autologous blood (40 cases), sutures (10 cases), fibrin glue (2 cases), and BOT-Graft using Botropase (52 cases). Mean surgical duration and postoperative complications, including graft displacement, retraction, or recurrence, were recorded. Follow-up was maintained for up to 10 months.

Results: Mean surgical times were 26.2 minutes (autologous blood), 29.1 minutes (sutures), 20.7 minutes (fibrin glue), and 18.3 minutes (BOT-Graft). The autologous blood group showed 2 cases of graft displacement and 3 cases of retraction, while BOT-Graft demonstrated only one minor displacement. Both suture and fibrin glue groups were uneventful. Botropase provided rapid fibrin formation, stable graft adhesion, and hemostasis throughout the 10-month follow-up. These findings highlight BOT-Graft as a safe, efficient, and affordable technique that combines the advantages of conventional methods while minimizing their limitations.

Conclusions: BOT-Graft leverages botropase’s dual hemostatic and adhesive properties for rapid, stable, and cost-effective graft fixation, making it a strong first-line option for pterygium surgery in diverse clinical settings. BOT-Graft demonstrated significant cost savings (95% less) over fibrin glue.

Abstract No.: 202259

Beyond the Demarcation Line: Optical Correlates of Corneal Remodeling After Collagen Cross-Linking

First Author: Srishti KHULLAR

Purpose: To determine whether demarcation line depth predicts changes in wavefront aberrations following collagen cross-linking in progressive keratoconus.

Methods: A prospective observational study carried out at a tertiary care center in Maharashtra, India, enrolling patients with progressive keratoconus treated with standard epithelium-off CXL

Results: A total of 108 patients were enrolled, including 52 males (48%) and 56 females (52%). The mean age was 18.52 ± 2.6 years. The average demarcation line depth was $210 \pm 10.82 \mu\text{m}$. A significant correlation was observed between deeper DL depth and reduction in total higher-order aberrations (HOAs) ($p < 0.05$), with coma aberration showing the strongest association ($p < 0.01$). Eyes with shallower DL depth demonstrated minimal improvement or even worsening of wavefront abnormalities postoperatively.

Conclusions: A deeper demarcation line following CXL is associated with greater improvements in corneal wavefront abnormalities, particularly coma aberration. While demarcation line depth serves as an established OCT biomarker for the efficacy of CXL, this study is the first to systematically explore its correlation with wavefront abnormalities, a relationship that has not been adequately addressed in existing literature.

Abstract No.: 206942

Can Immune Modulators Help in Stabilizing Keratoconus (KC): An Algorithmic Approach

First Author: Shweta DEV

Co-Author(s): Panaah SHETTY, Arka SUBHRA, Swaminathan SETHU

Purpose: Keratoconus is an ectatic inflammatory disease characterized by elevated biomarkers. This study explores the impact of biomarkers on KC progression and potential therapies for stabilization.

Methods: The cohort was divided into two groups ($n=178$ eyes). Group 1 received a placebo, while Group 2 received targeted biomarker therapy through randomization. Tears from untreated mild-to-moderate KC eyes were collected using Schirmer’s strip and analyzed for biomarkers using a point-of-care diagnostic kit. Corneal topography, epithelial and stromal mapping, and collagen imaging were performed at baseline and 8 months post-treatment.

Results: Group 1 showed progression in 78 eyes, with collagen weakening, Bowman’s layer (BL) thinning, and an unchanged biomarker profile. Conversely, Group 2 exhibited stabilization of KC in 86 eyes, with a change in maximum keratometry (K max) by $0.99D \pm 0.5D$,

improved collagen orientation, stable BL, and a 50-60% reduction in biomarker levels.

Conclusions: Biomarker therapy stabilizes early-to-moderate KC by reducing inflammation, promising new therapeutic avenues.

Abstract No.: 204613

Changes in Corneal Endothelial Cell After Phacoemulsification in Patients With Acute Angle-Closure Patients: A Prospective Study

First Author: Minh Man **TRAN**

Co-Author(s): C.T. T. Truyen **NGUYEN**, Ke To **TRAN**, Minh Huy **TRAN DINH**

Purpose: To evaluate changes in corneal endothelial cell density and morphology following phacoemulsification in patients diagnosed with acute angle closure.

Methods: This prospective, longitudinal study included 35 patients with acute angle closure and coexisting cataracts who underwent phacoemulsification. Corneal endothelial parameters were assessed preoperatively and at 1 month postoperatively using the specular microscope. Intraoperative metrics, including phacoemulsification time, cumulative dissipated energy (CDE), and total ultrasound energy, were recorded.

Results: The mean age of participants was 58.9 ± 7.3 years, with a predominance of female patients. Significant improvements in best-corrected visual acuity and intraocular pressure (IOP) were observed at 1 month postoperatively ($p < 0.05$). Endothelial cell density, coefficient of variation, and central corneal thickness showed statistically significant reductions. A positive correlation was identified between endothelial cell loss and intraoperative parameters, including phacoemulsification time, CDE, and ultrasound energy.

Conclusions: Acute angle closure is a common condition in the elderly, particularly among Asian populations and women. Phacoemulsification is a safe and effective procedure to lower intraocular pressure and improve visual acuity while mitigating progression to chronic angle-closure glaucoma. However, endothelial cell loss is significantly associated with intraoperative energy parameters, underscoring the importance of surgical technique and phacoemulsification energy modulation in preserving corneal health.

Abstract No.: 209232

Clinical Application of Keratoplasty in the Acute Stage of Fungal Keratitis

First Author: Dan **WU**

Co-Author(s): Hui **HUANG**, Qianqian **LAN**

Purpose: To observe the clinical efficacy and complications of optical keratoplasty (OPK) for Fungal Keratitis (FK) at the acute infective stage, one year after the operation.

Methods: Patients with acute fungal corneal ulcer in the People's Hospital of Guangxi Zhuang Autonomous Region from March 2019 to March 2024 who were treated with interventional surgery due to poor effect of active antifungal treatment were retrospectively selected. The patients were divided into two groups according to the extent and invasion of the corneal lesion. The first group was patients with the diameter of the corneal lesion ≤ 8 mm and the margin of the lesion ≥ 2 mm from the clear limbal zone, and the second group was patients with the diameter of the corneal lesion > 8 mm or the margin of the lesion < 2 mm from the clear limbal zone. According to the different surgical methods, the patients in the two cases were divided into one-stage group (optical keratoplasty was performed in the first stage) and two-stage group (conjunctival flap covering was performed in the first stage, and optical keratoplasty was performed in the second stage). The baseline data, medical history characteristics, time of fungal clearance, fungal recurrence, rejection after keratoplasty, other postoperative complications, and outcomes were recorded. The clinical efficacy of the one-step method group and the two-step method group at 1 year after operation was compared.

Results: (1) A total of 68 eyes of 68 patients were enrolled. There were 18 patients (18 eyes) in the first condition, including 13 patients (13 eyes) in the one-step group and 5 patients (5 eyes) in the two-step group. There were 50 patients (50 eyes) in the second condition, 27 patients (27 eyes) in the one-step group, and 23 patients (23 eyes) in the two-step group. The baseline data of the two conditions were not statistically significant. (2) In the first case, the average time of first fungal clearance in the one-step group and the two-step group was 0.32 ± 0.36 months and 2.97 ± 1.60 months, respectively, and the difference was statistically significant ($P < 0.001$). The number of patients with fungal recurrence in the one-step group and the two-step group was 1 (7.70%) and 0 (0.00%), respectively, and the difference was not statistically significant ($P = 0.72$). Rejection occurred in 3 patients (23.08%) in the one-step group and 4 patients (80.0%) in the two-step group, and the average time of rejection was 4.33 ± 3.51 months and 7.25 ± 4.5 months, respectively. The difference was statistically significant ($P = 0.047$). The 1-year graft survival rate of the one-step group and the two-step group was 11 (84.62%) and 1 (20.00%), respectively ($P = 0.01$). (3) In the second case, the average time of first fungal clearance in the one-step group and the two-step group was 0.37 ± 0.39 months and 1.69 ± 1.14 months, respectively, and the difference was statistically significant ($P < 0.001$). The number of patients with fungal recurrence in the one-step group and the two-step group was 4 (14.81%) and 0 (0.00%), respectively, and the difference was statistically significant ($P = 0.05$). There were 17 cases (62.96%) and 19 cases (82.61%) of rejection in the one-step group and the two-step group, respectively. The

average time of rejection was 4.77 ± 3.19 months and 3.13 ± 3.59 months, respectively, and the difference was not statistically significant ($P=0.12$). The 1-year graft survival rates of the one-step group and the two-step group were 11 (40.74%) and 6 (26.09%), respectively, without a significant difference ($P=0.062$).

Conclusions: (1) In the first case, the first time of fungal clearance in the one-step group was significantly shorter than that in the two-step group, the rejection rate in the one-step group was lower than that in the two-step group, and the 1-year survival rate in the one-step group was significantly higher than that in the two-step group. (2) In the second case, the first fungal clearance time of the one-step group was significantly shorter than that of the two-step group, the fungal recurrence rate of the one-step group was higher than that of the two-step group, and the 1-year graft survival rate was similar between the two groups.

Abstract No.: 206416

Clinical Efficacy of Platelet-Rich Plasma in the Treatment of Severe Dry Eye Secondary to Sjögren's Syndrome

First Author: Jianzhang YE

Co-Author(s): Jiannan LIU

Purpose: To evaluate the efficacy and safety of platelet-rich plasma (PRP) in treating severe dry eye secondary to Sjögren's syndrome.

Methods: A retrospective study was conducted at Dongguan Aier Eye Hospital from May 2023 to April 2025, including 53 patients with severe dry eye. The PRP group ($n=29$) received topical PRP (4 times/day), while the control group ($n=24$) received autologous serum (4 times/day). Both groups were additionally treated with cyclosporine eye drops (2 times/day) and carbomer gel (once nightly) for 8 weeks. Outcomes assessed included Schirmer's test, tear breakup time (TBUT), conjunctival hyperemia, corneal staining, tear lymphotoxin- α concentration, OSDI score, and adverse events.

Results: Baseline characteristics were comparable. After treatment, Schirmer's test and TBUT showed no significant difference ($P>0.05$). However, the PRP group had significantly lower conjunctival hyperemia, corneal staining scores, tear lymphotoxin- α levels, and OSDI scores compared with the control group ($P<0.05$). No adverse events occurred in either group.

Conclusions: PRP effectively improves signs and symptoms of severe dry eye in patients with Sjögren's syndrome, with no observed adverse reactions.

Abstract No.: 208188

Comparative Analysis of Ocular Surface Signs Associated With the Severity of Dependence Scale and Ocular Surface Disease Index in Cocaine, Methamphetamine and Poly-Substance Users

First Author: Hoi Nap TSANG

Co-Author(s): Kelvin KI CHONG, Kenneth Ka Hei LAI, Calvin Cp PANG, Stephany Wing Lam TAI, Clement Cy THAM

Purpose: To compare how the Severity of Dependence Scale (SDS) and standard reporting of Ocular Surface Disease Index (OSDI) each associate with clinical signs of Dry Eye Disease (DED) in cocaine, methamphetamine and poly-substance users.

Methods: A cross-sectional study was conducted on primary users of cocaine, methamphetamine, and poly-substance users who reported a use frequency of equal to or more than twice per month over 6 months within the last 2 years. Exclusions: other psychotic drug use and history of ocular surgery. SDS and OSDI scores were correlated with tear meniscus height, bulbar redness grading and non-invasive keratography break-up time by Keratograph® 5M, Lipid Layer Thickness by LipiView® II, Schirmer's test, pupil size by NeuroLight Pupillometer, and slit-lamp examination conducted by ophthalmologists.

Results: Comparison included right eyes of forty-one substance users (aged 39 ± 9 years; 25 male), comprising 7 cocaine, 12 methamphetamine and 22 poly-substance users. SDS and OSDI were not correlated ($P=0.109$). Significant correlations were observed between SDS and staphylococcal lash crusting ($r=0.330$, $P<0.05$), as well as demodex cylindrical collarettes ($r=0.345$, $P<0.05$). Neither was associated with the substance-use group suggested by Chi-Square analysis ($P=0.77$). Comparatively, OSDI correlated significantly with pupil size ($r=0.428$, $P<0.01$), bulbar conjunctival hyperaemia ($r=-0.349$, $P<0.05$), and lower tear meniscus height ($r=-3.76$, $P<0.05$).

Conclusions: Association between SDS and asymptomatic Meibomian Gland Dysfunction is established, suggesting a reduced adherence to ocular hygiene. This is distinct from the symptomatic DED signs correlated with the standard OSDI, demonstrating that addiction severity provides novel clinical insights beyond symptomatic reporting. Such results warrant future research with larger sample sizes.

Abstract No.: 203660**Comparative Therapeutic Potential of Keratocytes and Stem Cells in Corneal Stromal Repair***First Author: Qianwen GONG**Co-Author(s): Liang HU, Jodhbir MEHTA, Andri RIAU*

Purpose: To evaluate the comparative effects of corneal stromal keratocytes (CSK), corneal stromal stem cells (CSSC), and human umbilical cord mesenchymal stem cells (UCMSC) on corneal opacity.

Methods: We investigated the therapeutic potential of the three cell types following intrastromal injection in our validated rat model of corneal haze induced irregular phototherapeutic keratectomy (irrPTK). A multimodal analytical framework was employed, including clinical imaging via slit-lamp biomicroscopy, anterior segment-optical coherence tomography (AS-OCT), and in vivo confocal microscopy (IVCM), along with ultrastructural characterization with small-angle X-ray scattering (SAXS) and transmission electron microscopy (TEM).

Results: We found pronounced central stromal haze in untreated Injured eyes, which persisted in the PBS and SF groups. The UCMSC group showed variable improvement, with some corneas displaying partial central clearing but others retaining dense opacity. In contrast, CSK- and CSSC-treated corneas appeared clearer, with stromal transparency closely resembling that of normal controls. In the normal group, collagen fibrils were densely packed, forming a regular lamellar structure. In the Injured group, large collagen-free “lakes” were observed throughout the stroma, indicating significant disruption of the extracellular matrix. In contrast, the CSK, CSSC, and UCMSC groups showed markedly improved stromal architecture, with collagen fibrils reorganized into rather a compact and organized manner, resembling the Naïve group. CSSC and UCMSC groups, collagen fibrils were generally well defined and regularly aligned, but appeared slightly less compacted as compared to the Naïve and CSK groups.

Conclusions: CSK injection resolved corneal scarring, while the other two stem cells have comparative but some variable effects.

Abstract No.: 200735**Comprehensive Bioinformatics Analysis to Reveal Key Non-Coding RNA Biomarkers of Keratoconus (KC) Patients***First Author: Jingwen WANG**Co-Author(s): Ying LI, Shuai OUYANG, Jia QU*

Purpose: This study aimed to reveal core non-coding RNA biomarkers and hub competitive endogenous RNA (ceRNA) network and explored the potential regulatory mechanisms of ceRNA in KC patient.

Methods: The high-throughput sequencing datasets were analyzed to screen core non-coding RNA biomarkers for KC patients.

Results: We revealed that 428 differentially expressed mRNA and 68 differentially expressed lncRNA were shared between the public datasets. Functional enrichment results innovatively showed that the ubiquitin-dependent protein catabolic process, NF- κ B signaling and neurodegenerative pathway was upregulated in KC patients. In addition, we uncovered the top 20 hub genes in which FBXW11, FBXO9, RCHY1, and CD36 were validated by qPCR. Moreover, we innovatively discovered four core miRNAs (miR-4257, miR-4494, miR-4263, and miR-4298) and constructed a ceRNA network that contained 165 mRNA, eight lncRNAs, and four core miRNAs. Finally, we proposed a potential regulatory mechanism for KC.

Conclusions: We uncovered miR-4257, miR-4494, miR-4263, and miR-4298 could be valuable biomarkers and provided core RNAs therapeutic targets for KC patients.

Abstract No.: 207066**Conventional Corneal Collagen Cross-Linking Versus Accelerated Corneal Collagen Cross-Linking in Progressive Keratoconus: A Comparative Study***First Author: Madhusmita MAHAPATRA**Co-Author(s): Balmukund AGARWAL, Ankit AHIR, Harsha BHATTACHARJEE, Sangeeta KALITA*

Purpose: To compare the conventional corneal collagen cross-linking (C-CXL) with accelerated corneal collagen cross-linking (A-CXL) in terms of efficacy in cases of progressive keratoconus. Primary objectives: 1. To study the effect of the C3R on corneal curvature and corneal thickness in conventional and accelerated approaches. 2. Changes in topographical indices and endothelial cell density after the C3R procedure. Secondary objective: To study the effect of accelerated and conventional corneal collagen cross-linking (CXL) on the visual status.

Methods: We have taken 54 eyes of 52 patients with progressive keratoconus and have randomly assigned them to two groups, i.e., conventional C3R (C-CXL) and accelerated C3R(A-CXL). All the patients underwent standard clinical examination for the diagnosis of keratoconus. Pentacam and specular microscopy have been used to collect all the data. CXL system (PESCHSE, Germany, model UV-X-1000, using UV-A) was used in this study.

Results: The comparison of both CXL treatments in our study has shown promising results and supported the efficacy of the treatment. In case of acceptance cylinder correction, the changes were more significant in C-CXL than A-CXL at all visits, showing more efficacy of C-CXL in decreasing the cylinder power in treated eyes. Both C-CXL and A-CXL procedures are safe and

efficacious. Accelerated C3,R being faster than the conventional CXL procedure, is more beneficial for both patient and surgeon.

Conclusions: To conclude, Collagen Crosslinking treatment seems to be an effective conservative management option in halting the disease progression in keratoconus. It improves vision by significantly reducing the spherical power and astigmatism.

Abstract No.: 206478

Cornea Thickness and Curvature in Elderly Patients With Dry Eye Disease Versus Age-Matched Controls

First Author: Ka Yu Vanessa CHEUNG

Co-Author(s): Kendrick CO SHIH

Purpose: To evaluate and compare cornea thickness and curvature in Chinese elderly patients with dry eye disease versus age-matched controls.

Methods: This cross-sectional, random population-based study included Chinese subjects aged ≥ 50 between 27 September 2021 and 31 August 2023. In total, 1209 consecutive subjects underwent comprehensive dry eye assessment in order from least to most invasive, including dry eye questionnaire (OSDI score), non-invasive keratographic tear breakup time, tear meniscus height, and NEI cornea staining score. The OCULUS Keratograph 5M was used to determine OSDI, non-invasive keratographic tear breakup time, and tear meniscus height. Dry eye was defined per the Asia Dry Eye Society criteria. Swept Source-Optical Coherence Tomography was used to determine central cornea thickness (CCT), cornea astigmatism, average K, and KMax values. The right eye was used for analysis.

Results: Of 1209 subjects, 244 had dry eye disease, and 965 served as controls. The mean CCT was found to be significantly lower in dry eye patients (0.528 ± 0.067 mm) compared to controls (0.536 ± 0.044 mm). Cornea astigmatism was noted to be significantly higher in dry eye disease (0.858 ± 0.725 diopter) compared to controls (0.762 ± 0.639 diopter). No significant differences were observed in KMax and average K values between groups.

Conclusions: Elderly patients with dry eye disease had thinner corneas and greater corneal astigmatism compared to controls. Differences in cornea thickness and curvature may play a role in predisposing certain patients to dry eye disease. When investigating the underlying etiology of dry eye disease in patients, it is worthwhile to consider the possible impact of cornea shape on tear film stability.

Abstract No.: 207210

Corneal Biomechanics and Ocular Biometrics in Thyroid Eye Disease: A Systematic Review and Meta-Analysis

First Author: Fatema ALJUFARI

Co-Author(s): Kelvin, Kam Lung CHONG, Kenneth LAI, Chi PANG, Clement THAM

Purpose: This systematic review evaluated corneal biomechanics and ocular biometrics in TED.

Methods: A comprehensive search of PubMed, Web of Science, Medline via EBSCOhost, Medline Ovid, Scopus, and the Cochrane Library identified 727 articles; after removal of 152 duplicates and application of eligibility criteria, 18 studies were included. These studies investigated corneal biometric and biomechanical parameters in relation to TED activity, severity, treatment effects, and thyroid function status. Ocular assessments encompassed biometric, endothelial, topographic, tomographic, and biomechanical measures to assess structural and functional changes.

Results: TED was consistently associated with reduced corneal hysteresis and resistance factor, increased endothelial cell size variability, epithelial thinning, and keratoconus-like tomographic patterns, many of which progressed with disease severity. Orbital decompression induced further alterations, including axial length changes and shifts in dynamic corneal response metrics. Collectively, these findings highlight the potential of corneal biomechanical and tomographic indices as non-invasive tools for early detection, disease monitoring, and surgical planning in TED.

Conclusions: This systematic review and meta-analysis demonstrates that TED is associated with significant corneal structural and biomechanical alterations, including reduced corneal hysteresis and resistance factor, epithelial thinning, endothelial cell variability, and keratoconus-like tomographic changes that progress with disease severity. These findings suggest that corneal indices may serve as valuable biomarkers for early detection, disease monitoring, and risk assessment, while also guiding surgical planning and postoperative evaluation. The observed biomechanical shifts following orbital decompression further highlight the dynamic nature of corneal responses in TED and the importance of individualized ocular assessment.

Abstract No.: 202815

Corneal Lesion Characteristics in Microsporidial Keratoconjunctivitis

First Author: Thi Nga Duong NGUYEN

Co-Author(s): Thi Thu Thuy NGUYEN, Ngoc Dong PHAM, Huyen Trang TRAN

Purpose: To describe the morphological features of corneal lesions in patients with microsporidial keratoconjunctivitis.

Methods: A cross-sectional descriptive study was conducted on patients with microsporidial keratoconjunctivitis at Vietnam National Eye Hospital from January 2025 to August 2025. Collected data included: age, gender, duration of disease, onset factors, prior medications, visual acuity, and the morphological features of corneal epithelial lesions classified according to the criteria proposed by Amrita Mohanty MS et al. (2021).

Results: A total of 46 eyes from 41 patients (11 males, 30 females) were included, and the mean age was 17.31 years (11-80). Corneal epithelial lesions were categorized into three main morphological groups: 33 eyes (71.7%) in type 1, 1 eye (2.2%) in type 2, and 12 eyes (26.1%) in type 3. The most common were subtypes 1b and 1c, with each accounting for 11 eyes (23.9%). There were no significant differences among the types regarding age, gender, duration, previous medications, BCVA, or the severity of conjunctival congestion, corneal edema, and anterior chamber reaction. Subtype 1a had the highest rate of post-traumatic onset (80%). Conjunctival edema was most common in type 1 and was most frequently observed in subtypes 1b and 1c. The longest treatment duration was for subtype 1d (35.4 days), while the shortest was for 1b and 1c (9.22 and 8.04 days, respectively).

Conclusions: The corneal epithelial lesions of microsporidial keratoconjunctivitis present with diverse morphological features. Traumatic factors and conjunctival lesions are associated with the clinical manifestations of the disease.

Abstract No.: 208314

Corneal Toxicity of Belantamab Mafodotin in Relapsed Myeloma: A Longitudinal Clinical Analysis

First Author: Jing **TANG**

Co-Author(s): Hao **ZHANG**

Purpose: To characterize the incidence, progression, and reversibility of belantamab-associated keratopathy.

Methods: Prospective cohort study (May 2021-March 2025) at West China Hospital. Eight relapsed/refractory myeloma patients receiving BM underwent triweekly comprehensive ophthalmic evaluations. A key component of these evaluations was in vivo confocal microscopy, used to characterize and track the progression of belantamab-associated keratopathy at the cellular level.

Results: Among evaluable patients (median age 61.0, 87.5% male), 67% (4/6) developed keratopathy at first exposure (median onset: 17.0 days). Four patients (50%) developed corneal AE within 29 days of initial BM administration (median onset: 17.0 days), presenting with foreign body sensation (75%), dry eye (75%), and blurred vision (50%). In vivo confocal microscopy revealed that the presence of hyperreflective vesicles

in the corneal epithelium, neuropathic changes in Bowman's layer and stromal cell injury, which were associated with cumulative drug exposure. All corneal adverse events necessitated treatment interruption, with symptom recurrence upon rechallenge at reduced doses. Two long-term treated patients (31 months for one patient and 41 months for the other) exhibited irreversible epithelium, Bowman's layer and stroma off-target injury, persisting at final follow-up.

Conclusions: Belantamab mafodotin induces progressive, potentially incomplete irreversible corneal toxicity in most treated patients, with severity linked to treatment duration. Early confocal microscopy detects subclinical microcysts preceding visual symptoms. These findings advocate for ophthalmologic surveillance during treatment cycles, including cornea detection performed by corneal confocal microscopy.

Abstract No.: 203097

Deciphering Mitochondrial Dysfunction in Keratoconus: Insights Into ACSL4 From Machine Learning-Based Bulk and Single-Cell Transcriptome Analyses and Experimental Validation

First Author: Tianyi **ZHOU**

Co-Author(s): Yuchen **CAI**

Purpose: Keratoconus (KC) is a prevalent ectatic corneal disease and the leading cause of corneal transplantation globally. Despite evidence of mitochondrial abnormalities in KC, the underlying mechanisms remain unclear. Our aim was to investigate the role of mitochondrial dysfunction in this pathological condition.

Methods: Based on transcriptomics datasets of KC, mitochondria-related differentially expressed genes (mDEGs) were identified and analyzed for potential functional pathways, protein-protein interaction (PPI), and gene regulatory networks. Hub genes were further screened and validated by multiple machine learning (ML) algorithms, followed by a comprehensive visualization of the single-cell atlas and immune landscape. Additionally, bioinformatic results were validated through quantitative PCR, Western blot, and transcriptomics analysis in an in vitro KC model based on matrix stiffness using human stromal keratocytes.

Results: In total, 104 mDEGs were identified, enriched in pathways related to oxidative stress, apoptotic mitochondrial changes, ferroptosis, and inflammatory responses. Nine characteristic genes (CYP24A1, ACSL4, ACADL, HELZ2, AMT, DEPTOR, TUBA1A, TYMS, and ACSL5) were selected and validated using multiple ML models. Single-cell sequencing data highlighted ACSL4 as the most promising biomarker, primarily expressed in corneal stromal cells (CSCs). Immune infiltration analysis revealed that ACSL4 was positively associated with monocytes and negatively correlated with eosinophils in KC. In cellular experiments, ACSL4

expression was significantly upregulated in response to decreased substrate stiffness, suggesting its critical role in KC development.

Conclusions: These findings suggest a mitochondrial-related molecular mechanism implicated in KC pathogenesis. The identified pivotal biomarker ACSL4 provides a novel framework for future mechanistic and therapeutic studies of KC.

Abstract No.: 200446

Dematiaceous Fungi in the Eye: Emerging Threats and Antifungal Resistance From South India

First Author: Joveeta **JOSEPH**

Co-Author(s): Bhupesh **BAGGA**, Sourav **DAS**

Purpose: Ocular mycoses are a major cause of corneal blindness globally. Dematiaceous molds are the third most common fungal pathogens in keratitis and are increasingly associated with antifungal resistance, despite the lack of defined clinical breakpoints. This study evaluated species diversity and antifungal susceptibility profiles of melanized fungi causing ocular infections.

Methods: A total of 151 dematiaceous fungal isolates (Jan 2022–Mar 2025) from ocular infections were subjected to antifungal susceptibility testing (AFST) per CLSI M38 guidelines. Identification was based on LPCB mount and ITS sequencing, with phylogenetic analysis performed for 20 nonsporulating or rare isolates.

Results: Dematiaceous fungi were predominantly isolated from keratitis and included members from multiple taxonomic orders, with Pleosporales (43%) being the most common. *Curvularia* was the leading genus, followed by *Bipolaris*, *Exserohilum*, and *Colletotrichum*. Natamycin showed the least in vitro activity (MIC_{50}/MIC_{90} : 8/32 $\mu\text{g/ml}$), while voriconazole was the most active (0.12/4 $\mu\text{g/ml}$), followed by ketoconazole (0.25/4 $\mu\text{g/ml}$). Caspofungin had a high MEC_{90} (16 $\mu\text{g/ml}$). Posaconazole, amphotericin B, and itraconazole showed moderate activity (MIC_{90} : 8 $\mu\text{g/ml}$). Notably, 4.6% of isolates were pan-resistant. Sordariales were susceptible to all antifungals except natamycin, while Microascales, Glomerellales, Botryosphaerales, and Pleosporales showed higher resistance. Rare genera identified via phylogenetics included *Podospira*, *Humicola*, *Canariomyces*, *Cladosporium*, *Colletotrichum*, *Corynespora*, *Macrohomina*, and *Edenia*.

Conclusions: Voriconazole demonstrated the best in vitro activity against dematiaceous ocular pathogens, while natamycin was least effective. Large-scale AFST data help inform evidence-based antifungal choices, especially in the context of rare or resistant species.

Abstract No.: 202881

Demographic, Microbiological and Management Profile of Infective Corneal Ulcer at a Tertiary Center in Bangladesh

First Author: Rajashree **DAS**

Co-Author(s): Nawreen **ANWAR**

Purpose: To assess the demographic, microbiological and management profile of infective corneal ulcer at presentation.

Methods: Clinically diagnosed infective corneal ulcer patients were included in this prospective longitudinal study. Demographic profile, causative organisms, clinical signs, and treatment profile were the outcome variables of this study. Patients were clinically diagnosed as bacterial, viral, and fungal corneal ulcer after fluorescein dye test and slit lamp examination. Corneal scraping specimens were sent for microbiological examination for Gram staining, KOH initially, and Calcofluor White Staining whenever necessary. Culture-negative ulcers were treated as per clinical diagnosis. Patients were followed up for 1 month. Surgical measures were performed in cases with perforation or impending perforation.

Results: The overall mean age was 48.72 ± 16.95 years. Male: female ratio was 1.7:1. Majority (66.7%) of the patients came from rural areas. Fungal corneal ulcer had the highest incidence (52%) followed by bacterial corneal ulcer (18.1%). *Aspergillus* was the most common causative organism (38.9%) followed by *Fusarium* (13.9%), Gram positive cocci (12.5%), virus (4.2%) and candida (4.2%). In about 20.8% cases no causative microorganism could be isolated. Bacterial corneal ulcer had better response (92.3%) to medical management than Fungal corneal ulcer (71.2%). Fungal corneal ulcer required more surgical interventions than other corneal ulcers within 1 month of their initial presentation. Presence of hypopyon and fungal corneal ulcer were not statistically significant predictive factors for perforation and the need for surgical intervention.

Conclusions: *Aspergillus* keratitis is the most common infective keratitis presented in this study. Males and rural people had higher rate of infective keratitis.

Abstract No.: 201693

Descemet Stripping Only for Fuchs Endothelial Corneal Dystrophy in Chinese: A Five-Year Experience

First Author: Vanessa Ws **CHOW**

Co-Author(s): Jacqueline Wt **CHAN**, Julia Yy **CHAN**, Ke LIU, Rachel Wy **TSUI**, Vincent Lc **YUEN**

Purpose: To assess the clinical outcomes of Descemet stripping only (DSO) in the treatment of Fuchs endothelial corneal dystrophy (FECD) in the Chinese population, and to identify preoperative factors predictive of surgical success.

Methods: This retrospective cohort study included all patients who underwent DSO at the Hong Kong Eye Hospital from 2020 to 2025. Patient records were reviewed for demographic data, pre- and postoperative ocular parameters, including best-corrected visual acuity (BCVA), corneal clearance, central corneal thickness (CCT), endothelial cell density by specular microscopy, and use of ripasudil. The primary outcome was corneal clearance following DSO. Secondary outcomes included predictive factors of corneal clearance and BCVA over the follow-up period.

Results: A total of 20 eyes from 17 patients were included. All patients were ethnic Chinese, with a mean follow-up duration of 14.3 months and 25% (n=5) were followed for over 2 years. Corneal clearance was achieved in 50% (n=10) of cases, with a mean time to clearance of 7.3 weeks. BCVA improved in 55% (n=11) of cases, which sustained up to 24 months postoperatively (mean increase in logMAR 0.152, $P = 0.030$). Preoperative BCVA was significantly associated with successful corneal clearance ($P = 0.048$), whereas age, preoperative CCT, preoperative endothelial cell density, concomitant cataract surgery, and use of ripasudil were not predictive.

Conclusions: This is the first study to report outcomes of DSO in Chinese with FECD. Preoperative BCVA is significantly associated with surgical success and should be considered as a prognostic factor during evaluation for surgery.

Abstract No.: 203703

Development and Temporal Validation of an Interpretable Machine Learning Model for Long-Term Graft Survival Prediction of Moderate to High Risk Penetrating Keratoplasty

First Author: Zhewen **ZHENG**

Co-Author(s): Xueqin **GONG**

Purpose: To develop interpretable machine learning models for predicting the long-term graft survival probabilities of moderate to high-risk penetrating keratoplasty (PK).

Methods: We collected clinical features and survival status of moderate to high-risk grafts that underwent PK at Zhongshan Ophthalmic Center from January 2012 to December 2021. Feature selection was performed through multivariate Cox regression. Five machine learning prediction models were developed based on these predictors. Model performance was assessed through area under the receiver operating characteristic curve (AUC), calibration curves, and decision curve analysis (DCA). The final model was interpreted using the ranking of variable importance and implemented as a web-based platform.

Results: The study cohort comprised 2,298 grafts undergoing moderate to high risk penetrating

keratoplasty (PK) at Zhongshan Ophthalmic Center, divided into three datasets: training (n=1,338), internal validation (n=573), and temporal external validation (n=387). Six independent predictors for moderate to high risk penetrating keratoplasty were identified. Five machine learning models were constructed using these predictors, among which the random survival forest (RSF) model demonstrated superior performance in predicting graft survival in the internal validation set (7-year AUC=0.852). The RSF model maintained outstanding performance in the external validation set with an AUC of 0.810. Variable importance ranking identified 'the quadrants of corneal neovascularization' and 'recipient graft size' as dominant prognostic contributors. Additionally, we developed a web based on the RSF model for clinical use: https://webs-pred.shinyapps.io/RSF_model/.

Conclusions: The RSF model developed based on these risk factors demonstrated excellent predictive accuracy for long-term graft survival rates of moderate to high risk penetrating keratoplasty patients.

Abstract No.: 200601

Diabetic Corneal Neuropathy Precedes and Is Linked With Diabetic Retinopathy

First Author: Chang **LIU**

Co-Author(s): Ching-yu **CHENG**, Isabelle Xin Yu **LEE**, Yu-chi **LIU**, Cancan **XUE**, Mingyi **YU**

Purpose: To investigate the relationship between diabetic corneal neuropathy (DCN) and diabetic retinopathy (DR) by examining corneal nerve imaging features, clinical manifestations, and tear mediators in patients with type 2 diabetes.

Methods: This cross-sectional study included 1654 eyes of 822 participants. All subjects underwent ocular surface subjective and objective assessments and fundus examination. In-vivo confocal microscopy (IVCM) scans were performed to assess 7 corneal nerve metrics, 5 dendritic cell variables, and 3 microneuroma parameters. Tear cytokines were analyzed using an enzyme-linked immunosorbent assay.

Results: Compared to controls, eyes with no DR, non-proliferative DR (NPDR) and proliferative DR (PDR) had significantly impaired corneal nerve metrics (all $P < 0.001$). As DR progressed, eyes with NPDR and PDR showed a significant reduction in corneal nerve parameters compared to those with no DR ($P < 0.050$). Furthermore, PDR eyes presented significantly worse ocular surface clinical manifestations than controls, as well as eyes with no DR and NPDR (all $P < 0.005$). Tear Substance P concentrations were significantly lower across all stages of DR compared with controls (all $P < 0.001$), and tear MMP-9 concentrations were significantly increased in PDR eyes (all $P < 0.050$). These cytokines were significantly correlated with corneal nerve parameters and ocular surface assessments.

Conclusions: DCN precedes the onset of DR, and the impairment of corneal nerves worsens with the progression of retinopathy. Corneal nerve status holds the potential as an early indicator and predictor for DR.

Abstract No.: 206222

Diagnostic Accuracy of the 'Hong Kong Workflow' in Diagnosing Dry Eye Disease in a Hong Kong Population-Based Study

First Author: Shing Wai Joselyn **CHENG**

Co-Author(s): Arthur Chak Kwan **CHENG**, Kendrick Co **SHIH**

Purpose: The 2024 'Hong Kong Streamlined Dry Eye Workflow' streamlines dry eye diagnosis, severity grading, and classification in busy high-volume outpatient clinics. This study investigates its accuracy with reference to the optimal workflow, based on the Asia Dry Eye Society guidelines, as the gold standard.

Methods: This cross-sectional random population-based study initiated on 27 September 2021 and is ongoing. Chinese subjects aged 50+ were recruited through randomized mail invitations in Hong Kong's Southern District. Response rate was 96%, and cooperation rate was 49%. In total, 1075 consecutive subjects underwent comprehensive dry eye assessment from least to most invasive, including dry eye questionnaire (OSDI score), non-invasive keratographic tear breakup time, tear meniscus height, NEI cornea staining score, and meiboscore. We compared the accuracy of two proposed Hong Kong workflows (optimal vs streamlined) in diagnosis, classification, and severity grading. Optimal workflow requires OSDI score, tear breakup time (TBUT), staining, and tear volume measurements, and is based on the Asia Dry Eye Society guidelines, while the streamlined workflow needs only some dry eye symptoms in combination with TBUT and staining.

Results: The optimal workflow diagnosed dry eye disease in 15.6% of subjects, while the streamlined workflow diagnosed it in 10.9% of subjects. Overall, the streamlined pathway had 69.6% sensitivity, 100% specificity, and 95.3% accuracy ($df=1$, $p<0.001$) versus the optimal pathway, missing 51 cases. AUC was 0.760 (95% CI: 0.717-0.802, $p<0.001$) for the accuracy of the streamlined pathway result matching the optimal pathway result, showing only moderate performance. Among diagnosed dry eye disease cases, severity distributions were similar (optimal: mild 26.8%, moderate 13.7%, severe 59.5%; streamlined: mild 19.7%, moderate 19.7%, severe 60.7%; chi-square >39 , $p<0.001$). Regarding dry eye type classification, distributions between the two pathways were similar, but the streamlined pathway had marginally higher ADDE and lower DWDE proportions.

Conclusions: The streamlined pathway showed high specificity but low sensitivity for dry eye diagnosis. It performed similarly in classification and severity

grading to optimal. Therefore, the streamlined pathway suits monitoring/follow-up more than initial diagnosis. We still recommend the optimal pathway for the initial screening of symptomatic patients.

Abstract No.: 206267

Drug Depository (Reservoir) Contact Lens Reduces Antimicrobial Treatment Burden in Bacterial Keratitis: Results of a Randomized Controlled Study

First Author: Lional Raj **DANIEL RAJ PONNIAH**

Purpose: Microbial keratitis can lead to unilateral blindness, but drug delivery options are limited. Therefore, we evaluated the efficacy of a novel therapeutic drug-depository contact lens (DDCL) as an anti-microbial reservoir for bacterial keratitis (BK) treatment & its role in reducing the treatment burden. The lens was designed to increase the corneal lesion drug interaction time.

Methods: An open-labelled randomized controlled study to compare topical antimicrobial administration and antimicrobial administration with DDCLs for treating BK. Bacterial Keratitis (BK) patients were randomized (1:1) into two groups: topical antimicrobial treatment only, with an intensive loading dosage of hourly for the first two days and 2-hourly for the next 12 days (Group 1), and DDCL plus reduced antimicrobial treatment with 2-hourly for the first two days followed by 4-hourly for next 12 days (Group 2). Both groups received 0.5 % moxifloxacin. We evaluated BK recovery, anterior chamber (AC) reactions, corneal haze, and pain (on a 10-point scale) 12 hours and 1, 3, 5, and 14 days after treatment.

Results: The baseline corneal-infiltration (i.e., BK severity) values were comparable for Groups 1 (18 cases) and 2 (17 cases) ($P = 0.92$). After 12 hours, the scores improved in both groups and continued to improve throughout the follow-up period; the improvements were more pronounced in Group 2 than in Group 1 (all $P < 0.05$). Complete recovery occurred on Days 14 and 5 in Groups 1 and 2, respectively. Furthermore, the AC reaction was resolved by Day 3 in Group 2. The baseline pain scores were also comparable between Groups 1 and 2 ($P = 0.52$) and decreased throughout the follow-up period (all $P < 0.05$); the decrease was more pronounced in Group 2.

Conclusions: Novel DDCLs augment the drug-lesion interaction time by prolonging corneal antimicrobial availability, which hastens corneal healing in Bacterial Keratitis. Thus, a DDCL may decrease the antibiotic regimen and improve patient tolerance, eliminating the necessity for a loading dose.

Abstract No.: 206935**Dry Eye Disease in Cocaine and Methamphetamine Users: The Influence of Use Chronicity***First Author: King Him Cyrus **CHEUNG****Co-Author(s): Kam Lung Kelvin **CHONG**, Ka Hei Kenneth **LAI**, Chi Pui Calvin **PANG**, Chee Yung Clement **THAM*****Purpose:** To evaluate the impact and long-term effects of substance use on dry-eye disease parameters.**Methods:** Cross-sectional study of cocaine and methamphetamine users in the prior 24 months from CCPSAs under the support of Beat Drugs Fund (BDF210067). Symptoms were quantified through the Ocular Surface Disease Index (OSDI), dry-eye parameters were assessed through OCULUS_Keratograph_5M, TearScience™ LipiView™ II Interferometer, and the degree of MGD was examined by ophthalmologists.**Results:** Forty-six right eyes from substance-users (10 cocaine, 20 methamphetamine, 16 poly-substance) and 46 age-sex-matched controls (age: 36.50(44.25-31.00) years; $p=0.928$) were compared. Post-hoc analysis specified poly-substance users had worse OSDI (24.03(60.80-13.98) vs. 6.25(18.75-0.00); adj. $p=0.003$) and more meibomian gland capping (1.50(2-1) vs. 1.00(1-0); adj. $p=0.041$) compared to control. Overall group comparisons for First_NIKBUT($p=0.039$) and Meibomian_Gland_Yielding_Secretion_Score($p=0.048$) were significant, with substance-users showing lower-scores. However, no significant group-to-group differences were found. Pure-cocaine and methamphetamine users were stratified into long- and short-term use groups. Long-term-users have a lower Lipid_Layer_Thickness (LLT_Avg) compared to short-term-users (54.50(63.50 - 43.25) vs. 72.50(91.75-54.25); $p=0.040$). OSDI was also significantly lower for long-term-users (10.89(25.52-4.45) vs. 42.52(56.93-18.23); $p=0.003$). Long-term-users also presented a lower score for individual symptoms of sensitivity-to-light (0(0.00-0.00) vs. 2.00(3.75-0.00); $p=0.027$) and poor-vision (0.50(1.25-0.00) vs. 2.50(3.75-1.00); $p=0.024$). Correlation-analysis suggests chronicity is negatively-correlated with both LLT_Avg ($r = -0.383$, $p=0.036$) and OSDI ($r = -0.532$, $p=0.003$).**Conclusions:** Substance use is associated with a compromised ocular surface, with clear evidence of MGD, particularly in poly-substance users who exhibited more severe signs and symptoms. Among long-term users, despite worse objective parameters, fewer subjective symptoms were reported, including less light sensitivity and perceived poor vision, suggesting sign-symptom disparity. The potential substance-induced neurotrophic effect that developed over long-term use warrants further investigation.**Abstract No.: 209720****Effect of Different Fibroblast Subtypes in Corneal Transplant Rejection***First Author: Shudan **WANG****Co-Author(s): Hong **ZHANG*****Purpose:** Corneal transplant rejection has remained a major challenge in recent years. This study seeks to explore the functions of different types of fibroblasts in corneal transplantation, aiming to uncover their role in modulating immune responses and improving graft survival outcomes.**Methods:** C57BL/6 mice were selected as donors and BALB/c mice were selected as recipients to establish a mouse allogeneic corneal transplantation model. The cornea was obtained at the sixth week after surgery. High-quality transcriptomes were generated from single-cell RNA sequencing (scRNA-seq) data from 18 mouse corneas in each group. Cluster analysis was performed on the scRNA-seq data by known cell marker genes in order to identify different cell types. Immunofluorescence was used to verify the cell subtypes.**Results:** Eight cell types, including epithelial cells, fibroblasts, endothelial cells, T cells, macrophages, neutrophils, vascular endothelial cells, and schwann cells, were detected in the cornea after corneal transplant. Fibroblasts were divided into four clusters based on differences in cell gene expression, namely antigen-presenting cell (APC) type, inflammatory type, angiogenic type, and myofibroblasts. Additionally, we observed a significant increase in the proportion of inflammatory fibroblasts and myofibroblasts in the rejection group. Immunofluorescence verified the above four subtypes with Mrc2, Ly6c, Gpc, and α SMA, respectively. Th1 cells and fibroblasts showed strong connection networks, especially in VCAM, TGF β , and SEMA4 pathways.**Conclusions:** In conclusion, we applied scRNA-seq to rejection after corneal transplantation to deconstruct its heterogeneity. This study facilitates the understanding of the pathogenesis of corneal transplant rejection and identifies new targets for personalized therapeutic approaches.**Abstract No.: 207479****Effect of Limbal Stem Cell Deficiency on the Cosmesis Results Following Corneal Tattooing: A Retrospective Analysis***First Author: Raj Shekhar **PAUL*****Purpose:** To report corneal tattooing or keratopigmentation (KP) cases and their follow-up in the past 3 years. This study highlights the techniques, intraoperative and postoperative complications, and suggests measures for better aesthetic outcomes.

Methods: A total of 24 eyes (n=24) were included in this retrospective, hospital-based study conducted at an Eastern Indian tertiary care centre from December 2021 to November 2024. Preoperative anterior segment examination also included ocular surface staining, limbus analysis, pachymetry and intraocular pressure. Most eyes (n=18) underwent automated superficial KP; two underwent manual intrastromal KP. In 21 eyes, a commercially available India Ink dye was used for KP. In one eye, freshly prepared soot was used for manual intrastromal KP. Following a clinical grading of Limbal stem cell deficiency (LSCD), the eyes were classified into mild, moderate, and severe.

Results: There were fourteen males and ten females, aged 18 to 40. The most common preoperative ocular condition seeking cosmesis was post-traumatic corneal opacity (47.6%). Fourteen eyes had satisfactory cosmesis noted in their follow-up visits. Concerning complications were intraoperative perforation (n=1), corneal ulcers (n=2), immediate fading of dye (n=3), corneal melt with perforation (n=2), and endophthalmitis (n=1). 80% of eyes classified as severe LSCD had poor cosmesis following KP.

Conclusions: There was an overall increase in our success rate and reproducibility, with a notable decrease in fading (33% in the first year versus 14% in the last year), once ancillary surgeries such as pre-operative diamond burr polishing, amniotic membrane transplantations, and concurrent tarsorrhaphies were performed to combat ocular surface irregularities.

Abstract No.: 205149

Effect of Preservative-Free Versus Preserved Diquafosol Sodium 3% Eye Drops on Tear Film Inflammatory Markers and Clinical Severity of Dry Eye Disease: A Single-Center Randomized Controlled Trial

First Author: Joanna Mae O'SANTOS

Co-Author(s): Ruben LIM BON SIONG, Raymond Nelson REGALADO

Purpose: To compare the effects of preservative-free diquafosol sodium 3% (Diquas-S) versus preserved diquafosol eye drops on tear cytokine levels, ocular symptoms, and tear film stability in patients with dry eye disease.

Methods: This was a randomized, controlled, single-center, single-masked comparative study of 86 patients with DED. Patients received either preservative-free diquafosol (Diquas-S, Santen Pharmaceutical Co., Ltd., Japan) (n = 43) or preserved diquafosol (Diquas, Santen Pharmaceutical Co., Ltd., Japan) (n = 43) for 8 weeks. Tear concentrations of interferon gamma, interleukin-6, interleukin-17A, and tumor necrosis factor alpha were measured at baseline and after 8 weeks using the ProcartaPlex™ Human Mix & Match Panels (Thermo Fisher Scientific, USA). Associations between cytokine suppression and clinical measures, including SPEED

questionnaire scores, fluorescein tear break-up time, Schirmer's test, and ocular surface staining, were analyzed.

Results: Eighty-five eyes completed the study. Preservative-free Diquas-S achieved significantly greater reductions in cytokine levels compared with preserved diquafosol (mean reductions: IFN- γ -65.4%, IL-6 -72.1%, IL-17A -61.8%, TNF- α -70.3% vs. -18.7%, -22.9%, -24.1%, and -15.6%, respectively). Responder rates were markedly higher with Diquas-S across all markers. Cytokine suppression correlated with improvements in SPEED score, TBUT, and ocular surface staining, with IL-6 and TNF- α showing the strongest associations. Schirmer's test values showed weaker correlation. Subtype analysis indicated the greatest cytokine suppression in aqueous-deficient DED, particularly for TNF- α , while evaporative and mucin-deficient subtypes exhibited variable responses.

Conclusions: Preservative-free diquafosol provides superior cytokine suppression and clinical improvement compared with preserved formulations, underscoring its role in long-term DED management and supporting the utility of cytokines as biomarkers for treatment monitoring.

Abstract No.: 203341

Effectiveness of a Heparin-Like Glycosaminoglycan From Snail Mucus in a Murine Model of Dry Eye

First Author: Shangkun OU

Co-Author(s): Hao GU

Purpose: Dry eye disease (DED) is a prevalent multifactorial ocular disorder characterized by tear film instability, inflammation, and corneal epithelial damage. Despite the availability of treatments, effective and safe topical therapies remain limited. Heparin-like glycosaminoglycans have shown potential in epithelial regeneration and anti-inflammation. This study investigates the therapeutic effects and mechanisms of a purified glycosaminoglycan derived from *Achatina fulica* snail mucus (AFG) on DED.

Methods: This study employed both in vitro and in vivo approaches. Human corneal epithelial (HCE) cells were treated with varying concentrations of AFG to assess cytotoxicity, proliferation, migration, and gene expression related to epithelial regeneration and mucin secretion. A benzalkonium chloride (BAC)-induced DED mouse model was established, and animals were treated with AFG eye drops for 7 days. Corneal integrity, tear secretion, histological changes, inflammatory cell infiltration, and the expression of key markers were evaluated using fluorescein staining, Schirmer test, qRT-PCR, Western blotting, and immunofluorescence.

Results: AFG showed no cytotoxicity and significantly promoted HCE cell proliferation, migration, and mucin

gene expression (K14, KI67, MUC1, MUC4). In DED mice, AFG treatment markedly improved corneal integrity and tear secretion. It upregulated corneal expression of epithelial and mucin-related genes (K12, PAX6, MUC1, MUC4), while downregulating inflammatory markers (IL-1 β , IL-6, TNF- α , MMP-9, CD45). Histological analysis confirmed increased epithelial thickness and reduced inflammatory infiltration.

Conclusions: AFG demonstrates significant therapeutic potential for DED by restoring corneal epithelial homeostasis through cell proliferation, mucin secretion, and anti-inflammatory effects. This study provides a foundation for the development of AFG-based topical treatments for dry eye disease.

Abstract No.: 202794

Effects of Sympathetic Nerve Activity on Tear Components Secreted From Lacrimal Gland

First Author: Qun **WANG**

Co-Author(s): Qingjun **ZHOU**

Purpose: As the major component of the tear film, the aqueous phase is secreted principally by the lacrimal gland, a process controlled by neural regulation. This study aimed to evaluate the effects of sympathetic nerve activity on tear components secreted from the lacrimal gland.

Methods: We employed both pharmacological (isoproterenol, noradrenaline, 6-hydroxydopamine) and surgical (superior cervical ganglionectomy) approaches to manipulate sympathetic nerve activity in normal mice. Basal and reflex tear secretion were first assessed, followed by collection of tear samples for electrolyte concentration analysis. Subsequently, the collected tear fluid was subjected to proteomic sequencing, with functional enrichment analysis and selected targets validation through ELISA measurements. Finally, we established a dry eye disease model to systematically assess the therapeutic efficacy of the identified candidate targets.

Results: Sympathetic activity significantly influenced both basal and reflex tear secretion dynamics, modulated tear electrolyte concentrations and protein composition within the tear film. Importantly, sympathetic inhibition markedly improved the functional quality of tear proteins, as demonstrated through comprehensive proteomic and functional analyses. Subsequent validation studies identified two specific protein targets— α -amylase 2a (Amy2a) and amyloid precursor-like protein 1 (Aplp1)—that exhibited significant therapeutic potential in dry eye disease mouse model, effectively restoring tear film homeostasis and ocular surface integrity.

Conclusions: This study systematically investigated how sympathetic nerve activity regulates lacrimal gland-

derived tear components, providing critical insights for developing targeted therapies for dry eye disease.

Abstract No.: 204266

Efficacy and Safety of Mihe Keratoprosthesis in Chinese Population: A Retrospective Single-Center Study

First Author: Ying **JIE**

Co-Author(s): Yiran **HAO**

Purpose: To quantify anatomical and functional outcomes of the Mihe keratoprosthesis (KPro) in a Chinese population over 1 to 3 years and analyze the possible causes of postoperative complications.

Methods: Patients who completed both stage 1 and stage 2 Mihe KPro surgery more than or equal to one year were included. The interval between stage 1 and stage 2 of the procedure, specifications of the keratoprosthesis, prognosis, postoperative complications and any subsequent surgeries were documented. Indications, intraoperative characteristics, postoperative visual acuity and complications were analyzed.

Results: Twenty-nine eyes of 29 patients who underwent PK were reviewed with a mean follow-up of 14.3 ± 5.2 months. Chemical burn was shown to be the most common indication for keratoprosthesis surgery with 14 cases (48.3%). The final postoperative best-corrected visual acuity (BCVA) improved in 22 eyes (75.9%). Postoperative BCVA improved to 20/67 or better in 9 eyes (31.0%) and 20/400 or better in 14 eyes (48.3%) at 12 months. The retention rate of Mihe KPro was 100% (29 eyes). Complications including anterior proliferative membrane (24.1%), exposure of the keratoprosthesis stent (10.3%), glaucoma (6.9%), exposure of autologous auricular cartilage (6.9%), retroprosthetic membrane (3.4%), proliferative growth on the surface of the autologous auricular cartilage (3.4%), central retinal artery occlusion (3.4%), endophthalmitis and retinal detachment (3.4%).

Conclusions: Mihe KPro's wholly domestic design and production mark a pivotal milestone for Chinese ophthalmology. By delivering consistent visual restoration with an acceptable safety margin, it converts end-stage corneal blindness from an irreversible condition into a treatable one.

Abstract No.: 208602

Emerging Microsporidia Keratoconjunctivitis in China: A Call for Consensus

First Author: Hong **QI**

Co-Author(s): Yingyu **LI**, Zihan **SHEN**, Zhengze **SUN**, Pei **ZHANG**

Purpose: China is currently facing a newly emerging ocular infectious disease, microsporidia keratoconjunctivitis (MKC). However, no consensus

has yet been established on the diagnosis or treatment of MKC. This study aims to share our clinical experience with MKC to facilitate the development of a standardized consensus.

Methods: Since September 2024, more than twenty cases of MKC have been diagnosed and treated in our clinic. Detailed medical histories were obtained, and the patterns of corneal lesions were documented. Each patient underwent a comprehensive panel of ocular pathogen detection tests, including in vivo confocal microscopy, corneal scraping, conjunctival scraping, ocular bacterial culture, ocular viral PCR, and metagenomic next-generation sequencing (mNGS). Based on evidence from previous literature, a treatment regimen was developed, and its clinical efficacy was assessed.

Results: Our findings indicated that parrot exposure was the most significant risk factor for MKC. Early recognition of MKC required integrating a patient's animal exposure history, previous treatments, and the presence of diffuse, coarse corneal epithelial defects, which were characteristic of MKC. We recommend corneal scraping and mNGS as the primary diagnostic approaches for MKC. The proposed treatment regimen, consisting of two fluoroquinolones and one antifungal agent, produced favorable clinical outcomes. Co-infections were not uncommon in MKC patients and should be managed simultaneously.

Conclusions: Although it is still considered a rare condition, MKC may emerge as a more common ocular infectious disease in future clinical practice. At this pivotal moment, it is imperative to develop a unified consensus for MKC and to enhance microbiological diagnostic capacity across hospitals nationwide.

Abstract No.: 204987

Empagliflozin Attenuates High-Glucose-Induced Corneal Epithelial Injury and Wound Healing Delay

First Author: Zhitong **CHEN**

Co-Author(s): Kuangqi **CHEN**, Jiayun **GE**, Ye **SHEN**, Liusi **YANG**

Purpose: Diabetic keratopathy (DK), a vision-threatening complication of diabetes, is characterized by impaired corneal wound healing, epithelial erosion, and nerve dysfunction. Current treatments remain palliative, highlighting the need for mechanism-based therapies. This study aimed to investigate the therapeutic potential of empagliflozin (EMPA), an SGLT2 inhibitor, for DK treatment.

Methods: We employed an integrated approach combining in vivo, in vitro, and bioinformatics strategies to evaluate EMPA's effects and mechanisms in DK.

Results: EMPA treatment in diabetic mice significantly reduced corneal injury and improved corneal epithelial

wound healing, while preventing hyperglycemia-induced epithelial thinning. In vitro, EMPA protected human corneal epithelial cells (HCECs) against high glucose-induced damage, enhancing cell viability and migration. Mechanistically, EMPA reduced intracellular ROS, preserved mitochondrial membrane potential, and prevented mitochondrial loss. Bioinformatics analysis revealed 14 shared EMPA-DK targets, with MAPK1/3, ICAM1, and VCAM1 as core regulators of inflammation and metabolic pathways. Molecular docking confirmed strong binding affinity between EMPA and these targets.

Conclusions: EMPA demonstrates potential as a novel therapy for DK, addressing both systemic metabolic dysfunction and local corneal damage. Our findings provide the preclinical evidence supporting the repurposing of EMPA to prevent vision loss in diabetic patients.

Abstract No.: 207261

Epidemiological Insights Into Paediatric Infectious Keratitis: Exploring the Role of Vitamin A Deficiency

First Author: Nandita **TRIVEDI**

Co-Author(s): Ritu **ARORA**, Avani **HARIANI**, Parul **JAIN**

Purpose: Pediatric infectious keratitis (PIK) is a vision-threatening condition with limited data on nutritional risk factors. This study investigates the association between serum vitamin A deficiency and PIK, alongside microbial profiles and clinical outcomes, in children presenting to a tertiary eye care center in India.

Methods: In this prospective observational study, 45 children (53 eyes) with clinically diagnosed bacterial and/or fungal keratitis were enrolled. Age- and gender-matched non-ocular controls were included for serum vitamin A measurement. Clinical, microbiological, nutritional, and immunization data were collected. Serum vitamin A levels were quantified using ultra-high performance liquid chromatography. Associations between vitamin A status and keratitis risk were assessed by logistic and Cox regression analyses.

Results: The mean age was 4.0 ± 5.4 years; 44.4% were under 6 months. Bilateral involvement occurred in 18%, with younger children exhibiting higher odds (OR 3.79, $p=0.235$). Vitamin A deficiency was significantly more prevalent in cases than controls, notably in infants <6 months (0.088 ± 0.028 mg/L vs. 0.182 ± 0.047 mg/L, $p<0.001$). Vitamin A deficiency increased the risk of corneal ulceration by 3.89-fold (95% CI: 1.97–7.7, $p=0.000$) and by 36-fold in infants under 6 months. Bacterial pathogens predominated (54.7%), with *Staphylococcus aureus* most common. Clinical outcomes were poor, with 35.8% experiencing corneal perforation and 77.6% healing with corneal opacity.

Conclusions: Vitamin A deficiency is an independent, significant risk factor for PIK, particularly in early

infancy. This study is among the first to directly correlate serum vitamin A levels with pediatric corneal ulcer risk, underscoring the importance of nutritional interventions, exclusive breastfeeding, and immunization in preventing childhood corneal blindness.

Abstract No.: 208074

Evaluating the Efficacy and Feasibility of Manual Digital Meibomian Gland Compression in Meibomian Gland Dysfunction

First Author: Yingying GAO

Co-Author(s): Jingru WANG, Ling ZHANG

Purpose: To evaluate the therapeutic efficacy and clinical feasibility of manual digital meibomian gland compression compared to instrument-assisted mechanical compression in patients with meibomian gland dysfunction (MGD).

Methods: Medical records of 70 MGD patients were retrospectively analyzed. Participants were divided into manual (n=35) and mechanical compression groups (n=35). Primary outcomes included Ocular Surface Disease Index (OSDI) scores and ocular surface parameters at 2-week follow-up (14±2 days), and 8-week follow-up (56±2 days). Secondary outcomes assessed manipulation pain intensity (Visual Analogue Scale, VAS), treatment duration, and learning curve length.

Results: Both groups showed significant improvements in OSDI scores, gland plugging, Schirmer I test, and non-invasive break-up time (NIBUT) at both follow-ups (all $P < 0.05$). The manual group demonstrated earlier meibum quality improvements (2-week follow-up and 8-week follow-up, $P < 0.05$) compared to the mechanical group's 8-week follow-up improvement ($P = 0.01$), along with superior lid margin regularity at 8-week follow-up ($P = 0.04$). Significant intergroup differences favored manual compression in gland plugging ($P = 0.02$), meibum quality ($P = 0.03$), and NIBUT ($P < 0.001$) at 8-week follow-up. Manual compression consistently yielded lower pain scores (all $P < 0.001$) and required fewer training cases (13 vs 20).

Conclusions: Manual digital compression offers effective MGD management with enhanced patient comfort and faster clinical proficiency compared to mechanical methods. Its demonstrated therapeutic advantages support broader clinical implementation.

Abstract No.: 206081

Evaluation of Ocular Surface Inflammation and Systemic Conditions in Patients With Autoimmune Rheumatic Diseases

First Author: Yan HE

Co-Author(s): Xiang LI, Yingyi LIU

Purpose: To investigate the relationship between ocular surface inflammation and psychological, physiological, and disease characteristics, as well as systemic hematologic indices in patients with autoimmune rheumatic diseases (ARDs).

Methods: The study included 79 patients with ARDs (26 with rheumatoid arthritis, 33 with systemic lupus erythematosus, and 20 with primary Sjögren's syndrome) and 30 controls. Participants underwent ocular surface evaluations, including symptom and sign assessments, conjunctival impression cytology, and tear cytokine profiling. Systemic disease characteristics such as duration, activity, and serological markers were documented. Quality of life, anxiety/depression, daily functioning, and sleep quality were assessed using SF-36, HADS, HAQ-DI, and PSQI.

Results: Patients with systemic lupus erythematosus exhibited a lower incidence of dry eye and lower levels of proinflammatory tear cytokines compared to those with rheumatoid arthritis or primary Sjögren's syndrome. However, ocular surface squamous metaplasia was more severe in patients with systemic lupus erythematosus and primary Sjögren's syndrome than in those with rheumatoid arthritis. ARDs patients reported lower SF-36 scores and higher anxiety and HAQ-DI scores compared to controls. The Ocular Surface Disease Index showed moderate correlations with quality of life, anxiety, depression, and sleep quality.

Conclusions: The distinct patterns of dry eye and ocular surface immune inflammation observed across different ARDs are associated with underlying systemic conditions. Comprehensive ophthalmic assessments are essential for patients with ARDs. Effective treatment approaches should integrate both systemic management and psychological support.

Abstract No.: 203277

Evaluation of a Drug–Food Homologous and Health-Grade Traditional Chinese Medicine Formula (Jue-Ming Granules) for Dry Eye Disease

First Author: Ziming LIU

Co-Author(s): Yuanlong AN, Wei HE, Zongming PU, Zhenli YUAN, Donglei ZHANG

Purpose: Dry eye disease (DED) is characterized by chronic inflammation and a lack of effective long-term treatment options. Jue-Ming Granules (JMGs), a modified traditional herbal formulation composed entirely of drug–food homologous or health-grade

ingredients, may offer multi-target anti-inflammatory benefits. This study investigates both the mechanisms and clinical efficacy of JMGs using a multilevel, integrative approach.

Methods: Network pharmacology and molecular docking were applied to identify JMGs' active compounds and predicted key inflammatory targets. In vitro assays using human corneal epithelial cells assessed cell viability under benzalkonium chloride-induced damage. In vivo efficacy was evaluated in a murine DED model. A single-center randomized controlled clinical trial (n=88) evaluated JMGs' therapeutic outcomes.

Results: JMGs' active components—quercetin, caffeine, and luteolin—were associated with inflammation-related pathways such as PI3K/AKT, based on network analysis and pathway inhibition assays. In vitro, JMGs improved cell viability and mitigated BAC-induced cytotoxicity. In vivo, JMGs enhanced tear secretion, reduced corneal staining, downregulated inflammatory cytokines (TNF- α , IL-6, IFN- γ), and restored goblet cell density. Clinically, JMGs significantly improved Ocular Surface Disease Index (OSDI) scores, TCM symptom scores, quality of vision (QoV), corneal fluorescein staining (CFS), and corneal sensitivity, without adverse events.

Conclusions: JMGs exert multi-target anti-inflammatory effects against DED, supported by both preclinical and clinical evidence. These findings highlight the therapeutic potential of modified TCM formulas composed entirely of drug–food homologous and health-grade materials as safe adjunctive interventions for ocular surface diseases.

Abstract No.: 203929

Experimental Studies to Enhance the Efficacy of Corneal Crosslinking

First Author: Yu **LIU**

Co-Author(s): Dan **CHEN**, Lan **KE**, Xinlan **LEI**, Mengying **QI**, Jin **QUE**, Qingyan **ZENG**

Purpose: To evaluate chitosan (CS) as an adjunct to corneal cross-linking (CXL) for improving treatment outcomes in keratoconus.

Methods: Ninety rabbit right eyes were divided into groups: accelerated CXL (ACXL), ACXL with 0.2% chitosan soaking after de-epithelialization for 20 minutes (CS-ACXL), and controls. Riboflavin concentration was measured via Ultra-high performance liquid chromatography-tandem mass spectrometry (UHPLC-MS/MS). CCT, SSI, and collagen modulus (k1) using finite element analysis (FEA) were assessed at 7, 14, and 28 days. Imaging and histology via slit-lamp examination, OCT, IVCN, HE staining, second-harmonic generation (SHG) microscopy, two-photon (TP) fluorescence microscopy were performed. Quantitatively comparing fluorescence integrated

intensity (FI) was performed to examine structural changes at 0, 7, 14, and 28 days after surgery.

Results: The median riboflavin concentration of the corneal stroma of rabbits in the conventional mechanical debridement group was approximately 145 ng/mL. No significant difference was observed between the traditional mechanical de-epithelialization group and the group soaked in 0.2% chitosan solution ($P > 0.05$). At 14 days, k1 was significantly increased in both ACXL (36.94 ± 5.84 MPa) and CS-ACXL (37.98 ± 4.56 MPa) groups compared to controls (27.85 ± 1.57 MPa, $P < 0.001$). At 28 days, stiffness in the CS-ACXL group (36.72 ± 6.89 MPa) remained significantly higher than both controls ($P < 0.001$) and the ACXL group (31.46 ± 5.72 MPa, $P = 0.03$). The CS-ACXL group also showed notably higher fluorescence intensity at 7 days ($P = 0.007$), reduced inflammation, and a more regular collagen structure.

Conclusions: Using 0.2% chitosan in CXL is safe for at least 28 days. While it doesn't enhance riboflavin absorption, it improves corneal stiffness, promotes organized collagen remodeling, and suppresses inflammation.

Abstract No.: 202868

Exploration of Gene Therapy Targeting Corneal Endothelial Cells for Macular Corneal Dystrophy

First Author: Lin **CONG**

Co-Author(s): Lixin **XIE**, Bi Ning **ZHANG**, Qingjun **ZHOU**

Purpose: The corneal endothelium, a critical monolayer structure maintaining corneal optical properties and stromal nutrient metabolism, relies on its hexagonal cellular arrangement, intercellular tight junctions, and active transport functions for physiological homeostasis. Our preliminary studies identified corneal endothelial dysfunction as a primary pathogenic driver in macular corneal dystrophy (MCD). This study aimed to develop a novel gene therapy targeting corneal endothelial cells in MCD mice and evaluate its long-term efficacy.

Methods: AAV serotypes with high efficiency and specificity for corneal endothelial cells were screened. Dose-response experiments determined the minimum safe and effective AAV titer for anterior chamber injection. The therapeutic efficacy of AAV-Chst5 was validated in adult and juvenile MCD mouse models.

Results: One specific AAV was identified as the optimal serotype, enabling efficient and specific endothelial transfection. A single injection of 10^8 AAV particles was confirmed as the minimum effective dose, inducing no significant immune responses with transgene expression sustained for at least 1.5 years. AAV-Chst5 delayed corneal opacity progression in adult MCD mice and prevented corneal clouding in 90% of juvenile MCD mice, maintaining long-term corneal transparency.

Mechanistically, the Chst5-Wnt5a signaling pathway in corneal endothelial cells was found to participate in MCD pathogenesis, providing novel insights into disease mechanisms.

Conclusions: This study establishes a safe, effective, and endothelium-specific AAV-mediated gene therapy strategy. A single anterior chamber injection of AAV-Chst5 achieves long-term prevention of MCD-induced corneal opacity. Mechanistic explorations identify new therapeutic targets, offering theoretical foundations for translational application of gene therapy in MCD.

Abstract No.: 204807

Five-Year Follow-Up of Telocyte Cells in Fresh Lenticule Transplantation for Advanced Keratoconus

First Author: Ceren Ece **SEMİZ**

Co-Author(s): Merjem **PURELKU**, Faruk **SEMİZ**, Gamze **TANRIVERDI**

Purpose: To investigate the presence and potential of telocytes in the stroma extracted via SMILE (Small Incision Lenticule Extraction) surgery from keratoconus patients several years post-treatment.

Methods: This retrospective study included 60 eyes with stage 2–3 keratoconus (Amsler–Krumeich), corneal thickness between 300–419 μm , and indication for penetrating keratoplasty. Exclusion criteria were active anterior segment pathology, corneal thickness $\geq 420 \mu\text{m}$, and prior corneal or anterior segment surgery. Fresh convex-shaped lenticules harvested from myopic SMILE donors were implanted into recipient corneas. To characterize telocytes and progenitor cells, six lenticule samples (one untreated and five postoperatively explanted at 1–5 years) were analyzed using CD34 immunohistochemistry, CD34/PDGFR- β and CD34/c-kit double immunofluorescence, and transmission electron microscopy.

Results: In the untreated keratoconic lenticule, CD34 staining revealed irregular, thinned collagen fibers and reduced stromal cell density with degenerative changes. At 1–3 years post-surgery, stromal cell density increased, including CD34-positive progenitor cells and telocytes, but declined after 4–5 years. Double immunofluorescence staining confirmed the unique immunophenotype and morphology of telocytes. At the 5-year follow-up, uncorrected distance visual acuity improved from 1.34 to 0.58 logMAR and corrected distance visual acuity from 1.11 to 0.43 logMAR. Central corneal thickness increased from 367.5 μm to 480.4 μm . K1 and K2 decreased from 53.16/59.93 to 51.35/54.89. The Q-value improved from –0.75 to –0.47. All changes were statistically significant ($p < 0.001$).

Conclusions: Fresh lenticule transplantation is a safe, cost-effective, and reliable procedure that enhances

corneal thickness, improves visual acuity, and facilitates corneal restoration.

Abstract No.: 206869

Gender Differences in Ocular Surface Health Metrics Among Drug Users

First Author: Yan Hei Yannis **CHAN**

Co-Author(s): Kelvin Kl **CHONG**, Kenneth Kh **LAI**, Calvin Cp **PANG**, Clement Cy **THAM**, Kin Yip **YIN**

Purpose: This study investigates gender differences in ocular surface health among drug users, focusing on disparities in ocular health metrics between males and females.

Methods: 53 participants (16 females, 37 males) reporting regular drug use (cocaine or ice use within the past 24 months, at least 6 months which the subject used 24 times) were recruited, under the project supported by Beat Drug Fund (BDF210067). Comprehensive ocular assessments were conducted using the OCULUS Keratograph 5M, TearScience LipiView II Interferometer, and OSDI to evaluate ocular surface health.

Results: Significant gender-based differences were observed. Males had worse bulbar redness scores (median: 1.05) than females (median: 0.75, $p = 0.012$), indicating worse conjunctival hyperemia. Males showed a lower tear interferometric pattern score (median: 3) compared to females (median: 4, $p = 0.0295$), suggesting poorer tear film stability. Signs of meibomian gland dysfunction were more pronounced in males, with more shortening of the lower lid (median: 3 vs. 2, $p = 0.0391$) and higher meiboscores (median: 3 vs. 2, $p = 0.0111$). However, interestingly, females reported greater ocular discomfort, with a median OSDI score of 19.64 compared to 12.5 in males ($p = 0.0247$).

Conclusions: The findings highlight significant gender differences in ocular surface health among drug users. Males exhibited more severe signs of dysfunction and inflammation, yet females reported increased discomfort. These results underscore the need for gender-specific approaches in diagnosing and managing ocular surface diseases in drug users, warranting further research into underlying factors.

Abstract No.: 207285

Graft Detachment Rate Following Descemet Membrane Endothelial Keratoplasty Using a Short-Term High Intraocular Pressure Air Tamponade: A Clinical Observation

First Author: Chang LIU

Co-Author(s): Jie BAI, Zexia DOU, Ling LI, Shaowei LI, Lin ZHAO

Purpose: To evaluate the rate of graft detachment following DMEK using a Short-term High Intraocular Pressure Air Tamponade (SHPAT) technique.

Methods: In this retrospective study, 124 consecutive patients who underwent DMEK with SHPAT application between January 2023 and August 2025 were included. The surgical procedure involved optical coherence-assisted air injection into the anterior chamber to position the graft, followed by air filling to maintain an intraocular pressure >40 mmHg for 2 hours. Half of the air was then released to prevent pupillary block. The primary outcome was the postoperative graft detachment rate.

Results: Among the 124 DMEK procedures performed with SHPAT, graft detachment occurred in 27 cases (20.8%). The detachment group had a significantly higher proportion of patients with a history of glaucoma surgery (10 cases) or vitrectomy (4 cases) compared to the non-detachment group ($P = 0.006$). Additionally, at 2 hours postoperatively, 16 patients in the detachment group exhibited anterior chamber air filling of less than two-thirds of the chamber depth, which was significantly more frequent than in the non-detachment group ($P = 0.003$). The overall detachment rate in this cohort was lower than the range commonly reported for conventional DMEK procedures in the literature (26–56%).

Conclusions: The application of SHPAT in DMEK surgery is associated with a relatively low graft detachment rate. This technique facilitates faster visual recovery and minimizes potential endothelial cell damage. It appears to be a safe and effective adjunct for improving early graft adherence, particularly in high-risk eyes. Further prospective studies are warranted to validate its efficacy across broader populations.

Abstract No.: 202890

Helicobacter pylori Infection's Dual Impact on the Ocular Surface: Tear Secretion Disruption and Ocular Surface Microbiome Alteration

First Author: Yinjie GUO

Co-Author(s): Xiaobo XIA

Purpose: To investigate the impact of *Helicobacter pylori* (*H. pylori*) infection on ocular surface homeostasis, including dry eye symptoms, ocular microbiota alterations, and related immune responses.

Methods: A total of 31 *H. pylori*-positive (*Hp_pos*) and 30 *H. pylori*-negative (*Hp_neg*) subjects underwent dry eye assessments, including the Schirmer I test, non-invasive keratograph tear breakup times (NIKf-BUT, NIKav-BUT), tear meniscus height, meibomian gland loss, and the Ocular Surface Disease Index (OSDI). Sterile swabs were used to collect samples from each eye of subjects for 16S rRNA sequencing. Additionally, a murine *H. pylori* infection model was established to evaluate dry eye phenotypes and immune responses in the lacrimal gland.

Results: Compared with *Hp_neg* subjects, *Hp_pos* subjects showed significantly reduced Schirmer I test results, NIKf-BUT, and NIKav-BUT, along with higher OSDI scores (all $p < 0.05$), whereas tear meniscus height and meibomian gland loss did not differ between the two groups. The ocular surface microbiota of *Hp_pos* subjects exhibited altered alpha and beta diversity, with 10 enriched genera (dominated by *Veillonella* and *Capnocytophaga*), which were characteristically associated with dry eye manifestations. In the murine model, infected mice at 6 weeks post-infection displayed aqueous tear deficiency, corneal epithelial barrier impairment, lacrimal gland infiltration of CD4+ and CD45+ T lymphocytes, and upregulated proinflammatory cytokines (IFN- γ , IL-17A, IL-4, TGF- β , TNF α , IL-6, IL-1 β). However, no significant differences were observed at 2 or 4 weeks post-infection.

Conclusions: *H. pylori* infection disrupts tear secretion and ocular surface microbiota, potentially via inducing T lymphocyte infiltration and lacrimal gland inflammation, contributing to dry eye pathogenesis.

Abstract No.: 207471

Hexokinase-2 Inhibition Enhances Antiviral Signaling and Corneal Healing in HSK

First Author: Wei CHEN

Co-Author(s): Dan JIANG

Purpose: Herpes simplex keratitis (HSK) is a leading cause of infectious corneal blindness, and type I IFN responses are often blunted in HSV-1-infected corneas due to viral immune evasion and metabolic reprogramming.

Methods: RNA sequencing of corneal tissues from HSK patients identified significant glycolytic upregulation, particularly hexokinase-2 (HK2). HSV-1-infected corneal epithelial cells and mice were treated with HK2 inhibitors (2-DG or Ionidamine), evaluating antiviral signaling, HK2-MAVS interaction, viral load, and corneal healing.

Results: HK2 knockdown or inhibition with 2-DG or Ionidamine reduced viral proteins and enhanced interferon-stimulated gene expression. HK2 inhibition restored MAVS-TBK1-IRF3 signaling. In vivo, topical HK2 inhibition decreased corneal viral load and accelerated epithelial regeneration.

Conclusions: HK2-driven glycolytic reprogramming contributes to HSK pathogenesis. HK2 inhibition restores antiviral signaling, suppresses HSV-1 replication, and promotes corneal healing, offering a promising therapeutic strategy complementary to existing antivirals.

Abstract No.: 206383

Hong Kong Cross-Cluster, Collaboration for Corneal Neurotisation (HKC4N)

First Author: Julia **CHAN**

Co-Author(s): Karen Kar Wun **CHAN**, Tor **CHIU**, Kam Lung Kelvin **CHONG**, Wing See Vanessa **CHOW**, Wai Shan Sophia **KO**, Stephanie Hiu Wai **KWOK**, Eugenie **MOK**, Wenjin **WANG**, Alvin Lerrmann **YOUNG**, Kwok Lai Hunter **YUEN**

Purpose: To report the formation of a cross-cluster, multidisciplinary team (MDT) and early (6-month) outcomes of the first two unilateral corneal neurotization (CN) procedures in Hong Kong.

Methods: An MDT consisting of corneal and oculoplastic surgeons from two cross-cluster tertiary referral eye centers, as well as plastic surgeons from a teaching hospital, was established. The MDT met monthly to develop standard operating procedures for CN-related staff and instrumental preparation. The first CN operation was performed on a 50-year-old Chinese male who suffered right-sided neurotrophic keratopathy (NK) and a Cochet-Bonnet Asthesiometer (CBA) score of 1mm over 4 quadrants after a stroke using autologous sural nerve graft (ASNG) co-apted to the ipsilateral supraorbital and supratrochlear nerves (SON & STN). The second CN procedure was performed on a 42-year-old female for right-sided NK with a CB score of 1mm post-right petroclival meningioma removal using contralateral SON & STN and ASNG.

Results: Both CN operations were successfully conducted, and both patients showed uneventful postoperative recovery without any donor-site or operative-related complications. Early (6-month) outcomes, including vision, corneal structural, and sensation-related parameters, will be updated.

Conclusions: The formation of a cross-cluster MDT facilitated the smooth adoption of CN in HK using existing limited resources, and may continue to benefit CN patients across the rest of the territory.

Abstract No.: 207841

Impression Cytology-Based Quantitative Proteomics and Network Analysis of Conjunctival Cells in Diabetic Patients With Dry Eye

First Author: Sihan **DONG**

Co-Author(s): Guannan **HUANG**, Shu **YANG**, Jing **ZHANG**

Purpose: Dry eye disease (DED) is a common ocular complication in patients with diabetes mellitus (DM), yet its underlying pathophysiological mechanisms remain incompletely understood. This study aimed to investigate conjunctival proteomic alterations and molecular networks in diabetic patients with DED using impression cytology (IC) and advanced bioinformatics.

Methods: Conjunctival epithelial samples were collected via IC from four groups: (A) DM with DED, (B) DM without DED, (C) non-diabetic with DED, and (D) healthy controls (n=15 per group). Proteins were extracted and analyzed using isobaric tags for relative and absolute quantification (iTRAQ)-based proteomics. A total of 650 consistently quantified proteins were subjected to weighted gene co-expression network analysis (WGCNA) to identify key modules and hub proteins. Differential expression was validated by immunohistochemistry (IHC).

Results: iTRAQ analysis identified 1,814 quantifiable proteins, with significantly differentially expressed proteins among groups. WGCNA revealed 16 protein modules, with the Cyan module showing the strongest positive correlation with diabetic DED. Protein-protein interaction network analysis identified HP, HPX, and FGG as central hub proteins, significantly upregulated in diabetic DED. Gene Ontology enrichment highlighted pathways involved in acute-phase response, inflammation, and immune regulation. IHC confirmed elevated expression of HP, HPX, and FGG in conjunctival tissues of diabetic DED mice.

Conclusions: This study provides the first conjunctival proteome profile of diabetic DED using IC-based iTRAQ proteomics. Findings implicate key inflammatory and immune-related proteins in disease pathogenesis, offering potential biomarkers and therapeutic targets for diabetic DED.

Abstract No.: 201643

Improving the Diagnostic Efficiency of Forme Fruste Keratoconus by a New Combined Model With Fourier Parameters and Corneal Epithelial Aberrations

First Author: Rui **NING**

Co-Author(s): Jinhai **HUANG**, Yue **LI**

Purpose: To explore a new method to improve the diagnostic efficiency of forme fruste keratoconus (FFKC) using the combination of Fourier parameters and corneal epithelial aberrations.

Methods: This prospective study enrolled 55 FFKC patients and 68 healthy subjects. The same experienced operator performed Casia 2 and MS-39 examinations to obtain Fourier parameters and corneal epithelial aberrations of the cornea. Independent-samples T tests were applied to compare statistical differences between the two groups. Significant variables were selected through dual logistic regression analysis with a stepwise method. The areas under the receiver operating characteristic curves (AUROC) were calculated to estimate the diagnostic ability for each parameter and the combined model, and the Youden index was used to determine the cut-off value. Delong test was performed to compare the differences among the AUROC in different conditions.

Results: The spherical component in Fourier parameters of the posterior surface of the cornea ($P = 0.002$), the asymmetry of the posterior surface of the cornea ($P \leq 0.001$), the higher-order irregularity in Fourier parameters at the posterior surface of the cornea ($P = 0.026$), and corneal epithelial Z ($3, \pm 1$) coma ($P = 0.035$) were selected as explanatory variables. The combined model demonstrated significantly improved diagnostic efficiency with the highest AUROC value of 0.95. And the AUROC of the combined model was significantly different from that of the single parameter ($P \leq 0.05$).

Conclusions: The integration of Fourier parameters and corneal epithelial aberrations holds potential in enhancing the diagnostic efficacy of FFKC, thus serving as a valuable reference for future clinical applications.

Abstract No.: 202738

In Vitro Killing Effect of Berberine and Niclosamide on Ocular Demodex folliculorum

First Author: Yuwen LIU

Co-Author(s): Shujia GUO, Zuguo LIU

Purpose: To explore the in vitro killing effect of water-soluble berberine and lipid-soluble niclosamide against ocular Demodex folliculorum.

Methods: Demodex with good vigor were collected from patients' eyelashes. These mites were randomly distributed into different groups with 20 mites in each group. Saline, Double Distilled Water (DDW), Polysorbate 80 (TWEEN 80), Polyethylene glycol 300 (PEG 300) and Castor Oil were used to screen solvents and cosolvents. 20 % Tea Tree Oil (TTO) and Anhydrous Ethanol (EtOH) were used as positive controls. 0.2 % Berberine, 0.25 % Niclosamide and 0.5 % Niclosamide, were designated as experimental groups. Following treatment, the analysis of Kaplan-Meier survival curves and survival time of mites and safety of drugs were then performed.

Results: The survival of Demodex in vitro in Saline and DDW, was not significant different. Therefore, DDW, which was more conducive to the dissolution of

berberine, was chosen as the solvent for berberine. 0.2 % Berberine significantly inhibited the survival distribution and survival time ($P < 0.001$) of Demodex in vitro compared with the DDW group. Through the evaluation of several cosolvents, PEG300 had milder effects on Demodex. Hence, the proportion of PEG300 in the niclosamide solvent group was increased to reduce the irritability of the vehicle. Furthermore, niclosamide could significantly inhibit the survival of Demodex compared with the vehicle group, and the effect of 0.5 % Niclosamide was more obvious ($P < 0.001$), and was better than 20 %TTO ($P < 0.001$). In addition, after niclosamide administration, Demodex bodies exhibited gradual distortion along with increased transparency and the presence of blurred dark particles compared to those in the vehicle group. Moreover, both drugs showed good subjective tolerability and safety in a mouse model.

Conclusions: 0.2 % berberine and 0.5 % niclosamide effectively inhibited Demodex survival in vitro, with 0.5 % niclosamide superior to 20 % TTO. These two drugs, with anti-Demodex, anti-bacterial, and anti-inflammatory properties, may offer alternative treatment for Demodex blepharitis.

Abstract No.: 206584

In Vivo Confocal Microscopic Study of Cornea Verticillata and Limbus Deposits in Patients With Fabry Disease

First Author: Chenying BAO

Co-Author(s): Yuan WU, Xuecong ZHOU

Purpose: This study aimed to investigate the microstructure characteristics of cornea verticillata and limbus deposits in patients with Fabry disease (FD) using in vivo confocal microscopy (IVCM).

Methods: A total of 60 eyes from 30 patients diagnosed with FD were examined and compared with 36 eyes from 18 healthy controls in this prospective, cross-sectional, controlled, single-center study. The initial assessment of cornea verticillata (CV) was conducted using slit-lamp microscopy. Subsequently, IVCM was performed to assess deposits in the corneal and limbal epithelium. We compared the differences between the sexes (heterozygous and hemizygous) and phenotypes (classical and non-classical).

Results: The epithelial deposit detection rate with IVCM was statistically higher (52/60, 86.67%) compared to the biomicroscopic evaluation of CV using a slit lamp (46/60, 76.67%) ($p = 0.031$). A higher prevalence of corneal epithelial deposits was observed in the classical phenotype as compared to the non-classical phenotype ($p = 0.023$). Surprisingly, cardiac variants previously lacking cornea verticillata show a high prevalence (85.71%) of corneal epithelial deposits under IVCM. The prevalence and severity of deposits, especially in limbal epithelial rete pegs, were higher in FD than in controls ($p < 0.001$).

Conclusions: Compared with slit-lamp microscopy, IVCN provides a more effective tool for examining epithelial deposits in patients with FD. Patients with FD demonstrated a profound bilateral increase in corneal epithelial deposits and limbal hyperreflective cells compared to controls, with more prominent pathological changes observed in classical phenotype individuals. The high prevalence of epithelial deposits in the cardiac variant highlights the essential ability of IVCN as an effective diagnostic tool.

Abstract No.: 204670

Integrating Clinical and Mitochondrial Insights to Understand Keratoconus Progression

First Author: Shivam SHARMA

Co-Author(s): Seema KASHYAP, Tapas Chandra NAG, Seema SEN, Namrata SHARMA, Lata SINGH

Purpose: Keratoconus (KC) is a progressive corneal ectatic disorder causing visual impairment, primarily in young individuals. This study comprehensively evaluates clinical risk factors, disease severity, management outcomes, alongside mitochondrial DNA (mtDNA) variations, its morphological appearance and oxidative stress gene profiles to better understand KC pathogenesis and therapeutic implications.

Methods: A prospective study involving 710 KC patients documented demographics, environmental and hereditary risk factors, and corneal topographic severity. Outcomes after corneal cross-linking (CXL), deep anterior lamellar keratoplasty (DALK), and scleral lens fitting were assessed over follow-up. Additionally, subset of 50 patients underwent whole mtDNA sequencing of paired blood and corneal tissue, relative mtDNA copy number quantification by qRT-PCR, mitochondrial ultrastructural examination by TEM, and oxidative stress gene expression analysis.

Results: Mean diagnosis age was 21.6 years; 69.3% were males. Key risks included eye rubbing (64.1%) and atopy (62.4%). Disease severity was mild (31.1%), moderate (49.3%), and advanced (19.6%). CXL stabilized early/moderate KC while DALK markedly improved advanced cases. Scleral lenses enhanced vision in irregular astigmatism and post-surgical eyes. Molecular analysis identified 589 mtDNA coding variations, including 297 pathogenic mutations, with significant mtDNA depletion and ultrastructural mitochondrial damage. Oxidative stress-related genes SCARA3, HMOX1, SOD2, GPX4, and NRF2 were downregulated, while PRDX6 and NOX4 were upregulated, reflecting disturbed redox homeostasis.

Conclusions: This integrative clinical and molecular study highlights demographic and treatment features alongside mitochondrial genomic instability and oxidative stress dysregulation as central to KC pathophysiology. These molecular markers

hold promise as biomarkers for progression and personalized therapy guidance.

Abstract No.: 208507

Intense Pulsed Light Therapy for Moderate-to-Severe Perennial Allergic Conjunctivitis: Clinical Efficacy and Tear Fluid Untargeted Metabolomics

First Author: Qiu YAN

Purpose: To evaluate the clinical efficacy of intense pulsed light (IPL) in moderate-to-severe perennial allergic conjunctivitis (PAC) and investigate its potential mechanisms via analysis of tear inflammatory factor and untargeted metabolomics.

Methods: In this prospective self-controlled study, 18 patients received two IPL treatments at two-week intervals. Outcomes included symptom visual analog scale (VAS) scores and sign scores, bulbar redness index (BRI), tear breakup time (TBUT), and tear inflammatory factors (IgE, MMP-9, LTA). Untargeted metabolomics of tear fluid was performed using LC-MS/MS to identify differential metabolites and pathways.

Results: After treatment, symptom VAS scores [median difference: -25.0 (95% CI: -31.0, -21.0); $P < 0.01$] and sign scores [median difference: -4.0 (95% CI: -6.0, -4.0); $P < 0.01$] showed significant improvement. No significant changes were observed in TBUT or BRI. Although tear IgE and MMP-9 levels tended to decrease and LTA tended to increase, these changes didn't reach statistical significance. MMP-9 was positively correlated with BRI post-treatment ($r^* = 0.570$, $P < 0.05$), while LTA was negatively correlated with BRI at baseline ($r^* = -0.573$, $P < 0.05$). Untargeted metabolomics identified 65 differential metabolites. Adenine, guanine, adenosine, inosine, hypoxanthine, and stearic acid were downregulated, while oleic acid, 9-OxoODE, erucic acid, isobutylamine, and L-phenylalanine were upregulated. Key enriched pathways included purine metabolism and unsaturated fatty acid biosynthesis.

Conclusions: IPL alleviates moderate-to-severe PAC by reprogramming purine metabolism and unsaturated fatty acid biosynthesis, which suppresses purine activity and pro-inflammatory lipids while enhancing anti-inflammatory and antioxidant unsaturated fatty acids, thereby restoring ocular surface homeostasis.

Abstract No.: 205794

Interim Clinical Study Results of EndoArt®: A Novel Artificial Corneal Endothelial Layer for the Treatment of Chronic Corneal Edema

First Author: Zelin ZHAO

Co-Author(s): Wei CHEN, Jinyang LI

Purpose: To present interim outcomes of EndoArt® implantation in patients at high-risk for graft rejection.

Methods: EndoArt® (EyeYon Medical, Israel) is a water-impermeable implant that adheres to the posterior cornea, thereby limiting stromal hydration and reducing corneal edema. A prospective, multicenter, randomized, 2-arm-superiority study of 62 patients evaluated the safety and efficacy of EndoArt®. At Wenzhou Medical University Eye Hospital, five patients underwent EndoArt® implantation, and eight were treated with a bandage contact lens as the control arm.

Results: In the EndoArt® group, BCVA (best corrected visual acuity) improved from $1.65 \pm 0.49 \log \text{MAR}$ to $0.66 \pm 0.22 \log \text{MAR}$ ($p < 0.05$). Despite limited visual potential, all EndoArt® group gained ≥ 7 ETDRS (Early Treatment Diabetic Retinopathy Study) lines (range 7–15). CCT (central corneal thickness) decreased from $669 \pm 14 \mu\text{m}$ preoperatively to $485 \pm 28 \mu\text{m}$ at last follow-up (5.1 ± 3.6 months). Re-bubbling was performed in 2/5 eyes for better attachment. No infections, inflammation, or device-related adverse events occurred. Controls remained above normal CCT and showed no significant BCVA improvement ($p = 0.2$).

Conclusions: The implant demonstrated safety and efficacy in treating chronic corneal edema in high-risk patients prone to graft rejection. EndoArt® implantation safely reduced edema and significantly improved vision, demonstrating superiority over bandage lens in restoring corneal deturgescence. As a non-biologic device not subject to rejection, EndoArt® may provide a durable solution for patients at risk of tissue failure.

Abstract No.: 202843

Intraoperative Optical Coherence Tomography Guided Precise Corneal Suture in the Treatment of Acute Keratoconus

First Author: Suxia LI

Co-Author(s): Weiyun SHI

Purpose: This study aimed to observe the clinical efficacy of precise suturing of posterior elastic layer fissures guided by intraoperative optical coherence tomography (iOCT) in conjunction with corneal thermokeratoplasty for the treatment of severe acute edematous keratoconus.

Methods: Eighteen patients in the study group underwent precise suturing of posterior elastic layer fissures guided by iOCT, in combination with corneal thermokeratoplasty. Thirteen patients were in the control group. Preoperative visual acuity, corneal edema diameter, corneal thickness, and posterior elastic layer fissure length were collected. Evaluation was performed to assess the time of initial postoperative corneal edema resolution and closure of the posterior elastic layer fissure. The corneal bed scar repair and visual acuity of the two groups were compared after deep lamellar keratoplasty.

Results: In the suturing group, the cornea of all 18 patients was accurately sutured to the deep stromal layer near the posterior elastic layer. The time for corneal edema resolution was 2.50 (1.00, 6.25) days in the suturing group and 7.00 (6.00, 10.50) days in the control group. The fissure healing time was 7.50 (7.00, 12.00) days in the suturing group and 14.00 (9.00, 14.00) days in the control group. All 18 patients in the suturing group successfully completed deep lamellar keratoplasty.

Conclusions: In the treatment of severe acute edematous keratoconus, precise suturing of posterior elastic layer fissures and corneal thermokeratoplasty can rapidly alleviate corneal edema and promote the healing of posterior elastic layer fissures. The use of iOCT guidance makes more safety, thereby assisting surgeons in precise suturing.

Abstract No.: 207029

Introduction of a Grading System in Descemet Membrane Endothelial Keratoplasty (DMEK) Graft Preparations in Wetlab Training Before Transitioning to Actual Clinical Cases for Successful Outcomes

First Author: Ronak SOLANKI

Purpose: DMEK is fundamentally limited by the steep technical learning curve associated with the preparation and handling of the ultra-thin donor graft. The purpose of the study is to establish a quantitative, objective grading rubric for pre-clinical wet lab assessment, ensuring a surgeon meets defined, evidence-based proficiency benchmarks before undertaking their first procedure.

Methods: This grading system adapts 8 critical steps of donor preparation, i.e., Partial Trephine, Scoring of DM edge, Initial Peeling of DM, Dermal Punch, Stromal F Stamp, Final Donor punch, Final Peeling, and obtaining Free Graft, Loading in glass tube, and evaluation of Mean Donor Graft Preparation Time.

Results: The overall mean Preparation Time across all cases was 16.33 minutes. Time significantly decreased, demonstrating a clear learning curve progression: 19.85 minutes (cases 1–10), 15.55 minutes (cases 11–20), and 13.6 minutes (cases 21–30). Step-specific scoring revealed high proficiency in core technical maneuvers: Partial Trephine (100%), Scoring of DM edge (100%), Initial Peeling of DM (100%), Dermal Punch (100%), and Final Donor Punch (100%). Final integrity steps, including Final Peeling and Graft Loading, were also highly successful (96.7% each). However, critical areas for refinement included the Stromal F-Stamp (13.3% score, often smudged) and the management of Peripheral Tears (13.3% score) and Central Tears (3.3% score), highlighting persistent handling challenges.

Conclusions: Using the grading system improves competence in peeling, punching, marking, peripheral

and central tear management, and highlights the need for targeted training to ensure optimal graft quality, orientation, and, ultimately, improved clinical outcomes when subsequently doing actual clinical cases.

Abstract No.: 206988

Keratitis Due to Pigmented vs. Nonpigmented Fungi: Clinical Features and Outcome

First Author: Sujata DAS

Co-Author(s): Shalvika GUPTA, Smruti PRIYADARSHINI

Purpose: To compare the demographics, clinical characteristics, and treatment outcomes of pigmented versus non-pigmented fungal corneal ulcers.

Methods: A retrospective analysis was carried out on 100 consecutive culture-proven cases of keratomycosis (pigmented [n=50] and non-pigmented [n=50]) who presented between Jan-2024 to Jun-2024 at the L V Prasad Eye Institute, Bhubaneswar, India.

Results: There was no significant difference in ulcer size or presenting visual acuity between the two groups. Macroscopic pigmentation was observed in only 16% of eyes with keratitis due to pigmented fungus. Both groups responded favorably to medical therapy with similar rates of infiltrate resolution and scar formation. The final visual acuity was not significantly different between the groups. However, a trend towards higher frequencies of therapeutic penetrating keratoplasties and eviscerations was observed in the non-pigmented group compared to the pigmented group.

Conclusions: Macroscopic pigmentation was proven to be an unreliable diagnostic indicator. While medical therapy showed similar efficacy in both groups, the requirement for surgical interventions differed. These findings highlight the importance of species-specific treatment protocols and the need for aggressive management of deep ulcers to improve visual outcomes.

Abstract No.: 204158

Keratoconus Severity and Asymmetric Tomographic Patterns Between Eyes in Individuals With Down Syndrome: A Cross-Sectional Study From Southern India

First Author: Anitha VENUGOPAL

Co-Author(s): Nambi NALLASAMY, Meenakshi RAVINDRAN

Purpose: To evaluate the patterns of severity of Keratoconus and tomographic characteristics as classified by the Amsler Krumeich classification among individuals with Down syndrome.

Methods: We conducted a cross-sectional study at two tertiary eye care centres in Tamil Nadu, South India, in 192 eyes of 96 patients with Down syndrome and keratoconus (55 males, 41 females; mean age: 15.7 ± 7.3 years). Participants were classified into four

KC stages using Amsler-Krumeich classification with rotating Scheimpflug imaging (Pentacam HR) and slit-lamp biomicroscopy. Key parameters included mean keratometry (K), corneal thickness (CT), astigmatism, ARTmax, higher-order aberrations (HOA), and pachymetry.

Results: The tomographic indices, such as ARTmax and ZKmax, were the most statistically significant parameters for differentiating KC eyes from non-KC eyes. DSKC groups were divided into stages I (31), stage II (41), stage III (11) and stage IV (13), with 75% in the early stages of disease. As the severity increases, corneal parameters such as mean CT, mean K, astigmatism, ZKmax, HOA, and PE at the thinnest point show significant correlation with disease progression and are comparable to the results from other geographic locations among individuals with Down syndrome and Keratoconus. Logistic regression further confirms that these parameters, particularly mean CT, mean K, and astigmatism, are strongly associated with more severe stages of KC. Conversely, ARTmax, ARC and PRC are negatively related to the severity of KC in DS. I-S value and AVC showed weaker associations

Conclusions: The study highlights the need for early and targeted screening of KC in individuals with DS.

Abstract No.: 206040

Late-Onset Asymmetric Lattice Corneal Dystrophy: Documenting the H626R Phenotype

First Author: Vy LY NGOC PHUONG

Co-Author(s): Anthony J. ALDAVE, Doug CHUNG, Nguyen Viet Huong DUONG, Huan PHAM NGUYEN, Jhuwala VENKATAKRISHNAN

Purpose: To illustrate the characteristic asymmetric presentation of lattice corneal dystrophy through a case of 10-year delayed bilateral involvement in a young female, emphasizing the importance of long-term surveillance.

Methods: Case report.

Results: A 38-year-old female was diagnosed with unilateral lattice corneal dystrophy in the left eye (OS) in 2015. In 2021, she developed keratitis in the affected eye, leading to further deterioration of vision. Clinical examination revealed significant visual impairment in the OS with visual acuity of 4/10 vs 10/10 in the right eye (OD). A slit-lamp examination showed precipitates in the corneal stroma and corneal scarring in the OS. Sclerotic scatter showed lattice-like branching stromal lines in the OS. Initially, AS-OCT revealed hyperreflective deposits in the OS cornea. Genetic analysis of exon 14 of the TGFBI gene identified a pathogenic H626R variant (CAT>CGT heterozygous) associated with Lattice corneal dystrophy. Recent AS-OCT imaging shows the OD is beginning to develop

mild hyperreflective deposits 10 years after the initial diagnosis in the left eye.

Conclusions: This case exemplifies the characteristic asymmetric phenotype of H626R-associated lattice corneal dystrophy, demonstrating the typical delayed bilateral progression that defines this mutation's clinical signature and underscores the critical importance of lifelong bilateral surveillance.

Abstract No.: 203116

Long-Term Outcome and a Risk Score of Moderate to High Risk Corneal Transplantation

First Author: Zhewen **ZHENG**

Co-Author(s): Shiyu **ZHOU**

Purpose: To develop a risk score for moderate to high risk penetrating keratoplasty based on the risk factors of corneal transplantation, using the score to reclassify the moderate to high risk cohort.

Methods: This retrospective cohort study analyzed data from 2,298 moderate-to-high-risk grafts that underwent penetrating keratoplasty at Zhongshan Ophthalmic Center between January 1, 2012, and December 31, 2022. The clinical characteristics and survival status of the patients were obtained from electronic health records. The primary outcome was graft survival probability. We included 14 recipients, 2 transplant procedural, and 2 post-transplant factors. These factors were assessed using multivariate Cox regression (entry criterion: $P < 0.05$). Using the selected variables, we constructed a risk score based on the coefficients derived from the Cox PH (Cox proportional hazards) model. Risk stratification was performed based on the survival curves of risk score.

Results: A total of 2,298 moderate to high risk grafts underwent PK during the study period. The moderate to high risk grafts from January 1, 2012, to December 31, 2021, were randomly grouped into training (1,338 eyes), test (573 eyes), and temporal validation datasets (387 eyes). The 1-, 3-, 5-, and 7-year graft survival rates were 63.0%, 40.3%, 34.6%, and 32.2%, respectively. Six factors were finally identified. The AUC (Area under the Curve) of the risk score in the external validation set was 0.747. The study reclassified the moderate to high risk grafts into three groups: moderate-risk group (0-2 points), high risk group (3-5 points) and extremely high risk group (≥ 6 points), the survival curves across these stratified groups differed significantly (log-rank test, $P < 0.001$).

Conclusions: The risk score demonstrates good discriminatory ability for moderate to high risk corneal grafts and can further stratify these grafts.

Abstract No.: 202894

Long-Term Outcomes of Penetrating Keratoplasty or Lamellar Keratoplasty for Macular Corneal Dystrophy: A Multicenter Retrospective Cohort Study

First Author: Jun **CHENG**

Purpose: To compare the long-term efficacy of penetrating keratoplasty (PKP) and lamellar keratoplasty (LKP) in the treatment of macular corneal dystrophy (MCD).

Methods: Retrospective cohort study from six tertiary ophthalmic clinical centres. Data were collected retrospectively from chart review and electronic patient records for all patients during the study period. A 1:2 performed propensity score matching was used to minimize potential bias between the LKP and PKP groups. Kaplan-Meier survival curves and Cox proportional hazards regression models were used for analyses of graft survival and recurrence risk factors.

Results: A total of 307 eyes of 220 patients with MCD who underwent primary PKP or LKP between January 1, 1992, and December 31, 2023. The average follow-up duration was 9.4 ± 6.1 years (range: 1.0-32.8 years). There were no significant differences in VA between the PKP and LKP groups at 1, 5, and 10 years post-surgery. However, at 15 and 20 years postoperatively, the VA in the LKP group was significantly lower than that in the PKP group ($P = 0.000$ and $P = 0.014$, respectively). The long-term visual prognosis of patients < 40 years after undergoing PKP is better than that after LKP. The median graft survival time was 23.3 years in the PKP group and 9.1 years in the LKP group ($P < 0.0001$). The postoperative recurrence rate in the PKP and LKP groups was 10.2% and 48.1%, respectively ($P < 0.0001$). The risk of recurrence in the LKP group was 8.70 times higher than that in the PKP group (95% CI: 4.595–16.47, $P < 0.0001$). Multivariable analysis revealed that age at surgery ($P = 0.002$) and femtosecond laser preparation of the host bed ($P = 0.005$) were independent risk factors for recurrence after LKP. While no risk factors associated with recurrence after PKP were identified. Endothelium dark areas and guttae were found after surgery in the LKP group. Nine patients (11.4%) developed endothelial dysfunction after LKP, with a mean age of dysfunction of 58.7 ± 6.8 years (range: 45.2-70.0 years). Patients in the PKP group reported significantly higher satisfaction scores than those in the LKP group (8.5 ± 1.9 vs. 7.8 ± 1.8 , $P = 0.030$).

Conclusions: In the long run, PKP is a better option for treating MCD patients, as there is a relatively high recurrence rate after LKP. We should give more consideration to the corneal endothelial function when choosing the surgical method for elderly patients.

Abstract No.: 200320**Mechanism of Corneal Epithelial Wound Healing Defect in Patients With Rheumatoid Arthritis***First Author: Jiang BIAN*

Purpose: To explore the underlying mechanism of poor corneal epithelial wound healing in patients with rheumatoid arthritis (RA).

Methods: Ocular conditions were evaluated by slit-lamp examination, measurement of corneal epithelial repair time, Ocular Surface Disease Index (OSDI) scoring. Proteomic techniques were employed to screen for differential factors in tears. In vitro, corneal epithelial cells were treated with specific concentrations of differential factors. A collagen-induced arthritis mouse model (CIA) was established to observe the repair of ocular injuries, tear secretion, corneal sensitivity, and nerve repair in mice. Transcriptomic analysis was carried out, and combined with bioinformatics analysis, and mitochondrial electron microscopy, the effects of target inflammatory factors on corneal epithelial cells were investigated.

Results: It was found that the repair process of the corneal epithelium in RA patients was significantly slower after injury. Compared with the control group, the repair time was significantly prolonged. Proteomics revealed a significant increase in specific inflammatory factors in the tears of RA patients. Cell experiments demonstrated that the target factors could affect the proliferation, migration, and apoptosis of epithelial cells. CIA mice also exhibited slow corneal epithelial repair after injury, which was highly consistent with the manifestations of clinical patients. Transcriptomic analysis indicated abnormalities in mitochondrial-related biological processes such as mitochondrial translation and mitochondrial ATP synthesis.

Conclusions: Poor corneal epithelial wound healing in RA patients is closely related to the increase in specific inflammatory factors. This study provides a theoretical basis for the clinical treatment of RA-related corneal lesions.

Abstract No.: 203144**Mechanism of Resistance Difference Between C57 and Balb/C Mice to Pseudomonas aeruginosa Keratitis***First Author: Zhang ZHENZHEN*

Purpose: Pseudomonas aeruginosa is a gram-negative bacterium with strong virulence, which can invade the cornea through corneal wounds and cause acute corneal infection and ulcers. Previously we found C57 mouse cornea was highly susceptible to P. aeruginosa infection, while BALB/C showed strong resistance. Here, we studied the mechanism underlying the corneal resistance difference between these two mouse strains.

Methods: Fifteen C57 and BALB/C mice aged 6 to 8 weeks were selected for transcriptome sequencing. Corneal epithelial cells infected with 10^5 P. aeruginosa were collected. Cell invasion assay and Seahorse cell energy phenotype test were conducted.

Results: RNA sequencing showed 2342 genes were differentially up-regulated and 1563 genes were differentially down-regulated in BALB/C epithelium compared with C57. In the functional enrichment analysis, oxidative phosphorylation pathway showed the most significant difference, containing 15 up-regulated genes. The metabolic profiles were measured with the Seahorse XFp Flux Analyzer and XF cell mito stress test kit. Oxygen consumption rate (OCR) and extracellular acidification rate (ECAR) were determined in the presence of specific mitochondrial activators and inhibitors. We found there was no difference between these two mouse corneal epithelia before infection. When applied after infection, the inhibitor of oxidative phosphorylation-rotenone could exacerbate BALB/C corneal infectious severity.

Conclusions: RNA sequencing showed that there were significant differences in metabolism-related genes between BALB/C and C57 mouse corneal epithelial cells, suggesting that the resistance of BALB/C mice cornea to P. aeruginosa was related to oxidative phosphorylation pathway.

Abstract No.: 202826**Mesenchymal Stem Cell-Derived Secretome and Exosomes for Dry Eye: A Systematic Review of Preclinical and Clinical Evidence***First Author: Evelyn KOMARATIH**Co-Author(s): Chandra PRABASWARA, Siti ZAHRA AFIFAH*

Purpose: To systematically assess the therapeutic efficacy and safety of MSC secretome and exosome applications in dry eye, across preclinical and clinical studies.

Methods: Following PRISMA 2020 methodology, PubMed, Embase, Scopus, and Cochrane databases were searched (2015–2025). Eligible studies evaluated secretome or exosome interventions in experimental or clinical dry eye. Primary outcomes included tear volume, tear break-up time (TBUT), and ocular surface integrity. Risk of bias was assessed using SYRCLE's tool (animal studies) and the Newcastle-Ottawa Scale (clinical data).

Results: Ten studies met the inclusion criteria: nine animal experiments (94 subjects) and one randomized controlled trial in humans (n=40). Secretome treatment enhanced tear secretion ($p=0.008-0.01$), prolonged TBUT ($p=0.032$), increased goblet cell density nearly three-fold, and reduced fluorescein staining ($p=0.003$). Exosome administration further demonstrated substantial benefits, with tear secretion

improving more than two-fold, TBUT doubling, goblet cell counts rising significantly, and corneal fluorescein scores dropping by over 50% ($p < 0.001$). The clinical RCT corroborated these findings, showing sustained improvements in OSDI scores, TBUT, tear volume, and staining over 12 weeks (all $p < 0.05$). Importantly, no treatment-related adverse events were reported. Methodological concerns in animal studies included unclear allocation concealment and insufficient blinding.

Conclusions: Evidence from both animal and early clinical trials suggests that MSC-derived secretome and exosomes provide meaningful, safe, and durable improvements in dry eye outcomes. Nevertheless, further large-scale, rigorously designed clinical studies are required to validate these therapies and enable translation into routine ophthalmic practice.

Abstract No.: 202480

Microbiological Screening Methods for Donor Corneas: Impact on Graft Infections and Clinical Outcomes

First Author: Manvi **BANSAL**

Co-Author(s): Tushar **AGARWAL**, Aafreen **BARI**, Nishat **HUSSAIN**, Sridevi **NAIR**, Namrata **SHARMA**, Radhika **TANDON**

Purpose: The study aimed to evaluate the efficacy of microbiological screening methods for donor corneas and their correlation with clinical outcomes, particularly donor-related graft infections. The conjunctival tissue sampling method was compared with tissue storage media swab method and post operative donor rim tissue sampling, to ascertain the more effective technique for detecting microbial contamination of donor corneas.

Methods: This prospective observational study evaluated the microbiological contamination of donor corneal tissues retrieved over a 16-month period through a Hospital Cornea Retrieval Program (HCRP) at a tertiary eye care centre. Donor tissues were tested using 3 methods: tissue storage media swab cultures (conventional method), donor conjunctival tissue cultures (obtained at the time of corneo-scleral rim harvest), and corneo-scleral rim cultures after transplantation. The primary outcome measured was microbial positivity rates with the different testing methods. Secondary outcome measures were the correlation between the different sampling techniques and postoperative graft infection cases.

Results: Among 644 donor corneas analysed, media swab culture was positive in 6.67%. Conjunctival tissue culture showed a positivity rate of 38.09% and donor rim cultures had 38.01% positivity. Conjunctival tissue contamination significantly correlated with donor rim culture contamination ($p < 0.0001$), with no significant correlation with tissue storage media swab contamination ($p = 0.12$). Out of 644 tissues, 334

tissues were transplanted for non-infective indications, of which donor-related graft infection occurred in 1.49% ($n=5$) of keratoplasty cases. Conjunctival tissue cultures predicted the causative organism in 80% ($n=4$) of donor related graft infections, compared to 0% by storage media swabs and 40% predicted by donor rim cultures.

Conclusions: In a tropical setting, donor conjunctival tissue sample, obtained at the time of corneo-scleral rim harvest, can offer an early insight into the causative organism in cases of donor related corneal graft infections and can therefore aid in early institution of appropriate treatment.

Abstract No.: 203194

Motugivatrep, a TRPV1 Antagonist in Dry Eye Patients – Results of a Randomized, Double-Masked, Placebo-Controlled Phase 3 Pivotal Study

First Author: Yuichi **HORI**

Co-Author(s): Minoru **KANAMOTO**, Kazunori **OMATSU**, Tomoyuki **WADA**

Purpose: To confirm the efficacy and safety of motugivatrep 0.3% ophthalmic suspension in patients with dry eye disease.

Methods: A multicenter, randomized, double-masked, placebo-controlled, Phase 3 study was conducted in Japan. Outpatients aged ≥ 18 years with subjective dry eye symptoms (Dry Eye-related Quality of Life Score (DEQS) ≥ 1 , visual analogue scale (VAS) for eye dryness ≥ 40 , and 5-Item Dry Eye Questionnaire (DEQ-5) ≥ 6) and a mean tear break-up time of ≤ 5 seconds in both eyes were enrolled. After a 2-week placebo run-in period, participants were randomized 1:1 to receive either motugivatrep or placebo, four times daily for 8 weeks. The primary endpoint was the change in total DEQS from baseline at week 4.

Results: Of the 535 participants randomized, 268 received motugivatrep, and 267 received a placebo. At week 4, the DEQS score was significantly reduced by motugivatrep compared to placebo ($p=0.0433$). Statistically significant improvements were also observed in DEQS at all visits conducted between week 1 and week 4 and in eye dryness VAS at weeks 1 and 4 ($p < 0.05$). TEAEs were mild or moderate in severity. No serious TEAEs were reported.

Conclusions: Motugivatrep is the first-in-class TRPV1 antagonist that demonstrates efficacy and safety in patients with dry eye disease.

Abstract No.: 209011

Neurotrophic Keratopathy Patients After Minimally Invasive Corneal Neurotization Treated With rhNGF Eyedrops: A Case Series

First Author: Jin LI

Purpose: For patients with neurotrophic keratopathy (NK) induced by trigeminal nerve injury after intracranial surgeries, minimally invasive corneal neurotization (MICN) is a novel approach. However, the process of post-operative neurotization often lasts for over 2 years. Recombinant human nerve growth factor (rhNGF) is a new treatment targeting nerve growth in NK patients. Therefore, the authors applied rhNGF eyedrops to NK patients after MICN.

Methods: The authors highlight five cases that underwent MICN and were subsequently treated with rhNGF eyedrops. These cases include four patients who had undergone MICN over 1 year prior and one patient who had undergone MICN 6 months prior. Three patients who underwent MICN and were treated with conventional medications were enrolled as controls. Evaluation indicators included corneal sensation, sub-basal corneal nerve density, tear secretion and tear break-up time, best-corrected visual acuity, corneal epithelium condition, and clinical symptoms. All patients in the rhNGF group were treated with rhNGF eyedrops for 4 weeks.

Results: After 4 weeks of treatment with rhNGF eyedrops, corneal sensation significantly improved in all five patients. Corneal nerve fiber length and nerve branch density increased, and corneal nerve trunk diameter improved. Corneal damage was reduced, and best-corrected visual acuity improved. Compared to patients treated with conventional medications postoperatively, corneal sensation and nerve density, as well as corneal morphology, recovered more rapidly in the rhNGF group.

Conclusions: rhNGF eyedrops may accelerate the healing process of corneal neurotization and enhance corneal sensation. The optimal timing for initiating rhNGF eyedrops may depend on the baseline corneal nerve condition and the presence of Tinetti's sign, which typically occurs about 1 year after MICN.

Abstract No.: 200392

New Approaches of Corneal Epithelium Reconstruction in a Patient With Limbal Stem Cell Deficiency (LSCD)

First Author: Svetlana KALINNIKOVA

Co-Author(s): Sergey BORZENOK, Svetlana IZMAILOVA, Boris MALYUGIN

Purpose: To present the novel surgical methods of corneal epithelial reconstruction - Glueless Simple Limbal Epithelial Transplantation (G-SLET) with using Femtosecond laser assisted techniques.

Methods: The first modification of GSLET is to use the femtosecond laser (FSL) at the tunnel formation stage; n=65 patients were operated using this technology (FSL GSLET). The next generation of GSLET aims to develop program software and algorithms for the excision and fragmentation of limbs, which represents the most critical phase of the operation, n=10 (Full FSL GSLET). The last version of the GSLET technique was Femtosecond laser-assisted anterior (or deep) lamellar keratoplasty combined with GSLET, n=15. The follow-up period was 5 years. All these patients had LSCD after Ocular Burns.

Results: In the group of patients after FSL G-SLET, the anatomical success rate was 81% (stable re-epithelization), and functional success (improved visual acuity) 51,5%. The Full FSL GSLET group anatomical success was 70%, functional 50%. DALK combined with GSLET shows anatomical success 75%, functional 80%. Undoubtedly, the last two groups require more observations to conclude the results.

Conclusions: The FSL-assisted G-SLET is a new technique for autologous limbal stem cell transplantation in patients with unilateral LSCD. It allows for standardizing the corneal tunnel localization and dimensions, which increases the safety of the surgical procedure. Combined FSL-assisted DALK with autologous modified G-SLET is a preferred option for patients with unilateral LSCD and corneal opacity. It not only provides a stable ocular surface, but also significantly improves visual outcomes.

Abstract No.: 200647

Non-Contact Brill Esthesiometer: Large Cohort Study Investigating the Agreement With Contact Esthesiometer and Correlation With Corneal Nerve Metrics and Ocular Surface Assessments

First Author: Yu-chi LIU

Co-Author(s): Isabelle Xin Yu LEE, Chang LIU, Jodhbir MEHTA, Hon Shing ONG, Louis TONG, Regina Kay Ting WONG, Mingyi YU

Purpose: To evaluate the repeatability of the non-contact Brill esthesiometer (NBE), determine its agreement with Cochet-Bonnet esthesiometer (CBE), and investigate the relationship between corneal sensitivity, corneal nerve parameters, and ocular surface assessments.

Methods: This study included 880 eyes, comprising healthy controls (80 eyes), dry eye disease (DED, 170 eyes), neuropathic corneal pain (NCP, 140 eyes), post-refractive surgery (P-RS, 176 eyes), and diabetes mellitus (DM, 314 eyes). NBE and CBE measurements, in-vivo confocal microscopy for seven corneal nerve parameters, and four ocular surface parameters were assessed.

Results: NBE presented excellent intra- and inter-observer repeatability (both ICC>0.980, P<0.001). NBE measured significantly higher than CBE in all groups (all P<0.001). These inter-instrument measurements had good agreement in eyes with higher corneal sensitivity and showed significant correlations across all cohorts (all P<0.05). P-RS cohort exhibited the highest proportion of eyes within 95% limits of agreement (98.3%) and the strongest correlation ($r=0.853$, P<0.001) between NBE and CBE measurements. NBE measurements significantly correlated with corneal nerve parameters in control, DED, P-RS, and DM groups ($r=-0.157$ to -0.545 , all P<0.05), whereas CBE correlated with fewer nerve parameters. NBE measurements, to a greater extent than CBE, significantly correlated with ocular surface parameters in the control, NCP, and DM groups ($r=-0.126$ to -0.465 , all P<0.05).

Conclusions: NBE and CBE measurements showed good agreement at higher corneal sensitivity and are not interchangeable. NBE is potentially superior in reflecting corneal nerve and functional changes than CBE.

Abstract No.: 205953

Ocular Manifestations in Juvenile Xanthogranuloma and Histopathological Co-Relation: A Retrospective Case Series From a Tertiary Eye Care Centre in India

First Author: Swetha **BUGGAREDDIGARI**

Co-Author(s): Geetha K **VEMUGANTI**, Muralidhar **RAMAPPA**

Purpose: To describe the clinical spectrum, histopathological features, ocular involvement, and outcomes of juvenile xanthogranuloma in patients presenting to a tertiary eye care centre in India.

Methods: A retrospective review was conducted of 28 patients diagnosed with Juvenile Xantho Granuloma between 2002 and 2025 at a tertiary eye care centre. Data collected included demographics, site of involvement, clinical features, histopathology and immunohistochemistry, treatment, and outcomes.

Results: The cohort comprised 28 patients (17 females, 9 males, with ages ranging from neonates to 65 years). Eyelid and orbital lesions were the most frequent ocular adnexal manifestations. Intraocular involvement was rare ($n=2$; iris lesions with spontaneous hyphema with secondary glaucoma). Histopathology consistently demonstrated xanthogranulomatous inflammation with Touton giant cells, and IHC positivity for CD68 and Factor XIIIa with negativity for CD1a, S100, and Langerin. Surgical excision or debulking for extraocular lesions was effective, while topical, systemic, or intralesional corticosteroids were used in recurrent or diffuse lesions. Compared with published series, our findings highlight eyelid and orbital involvement as more frequent sites than the iris, which has been

reported as the predominant site in Western studies. The age spectrum extended beyond childhood, with adult-onset JXG accounting for several cases.

Conclusions: This represents one of the largest ocular juvenile xanthogranuloma case series reported from India. Juvenile xanthogranuloma is a benign, self-limiting histiocytic disorder, usually presenting as cutaneous lesions. Ocular and rarely systemic involvement necessitate careful evaluation, particularly in patients without skin lesions or with systemic associations. Early recognition and management are vital to prevent vision loss or systemic complications.

Abstract No.: 204788

Ocular Surface Toxicity of Novel Anti-Tumor Targeted Agents and Their Characteristics Under Confocal Microscopy

First Author: Wen Xin **ZHAO**

Co-Author(s): Li **LI**

Purpose: To characterize the ocular surface manifestations and in vivo confocal microscopy (IVCM) features associated with novel anti-tumor targeted therapies.

Methods: A retrospective analysis of 8 patients who developed ocular surface toxicity during treatment with novel targeted agents was conducted. All patients underwent detailed ophthalmic evaluation, including slit-lamp examination, corneal fluorescein staining, and IVCM.

Results: This study included a total of 8 patients, comprising 6 HER2-positive breast cancer patients on antibody-drug conjugate (ADC) therapy and 2 patients with advanced solid tumors treated with erlotinib. Two distinct toxicity profiles were identified: 1. ADC-associated ocular toxicity manifested as dry eye, characterized by reduced tear secretion, conjunctival injection, and punctate epithelial erosions. IVCM showed hyperreflective deposits in the subepithelial and anterior stromal layers, manifesting as discrete or clustered dots, with significant reduction of subbasal nerve fiber density. These changes were dose- and duration-dependent but reversible upon drug discontinuation. 2. Erlotinib-associated ocular toxicity presented with Stevens-Johnson syndrome-like features, including corneal epithelial defects, melting, perforation, pseudomembrane formation. Ocular involvement typically occurred after cutaneous and oral mucosa lesions. IVCM revealed the presence of abundant inflammatory cells infiltrating the corneal epithelium and stroma. Discontinuation of erlotinib combined with intensive topical immunosuppressive and regenerative therapy, supplemented with bandage contact lenses or corneal transplantation as needed, led to functional recovery.

Conclusions: Novel targeted agents exhibit distinct class-specific ocular toxicity profiles. ADCs are

associated with a dose-dependent keratopathy, while EGFR inhibitors like erlotinib may induce severe SJS-like reactions. Early recognition, multidisciplinary collaboration, and timely drug discontinuation are crucial for preventing sight-threatening complications.

Abstract No.: 206050

Outcomes of Artificial Endothelial Replacement Membrane Implantation, EndoArt, in Patients at High Risk for Human Graft Rejection

First Author: Ofer DAPHNA

Purpose: To compare 12-month safety and efficacy outcomes of EndoArt implantation in adult patients with chronic corneal edema who are at high risk versus those at normal risk for human graft rejection.

Methods: A retrospective analysis of 45 high-risk patients and 71 normal-risk patients. High-risk patients were defined as those who either failed multiple keratoplasties or had a condition placing them at risk for human graft failure. Safety and efficacy data, including central corneal thickness (CCT), best corrected visual acuity (BCVA) and pain score (measured by visual analogue scale, VAS) are presented for the first 12 months post implantation.

Results: At 12-month follow-up, an average CCT decrease of around 190µm was seen in both groups (p -value<<0.05). CCT improvement was stable and significant throughout follow-up. Pain (VAS) was markedly reduced from 17 ± 19 and 38 ± 37 pre-op (for high-risk and normal-risk, respectively) to 6 at 12 months post implantation (p -value<0.05). As CCT decreased, patients regained corneal clarity, which correlated with improved visual acuity. Despite presenting similar trendlines for CCT and for corneal clarity, the improvement in BCVA was more prominent in the normal-risk group- from 1.73 ± 0.58 pre-op to 1.22 ± 0.76 at 12-month versus from 1.74 ± 0.59 to 1.45 ± 0.65 in the high-risk group, presumably due to the co-morbidities of the latter population. There were no long-term reported infections or inflammation related to EndoArt implantation. The most common post-op intervention was re-bubbling, which occurred at a rate of 45.5% in the normal-risk population, and reached a rate of 61.9% in the high-risk population.

Conclusions: The implant demonstrated safety and efficacy in treating chronic corneal edema in high-risk patients prone to graft rejection, leading to reduced edema and pain while improving vision in most cases. A comparison with lower-risk patients showed similar trends, though visual acuity outcomes differed, likely due to reduced visual potential. As EndoArt is not subject to rejection, it may offer a durable long-term solution for high-risk patients.

Abstract No.: 202904

Peripheral Neuropathy Symptoms and Ocular Surface Lesions in Patients With Type 2 Diabetes Mellitus and Dry Eye: A Clinical Correlational Study

First Author: Yangyang ZHANG

Co-Author(s): Lixin XIE

Purpose: Reduced corneal sensation in individuals with type 2 diabetes mellitus (T2DM) leads to a dissociation between dry eye disease (DED) signs and symptoms, thereby affecting diagnostic accuracy. To investigate the correlation between ocular surface signs and diabetic peripheral neuropathy (DPN) symptoms in patients with T2DM-associated DED.

Methods: The Michigan Neuropathy Screening Instrument Questionnaire (MNSIQ) was used to categorize patients with T2DM into MNSIQ-DPN and non-DPN groups. Ocular irritation symptoms were evaluated using the Ocular Surface Disease Index (OSDI) questionnaire. Ocular surface lesions were assessed via Cochet-Bonnet esthesiometry, corneal fluorescein staining (CFS), the Schirmer I tear test (SIT), the tear meniscus height (TMH), the noninvasive keratography break-up time (NIKf-BUT), and the meibomian gland loss (MGL) grade detected by OCULUS. Corneal nerve fiber parameters were evaluated using in vivo confocal microscopy (IVCM).

Results: A total of 116 patients with T2DM, comprising 76 non-DPN patients and 40 MNSIQ-DPN patients, along with 51 age-matched participants without diabetes, were enrolled. Although OSDI scores were equivalent between MNSIQ-DPN patients and non-DPN patients, MNSIQ-DPN patients presented significantly more severe CFS ($p < 0.001$), meibomian gland dysfunction (MGD) ($p < 0.001$), corneal nerve fiber loss ($p < 0.001$), sensory dysfunction ($p = 0.02$), and corneal microneuromatosis ($p < 0.001$). The MNSIQ score was significantly positively correlated with CFS ($p < 0.001$); MGD ($p < 0.01$); corneal nerve fiber loss, including corneal nerve fiber density and length and branch density, in the paracentral (all $p < 0.001$) and inferior-whorl areas ($p < 0.01$, $p < 0.05$ and $p < 0.01$, respectively); and corneal microneuromatosis, characterized by increased microneuroma numbers ($p < 0.001$) and areas ($p < 0.001$) in these regions.

Conclusions: MNSIQ scores were significantly and robustly correlated with the presence of corneal epithelial defects, MGD, and nerve fiber loss in patients with T2DM. These findings suggest that DPN is a critical factor in diabetic ocular surface complications, highlighting the importance of the MNSIQ for assessing these conditions.

Abstract No.: 203302

Preclinical study of limbal niche cells as Drug

First Author: Guigang LI

Purpose: To Introduce the Preclinical Study of Limbal Niche Cells As a Drug by Reviewing the Literature and Preliminary Data From Our Group and Others Around the World.

Methods: LNC cells were first identified by Dr. Xie Huatao and Professor Scheffer C. G Tseng et al., reported in Miami, USA. Li Guigang et al. further studied its cultivation method and biological characteristics and found that LNC adhered to the surface of the plastic culture plate coated with Matrigel for growth; Expressing CD73, CD90, CD105, as well as positive markers such as CD34, CD31, but not CD45; It can induce differentiation into bone cells, chondrocytes, and adipocytes; It has the characteristics of vascular progenitor cells and can be induced to differentiate into vascular endothelial cells and vascular Pericyte.

Results: LNC could be expanded in vitro for more than 12 generations, and has a better effect than BMMSC in treating limbal stem cell deficiency in the rabbit eye with alkali burn. Subconjunctival injected LNC could be traced by CellTracker™ CM Dil in vivo.

Conclusions: LNC is a group of promising cell drug that deserves more attention.

Abstract No.: 206372

Preoperative Endothelial Cell Reserve as a Predictor of Corneal Outcomes After Phacoemulsification: The First Report From the Land of Kawanua

First Author: Andika Adiputra WITONO

Co-Author(s): Laya RARES, Novanita SATOLOM, Eugeni SUMANTI, Roy UMBOH

Purpose: Phacoemulsification risks endothelial cell loss and corneal edema. Preoperative Corneal Endothelial Cell Density (CCD) is a vital reserve indicator, its precise predictive value for early corneal stability is often unclear. This prospective cohort study aimed to determine if preoperative CCD significantly predicts post-phacoemulsification corneal stability and to evaluate key confounders (age, sex, phaco-time). We sought to establish a robust predictor model for optimizing surgical case selection. Although many previous studies have been conducted, this is the first study carried out in North Sulawesi, Indonesia, where accessibility of ophthalmology facilities remains a significant challenge.

Methods: The study was conducted in the northern peninsula of Sulawesi Island, Indonesia, from April to September 2025. We analyzed medical records of 22 eyes with nuclear sclerosis grade 3-4 cataracts who underwent phacoemulsification. The primary

independent variable was preoperative CCD. Data were coded, entered, and analyzed using SPSS version 24.

Results: The mean age was 58.41±11.86 years, with 95.5% having normal preoperative CCD. Bivariate analysis showed no significant correlation between CCD D+1 and phaco-time ($P=0.098$) or Cumulative Dissipated Energy (CDE) ($P=0.0237$). However, multivariate analyses revealed two key findings: 1) Preoperative CCD significantly lowered the odds of early edema ($OR=0.96$; $P=0.038$); and 2) Preoperative CCD was a highly significant predictor for postoperative Central Corneal Thickness ($P<0.001$, Standardized $\beta=0.632$).

Conclusions: Preoperative CCD is the critical determinant of early postoperative corneal health. This research conclusively establishes that endothelial cell reserve significantly reduces the risk of edema and is the key predictor of corneal thickness, outweighing standard surgical parameters. High preoperative CCD leads to better early corneal outcomes.

Abstract No.: 206740

Preserving the Globe: A Retrospective Study on Scleral Patch Graft in Corneal Perforation at a Tertiary Hospital

First Author: Nadida NURFADHILA

Co-Author(s): Angga FAJRIANSYAH, Elfa Ali IDRUS, Patriotika MUSLIMA, Arief Akhdestira MUSTARAM

Purpose: This study explores the clinical characteristics, causes, and complications in patients with corneal perforation who underwent scleral patch graft procedures at a Tertiary Hospital.

Methods: A retrospective cross-sectional review was performed on the medical records of patients treated with scleral patch grafts between January 2021 and December 2022. Inclusion criteria consisted of cases managed solely with a scleral patch graft and a minimum follow-up of three months. Data collected included age, sex, lateralization, etiology of perforation, microbiological findings, prior history of tectonic surgeries, and postoperative complications.

Results: Of 156 eyes included, most patients were male, with an average age of 47.7 years. The predominant cause of perforation was infectious corneal ulcer (84%), followed by autoimmune peripheral ulcer, trauma, and descemetocoele. Bacterial infection, especially gram-positive cocci, was the most frequent organism isolated from infectious cases. Most ulcers were 3 mm or larger in size, centrally located, and tested negative with the Scheidel test. Secondary glaucoma (26%), reoperation (15%), and complicated cataract (3%) were the main postoperative complications. Fourteen eyes with reoperation required evisceration, while anatomical globe integrity was successfully maintained in 85% of cases following the scleral patch graft procedure.

Conclusions: Scleral patch graft is a reliable option for saving eyes with corneal perforation, particularly when donor corneas are unavailable. This technique maintains anatomical integrity for most patients, although close postoperative monitoring for complications remains crucial.

Abstract No.: 203905

Prevalence, Risk Factors, and Environmental Associations of Dry Eye Disease in the Hong Kong Population Aged 50 and above

First Author: Pui Yui **NGAN**

Co-Author(s): Victor H **HU**, Kendrick Co **SHIH**

Purpose: Dry eye disease (DED) is a common condition, with age, female sex, and Asian ethnicity identified as risk factors. Given Hong Kong's (HK) aging population, subtropical climate, and high pollution levels, this study aimed to determine the prevalence and environmental associations of DED among adults aged 50 and above in the Southern District (SD) of HK.

Methods: This cross-sectional study included 1,230 participants who underwent dry eye assessments between September 2021 and August 2023. Examinations were performed with the OCULUS Keratograph 5M in a least-to-most invasive order, consisting of the Ocular Surface Disease Index questionnaire, non-invasive keratographic break-up time (NIKBUT), and corneal staining. SD environmental data were obtained from the HK Observatory and HK Environmental Protection Department databases. DED prevalence was reported separately for the Dry Eye Workshop (DEWS) II and Asia Dry Eye Society (ADES) definitions. Associations between ADES-defined DED and same-day environmental data were evaluated.

Results: The crude prevalence of DED was 15.0% (185/1230) for the ADES definition and 18.1% (222/1230) for the DEWS II definition. Age- and sex-standardised prevalence adjusted to the 2024 HK population was 14.3% for ADES-defined DED and 16.8% for DEWS II-defined DED. The prevalence of symptomatic DED (OSDI ≥ 13) and asymptomatic DED (NIKBUT < 10 s) was 9.11% and 46.42% respectively. Female sex (aOR: 1.99, 95%CI: 1.36–2.83; $p < 0.001$), increasing age (aOR: 1.03 per year increase, 95%CI: 1.01–1.06; $p = 0.002$), and higher nitrogen dioxide exposure (aOR: 1.19 per 10 $\mu\text{g}/\text{m}^3$ increment, 95%CI: 1.01–1.41; $p = 0.048$) were significantly associated with ADES-defined DED in both univariable and multivariable analyses.

Conclusions: DED prevalence among adults aged 50 and above in HK was lower than pooled estimates from Asian countries but consistent with the global range. A large portion of subjects had short NIKBUT without symptoms. Female sex, increasing age, and higher nitrogen dioxide exposure were associated with DED.

Abstract No.: 207399

Ray-Tracing Guided Customized Laser Ablation for Progressive Keratoconus

First Author: Prabhjot **SINGH**

Co-Author(s): Anushree **LINGAIAH**, Rohit **SHETTY**

Purpose: To evaluate clinical outcomes of ray-tracing-guided customized ablation combined with accelerated cross-linking in progressive keratoconus.

Methods: A total of 106 eyes with progressive keratoconus underwent customized ablation using ray-tracing software with a high-frequency excimer laser (2 kHz), followed by accelerated corneal cross-linking. Assessments at 1, 3, and 6 months included visual acuity, corneal tomography, and higher-order aberration (HOA) analysis.

Results: At 1 month, Kmax reduced by 6.3 ± 3.9 D ($p < 0.05$) and Kmean by 3.2 ± 1.5 D ($p < 0.05$), stable through 6 months. UCDVA and BCDVA improved ≥ 3 lines ($p < 0.05$). Mean spherical equivalent decreased by 1.4 D ($p < 0.05$). HOA reduced from 2.32 μm to 1.43 μm ($p < 0.05$).

Conclusions: Ray-tracing-guided ablation with cross-linking provides effective corneal regularization and visual rehabilitation.

Abstract No.: 200241

Regenerative Potential of Limbal Epithelial Stem Cells for Graft-Host Junction Modulation in Post-Penetrating Keratoplasty Corneal Haze

First Author: Srishti **KHULLAR**

Co-Author(s): Vijay **KUMAR SHARMA**, Prabhjot **SINGH**

Purpose: To evaluate the efficacy of microscope-integrated optical coherence tomography-guided, precisely placed limbal epithelial stem cells for modulating the graft-host interface.

Methods: Prospective interventional pilot study with a sample size of 7 patients with a mean age of 46 ± 20.09 years. Collaborative corneal transplantation study group hosts corneal clarity grade ≤ 2 , presence of superficial punctate keratopathy, epithelial defects at graft-host junction, epithelial defects, microcystic edema, ASOCT signs of visible gap $\geq 50\mu\text{m}$ between host and donor epithelium, difference in epithelial thickness $\geq 20\mu\text{m}$ were the inclusion criteria (≥ 3 months post penetrating keratoplasty) and eyes with previous ocular comorbidities, history of graft rejection/failure were excluded from the study. Selected patients underwent precise placement of limbal stem cells with amniotic membrane. The follow-up period for these patients was 3 months.

Results: Mean change in corneal clarity grade was 2 ± 0.5 . Mean BCVA prior to surgery was logMAR 0.72 ± 0.17 , and post-procedure was logMAR 0.43 ± 0.14 .

There was a significant improvement at the graft-host interface and regularised the junction.

Conclusions: Graft-host junction irregularities are a major but overlooked challenge post-PK. This is the first study to explore the application of iOCT-guided precisely placed limbal epithelial stem cells for addressing graft-host junction abnormalities and persistent corneal haze after PK. No major complications or adverse events were observed during the study period. However, longer follow-up is required.

Abstract No.: 206462

Reliability of Intraoperative Biometry (Optiwave Refractive Analysis) in Post-Radial Keratotomy Eyes Undergoing Cataract Surgery

First Author: Vipasha SHARMA

Co-Author(s): Lekha CHANDEL, Amit GUPTA, Chintan MALHOTRA, Garg SHIVAM

Purpose: To evaluate the refractive accuracy of intraoperative biometry using Optiwave Refractive Analysis (ORA) compared to preoperative IOL power calculations using the Barrett True-K formula in eyes with prior radial keratotomy (RK) undergoing cataract surgery.

Methods: This retrospective case series included 32 eyes of 24 patients with a history of RK (4–16 incisions) who underwent uncomplicated cataract surgery. Preoperative biometry was performed using IOLMaster 700 with Barrett True-K formula, and intraoperative aphakic measurements were obtained using ORA. Target refraction was adjusted based on RK incision count. Primary outcomes included mean absolute error (MAE), arithmetic mean error (AME), and the percentage of eyes achieving postoperative spherical equivalent (SE) refraction within ± 0.50 D, ± 1.00 D, and ± 2.00 D of predicted values.

Results: ORA demonstrated lower MAE (0.91 ± 1.18 D) compared to Barrett (1.38 ± 1.37 D), though not statistically significant ($p = 0.103$). Both methods showed a myopic bias (AME: ORA -0.63 ± 1.37 D; Barrett -0.46 ± 1.88 D). Mean postoperative SE was -1.73 ± 1.38 D. A higher proportion of eyes achieved refractive outcomes within ± 0.50 D, ± 1.00 D, and ± 2.00 D using ORA.

Conclusions: Intraoperative wavefront aberrometry with ORA offers reliable refractive outcomes in post-RK eyes undergoing cataract surgery. Although not statistically superior to Barrett True-K, ORA showed lower variability and better performance trends, suggesting its potential utility in complex corneal cases.

Abstract No.: 206916

Screening of Dry Eye Disease in Cocaine and Methamphetamine Users

First Author: King Him Cyrus CHEUNG

Co-Author(s): Kam Lung Kelvin CHONG, Ka Hei Kenneth LAI, Chi Pui Calvin PANG, Chee Yung Clement THAM

Purpose: To evaluate dry-eye disease-related ocular surface parameters among substance users in Hong Kong.

Methods: Cross-sectional study of cocaine and methamphetamine users in the prior 24 months recruited from CCPSAs. This study is supported by the Beat Drugs Fund (BDF210067). Dry-eye parameters included Fluorescein Tear Film Breakup Time (F-TBUT), Corneal staining (Modified Oxford / NEI), and grading of MGD by ophthalmologists. Subjective dry-eye symptoms were reported through the Ocular Surface Disease Index (OSDI). DED was diagnosed per the recent Hong Kong Dry Eye Disease Framework.

Results: Forty-six right eyes of substance-users and 46 age-sex-matched controls (male=29) were compared (age: 36.50(44.25-31.00) years; $p=0.928$). DED symptoms were more prevalent in substance-users than controls (58.7% vs. 13.0%; $p<0.001$), as were positive objective DED tests (82.6% vs. 58.7%; $p=0.021$). DED was diagnosed in 45.7% of substance-users vs. 4.3% of controls ($p<0.001$). Compared to controls, substance users had a lower F-TBUT (4.08(5.80-2.05) vs. 4.67(7.56-3.55) secs; $p=0.022$), worse capping (1.00(2.00-0.75) vs. 1.00(1.00-0.00); $p=0.045$), lid margin rounding (1.00 (2.00 – 1.00) vs. 0.00 (1.00 – 0.00); $p<0.001$) and worse Meibomian Gland Yielding Secretion Score (16.00(30.00-9.50) vs. 26.50(37.00-14.00); $p=0.011$). Substance users also reported higher OSDI (16.29(45.11-8.52) vs. 6.25(18.75-0.00); $p<0.001$) and higher scores for the individual symptoms of gritty eyes (0.50 (2.00 – 0.00) vs. 0.00 (1.00 – 0.00); $p=0.011$) and poorer vision (1.00 (2.25 – 0.00) vs. 0.00 (1.00 – 0.00); $p=0.002$).

Conclusions: As the first study to investigate dry-eye parameters in substance users, we found that substance use is associated with worsened parameters and a significant sign-symptom disparity. While symptom-based questionnaires may not truly reflect the dry-eye condition among substance users, active screening of the ocular surface is warranted.

Abstract No.: 200289

Seasonal Variation of Microsporidial Keratitis in Eastern Uttar Pradesh: A Retrospective Observational Study at a Tertiary Eye Care Centre

First Author: Akanksha DASS

Co-Author(s): Smriti GAUR, Anshupa PATNAIK

Purpose: To evaluate the seasonal trends and incidence patterns of microsporidial keratitis in

Eastern Uttar Pradesh over a defined one-year period. Seasonal and environmental factors may influence the incidence, but limited data are available from North India. Understanding the risk factors and transmission patterns aids in early diagnosis and management.

Methods: A retrospective observational study -conducted at a tertiary eye care center in Eastern Uttar Pradesh. Medical records of 283 patients diagnosed with microsporidial keratitis between September 2023 to September 2024 were reviewed. Diagnosis was confirmed through smear and staining techniques, including KOH, calcofluor white, and Gram staining. The monthly and seasonal distribution of cases was analyzed and correlated with regional climatic data—specifically temperature, humidity, and rainfall.

Results: Seasonal distribution showed a significant increase in cases from June to October, accounting for 76.4% of total cases. A positive correlation was noted between relative humidity levels above 70% and increased incidence ($r = 0.67$, $p < 0.05$). Predominantly affecting outdoor male workers (M:F = 6.8:1), this infection underscores the role of occupational and environmental exposure. This is the highest sample size studied to date, hence essential in identifying seasonal trends, so that the healthcare providers can be more vigilant during those times and offer timely intervention, potentially improving patient outcomes.

Conclusions: This study demonstrates a distinct seasonal pattern in the incidence of microsporidial keratitis, with a notable rise during humid months. Recognizing these trends is crucial for prompt diagnosis, timely management, and implementation of preventive strategies—particularly among high-risk populations during vulnerable seasons.

Abstract No.: 206803

TAZ-TGF Beta 1 Gene Driven Fibrotic Signalling in Chronic Ocular Chemical Injury Cases With Total Limbal Stem Cell Deficiency

First Author: Renu VENUGOPAL

Co-Author(s): Seema KASHYAP, Nikhil KUMAR, Seema SEN, Namrata SHARMA, Lata SINGH

Purpose: Chronic ocular chemical injury with total limbal stem cell deficiency (LSCD) is characterized by conjunctivalization and pannus formation, often leading to irreversible vision loss. Fibrosis in conjunctival pannus poses a major challenge to ocular surface reconstruction after injury. This study investigated the molecular mechanisms of fibrosis in this setting, focusing on emphasizing the interplay between Hippo pathway effectors and TGF- β 1 signalling in ocular chemical injury cases.

Methods: Conjunctival pannus specimens ($n = 58$) from patients with chronic ocular chemical injury and normal conjunctival controls ($n=4$) were analysed. Quantitative reverse transcription PCR (qRT-PCR) measured

mRNA expression of TAZ, YAP, TGF- β 1 (TGFB1), and TEAD1, normalized to ACTB (beta actin). Comparative expression profiling was performed between diseased and control tissues.

Results: Pannus tissues exhibited a distinctive fibrotic molecular signature. TAZ and TGF- β 1 were significantly upregulated ($p < 0.01$), while YAP1 expression was reduced and TEAD1 expression was negligible. These results implicate TAZ as the dominant Hippo pathway effector in fibrotic remodeling. The absence of TEAD1 suggests TAZ mediates profibrotic signaling via alternative transcriptional partnerships, likely involving Smad proteins, to amplify TGF- β 1-driven extracellular matrix deposition.

Conclusions: This study identifies a novel TAZ-centered, TEAD1-independent signaling axis as a key driver of conjunctival fibrosis. By revealing TAZ-Smad crosstalk as a central mechanism of ocular surface scarring, these findings highlight an innovative therapeutic target for antifibrotic strategies. This molecular insight advances the understanding of ocular surface repair biology and opens new avenues for improving long-term outcomes in patients with vision-threatening ocular surface injuries.

Abstract No.: 206879

Tackling the Untreatable: Long-Term Outcome of Sublingual Immunotherapy in Refractory Ocular Allergy

First Author: Gaurav PANDE

Co-Author(s): Yathish SHIVANNA, Vibha SINGH

Purpose: To evaluate indications and long-term outcomes of Sub Lingual Immunotherapy (SLIT) in the management of severe chronic ocular allergy.

Methods: Clinical records of allergic eye disease (AED) patients were studied as a retrospective observational study design. Refractory cases underwent allergen testing; SLIT was started based on results and history. Outcomes were measured by steroid use and allergy episodes.

Results: Of 805 AED patients, 121 refractory cases were referred; 52 were started on Allergen-specific immunotherapy (AIT) after allergen testing. 90% improved, with significant steroid reduction ($p<0.01$). Potent topical steroid use decreased from 32 to 15 patients ($p<0.05$). The mean follow-up of 25.5 months showed good control and minimal side effects.

Conclusions: SLIT improves long-term control in severe refractory AED by reducing symptoms, steroid use, and flare-ups via targeted immunotherapy. Early allergist referral and SLIT should be considered in refractory AED for personalized, steroid-sparing treatment and improved quality of life.

Abstract No.: 203962

Technique and Outcomes of 'Combined Single-Stage Keratoprosthesis Implantation With Mucous Membrane Grafting'

First Author: Gaurav VERMA

Co-Author(s): Jagadeesh Kumar REDDY, Vandhana SUNDARAM, Shruthi TARA

Purpose: To evaluate the clinical outcomes and benefits of a single-stage surgical approach combining Type I Keratoprosthesis (KPro) implantation with mucous membrane grafting (MMG) in adult patients with severe ocular surface disease.

Methods: A retrospective, interventional case series was conducted on 15 eyes of 15 adult patients who underwent single-sitting KPro implantation with MMG. All patients had a poor prognosis for traditional penetrating keratoplasty due to severe ocular surface disorders, including chemical injuries, Stevens-Johnson syndrome. Primary outcome measures were anatomical retention of the KPro, best-corrected visual acuity (BCVA), and postoperative complications.

Results: The mean patient age was 55.13 years (range:40-71), and anatomical retention of the KPro was achieved in 13 of 15 eyes (86.7%). Preoperatively, all eyes had a BCVA of light perception or hand motions. Postoperatively, 60% achieved a BCVA of 20/200 or better, with 26.6% achieving 20/40 or better. The single-stage approach demonstrated significant benefits, including eliminating the need for a second anesthetic event, reducing total recovery time, and facilitating immediate ocular surface rehabilitation. The most common complications were retroprosthetic membrane formation (33.3%), glaucoma progression (13.3%) and endophthalmitis (13.3%).

Conclusions: The single-stage KPro with MMG procedure is a highly effective and viable surgical strategy for visual rehabilitation in patients with complex ocular surface disease. It offers excellent anatomical and functional success rates by consolidating two procedures, thereby reducing surgical burden, enhancing patient convenience and potentially improving long-term outcomes.

Abstract No.: 204004

Ten-Year Graft Survival After Primary Endothelial Keratoplasty: Impact of Rebubbling in Pseudophakic Bullous Keratopathy and Fuchs' Endothelial Corneal Dystrophy in Asian Eyes

First Author: See Teng TAN

Co-Author(s): Marcus ANG, Hla Myint HTOON

Purpose: To compare 10-year graft survival after Descemet stripping automated endothelial keratoplasty (DSAEK) and Descemet membrane endothelial

keratoplasty (DMEK) in Asian eyes and to evaluate the impact of rebubbling.

Methods: Consecutive primary EK procedures recorded in the Singapore Corneal Transplant Registry (April 2006–May 2023) were analyzed. Eyes with pseudophakic bullous keratopathy (PBK) or Fuch's endothelial cornea dystrophy (FECD) undergoing DSAEK or DMEK were included; other aetiologies and repeat high-risk grafts were excluded. The primary outcome was 10-year graft survival (Kaplan–Meier, log-rank; Cox regression). Subgroup analyses were stratified by indication (PBK vs FECD) and rebubbling status.

Results: Of 1174 eligible eyes (mean age 69.0±10.9 years), 939 (80.0%) underwent DSAEK and 235 (20.0%) DMEK; 580 had PBK, and 594 had FECD. Rebubbling occurred in 4.6% (DSAEK) and 10.2% (DMEK). The 10-year cumulative probability of graft failure was higher in participants with rebubbling than those without in both DSAEK and DMEK (61.5% vs 76%; HR 2.4 (95% CI, 1.3–4.4; p<0.05; 77.2% vs 81%; HR 2.6 (95% CI 0.95–7.3, p=0.06). PBK eyes undergoing DSAEK had markedly poorer survival when rebubbling was required (41.3% vs 60.1%; HR 2.17, 95% CI 1.09–4.33, p<0.05). In FECD, the effect of rebubbling differed by procedure: non-significant for DSAEK (90.9% vs 89.8%; HR 2.40, p=0.24) but significant for DMEK (81.3% vs 86.6%; HR 4.56, 95% CI 1.13–18.43, p<0.05). Multivariable modelling identified surgical indication as the strongest independent predictor of survival, with FECD outperforming PBK.

Conclusions: Over 10 years, DMEK demonstrated superior late survival compared with DSAEK, while the adverse impact of rebubbling was most pronounced in PBK-DSAEK and FECD-DMEK. Indication and comorbid glaucoma outweigh procedure choice in prognostication.

Abstract No.: 203207

Ten-Year Outcomes of Descemet Stripping Endothelial Keratoplasty Versus Penetrating Keratoplasty in Chinese Patients: A Retrospective Cohort Study

First Author: Anson Chun Long WU

Co-Author(s): Ka Wai KAM, Stephanie Hiu Wai KWOK, Eugenie MOK, Alvin Lerrmann YOUNG

Purpose: To investigate and compare the long-term survival outcomes of primary penetrating versus endothelial keratoplasty in Chinese patients with Fuchs endothelial dystrophy (FED) or pseudophakic bullous keratoplasty (PBK).

Methods: Retrospective cohort study.

Results: A total of 74 eyes received primary keratoplasty, comprising 40 Descemet stripping endothelial keratoplasties (DSEK) and 34 penetrating keratoplasties (PKP), for FED or PBK between 2006–2015 with a mean follow-up of 95 months. Overall

graft survival rates were 76.1% at 5 years and 55.0% at 10 years. DSEK demonstrated higher survival rates than PKP, with 81.7% vs 69.0% at 5 years and 63.5% vs 43.6% at 10 years, although the differences were not statistically significant. Predictive factors of graft failure include older age, poorer preoperative best-corrected visual acuity (BCVA) and longer operative time. Postoperative BCVA was significantly better for DSEK compared to PKP at 5 years ($p=0.006$) but this difference diminished by 10 years. Graft ulcers occurred in fewer eyes receiving DSEK (5.0%) compared to PKP (20.6%) at 10 years ($p=0.04$). The cumulative rejection rate at 10 years were 12.5% for DSEK and 8.8% for PKP while 15.0% of DSEK and 11.8% of PKP required further transplantation.

Conclusions: Both primary DSEK and PKP yielded satisfactory survival outcomes among Chinese patients with FED or PBK. Patients undergoing DSEK experienced superior BCVA at 5 years and a lower risk of graft ulcers at 10 years, with similar rejection and regraft rates compared to PKP.

Abstract No.: 200300

Ten-Year Outcomes of Large-Diameter (9mm) Deep Anterior Lamellar Keratoplasty (DALK)

First Author: Gunjan **BUDHIRAJA**

Co-Author(s): Massimo **BUSIN**, Angeli **YU**

Purpose: To report the long-term outcomes of large-diameter deep anterior lamellar keratoplasty (DALK).

Methods: This single-center interventional case series included 643 eyes that underwent 9mm diameter DALK for keratoconus ($n=421$), infectious keratitis ($n=126$), corneal dystrophy ($n=32$), failed anterior lamellar keratoplasty (ALK) ($n=19$), other stromal disease ($n=42$), using a modified big bubble technique with stromal clearance limited to a central 6mm optical zone. Best corrected visual acuity, endothelial cell loss, and complications were evaluated annually postoperatively with 5- and 10-year follow-up available in 643 and 111 eyes, respectively.

Results: At 5 and 10 years, a Snellen BCVA of $\geq 20/40$ was achieved in 96% and 93% of eyes, while BCVA of $\geq 20/20$ was achieved in 41% and 39%, respectively. Mean ECL was $18 \pm 6\%$ at 5 years and $24 \pm 9\%$ at 10 years. Refractive astigmatism was greater than 4.5D in 36 eyes (5%). The 5- and 10-year cumulative probability for stromal rejection was 2% at 5 years and 3% and for graft survival was 99% and 98%, respectively.

Conclusions: The study provides evidence that 9mm DALK provides visual outcomes superior to those reported for PK, with excellent graft survival rates better than those reported for 8.0mm PK. These findings may encourage corneal surgeons to adopt large-diameter big-bubble DALK for stromal disease.

Abstract No.: 206963

Tenon's to the Rescue: Indications and Results in Corneal Melt Management

First Author: Smruti **PRIYADARSHINI**

Co-Author(s): Sujata **DAS**, Nisha **RANI**

Purpose: To study the indications, aetiology, outcomes, and complications of autologous Tenon's Patch Grafting in corneal melts.

Methods: This retrospective analysis included 51 eyes of 51 patients with corneal melts who underwent autologous Tenon's patch grafting between January 2021 and May 2025 at a tertiary eye care institute. Details about demographics, clinical features, aetiology, postoperative outcome were extracted from the electronic medical records.

Results: The average age was 45.24 ± 17.20 years (range 4 - 79 years), with a male-to-female distribution of 36:15. The most common indication was immune-mediated corneal melt in Stevens-Johnson Syndrome (15), trauma (9), microbial keratitis (6), viral keratitis (4), mycoplasma-induced rash and mucositis (3), chemical/thermal injuries (3), Sjögren's syndrome (2), descemetocoele following keratoplasty (2), ocular cicatricial pemphigoid (1), peripheral ulcerative keratitis (1), and miscellaneous causes (4). Eight patients were on systemic immunosuppressive therapy. Anatomical integrity was restored in 43 eyes (84.3%) with corneal scarring and vascularization. The procedure was effective in maintaining reasonable visual acuity ($>20/80$) in 14 cases (27.4%). Two patients (4%) had infection post Tenon's patch graft, and 3 (5.8%) had persistent leak, which required resurgery.

Conclusions: Autologous Tenon's patch grafting represents a simple yet effective surgical technique for restoring ocular integrity. It serves as a viable alternative to amniotic membrane transplantation and offers the advantage of deferring or even avoiding the need for therapeutic keratoplasty.

Abstract No.: 200843

The Effect of Perfluorohexyloctane on a Mouse Model of Blue Light-Induced Meibomian Gland Dysfunction

First Author: Zixuan **YANG**

Co-Author(s): Caihong **HUANG**, Zuguo **LIU**, Ya **SHI**, Ruochen **WANG**, Mingwu **ZHENG**

Purpose: Blue light exposure is a potential exacerbator of meibomian gland dysfunction (MGD), a leading cause of evaporative dry eye disease. Perfluorohexyloctane (SHR8058) has shown promise in stabilizing the tear film and delaying MGD progression. This study evaluated the protective effects of SHR8058 on meibomian glands in a mouse model of blue light-induced MGD.

Methods: C57BL6/J mice were divided into five groups: normal control (Ctrl), blue light exposure (BL), Perfluorohexyloctane treatment (BL+SHR8058), 0.55% NaCl Eye Drops control (BL+NaCl), and Dextran 70 Glycerol Eye Drops control (BL+Glycerol). All groups, except Ctrl, were exposed to blue light for 6 hours per day over 28 days to induce MGD. Treatment groups received their respective eye drops four times daily. On Day 28, lid margin examinations assessed gland function, while qPCR and Western blot analyzed inflammatory and fibrotic markers in meibomian tissues.

Results: Blue light exposure induced significant meibomian gland atrophy and openings obstruction, validating the MGD model. SHR8058 treatment partly decreased the corneal sodium fluorescein staining score, significantly reduced the number of obstructed gland openings and increased the relative meibomian gland areas compared to BL, BL+NaCl and BL+Glycerol. Besides, SHR8058 markedly decreased mRNA levels of inflammatory cytokines (IL-1 β , IL-6, TNF- α , IFN- γ) and protein levels of IL-1 β , IL-4, TNF- α , NOX4, and NF- κ B compared to the BL group.

Conclusions: Perfluorohexyloctane demonstrated significant protective effects against blue light-induced MGD by reducing gland obstruction, preserving glandular structure, and suppressing inflammation and fibrosis. These findings highlight its potential as an innovative therapeutic agent for MGD management.

Abstract No.: 203296

The Efficacy of Minimally Invasive Platelet-Rich Plasma Injection in the Treatment of Dry Eye Caused by Meibomian Gland Dysfunction

First Author: Xue Song MI

Co-Author(s): Wenting QIU

Purpose: There is a relative lack of consistent or efficient clinical therapy for meibomian gland dysfunction (MGD) at present. Meibomian gland probing is widely recognized for its effectiveness; however, it is not yet promoted widely in clinical settings due to the discomfort, hemorrhage, and expensive instrument costs. Platelet-rich plasma (PRP) injection mesotherapy has a clear effect on eliminating soft tissue inflammation but has not yet been promoted in the field of dry eye. In this study, we designed a new cannula for MG probing to explore the efficacy of the PRP micro-injection scheme on MGD.

Methods: Sixty eyes from patients diagnosed with MGD were randomly recruited into the PRP treatment group and the control group. The Ocular Surface Disease Index (OSDI), lipid layer thickness (LLT), tear meniscus height (TMH), noninvasive tear breakup times (NIBUT), ocular redness, meibomian gland loss (MGL), and meibum quality were measured respectively before and 1 week and 4 weeks after PRP treatment. Data analysis was performed using SPSS 26.

Results: 1. The average age of the treatment group was 51.87 ± 16.72 , and the average age of the control group was 42.46 ± 9.95 . 2. PRP injection therapy significantly alleviated subjective symptoms in patients with MGD. 3. Significant improvements were observed in the treatment group after PRP injection, including OSDI, LLT, TMH, meibum quality, and NIBUT compared to pre-treatment levels ($p < 0.05$). 4. Additionally, compared to the control group, PRP injection demonstrated superior efficacy at the 4-week follow-up in OSDI, LLT, meibum quality, and NIBUT ($p < 0.05$).

Conclusions: 1. The above modified PRP injection scheme is a safe and effective treatment for moderate to severe MGD. 2. The above-designed MG cannula can reduce pain, bleeding, and also be disposable, which will significantly reduce treatment costs.

Abstract No.: 205097

The Eye as a Window to Iron Burden: Uncovering Ocular Surface Disease in Indian Young Thalassemia Patients

First Author: Niharika BATRA

Co-Author(s): Nitika BERI, G.k. DAS, P.k. SAHU, Ankur SINGH, Tavishi SINGHAL

Purpose: To investigate the prevalence of Dry Eye Disease in Indian Young transfusion-dependent thalassemia and normal population, and further correlate its severity with systemic markers of iron overload.

Methods: This was a single-center, hospital-based, case-control study conducted at the Departments of Ophthalmology and Paediatrics at a university hospital in Delhi. The study included 45 thalassemia patients aged 8-18 years and 45 age and sex matched controls. All participants underwent a comprehensive ocular examination, including Schirmer tests, Tear Film Break-Up Time, and Tear Meniscus Height measurement. Outcomes were recorded using the Ocular Surface Disease Index, Dry Eye Workshop scale and Oxford grading. For the case group, data on serum ferritin, transfusion history, and chelation therapy were also collected.

Results: Thalassemic patients exhibited significantly worse Dry eye disease markers with lower Schirmer scores and shorter TBUT compared to controls ($p < 0.05$). A strong negative correlation was found between serum ferritin levels and both Schirmer (schirmer 1, schirmer 2) and TBUT scores ($p = 0.00$). Our study of thalassemic adolescents versus controls showed significantly impaired tear function with a majority of patients experiencing mild to severe Dry Eye Disease, unlike the almost entirely normal controls. Furthermore, the severity of DED as measured by OSDI, DEWS, and Oxford scores showed a significant positive correlation with the total number of blood transfusions ($p = 0.00$). Patients on combination chelation therapy, reflecting a higher iron burden, had the most severe

Dry eye disease ($p < 0.05$). Notably, patients on combination chelation therapy, who typically have the highest iron load, exhibited the most severe ocular surface disease ($p < 0.05$).

Conclusions: This study establishes transfusion-dependent thalassemia as a significant risk factor for Dry Eye Disease in adolescents. The pathology appears mediated by iron-overload-induced oxidative damage to ocular glands, with disease severity directly mirroring the systemic iron burden. These findings underscore the critical need to integrate routine ophthalmic screening into the standard multidisciplinary care for this vulnerable population.

Abstract No.: 203618

The Impact of Viral Load on the Demographics, Clinical Characteristics and Contagion of Quantitative Polymerase Chain Reaction (PCR)-Confirmed Acute Adenoviral Conjunctivitis in Hong Kong

First Author: Phoebe LAM

Co-Author(s): Alex KAN, Allie LEE, Michael NI, Siddharth SRIDHAR, Hunter YUEN

Purpose: This study aims to compare the difference in clinical and demographic parameters between adenoviral-positive and -negative conjunctivitis. It also explores the relationships between viral load and various clinical parameters, and investigates whether viruses may be spread by the conventional air puff tonometry (APT) in eye clinics.

Methods: This is a cross-sectional study. Patients aged 18 years or above with onset of symptoms within 14 days before the study visit, and clinical signs of conjunctivitis in at least one eye were included. Those diagnosed with conjunctivitis of non-infectious causes were excluded. The severity of conjunctival injection, type and severity of discharge in each study eye was graded from 0 to 3. Conjunctival swab samples were obtained and sent for viral PCR. Samples tested positive for adenovirus were called back for APT with air samples tested.

Results: Final analysis was done on 118 subjects, averaging 51.7 years with male-to-female ratio 1:1.36. The mean onset of symptoms to study visit was 4.53 days. 23 (19.5%) subjects tested positive for adenovirus on qPCR. The adenovirus-positive patients were significantly younger (40.5 years) than the adenovirus-negative patients (54.4 years) ($t = 3.50$, $p < .001$); they were also significantly more male-predominant (65.2% versus 36.8%) ($\chi^2 = 6.11$, $p = .01$). They were significantly less likely to have mucoid discharge when stratified by age (likelihood ratio 8.32, $p = .04$), and had significantly more severe conjunctival injection (likelihood ratio 26.1, $p < 0.001$). The severity of conjunctival injection was also positively correlated with the viral load, with a statistically significant ANOVA test. The viral load decreased with an increasing day of onset (Pearson's

correlation -0.30). Among 8 of the adenoviral-positive patients who came back for APT, none of their post-tonometry air samples tested positive for adenovirus.

Conclusions: Adenovirus affected younger males, and produced less mucoid discharge compared to other acute infectious conjunctivitis. The severity of discharge was similar between the two groups, but the degree of conjunctival injection was more severe in the adenovirus group. The viral load of adenovirus was also positively correlated with the severity of conjunctival injection. APT performed on infectious subjects did not appear to contaminate the air with viruses.

Abstract No.: 206350

The Utility of Strip Meniscometry in the Screening and Diagnosis of Dry Eye Disease in a Random Population-Based Cohort Study for Chinese Subjects Aged 50 and Over

First Author: Kendrick SHIH

Co-Author(s): Tin Yue Kaitlyn CHEUNG

Purpose: To investigate the accuracy of strip meniscometry tube (SMTube) in dry eye screening and diagnosis in the context of a Chinese community.

Methods: This cross-sectional random population-based study was initiated on 27 September 2021 and continues to this day. Chinese subjects aged 50 and above were recruited through a randomized mail invitation in the Southern district in Hong Kong. Overall, the response rate was 96%, and the cooperation rate was 49%. In total, 198 consecutive subjects underwent comprehensive dry eye assessment in order from least invasive to most invasive, including dry eye questionnaire (OSDI score), Non-invasive keratographic tear breakup time, tear meniscus height, tear breakup pattern, SMTube, and NEI cornea staining score. The definition of dry eye was adopted from the Asia Dry Eye Society. Incremental (1 mm) strip meniscometry readings were tested for accuracy of dry eye diagnosis. The right eye of each subject was used for analysis.

Results: Among the 298 recruited individuals, the mean age was 62.6 (± 7.20) years. Overall, 19.5% had dry eye disease (OSDI ≥ 13 and TBUT < 10 s). Among dry eye patients, random break was the most common tear breakup pattern, accounting for 62% of cases. Subjects with dry eye disease had significantly lower SMTube readings compared to those who did not have dry eye disease on Student's t-test. A low SMTube result had high specificity and high negative predictive value for dry eye disease, OSDI score ≥ 13 , and presence of significant cornea staining. A cut-off value of 3 mm was shown to achieve optimum specificity and negative predictive value for dry eye disease (90.8% and 80.4%), cornea staining (94.1% and 64.8%), and OSDI score ≥ 13 (91.7% and 78.1%)

Conclusions: In a community setting, where dry eye prevalence is relatively low, an abnormal SMTube

reading had high specificity and negative predictive value, suggesting excellent diagnostic value for an abnormal test result. A cut-off value of 3 mm was proven to have the highest diagnostic accuracy for dry eye disease.

Abstract No.: 206686

To Evaluate the Corneal Biomechanical Parameters Using Corvis ST and to Explore Their Correlation With Pterygium-Induced Astigmatism

First Author: Mehran ZAREI GHANAVATI

Purpose: To evaluate the corneal biomechanical parameters using Corvis ST and to explore their correlation with pterygium-induced astigmatism.

Methods: A total of 31 consecutive patients with unilateral primary nasal pterygium were enrolled. Unaffected fellow eyes of the patients were considered as controls. Corvis ST was used to assess biomechanical parameters and corneal topographical features using Pentacam. Additionally, the pterygium structure was evaluated by slit-lamp photography and AS-OCT.

Results: In the study, there were 23 male and eight female patients with an average age of 50.26 ± 13.35 years. Anterior keratometry astigmatism value in the pterygium-affected eyes ranged from 0.5 to 9.20 D, with a mean value of 3.98 ± 3.04 D. The method used to compare each patient's normal and pterygium eyes was the Generalized Estimating Equations (GEE). The following parameters were significantly different between normal and pterygium eyes: HC Time (p-value = 0.026), Peak Dist (p-value = 0.017), HCDArc Length (p-value = 0.004), dArc Length Max (p-value = 0.002), DARatio Max 2mm (p-value = 0.003), PachySlope (p-value < 0.005), ARTh (p-value < 0.0001), and TBI (p-value < 0.0001). The backward regression method identified a significant correlation between the difference in keratometric astigmatism measured by Pentacam and dArcLengthMax and pterygium extension (measured by AS-OCT).

Conclusions: The study revealed that while pterygium does not affect the biomechanical response of the central cornea, it does alter certain corneal deformation responses in the mid-periphery, which may indirectly indicate the tractional force exerted by the pterygium tissue on the cornea.

Abstract No.: 206298

To Evaluate the Efficacy of Zero-Shot LLMs in the Extraction of Microbial Keratitis Descriptors

First Author: Lokeshwari ARULJYOTHI

Co-Author(s): Tushar MUNGLE, Nambi NALLASAMY, Venkatesh PRAJNA

Purpose: To extract microbial keratitis (MK) descriptors from clinician notes in EHRs using a Large Language Model (LLM) and compare them with those identified by human annotators. In particular, we wished to evaluate LLM performance in MK descriptor extraction using a zero-shot prompting approach as compared to a human expert gold standard.

Methods: A cohort of 215 patients with culture-proven MK seen between 2019 and 2023 from a tertiary eye care Hospital was gathered. Free-text clinical notes from each patient's first encounter's corneal examination were obtained. A cornea specialist without access to additional clinical data, determined each of three binary MK descriptors from the notes: 1) centrality, 2) infiltrate depth, and 3) presence of thinning. Using the LLMs GPT-4o and GPT-4o mini, a zero-shot prompting method was employed to extract the same three MK descriptors. LLM responses were compared to human annotations using agreement measures such as Cohen's Kappa scores at 95% confidence interval, in addition to sensitivity and specificity.

Results: The detection of MK descriptors was influenced by limitations in the quality and consistency of EHR documentation. GPT-4o demonstrated mean sensitivity of 92%, 86%, and 97%, for centrality, depth, and thinning, respectively, and 96%, 93%, and 99% for specificity. Cohen's Kappa scores calculated for centrality, depth, and thinning were 0.88, 0.73, and 0.88, respectively, indicating good agreement.

Conclusions: Both GPT-4o and GPT-4o mini showed good agreement with human annotations in extracting MK descriptors. However, its utility is influenced by the non-deterministic nature of LLMs and limitations in data quality.

Abstract No.: 203164

Topical Azithromycin With or Without Oral Doxycycline for Meibomian Gland Dysfunction: A Prospective Double-Blind Randomized Controlled Study

First Author: Leo Ka Yu CHAN

Co-Author(s): Wing See Vanessa CHOW, Vishal JHANJI, Kee Ming Jasmine LAM

Purpose: To evaluate whether adding oral doxycycline to topical azithromycin improves outcomes in patients with meibomian gland dysfunction (MGD).

Methods: Fifty-two patients with symptomatic MGD unresponsive to lubricants and warm compresses were enrolled. Group 1 ($n = 26$) received topical azithromycin 1.5% and oral placebo for 28 days, and Group 2 ($n = 26$) received the same topical regimen plus oral doxycycline 100 mg daily for 28 days. Subjects were assessed on OSDI and SPEED questionnaires, slit-lamp, lipid layer thickness, non-invasive tear break-up times (NIBUTs), meibography, and bulbar redness at baseline, 2 weeks, 1 and 3 months.

Results: Both groups showed significant symptomatic improvement, starting at week 2 by OSDI and 1 month by SPEED, and continued to improve up to 3 months. Group 1's OSDI dropped 13.0 ± 15.3 ($p=0.000$), and Group 2's dropped 10.7 ± 15.4 at 3 months ($p=0.004$), but with no inter-group difference ($p>0.05$). Group 1 did not show significant improvement in other parameters, but Group 2 demonstrated a significant increase in first NIBUT ($11.87 \pm 6.26s$, $p=0.025$) and average NIBUT ($14.94 \pm 5.34s$, $p=0.001$) at 3 months.

Conclusions: Topical azithromycin improved symptoms of MGD. The effect can be seen at 2 weeks and was sustained at 3 months with only 1 month of therapy. Addition of oral doxycycline did not confer additional symptomatic improvement, but resulted in improved objective measurements of the NIBUT at 3 months.

Abstract No.: 202744

Topical Delivery of Cultivated Limbal Stem Cells via Porous Photocurable Hydrogel: A Noninvasive, Convenient, and Efficient Stem Cells Delivery Strategy for Limbal Stem Cell Deficiency

First Author: Shujia GUO

Purpose: This study aims to develop a non-invasive, efficient delivery system for cultivated limbal stem cells (LSCs) using a porous photocurable hydrogel to treat limbal stem cell deficiency (LSCD).

Methods: A porous Gelatin Methacryloyl (PG) hydrogel was synthesized and evaluated in vitro and in vivo for its ability to encapsulate LSCs, maintain their viability, and promote cell proliferation and migration. The PG hydrogel was applied in a rabbit LSCD model, using corneal bandage lenses to facilitate non-invasive stem cell delivery.

Results: The PG hydrogel, activated by the non-canonical Wnt signaling pathway, successfully maintained LSC viability and self-renewal. In vivo, the PG hydrogel-loaded LSCs significantly promoted corneal epithelial repair, preventing conjunctival invasion and resulting in avascular, scar-free corneal regeneration. Compared to conventional methods, this strategy reduced surgery time and enhanced patient compliance.

Conclusions: The developed PG hydrogel-based delivery system offers a promising non-invasive and

efficient approach for treating LSCD. It overcomes the limitations of direct stem cell eye drops and traditional transplantation techniques, providing a simplified and effective solution for LSCD treatment with strong potential for clinical application.

Abstract No.: 206297

Topical Insulin Eye Drops Enhance Corneal Epithelial Healing After Lamellar Keratoplasty: Results From a Randomized Controlled Trial

First Author: Muhammad AHAD

Purpose: To assess the efficacy and safety of topical insulin eye drops in promoting epithelial healing following lamellar keratoplasty (LKP) for keratoconus.

Methods: In this prospective, randomized controlled trial, 72 eyes of 72 patients undergoing LKP were randomized to receive either conventional therapy (CT: topical steroid, antibiotic, and lubricant) or conventional therapy plus topical insulin (CTI: 25 IU/ml insulin every 6 hours). Epithelial defects were documented intraoperatively with fluorescein staining and monitored at 24, 48, 72, and 96 hours using slit-lamp photography. The defect area was quantified with ImageJ software. The primary endpoint was complete epithelial healing at 96 hours. Secondary endpoints included the rate of epithelial defect reduction and adverse events.

Results: At 96 hours, complete epithelial healing was achieved in 88.9% of eyes in the CTI group compared with 61.1% in the CT group ($p=0.01$). Median time to full re-epithelialization was shorter in the CTI group (3.2 ± 0.7 days) versus CT (4.5 ± 1.1 days). Daily reduction in epithelial defect area was significantly faster with insulin therapy ($p<0.001$). No insulin-related adverse events were reported.

Conclusions: Topical insulin eye drops significantly accelerate corneal epithelial healing after lamellar keratoplasty with a favorable safety profile. These findings suggest that insulin drops may serve as a cost-effective adjunct to improve graft epithelialization and early postoperative outcomes.

Abstract No.: 204094

Transcriptomic Profiling Reveals Neural-Immune-Stromal Dysregulation and Risk-Associated Gene Signatures in Advanced Keratoconus

First Author: Kaiyue DU

Co-Author(s): Jing HONG

Purpose: This study aimed to characterize transcriptomic alterations and the effects of demographic and behavioral risk factors on disease-associated gene expression patterns in late-stage keratoconus (KC).

Methods: Corneal stromal tissues from 31 KC patients and four normal donors underwent bulk RNA sequencing. Differentially expressed genes (DEGs) and weighted gene co-expression network analysis (WGCNA) were used to identify key molecular changes. Subgroup analyses based on sex, allergy status, eye rubbing intensity (ERI), body mass index (BMI), and childhood socioeconomic status (SES) were conducted using gene set enrichment analysis (GSEA) and WGCNA. Key genes from WGCNA modules were validated by quantitative real-time PCR (qRT-PCR) and three public transcriptomic datasets.

Results: Enrichment analyses based on the 4469 identified DEGs ($P_{adj} < 0.05$) revealed suppression of extracellular matrix (ECM) organization, axon guidance, synaptic signaling, and immune activity ($P_{adj} < 0.05$). Subgroup GSEA demonstrated that high ERI correlated with ECM pathways, elevated BMI correlated with mitochondrial dysfunction, and low childhood SES correlated with upregulated mitochondrial metabolism and immune activation ($P_{adj} < 0.05$). Chromatin regulation and antioxidant activity were enriched in females ($P_{adj} < 0.05$). No transcriptomic associations were detected for allergy status. WGCNA revealed ERI-related modules involving Wnt and PI3K-Akt signaling and SES-related modules implicating cholinergic synapse and axon guidance pathways ($P_{adj} < 0.05$). Validation using qRT-PCR and public datasets confirmed the downregulation of all 15 selected genes in KC ($P_{adj} < 0.05$). qRT-PCR also confirmed differential expression of five subgroup-associated genes across KC subgroups ($P < 0.05$).

Conclusions: These findings emphasize the neural-immune-stromal axis dysregulation in KC and elucidate the contribution of common risk factors to disease progression.

Abstract No.: 200889

Ultrasonography Assessments of Meibomian Gland as a Noninvasive Method of Detecting Changes in Morphology

First Author: Hongbo YIN

Purpose: We employed 24 MHz ultrasonography to evaluate the morphological features of meibomian glands (MGs) and compared the differences in morphology between healthy volunteers and meibomian gland dysfunction (MGD) patients.

Methods: 24 MHz ultrasound examinations on both the upper and lower eyelids of healthy volunteers and MGD patients, using transverse and longitudinal sections. The reproducibility of ultrasonographic findings was evaluated, and a comparison of morphological characteristics at different examination sites between the two groups was made.

Results: Among 89 participants, 24 were healthy volunteers, and 65 had MGD. The cross-sectional

ultrasound findings showed well-organized punctate hyperechoic ducts within the tarsal plate, surrounded by hypoechoic acinar formations, which were further classified based on the extent of MG involvement into three categories: normal, $\leq 50\%$ involvement, and $> 50\%$ involvement. Additionally, a typical longitudinal ultrasound appearance of an MG consisted of a thin band-like hypoechoic acinar with uniform thickness, accompanied by an arc-shaped linear hyperechoic duct in its middle region. Furthermore, seven abnormal longitudinal ultrasound manifestations were categorized as distortion, ectasia, central duct truncation, cyst formation, structureless appearance, complete disappearance, or other findings. The intra- and inter-observer agreement for those categories was found to be high ($ICC > 0.6$). MGD patients exhibited a higher likelihood of abnormal ultrasound findings, particularly in relation to the middle part of the upper eyelid.

Conclusions: The study has developed an initial classification method to identify abnormalities in MG morphology using 24 MHz ultrasound in MGD patients.

Abstract No.: 203043

Ursolic Acid Ameliorates Ocular Surface Dysfunction in Dry Eye via Targeting EGFR/RAS/RAF/MAP2K1/MAPK1 Pathway

First Author: Qinghe ZHANG

Co-Author(s): Zuguo LIU

Purpose: To explore the therapeutic effect and mechanism of ursolic acid (UA) on ocular surface dysfunction induced by benzalkonium chloride (BAC) and scopolamine.

Methods: A hyperosmolarity (500 mOsm) culture medium was used to induce a dry eye model in HCEs, and a mouse dry eye model was established with 0.075% BAC eye drops and 0.25% atropine subcutaneous injections to evaluate UA. Potential targets were identified from TCSP, SWISS, and GeneCards databases. Protein-protein interaction (PPI) and GO & KEGG pathway enrichment analyses were conducted using STRING, Metascape, and Cytoscape to identify key targets and pathways. Single-cell analysis and RNA sequencing were performed, along with Western blot (WB) and immunofluorescence staining to explore UA's mechanism in treating dry eye.

Results: The results indicate that UA restores the viability of hyperosmolarity-damaged HCEs, significantly protects the ocular surface functional unit, and alleviates dry eye symptoms. PPI and GO & KEGG enrichment analyses identified core targets and pathways, revealing that the therapeutic effect of UA on dry eye involves the EGFR/RAS/RAF/MAP2K1/MAPK1 pathway. Single-cell sequencing database analysis showed that key proteins in this pathway are distributed in the anterior segment, particularly the cornea. Finally, Western blot (WB) and

immunofluorescence detection confirmed that UA eye drops treat dry eye through the EGFR/RAS/RAF/MAP2K1/MAPK1 pathway.

Conclusions: UA has the ability to treat benzalkonium chloride-induced dry eye-like ocular surface damage by regulating the EGFR-RAS-RAF-MAPK signaling pathway.

Abstract No.: 202899

VIP Improves Hyperglycemia-Induced Limbal Stem Cell Dysfunction During Corneal Wound Healing by Modulating the STAT1/STAT3 Signaling Balance

First Author: Yangyang ZHANG

Co-Author(s): Lixin XIE

Purpose: To explore how the parasympathetic neuropeptide VIP promotes corneal epithelial injury repair in diabetic mice by regulating the LESC cell cycle via its receptor VIPR1.

Methods: Human primary corneal LSCs were isolated from both non-diabetic and diabetic donor corneas and cultured in vitro to evaluate the effects of VIPR1-siRNA and VIP on cell proliferation, colony formation, and migration. Transcriptome sequencing was performed to identify differentially expressed genes (DEGs) following VIPR1-siRNA intervention. To further analyze by using single-cell databases to determine target genes, and then validate in vivo and in vitro. Protein-level interventions using agonists/inhibitors were applied to identify the key signaling pathways through which VIPR1 regulates corneal LESC function.

Results: VIPR1-siRNA significantly inhibited the proliferation, cloning, and migration of normal human primary corneal LSCs, while exogenous VIP enhanced these abilities in diabetic LSCs. VIPR1-siRNA also reduced corneal epithelial healing in normal mice. Transcriptome analysis showed that VIPR1-siRNA downregulated CCNB2, CDC20, CDC25B, and STAT3, but upregulated STAT1 and other cell cycle-related genes. These changes were consistent with those observed in a type I diabetic mouse model. The STAT1 antagonist fludarabine and the STAT3 agonist ML115 improved corneal healing in diabetic mice by increasing the expression of CCNB2, CDC25B, and CDC20, thereby enhancing the proliferation, cloning, and migration of diabetic LSCs.

Conclusions: VIPR1 regulates the expression of corneal LESC cell cycle-related proteins through STAT1/STAT3 signaling, thereby improving delayed corneal epithelial healing, cell cycle arrest, and apoptosis caused by diabetes mellitus.

Abstract No.: 203455

Visual Improvement in Post-CXL Keratoconus Patients With Scleral Contact Lens

First Author: Ashraful Huq RIDOY

Purpose: To assess the visual acuity level in keratoconus patients after 3 months of Collagen Cross-linkage by applying scleral contact lenses.

Methods: This prospective observational study comprised 91 eyes of 50 patients diagnosed with keratoconus treated with scleral contact lenses, all the patients underwent CXL with Isotonic or Hypotonic solution 3 months back of SCL trial. Out of them, 43 were male and 7 were female. The mean age of the patients was 26.74 ± 7.74 (mean $\pm$ SD) years. Before and after lens administration, the right and left eyes' visual acuity was measured in logMAR units. A paired t-test was used to compare the vision measurements for both eyes. The significance level was set at $p < 0.001$.

Results: The right eye had moderate to severe vision impairment, with a mean pre-lens logMAR visual acuity of roughly 0.9 and a Snellen equivalent of roughly 6/50. With an average reduction of 1.20 ± 0.77 units (95% CI: 0.98 to 1.42), the mean logMAR improved markedly after scleral lens fitting, leading to near-normal post-lens vision (about 6/6 on the Snellen scale). A statistically significant improvement was indicated by this difference ($t(49) = 11.07$, $p < 0.001$). Similar to this, the left eye's pre-lens logMAR was roughly 0.9 (about 6/50 Snellen), but after using the lens, it improved by an average of 0.86 ± 0.63 logMAR units (95% CI: 0.68 to 1.04), which translated back to near-normal vision (about 6/6 to 6/7.5 Snellen). This shift confirmed a considerable improvement in visual function and was also statistically significant ($t(49) = 9.71$, $p < 0.001$). All things considered, these results show that scleral contact lenses help patients with keratoconus see more clearly after collagen cross linking, both statistically and clinically.

Conclusions: The study shows strong evidence that scleral contact lenses significantly improve the vision of keratoconus patients after CXL. These findings provide credence to the result that scleral contact lenses are a useful treatment for people with refractive conditions like keratoconus.

Abstract No.: 206631

"Simultaneous Penetrating Keratoplasty With Simple Limbal Epithelial Transplantation: A Case Series"

First Author: Nikita DAS

Co-Author(s): Shilpa TARINI

Purpose: To evaluate outcomes of simultaneous penetrating keratoplasty (PK) with simple limbal epithelial transplantation (SLET) as a single-stage procedure in eyes with limbal stem cell deficiency (LSCD) and corneal scarring.

Methods: This retrospective case series included five eyes of five patients who underwent PK with concurrent SLET. Indications were chemical injury (n=4) and failed therapeutic PK with LSCD (n=1). Three eyes had vascularized corneal scars, one had corneal melt with perforation, and one had a failed large PK. Two eyes underwent PK with autologous SLET, two with cadaveric allogeneic SLET, and one with live-related allogeneic SLET. Demographics, indications, surgical details, visual acuity (VA, logMAR), intraocular pressure (IOP), complications, and graft clarity were analysed.

Results: Median age was 36 years (IQR 30–61); 4 patients were male. LSCD was total in 4 eyes and partial (9 clock hours) in 1. Corneal scarring was diffuse in 4 eyes and central, localised in 1. Median follow-up was 567 days (IQR 438–666). Preoperative VA was median logMAR 2.0 (IQR 2.0–2.3), improving to 0.5 (IQR 0.5–0.8) at 6 months. Paired t-test showed a mean difference of 1.56 ± 0.40 logMAR ($t(4)=8.78$, $p<0.001$; 95% CI 1.07–2.05). Repeated-measures ANOVA confirmed significant improvement across timepoints ($F(3,12)=28.1$, $p<0.001$, partial $\eta^2=0.88$). All grafts were clear and epithelialized by 6 months. Complications included one reversible graft/epithelial rejection and one corneal infiltrate at 3 months, both managed successfully.

Conclusions: Simultaneous PK with SLET is feasible in LSCD with corneal scarring, avoiding staged procedures. This combined approach achieved graft clarity, surface epithelialization, and meaningful visual recovery with manageable complications.

Glaucoma

Abstract No.: 203032

36-Month Multi-Centre Outcomes of XEN45 Gel Stent Implantation in Asian Versus Non-Asian Eyes With Primary Open Angle Glaucoma

First Author: Bryan ANG

Co-Author(s): Bjorn BETZLER, Syril DORAIRAJ, Hani HELWE, Yu Chieh KO, David SOLA-DEL VALLE

Purpose: To report 3-year outcomes of XEN45 Gel Stent (XGS) in Asian versus non-Asian eyes with primary open angle glaucoma (POAG).

Methods: Multicentre, retrospective, comparative study of 149 eyes (149 subjects) receiving XGS with or without phacoemulsification, between January 2017 and March 2023. Primary outcomes included reduction in medicated intraocular pressure (IOP) and medications, and cumulative success probabilities. Complete Success (CS) was defined as IOP reduction $\geq 20\%$ with $5 \leq \text{IOP} \leq 21 \text{ mmHg}$ for two consecutive visits, with no XGS revision and without medications. Qualified Success (QS) was defined as subjects

on $\leq$ baseline number of medications. Secondary outcomes included post-operative interventions and complications.

Results: A total of 90 eyes of Asian and 59 eyes of non-Asian ethnicity were included. Demographics differed in age, gender and baseline medications (Asian vs. non-Asian: 63.3 ± 12.1 vs 70.8 ± 10.2 years, 77.1% vs 45.2% male, 3.1 ± 0.9 vs 2.4 ± 1.2 medications, all $p \leq 0.001$), all of which were controlled for. Both groups experienced IOP and medication reduction at all timepoints. At post-operative month (POM) 12, non-Asian eyes had greater IOP reduction from baseline (Asian: -3.3 ± 5.9 vs non-Asian: -5.3 ± 5.1 mmHg, $p=0.029$). At POM24 and POM36, success probabilities were similar between groups for CS (Asian vs. non-Asian eyes: 18.8% vs. 11.3%, $p=0.54$; 12.7% vs. 7.5%, $p=0.66$) and QS (Asian vs. non-Asian eyes: 28.8% vs. 16.7%, $p=0.62$; 12.7% vs. 7.5%, $p=0.87$). Median survival times for Asian eyes were 171 days (CS) and 183 days (QS), and 273 days (CS) and 351 days (QS) for non-Asian eyes.

Conclusions: Both groups experienced similar long-term surgical efficacy. However, Asian eyes experienced failure earlier than non-Asian eyes.

Abstract No.: 204359

A Comparative Analysis of Measured Goldmann Applanation Tonometry Intraocular Pressure (GAT IOP) vs. Dynamic Scheimpflug Analyzer (CORVIS ST®) Biomechanically Corrected IOP (bIOP) Before and After Photorefractive Keratectomy (PRK) and Laser In-Situ K

First Author: Cristina TAN

Purpose: The Goldmann Applanation Tonometer (GAT) is the most widely used standard for the measurement of intraocular pressure (IOP). However, it heavily relies on central corneal thickness (CCT) and curvature to obtain accurate results. Changes in CCT occur in eyes after PRK and LASIK, resulting in underestimated IOP. Biomechanically-corrected IOP (CORVIS ST® bIOP) is a newer device using corneal biomechanics which is known to be independent of CCT.

Methods: This is a single-center, prospective, cross-sectional study of 212 eyes of 106 patients who underwent Photorefractive keratectomy (PRK) and Laser-in-situ Keratomileusis (LASIK). The level of agreement was compared between the devices pre- and post-operatively (1, 3, 6 months). The correlation with central corneal thickness was also assessed.

Results: PRK and LASIK had a significant decrease in mean GAT IOP in the pre-operative vs. post-operative periods at 1, 3, and 6 months (LASIK: 14.21 ± 1.74 vs. 11.48 ± 1.93 , 11.53 ± 1.63 , 11.66 ± 1.49 ; PRK: 31.14 ± 1.84 vs. 12.66 ± 2.18 , 11.18 ± 1.71 , 11.19 ± 1.59 respectively). CORVIS bIOP maintained consistently 32 higher values than GAT IOP in the post-op

periods (LASIK: 14.53 ± 1.66 vs. 19 ± 1.99 , 14.02 ± 1.57 , 13.94 ± 1.52 ; PRK: 15.01 ± 1.76 vs. 14.61 ± 1.97 , 14.66 ± 1.62 , 14.57 ± 1.55 respectively). Pre- and post-GAT IOP showed a significant correlation to central corneal thickness ($P < 0.05$) for both PRK and LASIK, while no significant correlation was found between bIOP ($P > 0.05$) and CCT.

Conclusions: GAT IOP had significant reductions post-operatively, while CORVIS ST bIOP were not significantly different from the pre- to post-operative periods.

Abstract No.: 201129

A Comparative Evaluation of Two Rapid Strategies for Visual Field Testing: SITA Faster and SPARK Quick

First Author: Cong YE

Purpose: This study compares the diagnostic performance of two rapid visual field testing strategies, SITA Faster (SF) and SPARK Quick (SQ), against the gold standard SITA Standard (SS). The measurement accuracy, agreement, and repeatability were evaluated.

Methods: In this prospective, cross-sectional study, 118 participants from a glaucoma clinic underwent multiple visual field tests. All subjects were naïve to SF and SQ, with SS 24-2 serving as the initial test. SF and SQ were then administered in random order. Among the 71 participants with visual field defects detected by SS, 49 underwent testing twice with both rapid strategies. Parameters were compared using one-way ANOVA with Bonferroni post hoc tests, and repeatability was assessed using intraclass correlation coefficients (ICC). A bootstrap method (5000 samples) evaluated the differences in repeatability. Agreement was analyzed using Bland-Altman plots, and diagnostic performance was assessed via receiver operating characteristic (ROC) curves.

Results: No significant differences in mean deviation (MD) and pattern standard deviation (PSD) were found between SS and SF; however, SQ demonstrated significantly better MD and PSD ($p < 0.001$). Test duration was reduced by 57.6% for SF and 73.9% for SQ compared to SS ($p < 0.001$). Bland-Altman analysis revealed that the mean difference in MD between SS and SF was not significantly different from zero ($p = 0.1775$), while SQ's difference was significant ($p < 0.001$). ICC values indicated excellent repeatability for SF, whereas SQ exhibited significantly lower ICCs ($p < 0.001$). Among the 118 participants, 71 (60.2%) had visual field defects identified by SS, 70 (59.3%) by SF, and 30 (25.4%) by SQ. Sensitivity and specificity for SF were 83.1% and 76.6%, respectively, compared to 40.8% and 97.9% for SQ. ROC analysis yielded AUCs for MD of 0.89 for SF and 0.87 for SQ ($p = 0.385$); for PSD, AUCs were 0.92 and 0.72 ($p = 0.004$). The Conger's Kappa coefficient indicated substantial agreement among the strategies.

Conclusions: Both SF and SQ significantly shorten testing duration. SF yields results comparable to SS, while SQ may underestimate defects. Each strategy offers distinct advantages for different clinical applications.

Abstract No.: 204627

A Cross-Sectional Study to Assess the Prevalence of Depression or Anxiety Among Glaucoma Patients and Examine Their Relationship With Various Factors Related to Glaucoma

First Author: Annamalai ODAYAPPAN

Co-Author(s): Rashmirita KAKOTY, Balagiri SUNDAR, Swati UPADHYAYA, Rengaraj VENKATESH

Purpose: To evaluate the prevalence of depression and anxiety among glaucoma patients compared to the general population. We also explored the association between these psychological disturbances and various factors related to glaucoma.

Methods: A cross-sectional study was conducted from February 2023 to January 2024 with 323 participants: 162 glaucoma patients and 161 age-matched controls from the general population. Participants underwent detailed ocular evaluations and completed the Hospital Anxiety and Depression Scale (HADS). Glaucoma severity was classified using the Hodapp, Parrish, and Anderson criteria.

Results: The prevalence of depression and anxiety was significantly higher in glaucoma patients compared to the general population (30.2% vs. 8.7% for depression, $p < 0.001$; 27.8% vs. 6.2% for anxiety, $p < 0.001$). Multivariable logistic regression showed that lower visual field index (VFI) in the worse eye (OR: 0.96, 95%CI: 0.93–0.98, $p = 0.006$), presence of sleep disturbance (OR: 3.3, 95%CI: 1.51–7.23, $p = 0.003$) and greater number of anti-glaucoma medications (OR: 1.9, 95%CI: 1.10–3.33, $p = 0.022$) were significantly associated with depression. Patients with lower VFI in the worse eye (OR: 0.96, 95%CI: 0.94–0.99, $p = 0.006$) and those with sleep disturbance (OR: 4.22, 95%CI: 1.89–9.46, $p < 0.001$) had significantly higher odds of anxiety.

Conclusions: Glaucoma patients experience significantly higher rates of depression and anxiety. Factors such as advanced disease, visual field loss, and sleep disturbance were identified as key risk factors. Routine psychological screening should be integrated into glaucoma management to identify at-risk patients and provide timely interventions, improving both ocular and mental health outcomes.

Abstract No.: 205274

A Multigroup Comparative Study of Five Trabeculotomy-Based MIGS Procedures in Open-Angle Glaucoma- GKIBT Study

First Author: Devendra **MAHESHWARI**

Co-Author(s): Nimrita **NAGDEV**, Madhavi **PILLAI**

Purpose: To compare the 12-month safety and efficacy of various trabeculotomy-based MIGS procedures—Gonioscopy-assisted transluminal trabeculotomy (GATT), Kahook Dual Blade (KDB) goniotomy, Interventional valve enhancing trabeculotomy (iVent), Bent Ab-interno Needle Goniectomy (BANG), and Tanito microhook trabeculotomy (TMH) combined with phacoemulsification in patients with open-angle glaucoma.

Methods: This prospective study included 234 eyes undergoing GATT (n=53), KDB (n=51), iVent (n=52), BANG (n=34), or TMH (n=44). All the MIGS procedures were combined with phacoemulsification. Baseline characteristics like Intraocular pressure (IOP), Best corrected visual acuity (BCVA), and anti-glaucoma medications (AGMs) were compared at each post-operative visit. Data were collected at 2 weeks, 1 month, 3, 6, and 12 months. Surgical success was defined as IOP ≤ 21 / ≤ 18 mmHg with > 20%/25% reduction from baseline, respectively (Criteria 1, 2). Complications, secondary interventions, and surgical risk factors were also analyzed.

Results: The mean (SD) IOP (mmHg) reduced from 21.58 ± 4.69 to 12.83 ± 3.01 at the end of 12 months in the GATT-Phaco group, with a corresponding reduction in AGM from 1.55 ± 0.75 to 0.15 ± 0.46 . Similarly, in the Phaco-KDB group (22.33 ± 2.69 mmHg to 14.51 ± 5.04 mmHg; 1.63 ± 0.75 to 0.08 ± 0.39 AGMs), iVent-Phaco group (20.85 ± 3.38 mmHg to 13.73 ± 2.88 mmHg; 1.75 ± 0.93 to 0.04 ± 0.19 AGMs), BANG-Phaco group (22.18 ± 2.46 mmHg to 15.42 ± 4.38 mmHg; 1.50 ± 0.71 to 0.29 ± 0.64), Tanito-Phaco group (22.48 ± 3.79 mmHg to 14.48 ± 4.13 mmHg; 1.43 ± 0.66 to 0.26 ± 0.63 AGMs). There was a significant reduction in IOP and AGM in each group at 12 months ($p < 0.001$). GATT-Phaco group had the maximum mean IOP percentage reduction of 38.7%, followed by KDB, TMH and iVent (34.1%, 34.5%, 33.1%) and the least with BANG (30.2%). Complete success by criteria 1 and 2 were more in GATT (89.1%, 79.3%) and KDB groups (86.3%, 82.4%), followed by iVent (76.9%, 69.2%), BANG (79.4, 79.4) and TMH (75%, 72.7%).

Conclusions: At the end of 12 months, GATT and KDB combined with phacoemulsification demonstrated similar and most favorable outcomes, followed by Tanito, iVent, and BANG in open-angle glaucoma. All approaches significantly lowered IOP and AGM.

Abstract No.: 203738

A Noninvasive Brimonidine-Loaded Conjunctival Insert to Sustainably Reduce Intraocular Pressure for Glaucoma Treatment

First Author: Zhutian **ZHANG**

Co-Author(s): Jianguo **SUN**, Xinghuai **SUN**

Purpose: Glaucoma is a leading cause of irreversible blindness worldwide. Reducing intraocular pressure (IOP) is the primary strategy to delay disease progression, and daily administration of eye drops is the common method. However, limited drug retention time and poor ocular bioavailability often compromise treatment efficacy and patient adherence. This study aimed to develop a sustained-release delivery system for brimonidine (BRI) to overcome these limitations.

Methods: A novel brimonidine-loaded silicone rubber insert (BRI@SR@PT) was prepared by incorporating BRI into a silicone rubber core, followed by sequential coatings of polydopamine and thermoplastic polyurethane. The physical properties, in vitro cytocompatibility, and drug release profile of the insert were evaluated. For in vivo assessment, the BRI@SR@PT was noninvasively placed into the conjunctival sac of rabbits. Subsequent analyses included in vivo drug release profiles, IOP-lowering efficacy, and biosafety evaluation.

Results: The BRI@SR@PT insert exhibited excellent thermal stability and mechanical elasticity. In vitro studies demonstrated continuous BRI release for up to 28 days with minimal cytotoxicity. In vivo, a single administration of the insert achieved significant IOP reduction for 21 days, far surpassing the short duration observed with conventional BRI eye drops. No signs of ocular toxicity or adverse reactions were observed throughout the experimental period.

Conclusions: The BRI@SR@PT conjunctival sac insert offers a promising noninvasive platform for long-term glaucoma treatment. Its ability to provide sustained IOP reduction effect may enhance treatment efficacy and patient compliance, representing a valuable alternative to traditional eye drops.

Abstract No.: 204214

A Novel Rabbit Model of Angle-Closure Glaucoma via Ciliary Block and Elevated Trans-Lens Pressure Difference

First Author: Xuanli **ZHENG**

Co-Author(s): Huan **CHEN**, Yuan-bo **LIANG**, Hai-shuang **LIN**, Fengping **ZHAO**

Purpose: While angle closure is a hallmark of primary angle-closure glaucoma (PACG), the upstream biomechanical drivers initiating this process remain poorly understood. It has been recently proposed that ciliary block elevates the trans-lens pressure difference, initiating anterior chamber shallowing. However, this mechanism lacks direct in vivo validation. To address

this gap, we established and characterized a novel rabbit model of angle-closure glaucoma induced by ciliary block-mediated trans-lens pressure difference.

Methods: Thirty rabbits were divided into three groups: intraocular lens with a capsular tension ring (IOL+CTR), IOL-only, and untreated control (n=10 each). Ciliary block was induced in the IOL+CTR group via extracapsular lens extraction and implantation of an oversized (13mm) CTR. Over 8 weeks, we monitored intraocular pressure (IOP), anterior chamber dynamics, and trans-lens pressure differences using tonometry and manometry, followed by histopathological evaluation.

Results: The IOL+CTR group developed sustained ocular hypertension with a significant trans-lens pressure gradient (8.5 ± 1.6 mmHg vs. 1.2 ± 1.6 mmHg in controls, $P < 0.001$). Quantitative analysis identified this gradient as the primary driver of anterior chamber shallowing (ACD: 4.06 ± 0.15 mm vs. 4.59 ± 0.11 mm in IOL group, $P < 0.001$) and complete angle closure—features absent in control groups. Mathematical modeling revealed a strong relationship between pressure gradient and ACD ($R^2 = 0.708$). Consequently, IOL+CTR animals exhibited classic glaucomatous optic neuropathy, characterized by 50% reduction in retinal thickness and marked optic nerve head excavation. Progressive exophthalmos occurred in 80% of these animals.

Conclusions: We successfully developed a reproducible rabbit model in which ciliary block-induced trans-lens pressure difference acts as a pivotal mechanistic link to anterior chamber shallowing, angle closure, and sustained IOP elevation, recapitulating key features of human angle-closure glaucoma.

Abstract No.: 206481

A Prospective Study on the Incidence of Normal Tension Glaucoma Among Chinese Patients With Treatment Naïve Obstructive Sleep Apnea Syndrome

First Author: Chi Him **TSANG**

Co-Author(s): Kendrick **SHIH**

Purpose: To investigate the incidence and risk factors for normal tension glaucoma (NTG) in Chinese patients with newly diagnosed and treatment naïve obstructive sleep apnea syndrome (OSAS).

Methods: This is a prospective cohort study conducted between 1st of July 2015 and 30th of June 2017. 220 consecutive subjects, who were referred to the respiratory clinic at Queen Mary Hospital for suspected OSAS, were recruited. Subjects with a pre-existing diagnosis of glaucoma or a history of OSAS treatment were excluded from analysis. Subjects underwent polysomnography (PSG), using Apnea-Hypopnea Index (AHI) as the diagnostic OSAS. The subjects further underwent a comprehensive glaucoma workup at

Grantham Hospital, including slit lamp examination, gonioscopy, intraocular pressure measurement, and at least two Humphrey Visual Field 24-2 and Optical Coherence Tomography (OCT) retinal nerve fiber layer assessments four months apart. Anderson's criteria were used for diagnosing glaucoma.

Results: A total of 195 Chinese patients consented to the study. On follow-up, 7 patients were excluded as they did not complete at least two ophthalmic assessments. The analyzed 188 patients had a mean age of 53.3 ± 9.9 , and 64.5% of them were male. The overall two-year incidence of normal tension glaucoma in this cohort was 6.34%. Subjects with more severe OSAS had a higher incidence of NTG. There were no significant correlations between AHI score and glaucoma parameters.

Conclusions: Patients with treatment naïve OSAS are at increased risk of NTG. Increased OSAS severity, as measured by AHI, is a marker for a higher risk of NTG. It is worthwhile to investigate the cost-effectiveness of glaucoma screening in this cohort.

Abstract No.: 203643

A Shark-Bioinspired Design of Aqueous Tesla Shunt: Bring Biomimeticism Into Minimally Invasive Glaucoma Surgery

First Author: Yingyan **MAO**

Co-Author(s): Luyi **HAN**, Qing **SANG**, Chu **WANG**, Ningli **WANG**

Purpose: To solve the critical gaps in glaucoma treatment—no approved external aqueous humor (AH) drainage devices and unaddressed reverse flow/infection risks—this study aimed to design, fabricate a shark-bioinspired aqueous Tesla shunt, and comprehensively verify its safety and efficacy as an innovative AH outflow pathway.

Methods: The design of the aqueous shunt was bioinspired by the spiral intestines of sharks. In vitro hydrodynamic experiments were subsequently conducted to validate the functional performance of the optimized shunt. For in vivo evaluations, normotensive rhesus macaques were used as animal models, with a follow-up period of 36 months. Additionally, preliminary clinical trials were carried out, with a 24-month follow-up duration, to assess the shunt's efficacy and safety in glaucoma patients.

Results: In the rhesus macaque models, the shunt exhibited efficacy in reducing IOP. Corneal endothelial density remained within normal ranges, showing no tissue damage. Anterior segment OCT confirmed stable device positioning without corneal remodeling or displacement. Clinically, 80% of patients maintained target IOP without hypotensive medications at 24 months, and no severe adverse events like infection or reverse flow occurred.

Conclusions: The shark-bioinspired Tesla shunt exhibits excellent biocompatibility and hydrodynamic efficacy. It enables an enhanced safety profile, reduced complications, increased efficacy of lowering IOP and reduced IOP fluctuations. It holds significant translational potential as a safe, long-lasting MIGS device for mild-to-severe glaucoma.

Abstract No.: 204885

A Study to Analyze the Cognitive Function in Normal Tension Glaucoma Patients

*First Author: Narayanan **BALAKRISHNAN***

Purpose: This study aims to analyze the cognitive function in Normal tension glaucoma (NTG) compared to High tension Glaucoma (HTG).

Methods: A case-control, cross-sectional analytical study involving 28 age and sex matched NTG participants and HTG controls was performed. Patients diagnosed with vision-related or neurological conditions were excluded. A detailed glaucoma evaluation was done, which included vision, IOP, Gonioscopy, CCT, HVF, and anterior and posterior segment examination. Both groups underwent a Montreal Cognitive Assessment Test (MoCA), and their cognition was documented. A cognitive function of <26/30 was considered significantly poor.

Results: All baseline characteristics were matched in both groups. The prevalence of cognitive impairment was high in the NTG group compared to the HTG group, and this value was statistically significant. A MoCA score of <26/30 was noted to a great extent amongst the NTG participants. Twenty-two NTG (78.6%) and twelve HTG participants (42.9%) had a mean MoCA score of <26/30 with a p value of 0.006. The mean deviation (MD) and pattern standard deviation (PSD) values were correlated with the cognitive impairment in the NTG group. However, Central corneal thickness (CCT) did not show any correlation. On calculating the odds ratio, the NTG group had 2.4 times greater risk of developing cognitive impairment compared to the HTG group (OR= 2.4, 95% CI: 1.148 to 4.904).

Conclusions: NTG patients have poorer cognition as compared to high tension glaucoma, and this may be associated with a risk of developing dementia in the future.

Abstract No.: 202350

A-Stream Glaucoma Shunt Versus Trabeculectomy: One-Year Results on Efficacy and Safety

*First Author: Hae Min **PARK***

*Co-Author(s): Jong Chul **HAN**, Eun Jung **LEE**, Do Young **PARK**, Seungsoo **RHO**, Jong Hoon **SHIN***

Purpose: To compare the effectiveness and safety of the A-stream Glaucoma Shunt (A-stream; MICROT Inc.,

Republic of Korea) to trabeculectomy in patients with primary open-angle glaucoma, pigmentary glaucoma, and pseudoexfoliative glaucoma. A-stream features a larger lumen compared to conventional MIGS devices, and promotes stable postoperative IOP control via preplaced ripcord; it is widely adopted in Korea.

Methods: Medical records of 30 eyes undergoing A-stream implantation and 38 eyes undergoing trabeculectomy were retrospectively reviewed. Primary outcomes were surgical success and intraocular pressure (IOP) reduction at 1 year, with success defined as IOP ≤ 21 mmHg and $\geq 20\%$ reduction without persistent hypotony (IOP < 6 mmHg > 1 month or with hypotony maculopathy). Success was classified as complete (without medications) or qualified (with/without medications). Ripcord removal, postoperative interventions, and complications were also assessed.

Results: A-stream and trabeculectomy demonstrated comparable efficacy, with qualified success rates of 90.0% and 84.2% and complete success rates of 60.0% and 50.0%, respectively. At 1 year, mean IOP significantly decreased from 24.5 to 12.4 mmHg in the A-stream group and 25.7 to 12.1 mmHg in the trabeculectomy group, with similar medication use. Ripcord removal was performed in most A-stream eyes at 2.5 months, yielding additional IOP reduction. Hypotony-related complications and postoperative interventions were more frequent after trabeculectomy, although no vision-threatening events were observed.

Conclusions: The A-stream Glaucoma Shunt demonstrated favorable one-year efficacy and safety compared to trabeculectomy. The ripcord enabled more controlled postoperative IOP management with a lower incidence of hypotony.

Abstract No.: 206352

Aberrantly Activated Unfolded Protein Response (UPR) in the Astrocytes of the Optic Nerve Head Accelerated Retinal Ganglion Cell Loss in Retinal Explants In Vitro

*First Author: Shaodan **ZHANG***

*Co-Author(s): Pin **WANG**, Jiayu **ZOU***

Purpose: To investigate the effect of UPR activation on the reactive state of optic nerve head astrocytes (ONHAs) and its impact on the survival of the co-cultured retinal explants.

Methods: Primary ONHAs isolated from adult wild-type mice were exposed to endoplasmic reticulum stress inducer tunicamycin (Tm, 0.5 and 2 mg/mL) for 48h. The expressions of UPR pathway-associated proteins were assessed by Western Blot. The neurotoxic phenotypic shift of ONHAs was evaluated by immunohistochemical staining and qPCR. Synthesis of astrocyte-derived neurotrophic factors by the ONHAs was quantified using qPCR and ELISA. A co-

culture system was established using ONHAs or ONHA-conditioned medium with the mouse neural retina explants. Retinal ganglion cell (RGC) survival was evaluated and compared between Tm-pretreated and control groups.

Results: Tm treatment induced a distinct UPR-reactivity profile in ONHAs. The PERK and XBP1 signaling pathway were significantly up-regulated in Tm-treated ONHAs at both the mRNA and protein levels. After 48 hours of Tm exposure, the pro-inflammatory A1 astrocyte markers were significantly up-regulated in ONHAs, while the expression of ciliary neurotrophic factor (CNTF) and brain-derived neurotrophic factor (BDNF) was markedly down-regulated in both ONHA and its supernatant. By day 4 and day 7, the number of RGCs in the retina explants co-cultured with both Tm-pretreated ONHA and ONHA-conditioned medium was significantly lower compared to their counterpart control groups.

Conclusions: Astrocytic UPR exerts an IOP-independent pathogenic role in the neurodegeneration of RGCs. It provides novel insights into the underlying mechanism of glaucomatous neuropathy and may be a potential therapeutic target for neuroprotective strategies.

Abstract No.: 204329

Accuracy of Intraocular Pressure Self-Measurement With Home-Tonometer

First Author: Kaichen **ZHUO**

Co-Author(s): Jingjing **HUANG**

Purpose: To assess the accuracy of the home-tonometer (iCute® Rebound Tonometer, iCute) against Goldmann Applanation Tonometry (GAT) for measuring intraocular pressure (IOP).

Methods: We recruited 45 patients from the outpatient clinic, including 33 glaucoma patients and 12 normal subjects. After training and passing a consistency assessment on the use of the iCute, participants performed IOP self-measured (iCute-pat). Afterwards, two ophthalmologists measured the IOP of each subject with iCute (iCute-doc) and GAT, respectively. The consistency of the measurements obtained by the doctor and patients using iCute was evaluated with paired t-test. The agreement and correlation between the measurements obtained with different tonometer were calculated using the Bland-Altman method and the Pearson correlation coefficient, respectively. Only the right eyes were used for statistical analysis to avoid statistical errors.

Results: There was no statistically significant difference between iCute-doc and iCute-pat. Mean differences (bias) between iCute-doc and iCute-pat, GAT and iCute-doc, and GAT and iCute-pat were -0.1087 mmHg, 0.6087 mmHg, and 0.5000 mmHg, demonstrating that the iCute tonometer tends to underestimate the IOP compared to GAT. The correlations of iCute-doc with both GAT ($r=0.8872$) and iCute-pat ($r=0.8024$) were

very strong, while the correlation between iCute-pat and GAT was strong ($r=0.7774$).

Conclusions: Self-measurement of IOP with the iCute® Rebound Tonometer shows acceptable accuracy compared to the Goldmann Applanation Tonometry.

Abstract No.: 206744

Additional Yield of a Neurophthalmological Evaluation in Patients Diagnosed With Glaucoma

First Author: Shantha **BALEKUDARU**

Purpose: To identify demographic and clinical markers for providing additional yield for neurological diagnosis in patients diagnosed with glaucoma.

Methods: Retrospective chart analysis of patients diagnosed with glaucoma, referred to the neurophthalmology department for further evaluation (January 2017 - December 2017). Demographic, clinical features, and investigation results were compared with those of consecutive patients identified with primary open-angle glaucoma as controls. Eyes with the worse visual acuity and/or visual field index was used as the unit of analysis.

Results: Cases (134) older than controls (100); 55.9 ± 15.5 years vs $63.8 \pm p < 0.001$. LogMAR visual acuity; cases 0.53 ± 0.75 vs 0.23 ± 0.53 controls ($p=0.02$). Cup: Disc ratio 0.6 ± 0.7 cases vs 0.8 ± 0.2 controls ($p=0.01$). Color vision abnormalities 29 (21.6%) cases vs 23 controls (23%) ($p=0.19$). Disc pallor; cases 60 (44.8%) vs controls 1 (1%), glaucomatous cupping cases 38 (28.4%), controls 92 (92%); pallor and cupping; 13 cases (9.7%) ($p < 0.001$). Visual field patterns were as follows; cases vs controls; neurological 34 (25.4%) vs 3 (3%), non-specific 13 (9.7%) vs 2 (2%), glaucomatous 60 (44.8%) vs 67 (67%) ($p=0.01$). Logistic regression identified the following factors for yielding a neurological diagnosis; Age; O.R 0.95 (0.93,0.97) $p < 0.001$, Logmar visual acuity: O.R 2.47 (1.39,4.34) $p=0.002$, Cup: disc ratio O.R 0.51 (0.3,0.87) $p=0.01$, Pallor O.R 7.2 (2.8,18.5) $p < 0.001$, neurological visual field pattern O.R 9 (2.22,36.89) $p=0.002$. Neurological diagnosis included space-occupying lesions; 7 (5%), intracranial aneurysm 1 (0.07%), Ischemic changes 16 (11.9%), miscellaneous, including toxic, nutritional, and traumatic optic neuropathy and optic neuritis, 20 (14.9%).

Conclusions: Clinical and visual field examination provided additional yield of important neurological diagnosis following neurological referral.

Abstract No.: 204782

Anterior Lens Capsule Proteomics Reveals Lysosomal Acidification Dysfunction and Pro-Fibrotic Remodeling in Primary Angle Closure Glaucoma

First Author: Jiamiao LIU

Co-Author(s): Rong RONG, Jing WANG, Xiaobo XIA

Purpose: To characterize proteomic differences in anterior lens capsules (ALCs) from patients having primary angle closure glaucoma (PACG) coexisting with age-related cataract (ARC) versus ARC alone, and to identify molecular clues to glaucoma pathophysiology.

Methods: This was a case-control study. ALCs were collected intraoperatively from 14 PACG patients with ARC and 15 age-matched ARC patients. Proteomic analyses were conducted using 4D-DIA mass spectrometry. Differentially expressed proteins (DEPs) were identified and subjected to pathway enrichment analysis, and protein-protein interaction networks were constructed to reveal key functional modules.

Results: A total of 1262 DEPs were identified. Enrichment analysis showed systemic disruption of protein homeostasis, marked by significant downregulation of protein NEDDylation/deNEDDylation and the TRiC/CCT chaperonin, including hub proteins such as COPS5, TCP1 and CCT2. Meanwhile, lysosomal acidification deficits were observed, evidenced by uniform downregulation of multiple vacuolar H⁺-ATPase subunits and Rag GTPases. These alterations were further associated with reduced activity of mechanistic target of rapamycin complex 1 (mTORC1), autophagy, and hypoxia-inducible factor-1 (HIF-1) signaling pathways. In contrast, Notch signaling and protein fucosylation pathways were significantly upregulated, suggesting activation of fibrotic remodeling programs.

Conclusions: The present work identified distinct proteomic profiles of ALCs in PACG and ARC patients. The systemic impairment of proteostasis and lysosomal dysfunction in PACG may cascade to suppress mTORC1 and autophagy signaling, thereby activating abnormal pro-fibrotic pathways. These findings highlight lysosomal acidification dysfunction and pro-fibrotic remodeling as central molecular features of PACG pathophysiology, providing novel insights for promising biomarkers and therapeutic intervention in glaucoma.

Abstract No.: 200420

Assessing the Efficacy of Vessel Density in Monitoring Visual Field Defects in Glaucomatous Eyes With Myopia: A Study in a Vietnamese Population

First Author: Truong Dang Minh PHAM

Co-Author(s): Kim Thanh DOAN, Ngoc Phuong Vy LY, Thao Huong NGUYEN, Thi Uyen Duyen NGUYEN, Anh Tuan TRAN

Purpose: Diagnosing and monitoring glaucoma in highly myopic eyes presents significant challenges. Vessel density (VD) measurements are less susceptible to the retinal and optic nerve head changes due to high myopia. This study evaluated the macular and peripapillary VDs, and their correlations with visual field mean sensitivities (VFMS) in patients with primary open-angle glaucoma and high myopia.

Methods: This observational cross-sectional study was performed on 40 primary open-angle glaucoma eyes with high myopia. Macular VDs, ganglion cell-inner plexiform layer thicknesses (GCIPLT); peripapillary VDs, and retinal nerve fiber layer thicknesses (RNFLT) were measured. These indices' global and sectoral correlations with the visual field mean sensitivities (VFMS) were assessed.

Results: The macular global, inner, and outer VDs were $34.38 \pm 8.15\%$, $35.00 \pm 8.79\%$, and $34.91 \pm 8.33\%$, respectively. The peripapillary global, superior, nasal, inferior, and temporal VDs were $35.44 \pm 4.55\%$, $34.96 \pm 4.51\%$, $34.91 \pm 4.22\%$, $35.29 \pm 4.85\%$, and $36.33 \pm 5.33\%$, respectively. The outer global VD correlated with the corresponding VFMS ($p = 0.026$). Macular inferior VFMS correlated with macular outer inferior VD ($p = 0.001$), more strongly than with corresponding GCIPLT. Peripapillary global VFMS and VFMSs of all sectors correlated with corresponding peripapillary VDs (all $p < 0.001$), more strongly than with corresponding RNFLT.

Conclusions: VD is a necessary adjunct to GCIPLT and RNFLT to monitor the progression of glaucomatous visual field defects in highly myopic eyes, especially in the outer inferior macula and the global, superior, nasal, inferior, and temporal peripapillary regions.

Abstract No.: 201818

Benefit of Omidenepag Isopropyl Ophthalmic Solution in Treatment Persistence in Japanese Patients With Glaucoma

First Author: Kenji KASHIWAGI

Co-Author(s): Masahiro FUWA, Reiko MIYAHARA, Tadashi NAKANO, Toru NAKAZAWA, Naomi OTSUKA

Purpose: To investigate the treatment persistence of antiglaucoma ophthalmic solution monotherapy, we conducted a retrospective observational cohort study in Japan.

Methods: Patients aged 18 years or older who were diagnosed with glaucoma between November 2018 and August 2020, and prescribed omdenepag isopropyl (OMDI), prostaglandin F receptor agonist (FP), or beta-blocker (BB) monotherapies were included. Data were obtained from the JMDC health insurance claims database (JMDC Inc., Tokyo, Japan).

Results: A total of 36,450 patients (5,865 patients prescribed OMDI, 20,715 patients prescribed FP, and 9,870 patients prescribed BB) were analyzed. The cumulative treatment persistence rate at three years was 27.0% (95% confidence interval [CI]: 25.9-28.1) in patients prescribed OMDI, which was significantly higher than 20.9% (95% CI: 20.4-21.5) in those prescribed FP; the hazard ratio was 0.835 (95% CI: 0.806-0.865, $p < 0.0001$), calculated with the multivariate Cox proportional hazards model. The median duration of treatment persistence, calculated with the Kaplan-Meier methods, was 281 days in those prescribed OMDI, 204 days in those prescribed FP, and 152 days in those prescribed BB; the treatment persistence of OMDI tended to be longer than FP or BB.

Conclusions: OMDI had a longer treatment persistence compared to other antiglaucoma ophthalmic solutions in the real-world setting, suggesting that OMDI would be a promising first-line treatment option in the long-term management of glaucoma.

Abstract No.: 200877

CIGAS: An Interpretable Deep Learning System for Glaucoma Screening

First Author: Ruyue **SHEN**

Co-Author(s): Jinyue **CAI**, Carol **CHEUNG**, Annie **LING**, Clement **THAM**

Purpose: To develop a clinically interpretable deep learning (DL) system for glaucoma screening—termed “CIGAS”—that leverages color fundus photographs (CFP) to detect glaucomatous optic neuropathy (GON) and visualize clinically relevant features, thereby enhancing diagnostic transparency and practical utility in clinical settings.

Methods: We developed a DL algorithm using a dataset of 109,899 CFP images, with labels of presence or absence of GON. The dataset was split into split into training, tuning, and test sets in a 7:1:2 ratio. The interpretable BagNet architecture was employed as the backbone to extract GON features from CFP. Text-based GON relevant features were identified using OpenAI-o3 and validated by glaucoma specialists. A heatmap-based visualization generated by Grad-CAM provided explainability, correlating identified features with expert annotations. Additionally, a lightweight large language model (LLM) was used to generate automated clinical reports based on the extracted features.

Results: The CIGAS system achieved an area under the receiver operating characteristic curve (AUROC) of 0.85 in external validation, with sensitivity and specificity exceeding 80%. Heatmap visualizations consistently highlighted clinically relevant regions, including optic disc and retinal nerve fiber layer defects, aligning well with expert assessments. The automated CFP reports showed that the heatmap-based features by the BagNet network and text-based features by LLM were similar to those highlighted by clinicians.

Conclusions: The CIGAS framework may assist glaucoma screening by combining interpretable feature identification with automated report generation. Additional external validation is warranted to confirm its generalizability and clinical applicability.

Abstract No.: 204357

CRISPR-Cas9-Mediated Deletion of Carbonic Anhydrase 2 in the Ciliary Body to Treat Glaucoma

First Author: Fei **LI**

Co-Author(s): Jiaxuan **JIANG**

Purpose: To investigate the therapeutic potential of CRISPR-Cas9-mediated deletion of carbonic anhydrase 2 (Car2) gene in the ciliary body as a novel gene therapy approach for treating glaucoma by sustainably reducing intraocular pressure (IOP).

Methods: We designed six sgRNA sequences targeting mouse Car2 gene and constructed a dual sgRNA-mediated CRISPR-Cas9 system delivered via ShH10 adeno-associated virus (AAV). Two mouse models were used: DBA/2J mice (genetic high-pressure glaucoma) and magnetic bead-induced chronic ocular hypertension (COH) model. Gene therapy was administered through single intravitreal injections, with IOP monitoring and comparison to brinzolamide. Safety was assessed using optical coherence tomography and electroretinography

Results: The dual-target CRISPR system achieved 97.3% gene editing efficiency ($p < 0.0001$) with low off-target rates (0.16–0.70%). Car2 knockout significantly reduced IOP in normal mice compared to controls ($p < 0.01$ to $p < 0.0001$), sustaining the effect for up to 2 months ($p < 0.05$ to $p < 0.0001$). In DBA/2J mice, IOP was lowered versus untreated groups ($p < 0.05$ to $p < 0.001$). In the COH model, Car2 disruption outperformed brinzolamide, with superior IOP reduction ($p < 0.05$ to $p < 0.0001$ between groups), preserved retinal thickness ($p < 0.05$ to $p < 0.0001$), higher Brn3a+ retinal ganglion cell counts ($p < 0.001$), and increased axon counts ($p < 0.01$ to $p < 0.001$), delaying optic nerve damage without systemic side effects.

Conclusions: CRISPR-Cas9-based Car2 disruption via intravitreal AAV delivery represents a promising, long-lasting gene therapy for glaucoma, offering superior IOP control and neuroprotection compared

to conventional treatments, with potential for clinical translation.

Abstract No.: 202030

Childhood Angle-Closure: Etiology and Treatment Outcomes from a Large Series Spanning Over 20 Years

First Author: Kasem **SERESIRIKACHORN**

Co-Author(s): Ta Chen Peter **CHANG**, Alejandro **PEREZ**

Purpose: To describe childhood angle-closure (CAC) causes and to compare the outcomes of glaucoma drainage devices (GDDs) and lens surgery in treating CAC glaucoma.

Methods: A retrospective, multicenter study of patients under 18 years of age diagnosed with CAC between 2003-2023. The study analyzed underlying causes, treatment patterns, and compared the outcomes of GDDs and lens surgery in CAC glaucoma.

Results: A total of 101 patients (159 eyes) were included, with a slight female predominance (51.49%) and a mean age at diagnosis of 10.34 ± 5.58 years. Acute CAC was observed in 5.7% of eyes, all secondary in nature. The remaining 94.3% had chronic CAC, most commonly associated with retinopathy of prematurity (ROP, 26.7%). Among chronic angle-closure glaucoma cases, ROP was the leading cause (21.85%), followed by glaucoma following cataract surgery (15.97%) and uveitis (7.56%). Surgical intervention was required in 63.3% of CAC glaucoma cases, with glaucoma drainage device (GDD) implantation being the most frequent (38.6%), followed by lens surgery (22.7%), peripheral iridotomy (15.9%), and trabeculectomy (7.9%). Lens surgery demonstrated a significantly higher complete success rate at 5 years compared to GDD ($p = 0.006$), while no significant differences were found in qualified success ($p = 0.20$) or serious surgical complications between the two groups.

Conclusions: CAC is primarily chronic and secondary, most often linked to ROP. Surgical intervention is frequently necessary in CAC glaucoma, with lens surgery demonstrating superior long-term complete success compared to GDDs and a comparable safety profile.

Abstract No.: 209610

Clinical Outcomes of Capsular Tension Ring Implantation During Combined Phacoemulsification and Trabeculectomy in Acute Primary Angle Closure

First Author: Yajie **SUN**

Purpose: To study the postoperative efficacy and safety of capsular tension ring (CTR) implantation during cataract surgery combined with trabeculectomy in patients with acute primary angle closure (APAC).

Methods: Prospective, Single-Center, controlled randomized clinical trial. Patients with APAC scheduled to undergo phacoemulsification with intraocular lens implantation and trabeculectomy (a triple procedure). This interventional study was conducted on consecutive patients with visually significant cataract and an acute attack of primary angle-closure glaucoma. Seventy patients were enrolled in the trial. Subjects were randomized 1:1 to receive or not receive CTR implantation during the triple procedure. All patients were evaluated at postoperative days 1 and 7, and at 1, 3, 6, 12, 18, and 24 months. Main Outcome Measures: Visual acuity and intraocular pressure (IOP) from postoperative day 1 to 24 months and at all follow-up visits, Intraocular Lens (IOL) tilt, refractive error, and anterior chamber depth (ACD) at 24 months. Safety measures included the frequency of complications and adverse events.

Results: There were 35 patients in each group. The baseline characteristics were similar between the two groups. At 12, 18, and 24 months postoperatively, the CTR group showed significantly better uncorrected distance visual acuity (UDVA) compared to the non-CTR group (median [interquartile range [IQR]], 0.22 [0.10-0.40] vs 0.40 [0.22-0.56], $P < 0.05$; 0.22 [0.10-0.40] vs 0.40 [0.22-0.56], $P < 0.01$; 0.22 [0.10-0.40] vs 0.40 [0.22-0.60], $P < 0.01$). No statistical differences in IOP were found between groups at any postoperative follow-up ($P > 0.05$). At 24 months, the CTR group exhibited significantly less IOL tilt and smaller refractive error compared to the non-CTR group (median [IQR], 0.16 [0.12-0.29°] vs 0.42 [0.31-0.61°], $P < 0.001$; mean [SD], 0.32 ± 0.73 D vs 0.77 ± 0.88 D, $P < 0.05$). The ACD measured 3554.68 ± 286.01 μ m in the CTR group and 3539.03 ± 258.86 μ m in the non-CTR group ($P = 0.826$). The CTR group had a lower rate of capsular contraction syndrome (CCS) (0% vs 20.6%, $P < 0.01$), but a higher rate of posterior capsule opacification (PCO) (58.1% vs 41.2%, $P < 0.05$) and IOL capture (19.4% vs 2.9%, $P < 0.05$) at 24 months. Postoperative antiglaucoma medication (AGM) was needed in one patient in each group. The CTR group experienced one case of IOL dislocation requiring surgical repositioning, while the non-CTR group had one case of medically refractory IOP elevation that required surgical intervention.

Conclusions: In patients with APAC, CTR implantation during the triple procedure significantly improved long-term UDVA, reduced IOL tilt and refractive error, and maintained stable IOP and ACD. However, this procedure was associated with a potential trade-off: a reduced incidence of CCS but an increased risk of PCO and IOL capture.

Abstract No.: 207008**Clinical Outcomes of XEN Gel Stent Implantation for Glaucoma: A Real-World Study***First Author: Qian TAN*

Purpose: To evaluate the clinical efficacy and safety of XEN Gel Stent implantation in patients with different types of glaucoma under real-world conditions.

Methods: A retrospective analysis was conducted on 39 patients (43 eyes) who underwent XEN Gel Stent implantation at Changsha Aier Eye Hospital between February 2020 and July 2023. The mean age was 47.2 ± 15.7 years. Diagnoses included primary open-angle glaucoma ($n=10$), primary chronic angle-closure glaucoma ($n=3$), and secondary glaucoma ($n=8$; due to ICE syndrome, uveitis, trauma, and post-congenital cataract surgery). Notably, 22 cases (51.2%) had prior failed glaucoma surgeries. Main outcome measures included postoperative intraocular pressure (IOP), use of antiglaucoma medications, and surgical complications.

Results: The mean IOP decreased significantly from 26.8 ± 8.6 mmHg preoperatively to 14.4 ± 6.1 mmHg postoperatively (46.3% reduction, $P<0.01$). The mean number of medications decreased from 2.9 ± 1.5 to 0.6 ± 1.3 , with 79.3% of patients requiring fewer medications. Complete surgical success was achieved in 58.1% of cases, with an overall success rate of 83.7%. The most common complication was shallow anterior chamber (18.6%), all of which resolved with conservative management.

Conclusions: XEN Gel Stent implantation effectively lowers IOP and reduces medication burden with an acceptable safety profile. It is particularly beneficial for refractory glaucoma patients with prior surgical failure, and represents a valuable option in the field of minimally invasive glaucoma surgery (MIGS).

Abstract No.: 202556**Clinical Trial on the Effects of French Maritime Pine Bark and Bilberry Fruit Extracts on Intraocular Pressure in Primary Open-Angle Glaucoma***First Author: Chisako IDA*

Co-Author(s): Akiko HARANO, Sho ICHIOKA, Mizuki IIDA, Kana MURAKAMI, Hinako OHTANI, Ayaka SHIMADA, Masaki TANITO, Yuto YOSHIDA

Purpose: To investigate the effects of a dietary supplement containing French maritime pine bark and bilberry fruit extracts on intraocular pressure (IOP) in primary open-angle glaucoma (POAG) patients.

Methods: In a randomized, placebo-controlled, two-period crossover study, 24 POAG patients (median age 60 years, range 27–68; 9 males, 15 females) treated with ≤ 3 medications and with at least one eye showing

IOP ≥ 15 mmHg by Goldmann applanation tonometry (GAT) were enrolled. Patients were randomized 1:1 to receive either supplement followed by placebo (GP group) or placebo followed by supplement (PG group), each for 8 weeks. The primary endpoint was GAT IOP; secondary endpoints included self-measured IOP with rebound tonometry (RBT), blood pressure, pulse rate, oxidative stress markers, carotenoids, advanced glycation end products (AGEs), autonomic balance, and adverse events.

Results: Twenty-two patients completed the supplement phase, and 23 the placebo phase. One mild, unrelated adverse event was observed. Mixed-effects analysis showed no significant effect on GAT IOP (estimate -0.38 mmHg; 95% CI -1.03 to 0.28). However, supplementation significantly reduced RBT IOP (-0.11 mmHg; 95% CI -0.18 to -0.04 ; $p = 0.0023$). No effects were observed on blood pressure, while pulse rate significantly decreased (-0.25 bpm; 95% CI -0.46 to -0.03 ; $p = 0.0251$). No significant changes were found in oxidative stress, carotenoids, AGEs, or autonomic balance.

Conclusions: Supplementation with French maritime pine bark and bilberry extracts significantly reduced self-measured IOP and pulse rate in POAG patients, though no significant effect on GAT IOP was detected.

Abstract No.: 206003**Combined Hydrus Microstent and Cataract Surgery in Normal Tension Glaucoma: 24-Month Real-World Outcomes***First Author: Nathan KERR**Co-Author(s): Keith BARTON*

Purpose: To evaluate the 24-month efficacy and safety of combined Hydrus Microstent implantation and cataract surgery in reducing anti-glaucoma medication burden in patients with normal tension glaucoma (NTG).

Methods: A registry-based ambispective cohort study utilising data from the International Glaucoma Surgery Registry (IGSR.org). We analysed 82 eyes of 59 patients with mild-to-moderate NTG (glaucomatous optic neuropathy with IOP ≤ 21 mmHg) who underwent combined Hydrus Microstent implantation and cataract surgery. The primary outcome was the change in anti-glaucoma medications from baseline to 24 months. Secondary outcomes included IOP reduction, percentage achieving IOP ≤ 15 mmHg, medication-free status, and safety parameters. Data was collected across centres in Australia, Canada, the United Kingdom, and the United States.

Results: At baseline ($n=82$), mean age was 74.2 ± 6.3 years with 72.0% female. Mean baseline IOP was 12.8 ± 3.6 mmHg on 1.6 ± 1.1 medications, with visual field mean deviation of -6.72 ± 5.84 dB. At 24 months ($n=45$), there was a 44% reduction in anti-

glaucoma medications, with mean medication count decreasing from 1.6 to 0.9 medications ($p < 0.001$). Fifty-one percent achieved medication-free status at 24 months. Mean IOP was maintained at 11.1 mmHg, with 91% achieving target IOP ≤ 15 mmHg. No post-operative complications were recorded and only 1.2% (1/82) required secondary surgical intervention (trabeculectomy).

Conclusions: Combined Hydrus Microstent implantation and cataract surgery demonstrated substantial and sustained medication reduction in NTG patients while maintaining excellent IOP control with outstanding safety. These findings support the Hydrus Microstent as an effective minimally invasive surgical option for medication reduction in NTG management, addressing an important unmet clinical need.

Abstract No.: 207068

Comparative Analysis of Ocular Biometric Parameters Between Primary Angle Closure Glaucoma Patients and Healthy Controls in the Indian Population

First Author: Rajat Mohan **SRIVASTAVA**

Co-Author(s): Siddharth **AGRAWAL**, Farheen **ANSARI**

Purpose: To compare ocular biometric parameters between Primary Angle Closure Glaucoma (PACG) patients and age- and gender-matched healthy controls.

Methods: Cross-sectional case-control study. Consecutive PACG patients and healthy controls were recruited. Ocular biometric parameters such as axial length (AL), anterior chamber depth (ACD), lens thickness (LT) were measured using A-scan ultrasound biometer and lens position (LP), relative lens position (RLP) and a novel biometric parameter (Lens-Anterior Segment Crowding Factor (LASC)) ($LT + ACD / LT$) were calculated and compared between the groups. The worse eye in the PACG and the right eye in the control group were considered for analysis. An independent t-test was used to compare the means between groups, and a p-value < 0.05 was considered statistically significant.

Results: A total of 100 eyes, each of PACG and healthy controls, were analyzed in the study. The ACD & LASC were significantly reduced among PACG patients compared to controls (2.40 ± 0.07 vs 2.58 ± 0.17 ; $p < 0.003$) & (1.520 ± 0.04 vs 1.63 ± 0.13 ; $p < 0.002$) respectively; whereas the LT was significantly increased among PACG patients. (4.64 ± 0.36 vs 4.20 ± 0.60 ; $p < 0.005$). There were no statistically significant differences between the LP & RLP between the groups.

Conclusions: PACG patients have reduced ACD and increased LT compared to healthy controls. LASC is a novel and reliable biometric indicator to suggest lens induced crowding of the anterior segment as observed in PACG compared to LP & RLP.

Abstract No.: 201632

Comparative Effectiveness of Minimally Invasive Glaucoma Surgeries In Indian Patients With Primary Open-Angle Glaucoma: The SKIBI Study

First Author: Prasanna Vekatesh **RAMESH**

Co-Author(s): M Nivean

Purpose: To evaluate and compare early outcomes of five minimally invasive glaucoma surgery (MIGS) techniques Suture-GATT, Kahook Dual Blade (KDB), iStent, Bent Ab Interno Needle Goniectomy (BANG), and iStent Inject in Indian patients with mild to moderate primary open-angle glaucoma (POAG) and cataract.

Methods: This prospective study included 113 eyes (Suture-GATT: 21, KDB: 28, iStent: 20, BANG: 31, iStent Inject: 13). Patients underwent phacoemulsification with one MIGS procedure. Intraocular pressure (IOP) reduction, antiglaucoma medication (AGM) use, and safety outcomes were assessed over 6 months. The procedure choice was influenced by patient preference and affordability.

Results: At 6 months, mean IOP reduction was Suture-GATT 6.41 ± 2.05 mmHg, KDB 5.88 ± 0.64 , iStent 2.81 ± 0.83 , BANG 5.27 ± 0.68 , and iStent Inject 6.14 ± 1.62 . AGM reduction was greatest with KDB (0.54 ± 0.15) and iStent Inject (0.64 ± 0.12), followed by Suture-GATT (1.05 ± 0.26), BANG (0.58 ± 0.11), and iStent (1.46 ± 0.38). Complications were least with iStent Inject and iStent. Complete success was highest with Suture-GATT (71%), contributing to 90% total success. Anterior segment imaging demonstrated characteristic outflow patterns for each procedure, which correlated with their relative efficacy and safety profiles.

Conclusions: All MIGS procedures effectively reduced IOP and AGM use. Suture-GATT and iStent Inject achieved the greatest IOP reduction, while KDB and iStent Inject offered superior safety. KDB may represent the most cost-effective option in Indian settings.

Abstract No.: 206799

Comparative Efficacy of Laser Trabeculoplasty Modalities and Antiglaucoma Medications for Open-Angle Glaucoma: A Network Meta-Analysis

First Author: Christina **WUNARDI**

Co-Author(s): Muhammad **ALFATIH**, Alfiani Zukhruful Fitri **RIFA'I**, Margaretha Cempaka **SWEETY**, Herdifitrienne Saintissa **YANUARISTI**

Purpose: To compare the effectiveness of various laser trabeculoplasty (LT) modalities and antiglaucoma medications in reducing intraocular pressure (IOP) and medication burden at 6 and 12 months in patients receiving LT (all laser-naïve) or medical therapy alone.

Methods: This systematic review was registered with PROSPERO (CRD420251071621). Five databases were searched through September 2025 for randomized and non-randomized studies evaluating LT techniques—argon (ALT), selective (SLT), micropulse (MLT), pattern scanning (PSLT), titanium-sapphire (TLT), and direct SLT (DSLT)—and antiglaucoma medications. Outcomes were the mean IOP reduction and the change in medication number at 6 and 12 months. Network meta-analyses using frequentist random-effects models were performed, and treatments were ranked by P-scores. Study quality was assessed using RoB-2 and ROBINS-I. Heterogeneity, inconsistency, sensitivity, and small-study effects were evaluated.

Results: Thirty-nine studies (4,614 eyes; 3,679 patients) were included. In the NMA, SLT 360° ranked highest for IOP reduction at 6 (P-score 77.2%) and 12 months (77.4%). Most comparisons were not statistically significant, except for SLT 360° versus SLT 180° at 6 months (MD −0.90 mmHg, 95% CI −1.56 to −0.23, $p = 0.008$). SLT 180°, SLT 360°, ALT 360°, and DSLT 360° significantly reduced medication burden compared with medical therapy (all $p < 0.0001$) at both time points. No severe adverse events were reported, and sensitivity analyses confirmed robust results with no single study influencing estimates.

Conclusions: In laser-naïve patients, SLT 360° ranked highest for IOP reduction and, along with several other LT modalities, significantly reduced medication burden with a favorable safety profile. These findings support laser trabeculoplasty as an effective and safe primary treatment option for open-angle glaucoma.

Abstract No.: 200592

Comparative Outcomes of Illuminated Microcatheter-Assisted Circumferential Trabeculotomy Versus Conventional Trabeculotomy in Congenital Glaucoma: A Systematic Review

First Author: Habiba **SULTANA**

Co-Author(s): Md Sajidul **HUQ**

Purpose: To systematically evaluate and compare the efficacy and safety of illuminated microcatheter-assisted circumferential trabeculotomy with conventional trabeculotomy in the surgical management of primary congenital glaucoma.

Methods: We systematically searched MEDLINE, Embase, Scopus, and the Cochrane Library for studies from 2000 to 2024. Eligible studies included 2 randomized controlled trials and 5 cohort studies comparing these surgical techniques in patients aged ≤ 18 years, and reporting outcomes such as IOP reduction, surgical success rates, complications, medication use, and reoperation rates at a minimum of 12 months follow-up. Risk of bias was assessed using Cochrane RoB 2 and Newcastle-Ottawa scales.

Results: Seven studies involving approximately 416 eyes with congenital glaucoma were included. Illuminated microcatheter-assisted trabeculotomy consistently resulted in greater mean IOP reductions (typically 45–52%) than conventional trabeculotomy (35–45%). At the latest follow-up (12–36 months), absolute surgical success (IOP control without medication) ranged from 64% to 90% with microcatheter-assisted surgery compared to 44% to 70% with conventional surgery. Both procedures were associated with self-resolving hyphema; rates of severe complications were low between groups. Microcatheter-assisted surgery led to less dependence on glaucoma medications and fewer reoperations. Quality assessment indicated overall moderate to low risk of bias among included studies.

Conclusions: Illuminated microcatheter-assisted circumferential trabeculotomy is superior to conventional partial trabeculotomy, providing enhanced IOP control, higher surgical success, reduced medication reliance, and fewer reoperations, without increased serious complications. Further multi-center RCTs with longer follow-up are warranted to confirm the durability of outcomes and clarify cost-effectiveness.

Abstract No.: 204394

Comparative Ultrastructural Analysis of the Trabecular Meshwork in Primary Open-Angle Glaucoma and Chronic Angle-Closure Glaucoma

First Author: Zhiqiao **LIANG**

Co-Author(s): Huijuan **WU**

Purpose: The trabecular meshwork (TM), the principal site of aqueous humor outflow resistance, plays a pivotal role in the regulation of intraocular pressure (IOP), the key modifiable risk factor for glaucoma. This study aimed to compare the ultrastructural characteristics of the TM in primary open-angle glaucoma (POAG) and chronic angle-closure glaucoma (CACG) using transmission electron microscopy (TEM).

Methods: TM specimens were obtained via Kahook Dual Blade goniotomy from 11 POAG and 9 CACG patients, immediately fixed, and processed for TEM analysis. The ultrastructural features examined included cellular morphology, extracellular matrix (ECM) organization, and collagen fibril architecture, with fibril diameters quantitatively measured using Feret's diameter.

Results: Both POAG and CACG samples exhibited a marked reduction in TM cell numbers accompanied by pronounced ultrastructural abnormalities, including plasma membrane rupture, mitochondrial swelling, chromatin aggregation, and dilated endoplasmic reticulum. ECM alterations in both groups included trabecular beam fusion and narrowed intertrabecular spaces, indicative of compromised tissue architecture and impaired aqueous humor outflow pathways.

Quantitative analysis revealed that collagen fibrils were significantly larger in CACG compared to POAG (60.27 ± 12.97 nm vs. 43.61 ± 8.62 nm, $p = 0.018$), with a larger cross-sectional area ($p = 0.027$).

Conclusions: These findings highlight distinct ultrastructural differences in the TM of POAG and CACG, with POAG characterized by thinner and CACG by larger fibrils, suggesting divergent ECM remodeling pathways that may contribute to subtype-specific outflow resistance and disease mechanisms.

Abstract No.: 201179

Comparing Outcomes Between Two Non-Valved Glaucoma Drainage Devices in a Tertiary Hospital

First Author: Jia Hui **LEONG**

Co-Author(s): Nor Idahriani **MUHD NOR**, Roslinah **MUJI**, Chew Ean **TAN**

Purpose: For the past decades, there have been no prior studies comparing Paul Glaucoma Implant (PGI) and Aurolab Aqueous Drainage Implant (AADI). We aim to compare the treatment outcome of PGI and AADI in medically uncontrolled glaucoma.

Methods: We retrospectively review 39 eyes that had undergone PGI ($n=19$) and AADI ($n=20$) implantation with a minimum of 12 months of follow-up. The primary outcome is defined as intraocular pressure (IOP) ≥ 6 and ≤ 18 mmHg and at least 20% IOP reduction from baseline (complete success: without medication; qualified success: with medications). Failure is defined as IOP < 6 mmHg and > 18 mmHg after 3 months, reoperation for IOP-related indication, explantation of the implant, and loss of light perception.

Results: There were no significant differences in baseline demographic and ocular characteristics between the groups, except for ethnicity. AADI has a higher complete success rate than PGI, 45% and 31.6% respectively ($p=0.44$). At 12 months, AADI scored a lower final mean IOP and greater IOP reduction (11.05 ± 3.35 mmHg, 68.5%) compared to PGI (13.74 ± 4.11 mmHg, 54%) ($p < 0.05$). Both groups achieved a reduction in the number of antiglaucoma medications from 3.84 ± 0.38 to 1.05 ± 1.27 in PGI versus 3.75 ± 0.44 to 0.70 ± 1.13 in AADI ($p=0.36$). There is no significant difference in mean visual acuity for both groups at baseline and final visits ($P=0.33$). There was a similar percentage of patients who experienced postoperative complications (31.6% PGI, 30% AADI, $P = 0.92$). Among these, PGI groups predominantly experience tube block ($n=3$) while hypotony is more commonly seen in AADI groups ($n=5$).

Conclusions: In summary, AADI showed a better outcome, whereby it achieves greater IOP reduction and significantly lower final mean IOP.

Abstract No.: 202277

Comparison of 24-2 Rapid Protocol of Melbourne Rapid Fields Online Perimetry With Humphrey Field Analyzer SITA-Standard and SITA-Faster

First Author: Kae **SUGIHARA**

Co-Author(s): Mitsuto **HOSOKAWA**, Yu Xiang George **KONG**, Toshio **OKANOUCHI**, Algis J. **VINGRYS**

Purpose: Melbourne Rapid Fields (MRF) web-browser perimetry software allows white-on-white increment threshold perimetry on any computer. This study evaluates the outcomes of MRF24-2 Rapid protocol (MRF24-2R), a new procedure that removes false negative trials, speeds fixation change, and adopts a neighborhood modified PDF, Bayes predictor.

Methods: This prospective, cross-sectional study included 223 eyes from 223 participants. The MRF24-2R results were compared to HFA24-2 SITA-Standard (HFA-SS) in 92 patients and to HFA24-2 SITA-Faster (HFA-SFR) in 131 patients. Mean Deviation (MD), Pattern Deviation (PD), and reliability indices were compared with Intraclass Correlation Coefficients (ICC) and Bland-Altman methods. Patients completed two MRF24-2R to define test-retest reliability.

Results: MRF24-2R returned high agreement with HFA-SS for MD (ICC = 0.96 {95% CI 0.94 to 0.98}) and PSD (ICC = 0.94 {95% CI 0.89 to 0.97}). Similar findings were found when MRF24-2R MD was compared to HFA-SFR (ICC = 0.95) and PSD (ICC = 0.90). Bland-Altman analysis for MRF24-2R and HFA-SS found a bias of -0.80 decibels (dB) (95% Limits of Agreement, LoA -5.48 dB, +3.87 dB) for MD and +0.95 dB (LoA -2.58 dB, +4.50 dB) for PSD. Reliability indices were similar for HFA-SS and MRF24-2R, but the mean false positive rate was lower than that of HFA-SFR [4.8 vs 7.1, $p=0.003$]. MRF24-2R (169 ± 45 seconds) was significantly faster than HFA-SS (346 ± 73 seconds) ($p < 0.001$) (approximately by 51%) and similar to HFA-SFR (192 ± 53 seconds) ($p=0.38$).

Conclusions: MRF24-2R provides fast, portable, reliable visual field tests for glaucoma screening and clinical management.

Abstract No.: 206509

Comparison of One-Year Surgical Outcomes of PreserFlo® MicroShunt, Trabeculectomy, and EX-PRESS® Glaucoma Filtration Surgery

First Author: Chihiro **KUGA**

Co-Author(s): Masashi **FUJIHARA**, Marika **HIROTA**, Yasuo **KURIMOTO**, Hirofumi **UYAMA**, Satoshi **YOKOTA**

Purpose: To compare the one-year surgical outcomes of PreserFlo® MicroShunt (PFM), trabeculectomy (LEC), and EX-PRESS® glaucoma filtration surgery (EX).

Methods: We retrospectively reviewed consecutive cases undergoing PFM, LEC, or EX between September 2012 and March 2024 with one year of follow-up. A

total of 68 eyes (PFM), 75 eyes (LEC), and 49 eyes (EX) were included. Postoperative intraocular pressure (IOP), medication score (MS), best corrected visual acuity (BCVA), and surgical success were evaluated. Surgical success was defined as an IOP ≥ 14 mmHg and $\geq 20\%$ reduction from baseline at the one year, with or without medications.

Results: Mean IOP (mmHg) was decreased from 16.9 to 9.6 in PFM, 21.9 to 9.6 in LEC, and 20.5 to 14.3 in EX ($p < 0.05$ compared with baseline in all groups). Mean MS also decreased from 4.4 to 0.3 in PFM, 4.5 to 0.5 in LEC, and 3.6 to 1.7 in EX ($p < 0.05$ compared with baseline in all groups). BCVA significantly worsened postoperatively in all groups compared with baseline in all groups and did not recover until one year ($p < 0.05$). At one year, IOP and MS were lower in PFM and LEC than in EX, with no difference between PFM and LEC. Survival rates were 84.2%, 77.8%, and 69.4% in PFM, LEC, and EX groups, respectively ($p = 0.15$).

Conclusions: At one year postoperatively, PFM achieved IOP reduction comparable to LEC and superior to EX, with similar surgical success rates.

Abstract No.: 202068

Comparison of Outcomes of 180-Degree Tanito Microhook Trabeculotomy Versus 360-Degree Gonioscopy-Assisted Transluminal Trabeculotomy Combined With Phacoemulsification in Open-Angle Glaucoma

First Author: Madhavi **PILLAI**

Co-Author(s): Devendra **MAHESHWARI**, Nimrita **NAGDEV**

Purpose: To compare the surgical outcomes of Tanito microhook Trabeculotomy combined with phacoemulsification (Phaco-TMH) and 5-0 prolene gonioscopy-assisted transluminal trabeculotomy combined with phacoemulsification (Phaco-GATT) in mild-moderate Open-angle glaucoma.

Methods: This was a prospective, comparative, interventional study of 110 patients who underwent Phaco-TMH (Group 1, N=55) and Phaco-GATT (Group 2, N=55). The primary outcome measures included changes in intraocular pressure (IOP), antiglaucoma medications (AGM), and best-corrected visual acuity (BCVA). Success was defined as a combination of at least 20%, 25%, or 30% reduction in IOP and an absolute IOP of less than 21, 18, or 15 mm Hg, respectively (Criteria 1, 2, and 3). Additionally, interventions and complications were compared between the groups. A sample size of 50 eyes per group was required to detect a clinically significant difference in intraocular pressure (IOP) between Phaco-TMH and Phaco-GATT groups. The significance level was set at 0.05, and the desired power was 80%. All statistical analyses were performed using the statistical software STATA 14.0 (Texas, USA).

Results: In Group 1, mean IOP reduced significantly from 24.38 ± 6.29 mmHg to 14.60 ± 3.87 mmHg, and in Group 2 from 25.45 ± 5.65 mmHg to 12.80 ± 3.12 mmHg at 12 months ($p < 0.001$), with a significant reduction in Group 2 than in Group 1 ($p = 0.007$). The percentage reduction of IOP in Group 1 was 37.5% and in Group 2 was 47.7%. AGM significantly reduced from 1.53 ± 0.66 to 0.22 ± 0.57 and from 1.64 ± 0.73 to 0.09 ± 0.29 in Groups 1 and 2, respectively ($p < 0.001$), with no significant difference between the groups ($p = 0.137$). Complete success by criteria 1, 2, and 3 in Group 1 was 74.6%, 69.1% and 52.7%; and in Group 2 was 89.1%, 88.1% and 65.4% respectively. Higher baseline IOP and higher age were associated with a lower likelihood of surgical failure ($p = 0.002, p = 0.045$). Hyphema was seen in one patient in Group 1, 7 patients in Group 2, and two patients in Group 2 required an anterior chamber wash. IOP spikes were seen in one patient in Group 1 and three patients in Group 2.

Conclusions: The 180 Degree Tanito microhook trabeculotomy is safe, efficacious, and comparable to the 360-degree GATT combined with phacoemulsification. Phaco-GATT fared better in terms of IOP reduction. This study provides valuable comparative data on two cost-effective, minimally invasive glaucoma surgery (MIGS) techniques when combined with cataract surgery.

Abstract No.: 203405

Comparison of Surgical Outcomes of 360-Degree Circumferential Trabeculotomy Versus Excisional Goniotomy With Kahook Dual Blade at 12 Months

First Author: Nimrita **NAGDEV**

Co-Author(s): Devendra **MAHESHWARI**, Madhavi **PILLAI**

Purpose: To compare the safety and efficacy of gonioscopy-assisted transluminal trabeculotomy (GATT) versus Kahook dual blade (KDB) with phacoemulsification in eyes with primary open-angle glaucoma.

Methods: A retrospective and comparative study included 122 eyes (61 GATT, group 1, and 61 KDB, group 2). Baseline characteristics like intraocular pressure (IOP), best corrected visual acuity (BCVA), and anti-glaucoma medications (AGMs) were compared at each postoperative visit. Data were collected at 2 weeks, 1 month, 3, 6, and 12 months. Surgical success was defined as IOP $\leq 21 / \leq 18 / \leq 15$ mmHg with $\geq 20\% / \geq 25\% / \geq 30\%$ reduction from baseline, respectively (Criteria 1, 2, and 3). Complications, secondary interventions, and surgical risk factors were also analyzed.

Results: The mean (SD) IOP decreased from 21.15 ± 3.76 to 13.20 ± 3.21 and from 22.90 ± 4.05 to 14.44 ± 5.01 in groups 1 and 2, respectively, at the end of 12 months ($p < 0.001$). AGM reduced from 1.64 ± 0.84 to 0.08 ± 0.28 and from 1.67 ± 0.77 to 0.08 ± 0.38 in groups 1 and 2,

respectively, at the end of 12 months ($p < 0.001$). The overall success was 85.3%, 78.7%, and 60.7% in group 1 by criteria 1, 2, and 3. In group 2, it was 86.9%, 83.6%, and 70.5%. Micro hyphemas were seen in 28 patients (20 (group 1), 8 (group 2)), and macro hyphemas were seen in 4 patients of group 1. 6 had IOP spikes (4 in group 1, 2 in group 2). AC wash was done in 2 patients.

Conclusions: Both GATT and KDB achieved significant reductions in intraocular pressure and anti-glaucoma medication use at 12 months, with KDB demonstrating safety and efficacy equivalent to 360° suture trabeculotomy.

Abstract No.: 201306

Comprehensive Genetic Landscapes and Clinical Heterogeneity in Nanophthalmos: New Insights From a Large Chinese Cohort

First Author: Qingdan **XU**

Co-Author(s): Yuhong **CHEN**, Xinghuai **SUN**

Purpose: Nanophthalmos is a rare ocular condition characterized by a significantly short axial length (AL) and high hyperopia, often associated with various complications. This study aims to provide a comprehensive analysis of the clinical and genetic features of nanophthalmos in a large Chinese cohort.

Methods: A total of 105 patients from unrelated families diagnosed with nanophthalmos were included. Genetic testing was performed using whole-exome sequencing to identify variants in genes associated with the condition. Clinical features, including demographic data, the presence of accompanying clinical findings, and various ocular parameters, were compared across different genetic groups.

Results: Whole exome sequencing revealed variants in four key genes: PRSS56, MFRP, MYRF, and TMEM98, with a detection rate of 71.43%. Autosomal recessive genes (PRSS56 and MFRP) were associated with shorter AL, higher hyperopia, shallower vitreous chamber depth, and steeper corneal curvatures (larger K1 and K2). In contrast, autosomal dominant genes (MYRF and TMEM98) were linked to earlier onset of glaucoma and a higher incidence of multiple ciliary body cysts. In the patients carrying variants in PRSS56 and MFRP, biallelic variants were associated with more severe phenotypes, including more extreme ocular parameters and increased risks of specific complications, compared to monoallelic variants.

Conclusions: This study represents the largest cohort of nanophthalmos patients reported to date, expanding the genetic and clinical understanding of the condition. It identifies novel variants and provides valuable insights into genotype-phenotype correlations, highlighting the impact of genetic variation on the disease severity and associated complications of nanophthalmos.

Abstract No.: 204345

Corneal Biomechanics and Its Association With Visual Field Progression in Primary Open-Angle Glaucoma (Normal Tension or Hypertension): A Prospective Longitudinal Investigation

First Author: Yu **CAI**

Co-Author(s): Ya Hui **WEI**

Purpose: To analyze effects of dynamic corneal response parameters (DCRs) on visual field (VF) progression in normal-tension glaucoma (NTG) and hypertension glaucoma (HTG).

Methods: This was a prospective cohort study. This study included 57 subjects with NTG and 54 with HTG, followed up for 4 years. The subjects were divided into progressive and nonprogressive groups according to VF progression. DCRs were evaluated by corneal visualization Scheimpflug technology. General linear models (GLMs) were used to compare DCRs between two groups, adjusting for age, axial length (AL), mean deviation (MD), etc. VF progression risk factors were evaluated by logistic regression and receiver operating characteristic (ROC) curves.

Results: For NTG, first applanation deflection area (A1Area) was increased in progressive group and constituted an independent risk factor for VF progression. ROC curve of A1Area combined with other relevant factors (age, AL, MD, etc.) for NTG progression had an area under curve (AUC) of 0.813, similar to the ROC curve with A1area alone (AUC = 0.751, $p = 0.232$). ROC curve with MD had an AUC of 0.638, lower than A1Area-combined ROC curve ($p = 0.036$). There was no significant difference in DCRs between the two groups in HTG.

Conclusions: Corneas in the progressive NTG group were more deformable than those in the nonprogressive group. A1Area may be an independent risk factor for NTG progression. It suggested that the eyes with more deformable corneas may also be less tolerant to pressure and accelerate VF progression. VF progression in the HTG group was not related to DCRs. Its specific mechanism needs further study.

Abstract No.: 201268

Correlating Macular Optical Coherence Tomography Angiography and Visual Field Results in Glaucoma: A Systematic Review and Meta-Analysis

First Author: Yihao Eric **JIN**

Co-Author(s): Chin Hou Bryan **ANG**, Zhi Rui John **CHEW**

Purpose: To evaluate the relationship between macular vessel density (mVD) and visual field (VF) results in primary open-angle glaucoma (POAG).

Methods: Pubmed, Embase and Cochrane Library were searched to September 2024. Eligible studies

assessed mVD using OCT Angiography (OCT-A), and VF using 24-2 or 10-2 Humphrey Visual Field (HVF). The primary outcome was the pooled correlation between mVD and VF indices. Secondary outcomes included the association between baseline mVD and VF progression and the relationship between mVD decline and VF deterioration. Statistical analyses were performed using R, with significance at $p < 0.05$.

Results: 20 studies comprising 2,238 eyes were included. Superficial whole and parafoveal mVD showed moderate correlations with HVF 24-2 mean deviation (MD) (pooled $r = 0.319$ and 0.333 , respectively; all $p < 0.01$). Superficial whole mVD also correlated strongly with central mean sensitivity (MS) (pooled $r = 0.514$, $p < 0.001$), with associations across superficial and deep parafoveal, perifoveal, foveal regions (all $p < 0.05$). Baseline deep whole mVD was inversely correlated with risk and rate of VF progression ($p < 0.05$). Greater rates of reduction in superficial mVD in whole macula, parafoveal, perifoveal, and FAZ300 regions were significantly associated with rate of VF progression (all $p < 0.05$).

Conclusions: There is significant correlation between baseline superficial mVD and VF indices of severity, as well as between rate of reduction in superficial mVD and rate of VF progression. Superficial mVD may be a useful indicator of glaucoma severity and progression, while baseline deep mVD may help predict risk and rate of future VF progression.

Abstract No.: 206377

Correlation Between Corneal UBM Features and Genetic Variants in Early Childhood Glaucoma

First Author: Shrushti **HUNASHYAL**

Co-Author(s): Vyshak A S, Sushmita **KAUSHIK**, Avilasha **MOHAPATRA**, Ashok **SINGH**

Purpose: To investigate whether specific corneal findings on ultrasound biomicroscopy (UBM) at presentation in early childhood glaucoma are associated with specific genetic variants.

Methods: This retrospective study included children under 3 years of age with glaucoma who underwent UBM imaging and genetic testing at presentation. Corneal changes on UBM were classified into six types: Type A (diffuse thickening), Type B (intracorneal hyper-reflectivity), Type C1/C2 (Descemet's membrane defects), Type D (intracorneal clefts), Type E (miscellaneous), and Type N (clinically clear cornea). All patients underwent whole-exome sequencing from blood samples. Only those with confirmed pathogenic variants were included. UBM patterns were correlated with genetic findings.

Results: A total of 221 eyes from 117 children were included. Type A (110 eyes) was associated with CYP1B1 variants (40%), TEK (11.1%), FOXC1 (6.8%), and others

(15.7%). Type B (45 eyes) showed CYP1B1 mutations in 77% of cases; 65% of these were Arg390His variant. Types C1/C2, with Peters Anomaly, showed 66% association with CYP1B1 Arg390His and 6.8% each with FOXC1 and PITX2. All three cases with Type D were CYP1B1 Arg390His and had the earliest onset and most severe glaucoma. Type N was associated with PAX6 mutations (70.5%), with other variants (FOXC1, LTBP2, NF1) present in 5.8% each, but no CYP1B1.

Conclusions: Specific UBM corneal patterns are strongly associated with distinct genetic variants. CYP1B1 variants affected the cornea the most, with Types B and D linked with CYP1B1 Arg390His mutation and poor outcomes. Type N is typically associated with PAX6 mutations and not CYP1B1. UBM imaging may aid early prediction of genetic aetiology and prognosis.

Abstract No.: 206677

Correlation Between Surgical Outcomes and Anterior Segment Optical Coherence Tomography-Derived Bleb Morphology Following XEN-45 Gel Stent Implantation

First Author: Huijuan **WU**

Co-Author(s): Zhiqiao **LIANG**, Kuankuan **WU**

Purpose: To investigate the associations between anterior segment optical coherence tomography (AS-OCT)-derived bleb morphology and surgical outcomes following XEN-45 gel stent implantation.

Methods: This cross-sectional study consecutively included 80 eyes from 70 patients following XEN-45 gel stent implantation. Postoperative IOP and glaucoma medications were assessed at 1, 3, 6, 12, 18, and 24 months. AS-OCT imaging was performed to evaluate bleb characteristics in different postoperative stages. Spearman's correlation and binary logistic regression were employed to analyze relationships between bleb features and postoperative IOP and complete surgical success.

Results: XEN-45 gel stent implantation significantly reduced IOP from 27.1 ± 10.9 mmHg to 14.1 ± 1.3 mmHg ($p = 0.010$) and glaucoma medications from 3.1 ± 1.0 to 0.2 ± 0.6 ($p = 0.001$) at 2 years postoperatively. Significant reductions were observed at all follow-up time points from 1 day to 24 months compared to preoperative values. Early-stage blebs on AS-OCT exhibited subconjunctival spaces (88%), cavernous/hyporeflective Tenon's capsule patterns (48%/40%), absent episcleral lake (92%), and an intratenon ostium (96%) with absent/hyporeflective surroundings (48%/36%), with spaces significantly decreasing later ($p = 0.014$). Higher IOP was correlated with increased peri-ostial reflectivity ($p = 0.014$) and a greater iris-internal ostium distance ($r = 0.234$, $p = 0.045$). Complete surgical success was significantly associated with surgical procedure (OR = 14.119; 95% CI: 1.338–148.962; $p = 0.028$).

Conclusions: The XEN-45 gel stent was an effective treatment for reducing IOP and glaucoma medications. Parameters derived from AS-OCT, notably the iris-internal ostium distance and peri-ostial reflectivity, were strong predictors of IOP outcomes, offering valuable insights for clinical follow-up.

Abstract No.: 204568

Correlation Study Between Primary Glaucoma and Choroidal Thickness and Blood Flow

First Author: Ruixue ZHANG

Co-Author(s): Yuan HE

Purpose: This study aimed to compare and analyze the choroidal thickness (CT) and blood flow parameters at the macula and optic disc among patients with acute primary angle-closure glaucoma (APACG), chronic primary angle-closure glaucoma (CPACG), primary open-angle glaucoma (POAG), and a normal control group. Correlation analysis between choroidal thickness and blood flow was conducted to explore the relationship between choroidal parameters and different types of primary glaucoma.

Methods: A retrospective study was conducted involving 52 eyes with APACG, 27 eyes with CPACG, 57 eyes with PAC/PACS, 32 eyes with POAG, and 20 eyes in the normal control group. Swept-source optical coherence tomography angiography (SS-OCTA) was used to measure and compare macular foveal and optic disc choroidal thickness (CT) and choroidal vascular index (CVI). Statistical methods were applied for data analysis.

Results: Compared with the normal control group, the temporal macular choroidal thickness was significantly thicker in the APACG and PAC/PACS groups ($t = 2.275$, $P < 0.05$; $t = 2.716$, $P < 0.05$). In CPACG patients, the subfoveal, inferior, nasal, and temporal macular choroidal thicknesses were significantly thicker than those in the normal control group ($t = 2.362$, $P < 0.05$; $t = 3.138$, $P < 0.05$; $t = 2.129$, $P < 0.05$; $t = 2.259$, $P < 0.05$). In POAG patients, the subfoveal, superior, nasal, and temporal macular choroidal thicknesses were significantly thinner than those in the normal control group ($t = -2.811$, $P < 0.05$; $t = -2.352$, $P < 0.05$; $t = -2.450$, $P < 0.05$; $t = -2.038$, $P < 0.05$). Compared with the normal control group, the blood flow indices in the inferior, superior, and nasal macular regions were significantly lower in the APACG group ($t = -2.074$, $P < 0.05$; $t = -3.362$, $P < 0.05$; $t = -2.251$, $P < 0.05$). In the PAC/PACS group, the blood flow indices in the subfoveal, inferior, and nasal macular regions were significantly lower than those in the normal control group ($t = -2.635$, $P < 0.05$; $t = -2.020$, $P < 0.05$; $t = -2.057$, $P < 0.05$). In the POAG group, the temporal macular blood flow index was significantly lower than that in the normal control group ($t = 2.579$, $P < 0.05$). Compared with the normal control group, the blood flow indices in the inferior and temporal regions of

the optic disc were significantly lower in the APACG group ($t = -2.108$, $P < 0.05$; $t = -2.839$, $P < 0.05$). In the POAG group, the temporal optic disc blood flow index was significantly lower than that in the normal control group ($t = -2.225$, $P < 0.05$). In the APACG, CPACG, PAC/PACS, and POAG groups, the choroidal thickness in the inferior, superior, nasal, and temporal regions of the optic disc was positively correlated with the blood flow index ($r = 0.721$, $P < 0.01$; $r = 0.496$, $P < 0.01$; $r = 0.612$, $P < 0.01$; $r = 0.367$, $P < 0.05$).

Conclusions: Angle-closure glaucoma is associated with increased macular choroidal thickness, while open-angle glaucoma is associated with decreased macular choroidal thickness. The APACG, PAC/PACS, and POAG groups showed reduced peri-macular blood flow indices compared to the normal control group. The APACG and POAG groups exhibited reduced peri-optic disc blood flow indices compared to the normal control group. In the PAC/PACS group, subfoveal CT was positively correlated with CVI. In the APACG, CPACG, PAC/PACS, and POAG groups, sub-optic disc CT was positively correlated with CVI.

Abstract No.: 208368

Cost-Effectiveness Analysis of Population-Based Glaucoma Screening Using OCT-Based AI System in Vietnam

First Author: Jiaying ZHOU

Co-Author(s): Carol Y. CHEUNG, Truong X. NGUYEN, Anran RAN, Clement C. THAM, Shuyi ZHANG

Purpose: Glaucoma is frequently diagnosed at advanced stages and relies on opportunistic findings in clinical practice, given its asymptomatic nature in early stages, while the high diagnostic costs of conventional approaches have prevented the implementation of population-based screening for early glaucoma. We aim to evaluate the cost-effectiveness of population-based screening using an optical coherence tomography (OCT)-based AI system in Vietnam.

Methods: We developed a Markov model comparing OCT-based AI screening for primary angle-closure (PACG) and open-angle glaucoma (POAG) versus opportunistic findings from a societal perspective. A cohort of 100,000 individuals aged 50 through 35 1-year Markov cycles. Parameters were derived from literature, with costs from Vietnam Binh Dinh Eye Hospital converted to USD (2024 exchange rate: 25,400 HKD/USD). Primary outcomes were incremental cost-utility (ICURs) using quality-adjusted life years (QALYs) and incremental cost-effectiveness ratios (ICERs) using years of blindness avoided. To reflect the uncertainty around ICURs and ICERs, both one-way deterministic and simulated probabilistic sensitivity analyses were done. Willingness-to-pay (WTP) thresholds used three times the local per capita gross domestic product (GDP).

Results: Over 35 years, opportunistic finding cost US\$3,422.65 per person (16.60 QALYs), while OCT-

based AI screening cost US\$732.25 (17.79 QALYs). OCT-Based AI screening achieved 63,000 years of blindness avoided among 100,000 individuals, with ICUR of -US\$2,572 and ICER of -US\$4,271. One-way sensitivity analysis demonstrated AI performance as the most influential factor. Probabilistic sensitivity analysis confirmed robust ICURs and ICERs.

Conclusions: The OCT-based AI system for population-based glaucoma screening is highly cost-effective compared to opportunistic finding, offering evidence for implementing the AI system in real-world.

Abstract No.: 201911

Cost-Effectiveness Analysis of Population-Based Glaucoma Screening Using an OCT-Based AI System

First Author: Jiaying **ZHOU**

Co-Author(s): Carol Y. **CHEUNG**, Anran **RAN**, Clement C. **THAM**, Shuyi **ZHANG**

Purpose: Glaucoma is frequently diagnosed at advanced stages and relies on opportunistic findings in clinical practice, given its asymptomatic nature in early stages, while the high diagnostic costs of conventional approaches have prevented the implementation of population-based screening for early glaucoma. We aim to evaluate the cost-effectiveness of population-based screening using an optical coherence tomography (OCT)-based AI system in Hong Kong.

Methods: We developed a Markov model comparing OCT-based AI screening for primary angle-closure (PACG) and open-angle glaucoma (POAG) versus opportunistic findings from a societal perspective. A cohort of 100,000 individuals aged 50 through 35 1-year Markov cycles. Parameters were derived from literature, with costs from Hong Kong Hospital Authority converted to USD (2024 exchange rate: 7.81 HKD/USD). Primary outcomes were incremental cost-utility (ICURs) using quality-adjusted life years (QALYs) and incremental cost-effectiveness ratios (ICERs) using years of blindness avoided. Willingness-to-pay (WTP) thresholds used three times the local per capita gross domestic product (GDP).

Results: Over 35 years, opportunistic finding costs US\$17,413 per person (17.55 QALYs), while OCT-based AI screening costs US\$7,745 (19.14 QALYs). OCT-Based AI screening achieved 71,900 years of blindness avoided among 100,000 individuals, with ICUR of -US\$9,571 and ICER of -US\$14,281.

Conclusions: The OCT-based AI system for population-based glaucoma screening is highly cost-effective compared to opportunistic finding, offering evidence for implementing the AI system in real-world.

Abstract No.: 205573

Cost-Utility of Preservative-Free Latanoprost Eye Drop Cationic Emulsion Versus Preserved First-Line IOP-Lowering Therapies in Open-Angle Glaucoma or Ocular Hypertension Across Seven Asia-Pacific Countries

First Author: Kun **SHI-VAN WIELINK**

Co-Author(s): David **CHAMPION**, Amish **CHATURVEDI**, Amit **KUMAR**, Jieyi **LI**, Prachi **SINGH**

Purpose: To assess the lifetime cost-utility and net monetary benefit (NMB) of preservative-free latanoprost eye drop cationic emulsion (PF-LAT E) compared to preserved first-line intraocular pressure (IOP)-lowering treatments in adults with open-angle glaucoma (OAG) or ocular hypertension (OHT) across seven Asian countries (Malaysia, Philippines, Singapore, South Korea, Taiwan, Thailand, Vietnam).

Methods: A hybrid decision-tree and Markov cohort model (30-day cycles) simulated disease progression and treatment pathways over a lifetime horizon (35-50 years). PF-LAT E was compared with country-specific preserved therapies, including betaxolol, bimatoprost, brimonidine, brinzolamide, carteolol, dorzolamide, latanoprost, tafluprost, timolol, travoprost. Patients with inadequate response escalated to second-line fixed-dose combinations and third-line surgeries. The analysis was conducted from a societal perspective, with costs in 2025 USD. Deterministic and probabilistic sensitivity analyses were performed to test model robustness.

Results: PF-LAT E consistently yielded QALY gains across all countries (0.03-0.41 per patient). Incremental costs ranged from cost-saving (-\$7,255) to modest increases (+\$473), depending on the comparator. Net monetary benefits were positive in all countries (except against preserved latanoprost in Thailand), ranging from -\$236 to \$15,633 based on local willingness-to-pay thresholds. Economic benefits were driven by fewer treatment escalations, improved treatment response, and lower adverse-event management costs. Results were robust in sensitivity analyses.

Conclusions: PF-LAT E offers enhanced clinical effectiveness and economic benefit versus preserved therapies, reinforcing that PF-LAT E is a cost-effective first-line option in routine glaucoma management.

Abstract No.: 200753

Cytomegalovirus US28 and CD8/CD69 Distribution in Human Eyes With Normal and Elevated Intraocular Pressure

First Author: Suqian **WU**

Co-Author(s): Xiangmei **KONG**, Xiaofen **MO**, Qilian **SHENG**, Jiajian **WANG**, Xiaobo **YU**

Purpose: To characterize the distribution of cytomegalovirus (CMV) US28 and CD8/CD69, markers

of tissue-resident memory T (TRM) cells, in human eyes with normal and elevated intraocular pressure (IOP).

Methods: Three cadaveric eyes with no history of glaucoma or high IOP were collected. In addition, aqueous humor and tissues of iris and trabecular meshwork (TM) were collected from patients of Posner-Schlossman syndrome (PSS), primary open-angle glaucoma (POAG), primary angle-closure (PAC), primary angle-closure glaucoma (PACG) and secondary angle-closure (SAC). Ciliary processes were obtained from five of those patients. CMV DNA and anti-CMV Immunoglobulins in aqueous humor were tested, and all the solid tissues collected were immunostained.

Results: US28 was found in almost all regions, with high light intensities observed in retinal neuroepithelium, followed by ciliary bodies, and was observed in all the patient samples of iris and ciliary process. Tissues of TM from 23.1% of the PSS patients, 50% of the PAC patients and 100% of the PACG and SAC patients were found US28 positive. CD8/CD69 co-expression was detected in all samples of iris and none of the TM samples, and was expressed abundantly in ciliary processes obtained from patients with POAG and PACG, but minimally in those from patients with PSS.

Conclusions: CMV can reside in nearly all regions of the eye. Its critical reservoirs may include the retinal neuroepithelium and the ciliary body. Furthermore, we hypothesize that the substantial reduction in TRM cell number within the ciliary bodies is a key contributing factor to the relapse of PSS.

Decoding Glaucoma Hemodynamics: Dual-Modality OCT-A and CDI Reveals Distinct Micro-Macro Vascular Signatures in Normal-Tension vs. High-Tension Subtypes

First Author: Wenbo HOU

Co-Author(s): Jun FENG, Xin LI

Purpose: To characterize optic nerve head (ONH) microcirculation via optical coherence tomography angiography (OCT-A) and upstream macrocirculation via color Doppler imaging (CDI) in patients with normal-tension glaucoma (NTG) and high-tension glaucoma (HTG).

Methods: This cross-sectional study included 67 HTG, 55 NTG, and 42 control eyes. Comprehensive exams comprised visual field, RNFL thickness via OCT, ONH vessel density (VD) by OCT-A, and CDI-measured hemodynamics [PSV, EDV, RI] of ICA, OA, CRA, SPCA. SPSS analyses used t-test, Mann-Whitney U, and Pearson correlation ($P < 0.05$).

Results: Glaucomatous eyes showed significantly reduced ONH VD and RNFL thickness versus controls (both $P < 0.001$) (Fig1, Table1, 2). The NTG group exhibited lower peripapillary VD than HTG ($P = 0.027$), particularly in nasal superior, inferior nasal, inferior tempo, and

tempo inferior sectors ($P < 0.05$) (Table2). Compared to controls, HTG showed decreased PSV (ICA: $P = 0.029$; CRA: $P = 0.023$) and EDV (ICA: $P = 0.023$; CRA: $P < 0.001$), and increased RI (ICA: $P = 0.019$; CRA: $P = 0.006$). NTG showed reduced PSV (OA: $P = 0.015$; CRA: $P < 0.001$) and EDV (OA: $P = 0.047$; CRA: $P = 0.001$) versus controls, with lower CRA PSV than HTG ($P = 0.034$). Peripapillary VD correlated with mean defect (MD, $P < 0.001$) and RNFL thickness ($P < 0.001$) but not with CDI parameters (all $P > 0.05$) (Fig2, Table3).

Conclusions: NTG and HTG exhibit distinct ONH microcirculatory and upstream macrocirculatory characteristics. OCT-A-derived VD correlates with glaucomatous structural-functional damage, whereas no correlation exists between micro- and macrovascular parameters, suggesting independent regulatory mechanisms in glaucoma subtypes.

Abstract No.: 204021

Decorin and Spironolactone Promote Retinal Ganglion Cell Survival in a Rat Retinal Explant Model Mimicking Glaucomatous Damage

First Author: Mariana BOTREL CUNHA

Co-Author(s): Francine BEHAR-COHEN, Emilie PICARD, Jenny YOUALE

Purpose: There is a critical need for neuroprotective therapies in glaucoma—particularly in normal-tension glaucoma (NTG), in which retinal ganglion cell (RGC) loss and optic nerve degeneration can progress independently of intraocular pressure. Mineralocorticoid receptor (MR) overactivation in ocular tissues contributes to neurovascular inflammation, neurotoxicity, oxidative stress, and glutamate-mediated excitotoxicity—mechanisms implicated in glaucoma pathogenesis, especially in NTG. Decorin (DCN) and spironolactone (SPR), both downregulated by MR activation, possess anti-inflammatory and neuroprotective properties. This study evaluated their neuroprotective effects in a rat retinal explant model of NMDA-induced excitotoxicity.

Methods: Twenty-four neuroretinas from two-month-old Wistar rats were assigned to four groups ($n = 6$ per group): (1) NMDA 680 μM (30 min); (2) NMDA + DCN 10 $\mu\text{g/mL}$ (pre- and post-treatment); (3) NMDA + SPR 4 $\mu\text{g/mL}$ (pre- and post-treatment); (4) Control. Explants were maintained in culture for 72 hours. NMDA was applied at 24 hours for 30 minutes and then washed out. DCN and SPR treatments were administered at 0 hours and again at 24.5 hours, immediately after NMDA removal. Cytotoxicity was quantified by LDH release, and RGC survival was assessed via RBPMs immunostaining. Automated cell counts using QuPath were verified manually. RGC counts were analyzed using Kruskal–Wallis and LDH kinetics with two-way ANOVA.

Results: Both DCN and SPR treatments reduced LDH release and cell mortality at 48 and 72 hours; however,

only SPR reached statistical significance ($p < 0.05$), indicating sustained cytoprotection. Furthermore, both SPR- and DCN-treated groups showed significantly higher RGC survival compared to NMDA-only explants (SPR: $p < 0.0001$; DCN: $p < 0.05$).

Conclusions: Decorin and spironolactone markedly attenuate NMDA-induced excitotoxicity in retinal explants at both molecular and cellular levels. These findings support their potential as neuroprotective candidates for glaucoma therapy, particularly in NTG.

Abstract No.: 208023

Development and Validation of a Multimodal Deep Learning Model for Latent Zonular Instability in Primary Angle Closure Disease

First Author: Ning **FAN**

Co-Author(s): Wei **CHI**, Sheng Li **MI**, Chun Yan **QIAO**

Purpose: This study aims to develop and validate a multimodal deep learning model for detecting latent zonular instability in patients with primary angle closure disease (PACD) and cataract.

Methods: This study included 102 patients with PACD who underwent cataract surgery at Shenzhen Eye Hospital from June 2022 to June 2024. The external validation set comprised data from 45 patients (59 eyes) with PACD at Beijing Tongren Hospital from May 2022 to May 2024. Intraoperative confirmation of zonular status served as the reference standard. A multimodal network, combining a ResNet-based convolutional neural network and a TabNet classifier, was developed and validated.

Results: The analysis included 102 eyes with PACD and cataract, with preoperative AS-OCT images and eight parameters. The parameters between latent zonular instability and zonular stability groups included anterior chamber depth, lens vault, angle opening distance at 750 μm , angle recess area at 750 μm , trabecular iris angle at 750 μm , anterior radius of the lens (F-R), anterior radius of the steep curvature of the lens (F-Rs), and lens thickness (all $P < 0.001$ except for F-R, $P = 0.017$). A multimodal model integrating AS-OCT images and clinical data achieved AUCs of 0.82 (95% CI: 0.75–0.88) and 0.78 (95% CI: 0.75–0.81), and accuracies of 79.55% and 75.20% in internal and external validations, respectively, outperforming doctors in diagnosis.

Conclusions: Combining clinical parameters and raw images, this multimodal artificial intelligence approach can effectively detect latent zonular instability in PACD, potentially enhancing early diagnosis.

Abstract No.: 206022

Diagnostic Accuracy of an AI-Based Fundus Camera for Glaucoma Detection: Comparison With Standard and Remidio-Based Grading System

First Author: Neha **YADAV**

Co-Author(s): Rohit **KHANNA**, Sirisha **SENTHIL**

Purpose: To evaluate the diagnostic performance of an AI fundus camera for glaucoma detection compared with two glaucoma specialists applying different grading criteria under two definitions: (i) disc suspect or referable glaucoma as disease positive, and (ii) disc suspect or normal as disease negative.

Methods: Fundus images were independently graded by two glaucoma specialists: one using standard glaucoma grading criteria and the other using Remidio grading criteria. The performance of the AI fundus camera was compared against both specialists. Disease prevalence, sensitivity, specificity, and area under the ROC curve (AUC) were calculated.

Results: A total of 594 participants (mean age 46.8 years; SD 15.3; range 13–92 years) were included. Definition 1 (disc suspect or referable glaucoma as disease positive): Sensitivity was highest for the Remidio criteria for glaucoma detection (80.8%), compared with the standard clinical grading (63.0%). Specificity was high for both (93.8–95.1%). AUC values indicated strong performance, highest for the Remidio criteria (0.87) and slightly lower for the standard clinical grading (0.79). Definition 2 (disc suspect or normal as disease negative): Sensitivity ranged from 76.9% (standard clinical grading) to 80.0% (Remidio criteria), with specificity 96.1–97.1%. AUC values were 0.87–0.88. AI performance was comparable to both specialists across definitions.

Conclusions: The AI-based fundus camera achieved diagnostic accuracy comparable to that of glaucoma specialists. High sensitivity, specificity, and AUC support its potential for ruling out glaucoma in community screening, providing a feasible and scalable approach for early detection.

Abstract No.: 204164

Diagnostic Value of CASIA2 for Zonulopathy Detection in Primary Angle-Closure Glaucoma

First Author: Chunyan **QIAO**

Co-Author(s): Yiyi **LI**, Mugen **LIU**, Arthur Labisi **SILOKA**

Purpose: To evaluate anterior segment characteristics of primary angle-closure glaucoma (PACG) using swept-source anterior segment optical coherence tomography (SS-OCT, CASIA2), and identify parameters that may improve clinical detection of zonulopathy.

Methods: This retrospective study included 122 eyes from 95 PACG patients who underwent combined cataract and glaucoma surgery. Eyes were classified into three groups: (1) Apparent zonulopathy, (2) occult zonulopathy (diagnosed intraoperatively), and (3) normal-zonule groups. Preoperative anterior segment parameters were obtained using CASIA2. Multivariate logistic regression was performed to identify independent risk factors associated with zonulopathy, and receiver operating characteristic (ROC) curves were used to evaluate diagnostic performance.

Results: Zonulopathy incidence was 47.5% (58/122). Of these, only 27.6% (16/58) were diagnosed preoperatively, while 72.4% (42/58) had occult zonulopathy. The occurrence was significantly higher in acute PACG eyes (64.8%, 35/54) than in chronic PACG eyes (33.8%, 23/68) ($P < 0.05$). Multivariate analysis indicated that greater lens thickness (LT) (OR=7.610, $P=0.009$) and greater lens vault (LV) (OR=0.237, $P=0.039$) were significant independent risk factors. ROC curve analysis revealed LT had moderate diagnostic value (AUC=0.703) for zonulopathy, with an optimal cutoff of 4.96 mm. A combined diagnostic model incorporating LT, LV, PACG subtype (acute vs. chronic), anterior chamber depth (ACD), and central ACD achieved the highest diagnostic efficacy (AUC=0.760).

Conclusions: Zonulopathy is commonly present in PACG eyes, particularly in acute cases. This study demonstrates that CASIA2-derived LT and LV are critical predictors for zonulopathy, and a multifactorial model enhances preoperative identification of occult Zonulopathy, providing clinical guidance for optimizing surgical strategy.

Abstract No.: 205439

Do Symptoms Match Signs? Agreement Between Questionnaires and Clinical Tests for Dry Eye Disease in Glaucoma and Normals

First Author: Amrita **PUGALENTHI**

Co-Author(s): Ronnie **GEORGE**, Baskaran **MANI**

Purpose: To evaluate the ocular surface and utility of symptom-based questionnaires in Dry Eye Disease (DED) in patients using anti-glaucoma medications (AGMs) and age-matched normals.

Methods: Prospective study of patients on >2 AGMs for ≥ 2 years and controls. Ocular surface disease index (OSDI), Standardized Patient Evaluation of Eye Dryness (SPEED), Dry Eye Questionnaires (DEQ-5), Schirmer's test (type I), and Tear film breakup time (TBUT) were graded as mild, moderate, severe and normal, and agreement was studied.

Results: Of 65 cases and 69 controls, age was similar, and gender was dissimilar ($p=0.009$). Mean AGMs were $2.88(\pm 1.02)$ in cases. TBUT ($6.72(\pm 2.07)$ vs $7.49(\pm 2.61)$; $p=0.062$) and Schirmer's ($14.4(\pm 5.88)$ vs $15.48(\pm 6.42)$; $p=0.313$) were reduced in cases. OSDI ($22.09(\pm$

$9.59)$ vs $10.83(\pm 9.06)$; $p=0.001$), SPEED ($8.25(\pm 3.46)$ vs $5.07(\pm 3.43)$; $p=0.001$), and DEQ-5 ($7.2(\pm 2.14)$ vs $4.07(\pm 3.09)$; $p=0.001$) were all worse in cases. Kappa (Schirmer's vs TBUT) was better in cases ($\kappa=0.285$, $p < 0.001$ vs $\kappa=0.113$, $p=0.06$). Agreement between Schirmer's and OSDI, SPEED and DEQ-5 for cases was best for OSDI ($\kappa=0.25$, 95% CI: 0.101-0.431) and <0.1 for the rest. For TBUT with questionnaires agreement was poor (<0.14 in all groups). Between OSDI and DEQ-5, kappa was (0.639, 95% CI: 0.474-0.804) for controls and (0.438, 95% CI: 0.269-0.607) for cases. Agreement between OSDI and SPEED was poor.

Conclusions: Given the ocular surface impact of long-term AGM use, patient-reported symptoms do not always reflect clinical signs of dry eye. Using validated questionnaires with objective testing is essential for accurate assessment of ocular surface dysfunction.

Abstract No.: 204187

Efficacy and Safety of Omidenepag Isopropyl vs Latanoprost for Glaucoma and Ocular Hypertension: A Meta-Analysis of Randomized Trials

First Author: Nghi Bao **TRAN**

Co-Author(s): Vinh Quang Tri **HO**, Neeran

NARAINSWAMI, Nhan **NGUYEN**, Vy Ngoc Dan **NGUYEN**

Purpose: To compare the effectiveness and safety of Omidenepag Isopropyl (OMDI) versus Latanoprost in patients with primary open-angle glaucoma or ocular hypertension, focusing on diurnal intraocular pressure (IOP) reduction and ocular adverse events.

Methods: This meta-analysis was registered in PROSPERO (CRD42024627603) and included randomized controlled trials comparing OMDI and latanoprost in patients with primary open-angle glaucoma or ocular hypertension. Systematic searches were conducted in PubMed, Embase, and Cochrane for English-language articles. Outcomes included diurnal IOP at 1 week, 2 weeks, 1 month, and final follow-up, as well as adverse events. Three reviewers independently screened and extracted data following PRISMA guidelines. Risk of bias was assessed using RoB 2.0, and evidence certainty was evaluated using GRADE. Pooled estimates were calculated using a random-effects model. Effect measures included mean differences (MDs) and risk ratios (RRs) with 95% confidence intervals (CIs).

Results: Four RCTs were included, comprising 817 patients. Follow-up ranged from one week to three months. There were no significant differences between groups in diurnal IOP reduction after one week (MD = -0.06 mmHg; 95% CI -0.61 to 0.50 ; $p = 0.84$). However, OMDI resulted in a slightly smaller IOP reduction compared to latanoprost up to 3 months (MD = 1.47 mmHg; 95% CI 0.82 to 2.11 ; $p < 0.00001$). Ocular adverse effects were more frequent in the OMDI group (RR = 1.42 ; 95% CI 1.16 to 1.75 ; $p = 0.004$). GRADE

assessment showed high certainty in diurnal IOP reduction at 2 weeks, 1 month, end of follow-up, and ocular adverse effects. Other outcomes were rated as moderate certainty.

Conclusions: OMDI offers a similar short-term IOP reduction to latanoprost but is slightly less effective over 3 months and has more ocular side effects. It may be an option for patients intolerant to prostaglandins, though its side-effect profile should be considered. The review is limited by a short follow-up time.

Abstract No.: 205917

Efficacy and Safety of Paul Implant in Refractive Glaucoma: A Long-Term Study

First Author: Saleh **AL OBEIDAN**

Co-Author(s): Danya **ALTURKISTANI**, Ahmed **MOUSA**

Purpose: To determine the long-term efficacy and safety of the Paul tube implant in refractory glaucoma.

Methods: Surgical intervention included using ripcord (6-0 prolene) inserted inside the tube at the time of surgery. Surgical quadrant was left to the surgeon's preference: superior-temporal position was chosen in the majority of cases, 53 (80.3%), while it was inferior-temporal in 11 (16.7%) of the cases. A 0.2 Mitomycin was used in 61 (98.4%) of the cases. The patch graft type was Tutoplast in all (100%) of the cases. Both demographic and clinical glaucoma indices were collected pre- and post-operative, then followed up to a minimum of 12 months. Reduction in IOP, and success rates were calculated, and postoperative complications were assessed.

Results: The IOP was significantly reduced from a preoperative average of 28.7 (10.7) mmHg to 15.7 (8.1) mmHg postoperatively, $p < 0.0001$. At the last follow-up assessment visit, the IOP reached up to 13.7 (5.7) mmHg, $p = 0.005$. The average number of anti-glaucoma medications was significantly reduced from 3.3 (0.9) preoperatively, to 0.2 (0.6) postoperatively, $p < 0.0001$, while at the last follow-up assessment, it was stable at 0.2 (0.6). The complete success rate was 53 (81.5%), qualified success was 7 (10.8%), and overall success was 60 (92.3%). Main complications were AMD 3 (4.5%), Choroidal after suture removal: 1 (1.5), Conjunctival Dehiscence: 2 (3.0), and Hyphemia: 3 (4.5) with an overall complication rate of 9 (13.6%).

Conclusions: Paul tube has a comparable efficacy and safety profile to other equivalent glaucoma devices; the implant safety is quite valid for both adult and congenital refractive glaucoma cases.

Abstract No.: 206709

Etiology-Dependent Divergent Microvascular Patterns under Translaminar Pressure Difference Change

First Author: Seraph Tianmin **REN**

Co-Author(s): Xiaowei **FAN**, Ningli **WANG**, Yanling **WANG**, Jingxue **ZHANG**

Purpose: To compare layer and bed-specific microvascular alterations induced by elevated translaminar cribriform pressure difference (TLCPD) from low intracranial pressure (LICP) versus intraocular pressure-driven ischemia-reperfusion (IR), and to relate these changes to multimodal structural and functional outcomes (OCT, ERG/PhNR, OKR), including retinal ganglion cell (RGC) injury.

Methods: Adult rats were assigned to: 1) LICP, via cerebrospinal fluid drainage, lowering intracranial pressure by ~ 8 mmHg; and 2) IR, via acute IOP elevation with two severities—mild ($+8$ – 10 mmHg) and high (~ 110 mmHg). High-resolution small-animal OCTA (axial < 5 μ m; 4×4 mm; depth 400 μ m) quantified choroid and retinal plexuses (SVP, IVP, DVP) at baseline, day 4, and day 7. OCT measured retinal/nerve-fiber layers. ERG/PhNR and OKR assessed function. Vascular metrics (diameter, skeleton density, tortuosity) and RGC apoptosis were analyzed region-wise. TLCPD was computed per eye; LICP and IR-mild produced an equivalent level of TLCPD disturbance.

Results: All groups showed early functional decline by day 4 (OKR and ERG/PhNR), concordant with OCT changes. LICP produced early, dominant compromise of the choroid and DVP (choroid -5.4% ; DVP -8.1% at day 4, nasal accentuation), with further DVP worsening by day 7 (diameter $\beta = -0.41$, $r^2 = 0.08$, $p < 0.0001$). Choroidal metrics correlated with optic-nerve damage (diameter $\beta = -0.25$, $r^2 = 0.02$, $p < 0.05$; tortuosity $\beta = -0.24$, $r^2 = 0.04$, $p < 0.01$; skeleton density $\beta = -0.23$, $r^2 = 0.06$, $p < 0.001$). Focal RGC loss predominated in the inferior region. IR showed a top-down pattern with primary SVP/IVP/DVP involvement. In IR-mild, SVP decreased by 12.1% with inferior–nasal emphasis at day 4, correlating with RGC apoptosis ($\beta = -0.24$, $r^2 = 0.15$, $p < 0.01$); DVP and choroid changes were smaller than in LICP. IR-high produced pan-plexus injury consistent with global ischemia. In the equivalent TLCPD comparison (LICP vs IR-mild), despite matched TLCPD disturbance, vascular alterations were larger with LICP—especially in the choroid—whereas IR-mild mainly affected SVP/IVP at day 4 and recovered quickly thereafter without significant regional RGC loss, and did not show inferior-predominant focal RGC loss. Enhanced OCTA depth penetration revealed previously undetectable deep vascular changes, demonstrating layer-, temporal-, regional-, and etiology-specific patterns of vascular injury.

Conclusions: TLCPD disturbance yields two macro injury phenotypes. Low ICP preferentially disrupts

the choroidal bed and deep retinal plexus, associates with inferior-predominant focal RGC loss, and exhibits a distinct multimodal pattern of change; IR mainly compromises SVP/IVP with secondary DVP involvement, and severe IR extends damage pan-plexus. Notably, at an equivalent level of TLCPD disturbance, LICP induces greater vascular change than acute mild IR. These patterns likely reflect differences between outer (choroidal) and inner-retinal circulations, informing etiology-tailored monitoring and intervention, and may help explain vascularly mediated mechanisms of neural injury in special glaucoma phenotypes such as normal-tension glaucoma.

Abstract No.: 207393

Evaluating the Outcomes of Kahook Dual Blade (KDB) in Primary Adult Glaucoma

*First Author: Dewang **ANGMO***

*Co-Author(s): Muskaan **BANSAL**, Tanuj **DADA**, Anuja **PATIL***

Purpose: To evaluate the outcomes of Kahook dual blade (KDB) in primary open-angle glaucoma (POAG) and primary angle closure glaucoma (PACG).

Methods: A total of 40 patients with POAG/PACG and cataract were included and underwent phacoemulsification with IOL insertion with KDB goniotomy. The patients were examined at baseline and at 1 week, 1 month, 3, 6, 12, and 18 months. The anterior chamber angle parameters on swept-source anterior segment OCT (SS-ASOCT) were noted at baseline, and at 3, 6, and 12-month follow-up. Main Outcome Measures: The primary outcome measure was reduction in intraocular pressure (IOP) and the number of anti-glaucoma medications. Secondary outcomes were changes in angle parameters and specular count

Results: The mean baseline IOP was 19.5 ± 7.2 mmHg. The mean IOP decreased to 13.9 ± 3.0 mmHg at 12 months. There was a significant reduction in the number of medications (4.1 ± 1.8 to 1.1 ± 0.8 mmHg; $p=0.02$ mmHg). Qualified success with IOP ≤ 12 mmHg was obtained in 80% of patients. No absolute failures were noted at 1-year follow-up. A significant widening of the angle parameters was noted postoperatively at 3, 6, and 12 months as compared to baseline in PACG patients. The other secondary outcome parameters, like BCVA, visual field changes, endothelial cell count, and complication rate, were also noted.

Conclusions: Phaco-KDB demonstrated significant reductions in both IOP and anti-glaucoma medications in both PACG and POAG patients.

Abstract No.: 208015

Evaluation of Results of Phacoemulsification-IOL Combined With Goniosynechialysis on Failed Trabeculectomy Eyes With Primary Angle-Closure Glaucoma

*First Author: Nguyen **HUONG***

*Co-Author(s): Doan Duc **LONG**, Do **TAN***

Purpose: To assess the results of phacoemulsification IOL combined with goniosynechialysis for failed trabeculectomy in primary angle-closure glaucoma.

Methods: Clinical interventional study.

Results: Preoperative characteristics: females: males ratio was 13:3. The mean age was 61.15 ± 8.45 years old. The average time after Trabeculectomy was 41.47 ± 43.95 months. Visual acuity (VA) and IOP were improved remarkably after surgery. IOP was reduced significantly at all time points from 28.79 ± 5.61 mmHg at baseline to 15.15 ± 3.46 mmHg at 6 months after surgery. Preoperative Log MAR VA was 1.71 ± 0.87 , which has been improved to 0.77 ± 0.44 at 6 months with $p < 0.001$. The number of IOP-lowering medications was decreased from 2.56 ± 0.63 to 0.31 ± 0.87 , with $p < 0.001$. The complete success rate was 87.5 %. Preoperatively, the anterior chamber angle was almost completely closed. After surgery, angles were widened to grade 3-4 Shaffer in almost all cases except for one case where the angle closure had recurred. Hyphema is the most common complication, which occurred in 50% cases, and was, luckily, transient and responded well to treatment.

Conclusions: Phacoemulsification/ GSL proved to be safe and effective in PACG eyes with previously failed trabeculectomy.

Abstract No.: 200137

Evaluation of the Effects of Direct Selective Laser Trabeculoplasty After 2 Years of Treatment Both in Primary Open Angle Glaucoma Eyes and in Primary Angle Closure Glaucoma Ones

*First Author: Michele **LANZA***

*Co-Author(s): Francesco **ABBATE**, Francesca **AGRICOLA**, Salvatore **AMBROSIO**, Rosa **BOCCIA**, Teresa **CANGIANO**, Italo **FATTORE**, Luigi **SERRA**, Francesca **SIMONELLI***

Purpose: To evaluate the efficacy and safety of direct selective laser trabeculoplasty (DSLT) on eyes with primary open-angle glaucoma (POAG) and on primary angle closure glaucoma (PACG) eyes at 2-year follow-up.

Methods: In this study, 55 eyes of 30 patients affected by POAG and 23 eyes of 12 patients affected by PACG have been included. Before each treatment and at each follow-up, every subject underwent a complete eye visit, including data regarding the IOP-lowering drugs assumed. The patients treated underwent

30-2 standardized automated perimetries (SAP) prior to DSLT, at 6 months, 12, and 24 months after the procedure. Each patient was checked after 1 week and subsequently after 1, 3, 6, 12, and 24 months.

Results: At 1-month follow-up, both the eyes affected by POAG and those affected by PACG showed significantly ($p < 0.01$) lower IOP (-4.23 ± 2.11 mmHg and -3.64 ± 2.08 mmHg, respectively) and a lower number of IOP-lowering drugs taken (-0.81 ± 0.38 and -0.75 ± 0.66 , respectively) after DSLT. These reductions remained stable until the 2-year follow-up, both for IOP and for the drugs assumed. The SAP mean values showed perimetry stability in both POAG and PACG eyes at 2-year follow-up. No major complications were observed in the eyes included in this study.

Conclusions: Although these results need to be confirmed in further ones with larger population and longer follow up, they suggest that DSLT would be a useful tool for the management of glaucoma patients.

Abstract No.: 205027

Exosomal miR-450b-5p Secreted From Exendin-4 Stimulated Vascular Endothelial Cells Protected Retinal Ganglion Cells From Acute Ischemia Reperfusion Injury

First Author: Xiangmei **KONG**

Co-Author(s): Yanan **SUN**

Purpose: Exendin-4 (Ex-4) has been reported to protect against ischemia-reperfusion (IR) injury in various vital organs. In this study, we aimed to investigate the potential neuroprotective effects of Exendin-4 (Ex-4) against retinal ischemia-reperfusion (RIR) injury and to elucidate the underlying mechanisms.

Methods: Immunofluorescence staining assay, hematoxylin and eosin (HE) staining were conducted to evaluate the neuroprotective role of Ex-4. A co-culture assay of human retinal vascular endothelial cells (HRVECs) and RGCs was established. Extracellular vesicles (EVs) were isolated from the culture supernatant of HRVECs with (E-EVs) or without Ex-4 treatment (O-EVs) under oxygen-glucose deprivation/reoxygenation (OGD/R) conditions. Transmission electron microscopy (TEM), Nanoparticle tracking analysis (NTA) and Nano-flow cytometry (NanoFCM) were used to detect the presence and purity of EVs. Cell activity, reactive oxygen species (ROS) level, and cell death rate of RGCs were evaluated. Further global miRNA sequencing was performed on E-EVs or O-EVs to explore potential mechanisms.

Results: Our findings revealed that Ex-4 had a GLP-1R-dependent neuroprotective effect on RGCs. Vascular endothelial cells (VECs) -derived EVs mediate the protective effect of Ex-4 on RGCs under acute RIR injury. We identified miR-450b-5p as a highly enriched miRNA in E-EVs. Treatment with either E-EVs or miR-450b-5p mimics significantly protected RGCs

against RIR-induced injury. Mechanistic investigations identified acyl-coenzyme A (CoA) synthetase long-chain family member 4 (ACSL4) as a direct target of miR-450b-5p.

Conclusions: Ex-4 exerts its neuroprotective effects under RIR injury by stimulating retinal VECs to secrete miR-450b-5p-enriched EVs, thereby revealing a novel endothelial-mediated neuroprotective pathway in ischemia diseases.

Abstract No.: 205473

Expert Annotations Enhance Ultra-Widefield Fundus Artificial Intelligence for Detecting Glaucoma and Myopia-Related Lesions

First Author: Lu **CHENG**

Co-Author(s): Jingjing **HUANG**, Lina **HUANG**, Weiguang **YU**, Qiting **YUAN**

Purpose: To develop and validate ultra-widefield (UWF) fundus-based artificial intelligence (AI) models for automated detection of primary open-angle glaucoma (POAG) in myopic eyes and automated segmentation of glaucomatous optic neuropathy, as well as simultaneous recognition of pathological myopia and other myopia-related lesions, and to evaluate the impact of expert-driven annotations.

Methods: A total of 6,096 UWF images were analyzed using InceptionV3-based deep learning models: an Annotation-Free UWF AI and an Annotated UWF AI trained with expert manual annotations. Tasks included binary classification (presence/absence of POAG, pathological myopia, and myopia-related lesions), ternary classification (glaucoma severity, tessellated fundus grading), four-class classification (mild myopia, mild myopia with POAG, high myopia, high myopia with POAG, according to clinical myopia and glaucoma diagnoses), and segmentation (vertical cup-to-disc ratio, cup-to-disc area ratio). Performance metrics included AUC, accuracy, and mean absolute error (MAE).

Results: The annotated AI model outperformed the annotation-free model across all tasks: binary AUCs 0.89–0.91 vs. 0.69–0.86; ternary macro-AUCs 0.94–0.95 vs. 0.90–0.91; four-class macro-AUC 0.84 with 66.0% accuracy vs. 0.47 and 34.4%. Segmentation achieved MAEs < 0.1 for both indices. Internal and external validation accuracies ranged from 72.5%–92.1% and 70.6%–93.0%, confirming robust generalizability.

Conclusions: Expert annotations significantly enhanced the diagnostic accuracy, interpretability, and generalizability of UWF AI models. Even in structurally complex myopic eyes, the annotated model reliably detected glaucoma and myopia-related lesions, demonstrating potential for large-scale screening, early diagnosis, and cost-effective clinical application.

Abstract No.: 202135

Factors Influencing Glaucoma Progression in Patients With Disc Hemorrhage

*First Author: Tanasuang WIROTIJUNLASAK
Co-Author(s): Sune CHANSANGPETCH, Rath ITTHIPANICHPONG, Anita MANASSAKORN, Kitiya RATANAWONGPHAIBUL, Prin ROJANAPONGPUN, Charturong TANTIBUNDHIT, Visanee TANTISEVI*

Purpose: To determine clinical characteristics and glaucoma prognostic factors in patients presenting with disc hemorrhage (DH).

Methods: Fundus photographs taken between 2013-2018 were reviewed. DH was defined as bleeding within one disc diameter of the optic disc border, and types and locations were classified. Hemorrhages associated with other retinal hemorrhages were excluded. At least 12 months of follow-up, DH recurrence, intraocular pressure (IOP), and classes of anti-glaucoma medications at each visit were collected. Glaucoma progression was assessed by visual fields, optical coherence tomographs and fundus photographs.

Results: Of 5,319 eyes, DH was observed in 100 eyes of 91 subjects (1.9%, 95%CI 1.5-2.3%). The predominant types were peripapillary (49%) and rim type (34%). Glaucoma progression occurred in 58 eyes (58%) over a mean follow-up of 57.1 (15.6) months. The mean IOP during the follow-up was 12.9 (2.0) mmHg. Glaucoma progression was associated with DH recurrence (odds ratio [OR] 2.59, $p=0.012$) and beta-blocker use (OR 2.49, $p=0.049$). No significant associations were observed between glaucoma progression and IOP factors, DH type, or DH location. The mean time to progression was 27.4 (16.3) months. Recurrence of DH was detected in 33 eyes (33%, range 1-6 times). The observed minimum IOP (lowest IOP recorded during follow-up) was shown reversely associated with DH recurrence (OR 0.73, $p=0.023$).

Conclusions: More than half of the eyes with DH showed subsequent glaucoma progression. DH recurrence and beta-blocker use were associated with higher progression risk. While IOP factors was not significantly related to progression, a lower minimum IOP during follow-up protects against DH recurrence.

Abstract No.: 201454

Five-Year Safety and Efficacy Results of a Supraciliary Drainage Device in Open Angle Glaucoma Patients (STAR-GLOBAL)

*First Author: Jason CHENG
Co-Author(s): Iqbal Iqbal AHMED, Philippe DENIS, Antonio FEA*

Purpose: The five-year safety and efficacy of a minimally invasive glaucoma surgery (MIGS) device, MINInject® (iSTAR Medical, Belgium), is described.

Methods: The device was implanted ab interno into the supraciliary space in a standalone procedure in four prospective trials (STAR-I,II,III,IV). Upon study completion at two years, subjects were invited to enrol into STAR-GLOBAL to continue follow-up annually until five years post-implantation. Outcome measures were intraocular pressure (IOP), IOP-lowering medications (meds), adverse events, and measurement of corneal endothelial cell density. Fifty-six subjects from the STAR-I, II, and III trials were enrolled in the STAR-GLOBAL trial, with 47 completing 5-year post-implantation follow-up (83.9%). These are preliminary, interim results of subjects who have completed the STAR-GLOBAL trial.

Results: In this STAR-GLOBAL population, the mean baseline diurnal IOP prior to implantation was 23.8 ± 3.5 mmHg with a mean of 2.4 ± 1.2 IOP-lowering meds ($n=56$). At 2 years post-implantation, mean diurnal IOP was 14.3 ± 4.2 mmHg (-9.6 mmHg, -39.5% ; $p<0.0001$) on 1.4 ± 1.4 meds ($n=55$). At 5-year post-implantation follow-up ($n=47$), mean diurnal IOP was 14.8 ± 5.6 mmHg (-9.1 mmHg, -38.4% ; $p<0.0001$) on 1.5 ± 1.4 meds ($p<0.0001$). Further, 83.0% of subjects achieved a $\geq 20\%$ IOP reduction, 78.7% of subjects achieved an IOP ≤ 18 mmHg, and 31.9% of subjects were med-free at 5 years.

Conclusions: This supraciliary MIGS device offers an effective, bleb-free treatment option for patients with medically uncontrolled primary open angle glaucoma.

Abstract No.: 202827

From Metallogenomics to Ferroptosis: Multi-Omics Evidence Chain Unraveling Digoxin-Regulated Iron Homeostasis in Glaucomatous Trabecular Meshwork

*First Author: Xiaoyu ZHOU
Co-Author(s): Xuanchu DUAN*

Purpose: Recent studies have found that ferroptosis may be involved in the process of trabecular meshwork injury in glaucoma. This study aims to reveal the ferroptosis-related gene signature in primary open-angle glaucoma (POAG) and identify small-molecule drugs as a new direction of therapy.

Methods: Mendelian randomization (MR) analysis of East Asian GWAS data to assess causal relationships between blood metals and POAG. Ferroptosis-related indicators in POAG patients and chronic ocular hypertension (COH) rats were detected by ELISA kits. Integration of trabecular meshwork (TM) transcriptomes from POAG patients and ferroptosis-related gene sets (FerrDb) to identify core regulatory genes. CMap database screening and molecular docking to predict therapeutic compounds, followed by in vitro validation using hydrogen peroxide-induced TM ferroptosis models. Digoxin was formulated as ophthalmic drops and administered topically twice

daily to the eyes of COH rats to verify its intraocular pressure (IOP) lowering effect in vivo.

Results: MR results demonstrated that elevated serum iron levels causally increased POAG risk. Ferroptosis levels were enhanced in POAG patients and COH eyes of rats. A total of 14 ferroptosis-related differentially expressed genes were identified. PPI analysis identified SLC2A3, SCD and HBA1 as ferroptosis-TM injury hub genes, whose dysregulation amplified lipid peroxidation. CMap and molecular docking indicated that ATPase inhibitors digoxin might be considered as potential therapeutic drugs for POAG. Digoxin administration alleviated H₂O₂-induced HTMCs ferroptosis and lowered IOP of COH eyes.

Conclusions: This study identifies digoxin as a promising agent targeting the SLC2A3/SCD/HBA1 pathway to suppress ferroptosis and lower IOP, offering a transformative strategy for POAG therapeutics.

Abstract No.: 204290

Genetic Spectrum and Genotype-Phenotype Correlations in a Chinese Cohort With Nanophthalmos With Secondary Angle-Closure Glaucoma

First Author: Hanxue ZHAO

Purpose: This study aimed to characterize the genetic spectrum and clinical features of nanophthalmos with secondary angle-closure glaucoma (NSACG) in a large Chinese cohort, with emphasis on novel developmental and pathogenic mechanisms.

Methods: The participants underwent ocular and systemic examinations and whole-exome sequencing. The main outcome measures were pathogenic genetic variants, axial length (AL), refractive spherical equivalent (SE), vitreous chamber depth (VCD), white-to-white (WTW), radius of corneal curvature (flat and steep K: K1 and K2), anterior chamber depth (ACD), lens vault (LV), lens thickness (LT), extent of angle closure, anterior segment crowding value, retinal nerve fiber layer (RNFL) thickness, central subfield thickness (CST) in macular, cup-to-disc ratio (C/D), mean defect in visual field, and onset age of angle-closure glaucoma (ACG).

Results: Pathogenic variants were identified in 51.1% of patients. PRSS56 and MFRP were the predominant AR variants, whereas MYRF and TMEM98 were the main AD variants. Genetically diagnosed patients exhibited disproportionate reduction in VCD relative to AL, challenging the conventional view of nanophthalmos as a proportionally small eye. AR variants were associated with more extreme anterior segment crowding and limited corneal expansion, whereas AD variants were linked to earlier glaucoma onset and more severe visual field defects. Furthermore, retinal detachment and ciliochoroidal detachment occurred more frequently in genetically diagnosed patients, even after adjusting for

AL and age, implicating impaired vitreous development and altered intraocular fluid dynamics.

Conclusions: This is the first large-scale genotype-phenotype study of NSACG in a Chinese population. Our findings expand the mutational spectrum and may reveal novel mechanisms involving vitreous underdevelopment. The faster glaucoma progression in AD cases highlights the need for early intervention.

Abstract No.: 202834

Glaucoma Burden Among First-Degree Relatives: Insights From a National Referral Hospital in Indonesia

First Author: Nizma PERMAISUARI

Co-Author(s): Virna Dwi OKTARIANA, Agus SUGIHARTO, Astrianda Nadya SURYONO

Purpose: Glaucoma remains a major cause of irreversible blindness worldwide. Identifying high-risk groups, particularly first-degree relatives of primary open-angle glaucoma (POAG) patients, is essential for cost-effective early detection strategies. This study aimed to determine the glaucoma prevalence and risk factors among first-degree relatives of POAG patients in Indonesia.

Methods: A cross-sectional study was conducted at a national referral hospital in Indonesia involving first-degree relatives (parents, siblings, and offspring) of POAG patients aged ≥ 40 years. Participants underwent standardized ophthalmic assessment, including visual acuity, refraction, Goldmann applanation tonometry, gonioscopy, optic disc evaluation, perimetry, and central corneal thickness measurement, along with systemic evaluation for diabetes and hypertension. Glaucoma diagnosis followed the International Society of Geographical and Epidemiological Ophthalmology (ISGEO) criteria.

Results: A total of 359 relatives from 198 POAG patients were examined. Median age was 47 years, with 60.4% identifying as female. The overall glaucoma prevalence was 16.2%. On bivariate analysis, elevated intraocular pressure (IOP) ($p=0.002$), reduced ocular perfusion pressure (OPP) ($p=0.015$), and sibling status ($p=0.031$) were significantly associated with glaucoma. Siblings had nearly twice the prevalence compared with offspring. Higher prevalence was also observed among participants with moderate-to-high myopia, age ≥ 60 years, and diabetes mellitus, although not statistically significant. Multivariate logistic regression identified IOP ($\beta=0.090/\text{mmHg}$, $p=0.019$) and sibling relationship (aOR 2.59; 95% CI 1.32–5.09; $p=0.006$) as independent predictors.

Conclusions: The prevalence of glaucoma among first-degree relatives was higher than in the general population, with elevated IOP, reduced OPP, and sibling relationship contributing to risk. Targeted screening of

high-risk families could facilitate earlier detection and prevention of blindness.

Abstract No.: 201289

Glaucoma and Risk of Dementia: The UK Biobank Study

First Author: Vincent **YUEN**

Co-Author(s): Clement **THAM**, Jason **YAM**, Yuzhou **ZHANG**

Purpose: To evaluate the association between glaucoma and the risk of developing dementia, and to identify optical coherence tomography (OCT) biomarkers predictive of dementia using data from the UK Biobank.

Methods: Participants from the UK Biobank were included if they had no prior diagnosis of dementia and either no glaucoma or glaucoma diagnosed before recruitment. Diagnoses of glaucoma and dementia were obtained from linked hospital inpatient and death records. OCT parameters were analysed in a subset of participants with available imaging data.

Results: A total of 488,085 participants were included, of whom 7,671 had glaucoma at baseline. The mean follow-up duration was 16.5 years. After adjusting for age, sex, hypertension, diabetes, hyperlipidaemia, cardiovascular disease, and education level, glaucoma was significantly associated with increased risk of all-cause dementia (hazard ratio [HR]=1.354, $P<0.001$), dementia in Alzheimer's disease (HR=1.314, $P=0.023$), and vascular dementia (HR=1.402, $P=0.010$). OCT analysis revealed that individuals who developed dementia had significantly larger vertical cup-to-disc ratio (mean difference [MD]=0.082, $P=0.036$) and larger optic disc diameter (MD=0.114 mm, $P=0.003$).

Conclusions: Glaucoma is associated with a heightened risk of developing dementia, including Alzheimer's and vascular subtypes. Structural changes in the optic nerve head, as captured by OCT, may serve as indicators of neurodegeneration and cognitive decline.

Abstract No.: 208016

Goniotomy for Adult Refractory Glaucoma: A 24-Month Prospective Observation Study

First Author: Chunxin **LAI**

Co-Author(s): Yongjie **QIN**, Hongyang **ZHANG**

Purpose: To evaluate the surgical outcomes of goniotomy in refractory glaucoma.

Methods: A prospective study was conducted on refractory glaucoma patients who underwent goniotomy. Study outcomes included changes in intraocular pressure (IOP), anti-glaucoma medication (AGM) usage, and complications over a 24-month period. Postoperative IOP > 21 mmHg at two consecutive follow-up visits or reduced $< 20\%$ from baseline, IOP ≤ 5 mmHg, re-operated for glaucoma,

and required more AGM than baseline was regarded as failure. Logistic regression analysis was used to investigate the potential factors for surgical failure.

Results: A total of 81 eyes from 72 patients were included. All participants had undergone at least one prior incision surgery: 66 eyes (81.48%) had undergone one prior surgery, 11 eyes (13.58%) had two, 4 eyes (4.94%) had three or more surgeries. Following goniotomy, IOP significantly decreased from 23.27 ± 11.12 mmHg preoperatively to 15.70 ± 2.78 mmHg at 24 months ($P<0.001$), along with a significant reduction in AGM use (from 2.79 ± 1.02 preoperatively to 1.43 ± 1.37 at 24 months, $P<0.001$). 27 eyes (33.33%) reached the criteria of complete success and 66 eyes (81.48%) met the qualified success at 24 months. 15 eyes (18.52%) were regarded as surgical failure and 3 of them underwent re-operation. Higher preoperative IOP was identified as a risk factor of surgical failure ($P<0.05$). 18 eyes (22.22%) developed hyphema and 8 eyes (9.88%) complicated with transient IOP spike.

Conclusions: Goniotomy effectively reduced IOP and AGM use in refractory glaucoma at 24 months, and may serve as a low-risk therapeutic option.

Abstract No.: 204496

High Polygenic Risk Predicts Future Need for Surgery in Suspect and Early Glaucoma

First Author: Victoria **TANG**

Co-Author(s): Jamie **CRAIG**, Mark **HASSALL**

Purpose: To examine the utility of a polygenic risk score (PRS) for predicting progression to surgical intervention in individuals with suspect or early glaucoma.

Methods: Longitudinal, prospective observational cohort study (PROGRESSA). Incisional surgery, defined as trabeculectomy, tube or drainage device insertion, was the outcome of interest. All participants had a PRS expressed as a percentile. Relative risks were estimated, Kaplan-Meier analysis was used to assess the cumulative incidence of surgery, and logistic regression evaluated the association between PRS and surgery.

Results: We included 2,486 eyes with suspect and early manifest glaucoma (mean age 64.0 ± 10.1 years; 42% male) with an average follow-up time of 8.6 ± 2.1 years. Overall, 4.8% ($n=119/2486$) underwent incisional surgery. Median PRS was higher in eyes requiring surgery (84.7 vs 76.1, $p = 0.016$). No eyes in the bottom PRS decile required surgery within 5 years (0/24; 0%). At 5 years, eyes within the top 10% of PRS had nearly twice the risk of surgery compared with the bottom 90% (2.6% vs 1.3%, RR1.97, 95% CI 1.07–3.65, $p = 0.03$). Across their entire follow-up, the top decile had a 1.74-fold higher risk of surgery compared with the rest (6.7% vs 3.8%, 95% CI 1.20–2.51, $p = 0.004$). Within the top PRS decile, there was a higher cumulative incidence of surgery (log-rank $p = 0.001$), and logistic regression

also demonstrated higher odds of surgery (OR 1.70; $p = 0.004$).

Conclusions: A high PRS is associated with a greater likelihood of surgery amongst glaucoma suspects, supporting its use in assisting surgeons in identifying high-risk individuals earlier and prioritising them for closer monitoring.

Abstract No.: 200273

Hypothalamic Atrophy in Glaucoma Is Linked to IGF-1 Dysregulation and Glial Inflammation

First Author: Ji Won **BANG**

Co-Author(s): Sang Won **BAE**, Kevin **CHAN**, Joel **SCHUMAN**, Justin **VEERASAMI**, Gadi **WOLLSTEIN**

Purpose: Glaucoma involves degeneration of retinal ganglion cells, including intrinsically photosensitive subtypes that project to the hypothalamus. The hypothalamus regulates systemic inflammation through hormonal release and autonomic pathways. However, it remains unclear if such pathways are impaired in glaucoma. Here, we investigated whether glaucoma-related hypothalamic atrophy is linked to hormonal dysregulation and glial inflammation.

Methods: Data from UK Biobank (healthy: $N=480$, 62.42 ± 0.22 [SE] yrs, glaucoma: $N=480$, 62.44 ± 0.22 yrs) and an independent prospective cohort (healthy: $N=27$, 63.93 ± 1.47 yrs, glaucoma: $N=52$, 65.71 ± 1.02 yrs) were used. Structural MRI provided hypothalamic volumes, ophthalmic measures assessed vision and retinal structure, and blood proteomics quantified activation markers for astrocyte (CHI3L1, LCN2, C3) and microglia (TREM2, MSR1, HAVCR2). Structural equation modeling (SEM) tested mediation pathways linking glaucoma, hypothalamic volume, insulin growth factor-1 (IGF-1), and glial activation, adjusting for age and sex. SHapley Additive exPlanations (SHAP) identified top proteomic features associated with glaucoma classification.

Results: Glaucoma patients had smaller hypothalamic volume than controls ($P < 0.001$), which correlated with visual field loss and retinal thinning (all P s < 0.05). SEM revealed that hypothalamic shrinkage predicted both greater astrocytic activation ($P = 0.008$) and reduced IGF-1 ($P = 0.013$), which in turn was associated with higher microglial activation ($P = 0.014$). SHAP identified 8 of the top 10 features linked to glaucoma classification as inflammation-related.

Conclusions: Our findings suggest a feed-forward pathway linking glaucoma, hypothalamic atrophy, hormonal dysregulation, and heightened glial inflammation. These results highlight the systemic hypothalamic-inflammatory involvement in the pathophysiology of glaucoma.

Abstract No.: 205342

Identification of Glaucoma Endotypes From Aqueous Humor Analysis: A Novel Framework for Patient Stratification and Targeted Therapy

First Author: Muneeb **FAIQ**

Co-Author(s): Kevin **CHAN**, Rima **DADA**, Tanuj **DADA**, Daman **SALUJA**, Himanshu **SINGH**

Purpose: To identify molecular endotypes of primary open-angle glaucoma (POAG) from aqueous humor (AH) proteo-metabolomics and map them to targetable biological pathways.

Methods: AH (0.5 mL) from cataract controls ($n=30$), early POAG (MD -6 to -12 dB; $n=30$), and advanced POAG (MD < -20 dB; $n=30$) underwent LC-MS proteomics/metabolomics. A 46-protein/50-metabolite panel was analyzed by consensus k-means (1,000 resamples) to define clusters ("endotypes"), with stability assessed by PAC and silhouette indices. Pathway scores (insulin/GLP-1, mitochondrial/TCA, inflammatory eicosanoids, kynurenine, neurotrophic/stress) were computed from z-scored composites. Associations with MD used ANCOVA adjusting for IOP, age, and sex.

Results: Three robust endotypes emerged (consensus PAC < 0.05): (E1) Insulin-deficient, characterized by low INSR/PI3K/AKT/mTOR and low GLP-1/IGF-1; (E2) Mito-inflammatory, with TCA depletion (citrate, α -ketoglutarate, cardiolipin) plus high TNF α /IL-6/PGE2; and (E3) Stress-dominant, marked by high cortisol/kynurenine/quinolinic acid and reduced BDNF/ β -endorphin. Endotypes differed in MD ($p < 0.001$): E1/E2 worse than E3, and E2 worst after IOP adjustment ($p < 0.01$). AQP4 expression was highest in E2 ($p < 0.01$), linking fluid-transport disturbance with mito-inflammation. Stability analyses confirmed cluster reproducibility.

Conclusions: AH proteo-metabolomics resolves clinically relevant endotypes of POAG with distinct, targetable biology—insulin/GLP-1 augmentation (E1), mitochondrial stabilization/anti-inflammatory therapy (E2), and HPA/kynurenine modulation with neurotrophic support (E3). Endotyping may enable precision stratification and tailored interventions.

Abstract No.: 206480

Impact of Expanding Antiglaucoma Medication Use on Trabeculectomy Outcomes: A Four-Decade Analysis

First Author: Smita **PANDA**

Co-Author(s): Dharshini R, Ronnie **GEORGE**, Deepa M, Trupti **PATIL**

Purpose: To evaluate whether the expanding availability and use of antiglaucoma medications (AGMs) over four decades has influenced trabeculectomy outcomes.

Methods: A retrospective comparative analysis was conducted on patients with primary open-angle and angle-closure glaucoma who underwent trabeculectomy between 1985 and 2024. Cases were grouped by decade, with a minimum follow-up of 1 year. Demographic and clinical parameters, survival outcomes were compared.

Results: A total of 397 eyes of 289 patients were assessed: 1985–1994 (n=99 eyes), 1995–2004 (n=98), 2005–2014 (n=100), and 2015–2024 (n=100). Significant differences were observed in sex (p=0.002), number of preoperative AGMs (p<0.001), and duration of use (p=0.048). Use of antimetabolites increased markedly over time (from 6% in decade 1 to 58% 5-fluorouracil use +17 % Mitomycin-C(MMC) use in decade 2, 100 % MMC in later decades). At 1-year follow-up, failure rates showed a decade-wise increase (8%, 8.1%, 15%, 14%). Kaplan–Meier survival analysis showed cumulative success rates 95%, 92%, 94%, 96% at 2 years, 91%, 90%, 89%, 83% at 5 years, 82%, 76%, 75%, 69% at 10 years, with a trend towards declining success over time but statistically insignificant. However, an earlier re-initiation of AGMs (p=0.011) after trabeculectomy was needed over the decades. There was an increase in need for bleb needling (0%, 3.5, 1.6%), but it was statistically insignificant.

Conclusions: Over four decades, the growing availability of AGMs and longer exposure to multiple AGMs prior to surgery have altered the postoperative outcomes even with Mitomycin-c use. The survival rates decrease over a longer period of time, and the need for postoperative AGMs has increased.

Abstract No.: 202215

Impact of Skin Fibrosis on Risk of Primary Open-Angle Glaucoma and Surgical Outcomes

First Author: Chien-yun **TSAI**

Co-Author(s): Chien-chih **CHOU**

Purpose: To investigate whether skin fibrosis is associated with an increased risk of developing primary open-angle glaucoma (POAG) and requiring revision glaucoma surgeries.

Methods: This retrospective cohort study used the TriNetX database to analyze two cohorts of patients aged ≥18 years: one without prior glaucoma (skin fibrosis vs. non-fibrosis) and one with glaucoma who underwent their first surgery (trabeculectomy or glaucoma drainage device), also categorized by skin fibrosis. The study aimed to evaluate the risk of POAG in patients without a glaucoma history and the risk of revision glaucoma surgeries in those with a glaucoma history. Hazard ratios and 95% confidence intervals were calculated, with cumulative incidence assessed using Kaplan-Meier analyses.

Results: Among 100,383 matched pairs without prior glaucoma, those with skin fibrosis had a significantly elevated risk of POAG (HR, 2.10; 95% CI, 1.70–2.58). Among 368 matched pairs with a history of glaucoma surgery, skin fibrosis was associated with a higher likelihood of undergoing revision procedures (HR, 1.56; 95% CI, 1.05–2.32). Kaplan-Meier curves demonstrated significantly greater cumulative incidences of both POAG and revision surgeries in the skin fibrosis group compared to the non-skin fibrosis group.

Conclusions: Skin fibrosis is associated with an increased risk of POAG and a higher likelihood of requiring revision surgery, suggesting that it may serve as a clinically observable marker for glaucoma risk and suboptimal surgical outcomes.

Abstract No.: 204240

Impact of Switching From Prostaglandin Analogues to Omidenepag Isopropyl on Signs of Prostaglandin-Associated Periorbitopathy

First Author: Jin Wook **JEOUNG**

Co-Author(s): Jong Jin **JUNG**, Chan Yun **KIM**, Joon Mo **KIM**, Michael S **KOOK**, Hye-young **Iopilly PARK**, Chungkwon **YOO**

Purpose: To assess changes in signs of prostaglandin-associated periorbitopathy (PAPS) after switching from prostaglandin analogues (PGAs) to omidenepag isopropyl ophthalmic solution 0.002% (OMDI) in patients with glaucoma or ocular hypertension (OHT). The primary outcome was improvement in deepening of the upper eyelid sulcus (DUES); secondary outcomes included changes in other PAPS features and intraocular pressure (IOP).

Methods: This multicenter study enrolled 96 patients with PAPS previously treated with PGAs for over three months; one eye per patient was selected. All patients were switched to OMDI and followed for 24 weeks. Outcome measures included intraocular pressure (IOP) and PAPS features: DUES, flattening of the lower eyelid bag (FLEB), upper eyelid blepharoptosis, hyperpigmentation, and ciliary hypertrichosis. PAPS signs were graded using standardized photographs by masked observers, with improvement defined as any positive change in these features.

Results: DUES improved in 70.8% of patients at 24 weeks compared to baseline (p<0.001), which was statistically significant. Improvements were also observed in hyperpigmentation (72.9%), ciliary hypertrichosis (37.5%), upper eyelid ptosis (26.0%), and FLEB (17.7%). Overall PAPS improvement, as assessed independently by third-party evaluators, was reported in 61.5% patients. After switching, mean IOP decreased from 16.7 to 14.6 mmHg (p<0.001), showing statistical significance; 42.7% of eyes achieved >15% reduction and 27.1% achieved >20% reduction. No adverse events were recorded.

Conclusions: Switching to OMDI significantly improved PAPS signs and reduced IOP, supporting its potential as a safe therapeutic option for patients with PAPS.

Abstract No.: 201582

In Silico Enabled Discovery of Novel ROCK Inhibitors With IOP-Lowering Effect for Glaucoma

First Author: Jiakai PI

Co-Author(s): Rongbiao PI, Zhixian ZHANG

Purpose: To discover a novel Rho-associated coiled-coil kinase (ROCK) inhibitor with intraocular pressure (IOP) lowering effect and minimum side effects for Glaucoma in silico.

Methods: A series of novel phenylamides was designed and followed by virtual screening using molecular docking to identify candidates with high binding affinity to ROCK. Eight phenylamides were synthesized, and their inhibitory activity against ROCK1 and ROCK2 was assayed in a tube and at the cellular level. In addition, effects on conjunctival cells and neural cells were evaluated. Moreover, conjunctival congestion and IOP-lowering efficacy were assessed in rabbit, rat, and mouse glaucoma models.

Results: Compound 5 emerged as the most promising candidate, demonstrating potent ROCK1 and ROCK2 inhibition, with IC₅₀ values of 41.81 nM and 14.26 nM, respectively. Compared with marketed drugs, Compound 5 exhibited comparable cellular-level effects on corneal recovery and has superior efficacy in neuroprotection against H₂O₂ toxicity. Further conjunctival congestion evaluation in a rabbit revealed that Compound 5 exhibited only mild conjunctival congestion, suggesting favorable ocular tolerance. In glaucoma mice and normal rats, Compound 5 significantly reduced IOP in 12 h, which is similar to that of Netarsudil.

Conclusions: Our findings demonstrated that Compound 5 represents a potent ROCK inhibitor and significant potential for Glaucoma with reducing IOP and minimal ocular side effects, suggesting that Compound 5 is a promising lead compound for the development of novel ROCK inhibitors for the treatment of Glaucoma.

Abstract No.: 204118

In Vivo Neuronal Visualization Using a Novel NIR-II Neurotracer: Evaluation in Ocular Disease Models

First Author: Wenhan LU

Co-Author(s): Xinghuai SUN

Purpose: Real-time in vivo visualization of the optic pathway under pathological conditions remains challenging due to limitations in deep-tissue penetration and spatiotemporal resolution of

conventional neural tracers. The utilization of NIR-II regions in optical imaging offers enhanced resolution and heightened imaging contrast, owing to minimal background interference, as well as increased tissue penetration depth for longer wavelengths. This study aimed to realize in vivo observation and analysis of RGC central projection damage under different ocular disease models.

Methods: Here, we developed a novel NIR-II neurotracing probe for anterograde labeling of retinal ganglion cells (RGCs) via intravitreal injection. Comprehensive evaluations were performed to assess the probe's physicochemical characterization, biosafety profile, and functional efficacy. This probe enabled longitudinal monitoring of axonal dynamics in: (1) mice acute ocular hypertension (AOH) models, (2) rat optic nerve crush (ONC) injuries, and (3) visual pathway compression (VPC) model using real-time NIR-II fluorescence microscopy.

Results: The probe achieved effective labeling and real-time imaging of the soma and axons of RGCs via NIR-II imaging with signal persistence >1 week. In the AOH and ONC models, the gradual RGC degeneration was detected with time. In models with visual pathway compression by B16-derived tumor, aberrant visual behaviors together with reduced NIR-II signal in the visual pathway and contralateral eyes were detected. Biosafety assessments confirmed the probe's safety on critical physiological parameters of major organ systems.

Conclusions: This NIR-II probe facilitates high-fidelity in vivo mapping of pathological axonal alterations across glaucomatous and neoplastic contexts, providing a critical tool for evaluating therapeutic interventions targeting optic neuropathies.

Abstract No.: 206443

Integrative Genetic Analyses of Metabolomics in Primary Open-Angle Glaucoma Indicate an IOP-Mediated Sphingomyelin Link

First Author: Hengtong LI

Co-Author(s): Jiahui CAO, Ching-yu CHENG, Sushan WANG, Can Can XUE, Xiayin ZHANG

Purpose: Primary open-angle glaucoma (POAG) is a major cause of irreversible blindness. Although many genetic loci and metabolic biomarkers have been linked to POAG, causal metabolic pathways remain unclear due to confounding and intercorrelations between metabolites.

Methods: We screened candidate metabolites using four complementary approaches: prospective-cohort, genetic correlation, two-sample MR, and latent causal variable (LCV) analysis. To address correlations among metabolites, we controlled for multicollinearity and instrument strength, then performed multivariable MR to estimate independent metabolic effects on POAG.

Additionally, we applied genomic structural equation modeling (GSEM) for glaucoma endophenotypes mediation, drug-target MR and colocalization for mechanistic insights. We also constructed a direct-effect network among metabolites and mapped their connections to POAG risk.

Results: We found that higher levels of sphingomyelin were associated with increased POAG risk (OR = 1.58, 95% CI: 1.04 - 2.40, P = 0.03) in multivariable MR. GSEM showed that this effect was mediated by IOP (indirect effect β = 0.049; 95% CI: 0.007 - 0.091; P = 0.023). The association between sphingomyelin and IOP was observed in both European (β = 2.67; 95% CI: 2.30 - 3.05; P = 4.07E-10) and Asian (β = 2.56; 95% CI: 1.71 - 3.40; P = 3.21E-10) cohorts. Drug-target MR identified three proteins in the sphingomyelin pathway as potential therapeutic targets, although these results are exploratory and require further validation. Network deconvolution analysis revealed that metabolites influence POAG through interconnected direct-effect pathways.

Conclusions: These results highlight the value of multivariable approaches in metabolomic studies, clarify the role of sphingomyelin in POAG, and may help guide future research on metabolic biomarkers and new therapies for POAG.

Abstract No.: 204144

Interaction of CYP39A1 and LOXL1 Genetic Variants in the Pathogenesis of Exfoliation Glaucoma

First Author: Mineo **OZAKI**

Co-Author(s): Tin **AUNG**, Ying Swan **HO**, Chiea Chuen **KHOR**, Zhenxun **WANG**

Purpose: Exfoliation syndrome (XFS) is an age-related disorder, with 15–40% progressing to exfoliation glaucoma (XFG) or ocular hypertension. Recent exome sequencing identified rare CYP39A1 variants affecting cholesterol metabolism. We investigated the relationship between cholesterol abnormalities, LOXL1 release, and exfoliation material (XFM) formation in XFS/XFG.

Methods: Aqueous humor samples from XFS/XFG patients were analyzed. To investigate the connection between the CYP46A1/CYP39A1 pathway and LOXL1, we chose human fetal retinal pigment epithelium cells as a substitute for pigmented ciliary cells, where CYP39A1 is highly expressed. We investigated how genetic abnormalities contribute to the pathological mechanism of XFG by employing specific inhibitors.

Results: We demonstrate that reduction of CYP39A1 activity, either by mutation or decreased expression, leads to 24(S)-hydroxycholesterol (24-OHC) accumulation in hFRPE cells, activating the nuclear receptor LXR and driving cholesterol efflux pathways. Elevated esterified cholesterol and higher LOXL1

protein were observed in aqueous humor from XFS/XFG patients. Our findings indicate that XFS may be triggered by lipid metabolic dysfunction, where excess 24-OHC promotes LOXL1 release and misfolding, highlighting LOXL1 as a key mediator of XFM formation.

Conclusions: The cellular assays we established provide a representative model of XFM deposit formation, which has been confirmed through validation in aqueous humor from patients as well as unaffected controls. Collectively, the data suggest that strategies aimed at lowering 24-OHC abundance or facilitating the correct folding of LOXL1 may constitute feasible therapeutic avenues for controlling XFM deposition in XFS.

Abstract No.: 203152

Investigating the Link Between Neuroticism and Glaucoma: Insights From a Mendelian Randomization Study

First Author: Gehan **AI**

Co-Author(s): Hongxi **WANG**

Purpose: Emotional instability is often suspected to elevate glaucoma risk, yet causality remains unclear. We explored whether neuroticism—a stable, heritable personality trait—has a causal relationship with glaucoma using a bidirectional Mendelian Randomization (MR) approach.

Methods: Genetic instruments for overall neuroticism and its 12 subclusters were derived from UK Biobank GWAS data (N = 380,506). Glaucoma outcome data, including primary open-angle glaucoma (POAG), normal-tension glaucoma (NTG), and primary angle-closure glaucoma (PACG), came from FinnGen R11. Bidirectional two-sample MR was performed, using inverse variance weighted (IVW) as the main method. Significant associations were further tested using multivariable MR (MVMR) to account for subcluster intercorrelations. Multiple testing was controlled via Benjamini-Hochberg correction.

Results: Forward MR suggested potential protective effects of specific subclusters: ‘worry too long after an embarrassing experience’ was inversely associated with POAG (OR = 0.46, P = 0.005), and ‘mood often goes up and down’ with NTG (OR = 0.35, P = 0.002). However, these associations lost significance after MVMR and correction for multiple testing. No reverse causal effects of glaucoma on neuroticism were observed. Sensitivity analyses revealed no pleiotropy or weak instrument bias.

Conclusions: To our knowledge, this is the first MR study evaluating personality traits in glaucoma. While initial findings hinted at protective associations, neuroticism likely does not causally influence glaucoma risk. Our results challenge clinical assumptions linking emotional instability to glaucoma and highlight the

importance of integrating psychological and genetic perspectives in ophthalmic research.

Abstract No.: 202856

Kurarinone Attenuates Inflammation Stress and Neuronal Damage After Acute Glaucoma by Suppressing Lipocalin-2 and Ferroptosis

First Author: Yunhong SHI

Co-Author(s): Honghua YU, Naiyuan ZHANG

Purpose: Glaucoma is the leading cause of irreversible blindness worldwide, with neuroinflammation playing a key role in its pathological progression. Targeting neuroprotection remains a critical therapeutic challenge. Here, we report a promising strategy using Kurarinone—a natural compound derived from the roots of the traditional Chinese medicine *Sophora flavescens*—to protect retinal ganglion cells (RGCs) by suppressing neuroinflammation.

Methods: In vivo, retinal structure and RGC density were assessed using immunohistochemistry, H&E staining, and retinal flat-mount imaging. Mitochondrial morphology and ferroptosis were evaluated via transmission electron microscopy. In vitro, microglial cell viability and Kurarinone toxicity were determined using CCK-8 assays. Ferroptosis levels were measured with reactive oxygen species (ROS) assay kits, FerroOrange staining, and Western blot. Fresh retinas were prepared for 10x Genomics single-cell RNA sequencing to investigate the underlying mechanisms.

Results: Kurarinone treatment significantly reduced RGC loss after AOH injury, largely preserved the normal thickness of the ganglion cell layer (GCL), downregulated lipocalin-2(Lcn2), decreased the p-STING/STING ratio, and reduced expression of TFR and FTH1 in vivo. It also ameliorated mitochondrial structure and prevented excessive ROS production. The neuroprotective effects were attributed to inhibition of the cGAS–STING pathway. Single-cell sequencing identified Lcn2 as a core functional molecule affected by Kurarinone. While DIABZI (a STING agonist) suppressed OGD/R-induced oxidative stress and ferroptosis, the anti-inflammatory effect of Kurarinone was retained upon treatment with ZINC00640089 (a Lcn2 inhibitor).

Conclusions: Our findings identify Kurarinone as a promising therapeutic candidate for acute glaucoma-related ischemia–reperfusion injury. It exerts its effects by inhibiting the cGAS–STING pathway and Lcn2 secretion, thereby suppressing microglial ferroptosis.

Abstract No.: 205117

Label-Free Structural and Functional Evaluation of Mice Retina by Dual-Mode Full-Field Optical Coherence Tomography

First Author: Shilong YU

Co-Author(s): Yiqing LI, Zhongzhou LUO, Jiahui TANG, Peng XIAO

Purpose: This study aims to establish a novel structural-functional evaluation system for retina (especially retinal ganglion cells (RGCs)) based on dual-mode Full-Field Optical Coherence Tomography (FFOCT).

Methods: Thirty C57BL/6J mice were randomly assigned to two groups: control (CTRL) and optic nerve crush (ONC). Mice were euthanized at 1, 3, 5 or 7 days post-injury. Following enucleation, fresh retinal tissues were carefully dissected. Their Dual-mode FFOCT imaging was performed using a customized setup.

Results: Dual-mode FFOCT images reveal well-organized retinal layers in control specimens, with consistently strong structural contrast across different layers of retina. In contrast, retinal tissues from ONC mice exhibit progressive structural disorganization in both static and dynamic images. The dynamic FFOCT signal notably declines with time after injury, reflecting impaired cellular motility and viability. Quantitative analysis revealed a significant and progressive reduction in mean signal intensity in all ONC groups compared to control. The degree of functional damage and cell size varies in different cells, which can correspond to the immunostaining results, reflecting different cell types and even subtypes.

Conclusions: These findings demonstrate that dual-mode FFOCT offers a sensitive and label-free approach for detecting both structural and functional deterioration in the retina following optic nerve injury. By enabling real-time assessment of retina structure-function dynamics, this method may facilitate the development of targeted therapeutic strategies aimed at promoting RGC survival and optic nerve regeneration. Nonetheless, the cellular and molecular mechanisms underlying the observed dynamic signal changes need further investigation to explain the correlated biological processes.

Abstract No.: 205618

Long-Term Comparative Outcomes of Hydrus vs iStent Inject Microinvasive Glaucoma Surgery Implants Combined With Cataract Surgery

First Author: Jeremy TAN

Co-Author(s): Ashish AGAR, Colin CLEMENT, Paul HEALEY, Mitchell LAWLOR, Ridia LIM, Andrew WHITE, Joshua YUEN

Purpose: To compare the long-term effectiveness of combined phacoemulsification and Hydrus microstent (phaco-Hydrus) vs iStent inject (phaco-iStent) using

MIGS-specific surgical success definitions in a large observational cohort.

Methods: Retrospective study of eyes in the Fight Glaucoma Blindness registry that underwent phaco-Hydrus or phaco-iStent with a minimum of 48-month follow-up. The prespecified primary endpoint was $\geq 20\%$ IOP decrease and IOP ≤ 21 mmHg, or ≥ 1 medication reduction vs baseline at 48 months with no pre-operative washout. Propensity score matching of baseline covariates was used to examine outcomes in a subcohort (matched cohort).

Results: 431 eyes (98 phaco-Hydrus: 331 phaco-iStent) were included in the overall cohort and 177 eyes (59 phaco-Hydrus: 118 phaco-iStent) in the matched cohort. There was no significant difference in the rate of surgical success between each group in achieving the primary endpoint at 48 months (adjusted overall cohort, 41.2% vs 43.0% in phaco-Hydrus vs phaco-iStent respectively, $p = 0.44$; matched cohort, 44.1% vs 43.2%, $p = 0.99$). There was no significant difference in degree of IOP reduction, medication reduction and adjusted secondary outcomes between the phaco-Hydrus vs phaco-iStent groups in both overall and matched cohorts. The incidence of adverse events and secondary procedures was similar between both groups.

Conclusions: There was no significant difference in surgical success between phaco-Hydrus and phaco-iStent groups at 48 months. Over 40% of eyes maintained the primary success endpoint of $\geq 20\%$ IOP decrease and IOP ≤ 21 mmHg or ≥ 1 medication reduction vs baseline without the need for secondary glaucoma surgery.

Abstract No.: 208466

Long-Term Corneal Biomechanical Changes Following Intraocular Pressure Reduction in Primary Open-Angle Glaucoma: A 12-Week Prospective Analysis

First Author: Yunzhi XU

Co-Author(s): Wei CHI, David C.C. LAM, Minbin YU

Purpose: Corneal biomechanical parameters are strongly influenced by intraocular pressure (IOP), complicating the interpretation of longitudinal changes. This study aimed to investigate corneal stiffness and modulus alterations over 12 weeks following IOP-lowering therapy in primary open-angle glaucoma (POAG).

Methods: A prospective cohort of 31 treatment-naïve POAG patients underwent corneal stiffness and modulus assessment via a corneal indentation device at weeks 1 and 12 after treatment. IOP was measured by Goldmann applanation tonometry. Paired t-tests evaluated changes, with significance set at $\alpha=0.05$. Correlation coefficients quantified within-eye parameter stability.

Results: Corneal stiffness increased significantly from 67.76 ± 9.94 N/m to 71.91 ± 8.81 N/m (mean difference 4.15 N/m, 95% CI 0.79–7.51; $t=-2.520$; $p=0.017$). Corneal modulus also increased from 0.559 ± 0.097 MPa to 0.592 ± 0.084 MPa (mean difference 0.033 MPa, 95% CI 0.005–0.061; $t=-2.396$; $p=0.023$). IOP remained clinically stable (14.28 ± 2.79 vs 14.68 ± 3.24 mmHg; $p=0.394$).

Conclusions: The cornea becomes significantly stiffer at 12 weeks compared to 1 week after IOP reduction, despite stable IOP. This biomechanical stiffening may reflect time-dependent corneal tissue remodeling that may impact IOP measurement accuracy and long-term glaucoma management.

Abstract No.: 205818

Long-Term Outcomes of Early Versus Late Phacoemulsification in Acute Primary Angle Closure (APAC): A Multicentre Retrospective Study

First Author: Thomas Chi-ho LAM

Co-Author(s): Poemen CHAN, Man Hin LUI, Vikki NG, Jolly TSUI

Purpose: This multicenter retrospective study compared long-term outcomes of phacoemulsification for acute primary angle closure (APAC) across different surgical intervals, evaluating intraocular pressure (IOP) control, medication requirements, and treatment success rates using rigorous statistical methods.

Methods: We analyzed 89 consecutive APAC patients treated at four tertiary referral centers using a standardized protocol. Participants were stratified into three surgical timing groups: early (<90 days post-APAC, $n=27$), intermediate (90–360 days, $n=32$), and delayed phacoemulsification (>360 days, $n=29$) through comprehensive chart review. Complete success was defined as maintained IOP ≤ 21 mmHg without any glaucoma medications throughout follow-up.

Results: At a mean follow-up of 3.25 years, the cohort demonstrated good intraocular pressure control with a mean IOP of 14.44 mmHg on 1.8 medications. Primary IOL implantation was successfully performed in 87 cases (97.8%). Surgical complications included two cases requiring anterior vitrectomy (1 posterior capsule rupture, 1 zonulysis). Three patients (3.4%) required subsequent trabeculectomy, and two (2.2%) required micropulse cyclophotocoagulation. Initial unadjusted analysis revealed statistically significant early disparities: the early intervention group showed substantially higher 1-month IOP (20.59 mmHg vs 16.94 mmHg, $p=0.009$) and required significantly more glaucoma medications (2.37 vs 1.14 , $p<0.001$) compared to the delayed group. These initial differences completely normalized long-term, with no significant intergroup variation in final IOP ($p=0.130$) or medication burden ($p=0.227$). Survival analysis initially appeared to favor delayed surgery for complete

success ($p < 0.05$). However, multivariate Cox regression adjusting for confounding factors that reflected disease severity demonstrated that surgical timing itself was not an independent predictor of outcome ($p = 0.95$). Elevated average IOP during the critical first week after initial presentation emerged as the strongest predictor of treatment failure (Hazard Ratio: 1.062 per mmHg increase, $p = 0.067$).

Conclusions: Phacoemulsification demonstrates consistent safety and efficacy across all surgical timepoints. The observed superiority of delayed surgery reflects case selection bias rather than therapeutic timing advantages. Initial disease severity, particularly early IOP control characteristics, represents the primary determinant of long-term treatment outcomes in APAC management.

Abstract No.: 202819

Mechanobiology Dysregulation in Glaucomatous Target Tissues Under Chronic Ocular Hypertension

First Author: Yuan **HE**

Co-Author(s): Huan **DU**

Purpose: This study systematically explores mechanobiological alterations in glaucomatous target tissues, including retina, optic nerve, lamina cribrosa, and sclera, during glaucoma pathogenesis. It elucidates the biological responses of these tissues to mechanical microenvironmental changes induced by chronic ocular hypertension (COH), clarifies cross-tissue mechanobiological response pathways, refines the pathogenic mechanisms of glaucoma, and provides a basis for interventions.

Methods: Chronic ocular hypertension-induced glaucoma models were established. At the early, middle, and late disease stages, the eyeballs were enucleated and processed into frozen sections. Atomic force microscopy (AFM) was used to quantify the tissue elastic modulus; Masson's trichrome staining was performed to observe collagen deposition; and immunofluorescence, Western blotting, and RT-PCR were employed to detect the expression of mechanosensitive channels, including Piezo1/2 and TRPV1/4.

Results: COH exerts the following effects on rats: (1) upregulating Piezo1 expression in the retina and optic nerve, accompanied by increased collagen deposition and elevated elastic modulus; (2) inducing collagen deposition at the lamina cribrosa; and (3) upregulating Piezo1, Piezo2, and Trpv1 expression in the sclera, along with increased collagen deposition and a higher elastic modulus.

Conclusions: COH triggers dysregulated mechanosensitive channel expression in target tissues, modulating collagen metabolism to cause lamina cribrosa collagen deposition and scleral fiber

remodeling. This leads to mechanical abnormalities, disrupting retinal ganglion cell mechanosensation and optic nerve axonal transport, forming a persistent «elevated IOP-abnormal channels-structural remodeling-mechanical dysfunction» loop in glaucoma progression.

Abstract No.: 204220

Metabolomic Profiling of Retinal Ischemia-Reperfusion Injury in Mice: An Untargeted Approach

First Author: Yan **TONG**

Co-Author(s): Poemen P. **CHAN**, Wai Kit **CHU**, Jingna **HE**, Chi Pui **PANG**, Clement C. **THAM**, Shushu **XU**, Mingming **YANG**, Jiaxin **ZHANG**

Purpose: Retinal ischemia-reperfusion (I/R) injury is a critical pathological process leading to irreversible retinal ganglion cell (RGC) degeneration and visual dysfunction, with implications for glaucoma, retinal artery occlusion, and other neurodegenerative disorders. Despite its clinical significance, the metabolic perturbations underlying retinal I/R remain not fully understood. This study employs an untargeted metabolomics approach to uncover key metabolites alterations and dysregulated pathways involved in retinal I/R, providing novel insights into potential therapeutic targets for neuroprotection.

Methods: Retinal I/R was induced in the C57BL/6J mice ($n = 6/\text{group}$), with RGC survival quantified via RBPMs+ immunohistochemistry and retinal function assessed by electroretinography (ERG) at 7 days post-injury. To investigate alterations in the global metabolite profile during retinal I/R, we isolated retinal tissues from mice in both sham surgery and I/R groups. Untargeted metabolomics analysis was performed via ultra-performance liquid-chromatography tandem mass spectrometry (UPLC-MS/MS) to profile the metabolites in retinal tissues. Bioinformatics analysis was then conducted to identify dysregulated metabolic networks associated with the altered metabolite profiles.

Results: Phenotypic validation confirmed significant RGC loss ($P < 0.001$) and ERG amplitude reduction (scotopic a- and b- wave, $P < 0.001$) in I/R retinas. Comparative metabolomics revealed 135 significantly dysregulated metabolites (96 in positive-ion mode, 39 in negative-ion mode, $VIP > 1.0$, $P < 0.05$) in I/R retinas, compared to the control group. Key findings included perturbations in amino acid metabolism (such as L-lysine, arginine, proline), fatty acids and lipids homeostasis, and energy metabolism-related metabolites (such as carnitine, and succinic acid). Pathway analysis highlighted disruptions in amino acid biosynthesis, mitochondrial metabolism (e.g., «central carbon metabolism in cancer»), and neurotransmitter-related pathways («ABC transporters»), suggesting metabolic reprogramming as a compensatory response to I/R stress.

Conclusions: This study provides the first comprehensive metabolomic signature of retinal I/R injury, identifying critical disruptions in amino acid and lipid metabolism that may drive RGC degeneration. The convergence of these metabolic pathways suggests synergistic roles in neuroprotection and energy crisis resolution, offering a foundation for future therapeutic strategies targeting metabolic reprogramming to mitigate retinal I/R injury.

Abstract No.: 201938

Microcirculation Disorders and Inflammation Caused by Abnormal Lipid Metabolism Impair the Structure and Function of the Retina

First Author: Rucui YANG

Co-Author(s): Shaolang CHEN, Minru DENG, Changzhen FU, Jiajian LIANG, Qingping LIU, Tsz Kin NG, Yaru SUN, Zhenggen WU, Mingzhi ZHANG

Purpose: To investigate whether lipid metabolism abnormalities induced by high-feed diet (HFD) of ApoE^{-/-} mice of different weeks of age cause damage to retinal structure and function.

Methods: A mouse model of atherosclerosis induced by abnormal lipid metabolism was established by feeding HFD and ApoE^{-/-} in C57BL/6 mice. Blood lipid levels and plaque formation in mouse models were investigated by hematoxylin-eosin staining and oil red staining. Fundus fluorescein angiography was performed to investigate the microcirculation of retinal vessels. Quantitative real-time PCR and western blot were used to evaluate inflammatory factors and key proteins. Retinal ganglion cells were detected by β III-tubulin immunofluorescence staining. The structure and function of the retina were evaluated using optical coherence tomography, HE staining, and electroretinogram.

Results: C57BL/6 mice with ApoE^{-/-} were fed HFD to 42 weeks of age, and total cholesterol and low-density lipoprotein cholesterol increased, plaque area increased, and a model of atherosclerosis caused by abnormal lipid metabolism was established. Retinal blood perfusion decreased significantly in atherosclerotic mice, and microcirculation disorders appeared. The increased expression of $\text{Tnf-}\alpha$ indicates retinal inflammation. The thickness of the nerve fiber layer was reduced, and the number of RGCs decreased. The amplitudes of a-wave, b-wave, and Photopic Negative Response were reduced, and the latency was prolonged, suggesting that the structure and function of the retina were seriously damaged.

Conclusions: Atherosclerosis caused by abnormal lipid metabolism can aggravate the abnormal microcirculation and microenvironment inflammation in the eye, causing retinal structural and functional damage in the later stage.

Abstract No.: 205757

Microglial TIGAR Preserves Retinal Ganglion Cells by Shifting Microglial Glycolysis and Attenuating Neuroinflammation in Glaucoma

First Author: Yuxun SHI

Co-Author(s): Jingjing HUANG

Purpose: Microglial activation drives neuroinflammation and retinal ganglion cell (RGC) loss in glaucoma. While metabolic reprogramming to glycolysis is a pivotal trigger for pro-inflammatory microglial activation, its regulatory mechanisms in glaucoma remain elusive. This study investigates the role of TIGAR, a glycolytic regulator, in microglial function and glaucomatous RGC degeneration.

Methods: An acute ocular hypertension (AOH) model was induced in mice. TIGAR was knocked down via intravitreal injection of AAV-shTIGAR. RGC survival and function were assessed by retinal wholemounts and pattern electroretinogram (PERG), respectively. Inflammatory factors were evaluated by qPCR. In primary microglia under oxygen-glucose deprivation/reoxygenation (OGD/R), the effects of TIGAR on glycolysis were determined.

Results: Following AOH, TIGAR was upregulated in retinal microglia. TIGAR knockdown exacerbated RGC loss and functional decline, which was associated with increased retinal levels of IL-1 β and IL-18. In primary microglia under OGD/R, TIGAR knockdown enhanced glycolysis and promoted inflammation in microglia after OGD/R. Conversely, TIGAR overexpression suppressed glycolysis and attenuated inflammation.

Conclusions: Our findings identify microglial TIGAR as a critical protector in glaucoma, safeguarding RGCs by constraining glycolytic metabolism and inhibiting the subsequent neuroinflammatory response.

Abstract No.: 204988

Nervonic Acid Provides Neuroprotection Against Experimental Glaucoma

First Author: Zhitong CHEN

Co-Author(s): Songhui HU, Ye SHEN, Liusi YANG, Xiangnan ZHANG

Purpose: This study aimed to investigate the potential neuroprotective effects of Nervonic Acid (NA) against N-methyl-D-aspartate (NMDA)-induced experimental glaucoma models both in mice and R28 cells.

Methods: NMDA was intravitreally injected in mice, accompanied by administration of NA eye drops (0.1 or 0.5 mg/kg) for continuous 14 days. Retinal ganglion cell (RGC) survival was quantified using Tuj1 immunofluorescence on flat-mounted retinas. Retinal structural integrity was assessed by hematoxylin and eosin staining and measurement of layer thickness. Retinal function was evaluated using electroretinography (ERG). Apoptosis proteins,

including Bcl-2, Bax, and cleaved Caspase-3, were analyzed by Western blotting. Rat R28 cells were subjected to glutamate-induced excitotoxicity, and the effects of NA on cell viability (CCK-8), apoptosis (TUNEL), and oxidative stress (DCFH-DA staining) were assessed.

Results: NA treatment significantly attenuated NMDA-induced RGC loss and mitigated inner plexiform layer (IPL) thinning in mice in a concentration-dependent manner. ERG recordings demonstrated that NA restored the amplitudes of the b-wave and oscillatory potentials, indicating functional recovery. In R28 cells, NA alleviated glutamate-induced damage by enhancing cell viability, reducing apoptosis, and decreasing intracellular ROS levels. Mechanistically, NA alleviated excitotoxicity-induced retinal apoptosis as revealed by reversed Bcl-2/Bax ratio and Caspase-3 activation.

Conclusions: Nervonic acid confers significant protection against NMDA-induced excitotoxic damage by preserving retinal structure and function by inhibiting apoptosis and oxidative stress in retinal cells. These findings suggest NA has promising therapy for excitotoxicity-related retinal pathologies like glaucoma.

Abstract No.: 201251

Neuroprotective Effects of BMSC-Apoptotic Vesicles on Retinal Ganglion Cells: Therapeutic Potential for Glaucomatous Injury

First Author: Si **CHEN**

Co-Author(s): Xiaobo **XIA**, Mengling **YOU**

Purpose: Glaucoma is the leading cause of irreversible blindness worldwide, characterized by progressive degeneration of retinal ganglion cells (RGCs). Retinal ischemia/reperfusion (I/R) injury induced by elevated intraocular pressure (IOP) is a major contributor to RGC loss. Bone marrow mesenchymal stem cell (BMSC)-derived extracellular vesicles (EVs), especially apoptotic EVs (ApoEVs), have shown regenerative and immunomodulatory properties in various tissues. However, their neuroprotective potential in glaucoma remains largely unexplored.

Methods: Bone marrow-derived MSCs (BMSCs) were induced to undergo apoptosis using STS. ApoEVs were isolated via differential centrifugation. For enhanced therapeutic efficacy, ApoEVs were co-incubated with berberine (BBR) at a mass ratio of 1:1.5 (ApoEV protein:BBR) under gentle agitation overnight. A mouse model of retinal I/R injury was established by transient elevation of IOP. ApoEVs or ApoEV-BBR complexes were intravitreally injected 24 hours before I/R induction. RGC survival was assessed via immunohistochemistry and retinal flat-mount staining. Retinal function was evaluated using ERG and VEP. Transcriptomic analyses were conducted to identify differentially expressed genes and underlying mechanisms which were later verified with molecular biology experiments.

Results: Intravitreal ApoEVs penetrated the retina, preserved RGC survival, and maintained function after I/R injury. Transcriptomics revealed Irgm1 downregulation with ApoEVs. Berberine alone was protective, while ApoEVs plus Berberine produced a synergistic effect via MAPK modulation and inflammation suppression.

Conclusions: BMSC-derived ApoEVs confer neuroprotection in an acute glaucoma model. Co-delivery with BBR enhances this benefit, highlighting a promising synergistic therapeutic strategy for glaucoma and retinal neurodegeneration.

Abstract No.: 200640

Neuroprotective Effects of the Umbelopsis-Derived Small Molecule Compound U-7 on RGCs in Glaucoma via Inhibition of the cGAS-STING-PERK Pathway

First Author: Xingyi **CHEN**

Co-Author(s): Xiaobo **XIA**

Purpose: Glaucoma is a leading cause of irreversible blindness, characterized by progressive retinal ganglion cell (RGCs) loss. Current therapies mainly focus on lowering intraocular pressure, with limited effect on neuroprotection. This study aimed to investigate the role of the cGAS-STING pathway and endoplasmic reticulum (ER) stress in RGCs damage under glutamate excitotoxicity, and to evaluate the neuroprotective potential of a novel compound, U-7.

Methods: Glutamate-induced R28 cell and NMDA-induced mouse models were used. Proteomic analysis and western blotting assessed cGAS-STING and PERK-ATF4-CHOP pathway activation. U-7, isolated from *Umbelopsis* sp. DWS 372, was screened for neuroprotective activity. RGCs survival was evaluated using CCK8, Hoechst/PI staining, retinal flatmounts, and immunofluorescence. Visual function was tested via f-VEP, f-ERG, and the Optodrum system. ROS levels, inflammation, and ER stress markers were assessed by flow cytometry, qRT-PCR, and microscopy.

Results: cGAS-STING and downstream ER stress pathways were significantly activated in both models. STING inhibition reduced PERK pathway activity and RGCs loss. U-7 improved RGCs survival and reduced PI-positive cells. Functional tests confirmed that U-7 alleviated visual dysfunction and preserved optic nerve integrity. U-7 also decreased ROS levels, ER stress markers, and inflammatory responses, leading to reduced RGCs apoptosis.

Conclusions: U-7 protects RGCs by inhibiting cGAS-STING-mediated ER stress and oxidative and inflammatory damage, offering a promising neuroprotective approach for glaucoma treatment.

Abstract No.: 204857

New Findings on Mechanism of Primary-Angle Closure: Trans-Lens Pressure Difference

First Author: Yuanbo **LIANG**

Purpose: To propose and systematically validate a new hypothesis for the mechanism of primary angle-closure glaucoma (PACG)—the «trans-lens pressure difference» (TLPD) theory. This hypothesis posits that resistance to aqueous humor flow caused by a narrowed space between the ciliary body and the lens (cilio-lenticular block) is the core driver of anterior lens displacement and anterior chamber shallowing.

Methods: The study was conducted in three parts: 1) Clinical Imaging Study: A case-control study using 3.0T magnetic resonance imaging (MRI) was performed to precisely measure and compare the cilio-lenticular distance between 25 PACG patients and 19 age- and gender-matched normal controls. 2) Animal Model Study: An animal model was established in New Zealand white rabbits by artificially inducing a cilio-lenticular block with a capsular tension ring (CTR). The TLPD was directly measured by cannulating the anterior and vitreous chambers, while intraocular pressure (IOP) and anterior chamber depth (ACD) were monitored. 3) Interventional Study: A novel fenestrated intraocular lens (IOL) was designed and tested in the animal model to verify if physically relieving the pressure difference could effectively lower IOP and deepen the ACD.

Results: 1) The MRI study revealed that the cilio-lenticular distance in PACG patients (0.53 ± 0.10 mm) was significantly smaller than in controls (0.83 ± 0.18 mm, $P < 0.001$), serving as a strong independent predictor for PACG. 2) The animal model successfully induced a significant TLPD (8.50 ± 1.60 mmHg), leading to sustained ocular hypertension and a shallower ACD. 3) Implantation of the fenestrated IOL, followed by a YAG posterior capsulotomy, significantly reduced the TLPD (from 8.67 mmHg to 2.67 mmHg), normalized IOP, and increased ACD, while the standard IOL group showed no significant changes.

Conclusions: The collective clinical and experimental evidence consistently demonstrates that cilio-lenticular block is a key anatomical feature in PACG. It generates a significant trans-lens pressure difference that drives the lens forward, ultimately leading to angle closure. Alleviating this pressure difference can effectively reverse this pathological process.

Abstract No.: 207004

OCT-Angiography-Based Analysis of Macular Vascular Density and Peripapillary Perfusion in a Patient of Primary Open Angle Glaucoma (POAG)

First Author: Medha **RAI**

Purpose: 1. Measurement of macular vascular density and peripapillary perfusion on OCT-Angiography in

POAG patients 2. To correlate these changes with the severity of glaucoma

Methods: An analytical cross-sectional study was conducted at King George's Medical University, Lucknow, from February 2024 to February 2025, including 130 subjects (65 POAG and 65 non-glaucomatous controls). All participants underwent detailed ophthalmic evaluation, including best corrected visual acuity, slit-lamp examination, gonioscopy, fundus examination, and visual field analysis. Retinal nerve fiber layer (RNFL) thickness and macular parameters were assessed using Cirrus HD-OCT, while peripapillary and macular perfusion densities were measured with OCTA. Exclusion criteria included systemic vascular diseases, previous ocular trauma/surgery (except cataract/glaucoma), and retinal vasculopathies. Statistical analysis was performed using SPSS v23, with ANOVA, t-tests, and correlation analysis applied.

Results: POAG patients demonstrated significantly reduced central corneal thickness and corneal hysteresis compared to controls ($p < 0.01$). Cup-to-disc ratio was significantly higher in POAG eyes (0.7 ± 0.1 vs. 0.4 ± 0.1 , $p < 0.01$). Vessel density and perfusion indices on OCTA were markedly decreased with advancing glaucoma severity ($p < 0.01$). Central and perifoveal perfusion showed a strong correlation with RNFL thinning and visual field loss.

Conclusions: OCTA-derived parameters, including vessel density and perfusion indices, significantly reflect glaucomatous damage and correlate with disease severity. These findings suggest OCTA as a valuable non-invasive tool for early detection, monitoring, and prognostication of POAG beyond IOP measurement.

Abstract No.: 207411

OCTA-Based Peripapillary Perfusion and Macular Microvasculature As Early Markers of Pre-Perimetric Glaucoma

First Author: Harshitha C

Co-Author(s): Sasankadhar Reddy **MUDUMALA**, Nishitha **NARUKULLA**

Purpose: To evaluate whether OCTA-derived peripapillary perfusion and macular microvasculature parameters can detect pre-perimetric primary open-angle glaucoma (POAG) earlier and more accurately than RNFL thickness alone.

Methods: This prospective case-control study included 60 eyes of POAG suspects with normal visual fields and disc changes suggestive of glaucoma, and 60 age-matched healthy controls. All eyes underwent Cirrus AngioPlex OCTA with 4.5×4.5 mm ONH (RPC) and 6×6 mm macular scans. Global and sectoral radial peripapillary capillary (RPC) vessel density, macular superficial capillary plexus (SCP) density, ganglion cell

complex (GCC), and RNFL thickness were analyzed. Receiver operating characteristic (ROC) curves were used to compare diagnostic accuracy. Superior–inferior perfusion asymmetry and correlations with mean deviation (MD) and pattern standard deviation (PSD) were assessed.

Results: POAG suspect eyes showed significant reduction in global and inferotemporal RPC perfusion and macular SCP density, with increased superior–inferior asymmetry (all $p < 0.01$). ROC analysis demonstrated higher diagnostic accuracy for RPC global perfusion (AUC 0.91) compared with RNFL (0.86) and GCC (0.88). A composite index combining RPC IT sector, S–I asymmetry, and GCC achieved the highest AUC (0.94), reclassifying 23% of suspects with normal RNFL as glaucomatous. Perfusion metrics showed moderate correlation with MD and PSD ($r = 0.42–0.55$, $p < 0.01$).

Conclusions: OCTA-based peripapillary perfusion and macular microvasculature analysis provide highly sensitive, objective biomarkers for early glaucomatous damage, outperforming RNFL thickness alone. Incorporation of these parameters into clinical screening protocols may enable earlier diagnosis, risk stratification, and timely intervention to prevent vision loss.

Abstract No.: 207003

One Decade Glaucoma Trend in Indonesia: Retrospective Analysis of Big Data National Health Insurance 2015–2024

First Author: Krisna **JATI**

Co-Author(s): Muhammad **BAYU SASONGKO**, Yessi **PRIMANDA SARI**, Indra **TRI MAHAYANA**

Purpose: Glaucoma is a leading cause of irreversible blindness, with prevalence rising alongside population aging. This study aimed to assess national trends in glaucoma cases and healthcare expenditures in Indonesia from 2015 to 2023 using claims data from the National Health Insurance program (Jaminan Kesehatan Nasional/JKN).

Methods: A secondary data analysis was conducted using a random 1% sample of JKN health claims, representing 2.4 million beneficiaries. Glaucoma cases were identified with ICD-10 codes H40, H44.51, and Q15 from primary or secondary diagnoses at advanced-level facilities. Demographic, clinical, and healthcare utilization data were analysed using STATA IC version 14.0. Case numbers and costs were extrapolated to national estimates and stratified by intervention category.

Results: From 2015 to 2023, glaucoma cases increased by 75.9%, with prevalence rising from 0.2 to 2.6 per 1,000 population. Female patients represented a slightly higher proportion, and the mean age was 54.76 years ($SD = 17.47$). Glaucoma-related claims increased by 68%, from IDR 135 billion in 2015 to IDR 419 billion

in 2023, with declines in 2016 and 2020 reflecting service disruptions and COVID-19 restrictions. Surgical claims rose 7.5-fold, with cataract extraction most frequent. A total of 12,650 unique patients were identified, with 1–47 visits annually and expenditures ranging from IDR 140,700 to IDR 34,122,000.

Conclusions: This first nationwide analysis highlights the increasing prevalence and economic burden of glaucoma under JKN. Future studies should incorporate disease severity and hospital-level factors to inform efficient, evidence-based glaucoma care.

Abstract No.: 206920

Optical Coherence Tomography Assessment of Retinal Nerve Fibre Layer Changes in Chronic Kidney Disease Patients

First Author: Subhangi **SAHU**

Co-Author(s): Saswati **SEN**

Purpose: To analyze the retinal nerve fiber layer (RNFL) and ganglion cell complex (GCC) thickness in patients with chronic kidney disease (CKD) compared with age and sex matched healthy controls, and to correlate retinal changes with disease duration and renal function.

Methods: This was a prospective case control study which included 100 patients with CKD (duration ≥ 3 months, aged 30–70 years) and 100 age- and sex matched controls. A detailed ophthalmic examination, including visual acuity, slit-lamp biomicroscopy, intraocular pressure measurement, fundoscopy, and spectral-domain optical coherence tomography (OCT), was done. Parameters analyzed included peripapillary RNFL thickness, GCC thickness, and optic nerve head morphology. Exclusion criteria were glaucoma, diabetic or hypertensive retinopathy, macular pathology, high refractive errors, and media opacities. Clinical data such as estimated glomerular filtration rate (eGFR) and duration of CKD were also recorded.

Results: The mean retinal nerve fiber layer (RNFL) thickness was significantly reduced in the case group compared to controls ($72.0 \pm 7.0 \mu\text{m}$ vs. $95 \pm 8.0 \mu\text{m}$; $p < 0.001$). Similarly, ganglion cell complex (GCC) thickness was markedly lower in cases than in controls ($85.0 \pm 8.0 \mu\text{m}$ vs. $95.5 \pm 7.5 \mu\text{m}$; $p < 0.001$). Quadrant-wise analysis demonstrated significant RNFL thinning in the inferior ($120.0 \pm 10.0 \mu\text{m}$ vs. $130.0 \pm 15.0 \mu\text{m}$; $p = 0.002$), superior ($115.0 \pm 10.0 \mu\text{m}$ vs. $125.0 \pm 12.0 \mu\text{m}$; $p = 0.004$), and nasal quadrants ($105.0 \pm 10 \mu\text{m}$ vs. $115.0 \pm 10.0 \mu\text{m}$; $p = 0.001$). There was a relatively insignificant difference in the temporal quadrant ($70.00 \pm 8.0 \mu\text{m}$ vs. $73.0 \pm 7.00 \mu\text{m}$; $p = 0.28$). Importantly, patients with advanced stages of CKD, as well as those with a duration of CKD exceeding 10 years, exhibited significantly greater RNFL and GCC thinning compared to those in early stages and those with disease duration under 10 years, indicating progressive retinal

neurodegeneration correlating with prolonged CKD exposure.

Conclusions: OCT-based RNFL and GCC measurements provide a reliable, non-invasive means to detect early retinal neurodegeneration in CKD. These findings underscore the role of ophthalmic screening as an adjunct to systemic evaluation, potentially aiding in early intervention and better patient outcomes.

Abstract No.: 202369

Outcome of Goniotomy Over 120°, 240°, and 360° in Juvenile Open-Angle Glaucoma: A Multicenter Study

First Author: Zhixuan **WANG**

Co-Author(s): Fengbin **LIN**, Yunhe **SONG**, Zefeng **YANG**, Xiulan **ZHANG**

Purpose: To compare the surgical efficacy and safety of 120-, 240-, and 360-degree goniotomy (GT) for patients with juvenile open-angle glaucoma (JOAG).

Methods: This multicenter retrospective study included 102 eyes of 102 JOAG patients, who underwent GT with a follow-up of at least 6 months. Patients were categorized into three groups: (1) 120°GT, (2) 240°GT, and (3) 360°GT. Intraocular pressure (IOP), glaucoma medications, and complications were recorded at baseline and the final visit. Complete success and qualified success were defined as a postoperative IOP ≤ 21 mmHg without and with medications, respectively.

Results: The mean age of the participants was 24.4 ± 7.9 years. After a mean follow-up of 8.1 ± 2.7 months, complete success rates were similar between the 240°GT (45.2%) and the 360°GT (63.2%) ($P = 0.135$), and both were superior to 120°GT (18.2%) ($P < 0.05$). Qualified success rates among patients in the 120°, 240°, and 360° GT groups were 93.9%, 96.8% and 100%, respectively, and showed no statistically significant difference ($P = 0.292$). 360°GT required fewer medications than 240°GT and 120°GT ($P < 0.05$), with no significant difference in medications between 120°GT and 240°GT ($P > 0.05$). Hyphema was the most common postoperative complication, with a significantly higher incidence in the 360°GT (68.4%) compared to the 240°GT (41.9%) and 120°GT (33.3%) ($P < 0.05$).

Conclusions: 240° and 360°GT showed similar efficacy in IOP reduction, and were superior to 120°GT. More extensive GT may provide better outcomes in JOAG.

Abstract No.: 204288

Outcomes of Combined Phaco, Irido-Zonulo-Hyaloid-Vitrectomy, Ahmed Valve and Scleral Windows for Angle-Closure Glaucoma Secondary to Nanophthalmos

First Author: Zhigang **FAN**

Co-Author(s): Yan **GAO**

Purpose: To summarize outcomes of a modular surgical approach with phacoemulsification, irido-zonulo-hyaloid-vitrectomy (IZHV), Ahmed glaucoma valve (AGV) and scleral windows for angle-closure glaucoma (ACG) secondary to nanophthalmos.

Methods: This was a retrospective and interventional case series including 92 eyes in 62 consecutive cases of nanophthalmos with ACG. All patients underwent a modular surgical approach tailored to their clinical characteristics: Procedure I, phaco + GSL; Procedure II: Procedure I + IZHV; Procedure III, phaco + IZHV + AGV; Procedure IV: Procedure III + scleral windows.

Results: Ninety-two eyes from 62 patients, with a mean age of 50.52 ± 14.03 years and a median axial length of 19.89 (range: 14.84 - 20.99) mm, were included. Depending on different clinical characteristics, 14, 26, 22, and 30 eyes underwent surgical procedures I, II, III and IV, respectively. The median follow-up was 13 (range: 12-36) months. At the last visit, intraocular pressures in all patients were maintained below 21 mmHg with no anti-glaucoma medications. Complications included malignant glaucoma (MG, 9 eyes), uveal effusion (UE, 5 eyes), suprachoroidal hemorrhage (1 eye), fibrin membrane formation (4 eyes), uveitis (1 eye), macular edema (1 eye), and compromised corrected distance visual acuity (CDVA, 6 eyes). Younger age was associated with a higher risk of MG (OR: 1.06, $P = 0.04$), UE (OR: 1.07, $P = 0.046$) and compromised CDVA (OR: 1.11, $P = 0.02$).

Conclusions: The modular surgical approach achieves consistency in a relatively great prognosis and reducing complications in these challenging cases of ACG secondary to nanophthalmos.

Abstract No.: 202048

Outcomes of Low-Energy Selective Laser Trabeculoplasty

First Author: Hinako **OHTANI**

Co-Author(s): Yuri **FUJINO**, Chisako **IDA**, Mizuki **IIDA**, Sayaka **KAWAMOTO**, Kana **MURAKAMI**, Masaki **TANITO**

Purpose: To evaluate the mid- to long-term outcomes of selective laser trabeculoplasty (SLT) performed with lower energy (≤ 0.5 mJ) than conventional settings (0.6–1.2 mJ).

Methods: This retrospective study included 100 eyes of 55 patients (mean age 55.5 years, 49% male) who underwent SLT at a mean energy of 0.34 mJ and were

followed for ≥ 36 months. Treatment failure was defined as either an increase in medication score or need for additional glaucoma surgery (Definition 1), or the need for glaucoma surgery (Definition 2). Cox proportional hazards models were applied.

Results: During follow-up, 37 eyes required one repeat SLT and 8 eyes required two. Mean intraocular pressure (IOP) decreased from 16.7 mmHg preoperatively to 15.1, 14.5, and 13.9 mmHg at 12, 36, and 60 months, respectively ($p < 0.0001$, mixed-effects model). Medication scores were 2.2, 2.4, 2.1, and 2.8, respectively ($p = 0.0003$). Success rates at 12, 36, and 60 months were 71%, 37%, and 26% by Definition 1, and 90%, 68%, and 61% by Definition 2. At 36 months, success rates by preoperative medication score (0, 1–2, ≥ 3) were 11%, 49%, and 38% for Definition 1 ($p = 0.0003$), and 83%, 73%, and 58% for Definition 2 ($p = 0.02$). By Definition 2, younger age, lower preoperative IOP, and lower baseline medication score were significantly associated with success (HR = 0.1 for 0 vs ≥ 3 , $p = 0.0006$; HR = 0.4 for 1–2 vs ≥ 3 , $p = 0.03$).

Conclusions: Performing low-energy SLT using approximately one medication can delay the need for additional therapy or surgery.

Abstract No.: 202897

Outcomes of Phacogoniotomy for Medically Controlled and Uncontrolled Primary Open Angle Glaucoma With Cataract: A Multicenter Study

First Author: Guihua XU

Co-Author(s): Yunhe SONG

Purpose: To evaluate the efficacy and safety of PEI combined with 120-degree GT in the treatment of medically controlled or uncontrolled POAG with cataract.

Methods: Multicenter observational study conducted in 9 ophthalmic institutes/general hospitals in China. Patients with medically controlled [baseline intraocular pressure (IOP) ≤ 21 mmHg] or uncontrolled (baseline IOP > 21 mmHg) POAG with clinically significant cataract were included, who were followed up with at least 12 months. The IOP, topical hypotensive medication, surgery complications, and visual acuity surgery success were recorded and compared between groups at baseline and the final visit. Complete surgical success was defined as postoperative IOP of 5–18 mmHg without additional topical medications, vision-threatening complications, or reoperation for glaucoma. Qualified success is the same as complete success except allowing the use of ocular hypotensive medications.

Results: One hundred participants with 132 eyes were included with a mean follow-up time of 17.5 ± 5.2 months (range: 12–32) postoperatively. In general, the mean IOP reduced from 21.2 ± 7.4 mmHg at baseline

to 14.7 ± 2.9 mmHg postoperatively ($P < 0.05$), with an average reduction of 6.4 ± 7.9 mmHg ($23.5 \pm 25.6\%$). The mean number of hypotensive medications declined from 1.6 ± 1.2 to 0.3 ± 0.6 , with a mean reduction of 1.4 ± 1.2 . One hundred and eight out of 132 (81.8%) eyes achieved complete success and 118 (89.4%) achieved qualified success of surgery, respectively. The chief complications involved hyphema (15.2%), corneal edema (19.7%), IOP spike (8.3%), or hypotony (1.5%). In subgroup analysis of medically controlled versus medically uncontrolled participants, difference was found neither in IOP at final visit (14.5 ± 0.3 vs 15.1 ± 0.4 mmHg; $P = 0.28$), medication (1.8 ± 1.1 vs 1.4 ± 1.3 ; $P = 0.54$), and complete (85.3% vs 77.2%; $P = 0.23$) or qualified success rate (95.0% vs 86.0%; $P = 0.27$), nor in any kind of surgery complications (all P s > 0.05), respectively.

Conclusions: POAG with cataract could be effectively treated by phacogoniotomy, regardless of medically controlled or medically uncontrolled status at baseline.

Abstract No.: 207092

Peripapillary Microvascular Density and Visual Field Damage in Moderate and Severe Primary Open-Angle Glaucoma

First Author: Khoa NGUYEN

Co-Author(s): Thanh DOAN, Quyen HUYNH, Nghiep TRANG

Purpose: To assess the correlation between peripapillary vessel density (VD) parameters and 24-2 visual field (VF) outcomes in eyes with moderate and advanced primary open-angle glaucoma (POAG).

Methods: This observational, cross-sectional study included 74 eyes of 56 POAG patients. Based on the Hodapp–Parrish–Anderson VF grading scale, eyes were classified as having moderate POAG (37 eyes) or severe POAG (37 eyes), and all underwent optical coherence tomography angiography (OCTA) and optical coherence tomography (OCT) testing. Mean deviation (MD), mean sensitivity (MS), VD, and retinal nerve fiber layer (RNFL) thickness were analyzed globally and by sector according to the modified Garway–Heath mapping. Correlations between structural indices and VF parameters were evaluated using Pearson regression.

Results: The mean patient age was 54.88 ± 15.32 years, with an MD of -16.32 ± 8.57 dB and a mean VD of $40.93 \pm 3.70\%$. Statistically significant differences in all vascular indices were found between the moderate and severe POAG groups ($p < 0.05$). Among all vascular and structural parameters, superior VD and peripapillary VD showed the strongest correlations with MD ($r = 0.728$ and 0.669 , respectively; $p < 0.001$). In addition, superior VD demonstrated the highest correlation with the MS of the corresponding VF sector ($r = 0.781$, $p < 0.001$).

Conclusions: In moderate and severe POAG, there was a strong correlation between peripapillary VD (both total and regional) and VF deficits, particularly in the superior quadrant.

Abstract No.: 205678

Peripapillary Staphyloma and Asymmetric Fundus Unevenness As Risk Factors for Open-Angle Glaucoma in Eyes With Myopia

First Author: Nan LUO

Co-Author(s): Ying HAN, Jingjing HUANG, Yuzhou XIANG

Purpose: To investigate the association between posterior staphyloma, fundus curvature, and open-angle glaucoma (OAG) in myopic eyes.

Methods: Myopic eyes were collected from a cohort at the Zhongshan Ophthalmic Center and grouped based on the diagnosis of OAG, with a 1:1 ratio of case-control matching for age and sex. OAG was subclassified into normal-tension and high-tension, juvenile-onset and adult-onset. Pathologic myopia was defined as the presence of posterior staphyloma and/or myopic maculopathy equal to or more severe than diffuse chorioretinal atrophy. Posterior staphyloma was categorized by its location and extent. Fundus steepness, unevenness, and asymmetry were quantitatively assessed using Gaussian curvature in the macular, superior, temporal, inferior, and nasal regions. The association between fundus morphology and OAG was evaluated using logistics regression adjusted for confounding covariates.

Results: A total of 334 myopic eyes (164 males and 170 females) were analyzed, of which 167 had OAG and 91 had pathologic myopia. Peripapillary staphyloma was more prevalent in myopic eyes with OAG than in those without OAG (6.6% versus 2.4%; $P=.04$). Peripapillary staphyloma was identified as a risk factor for OAG in eyes with pathologic myopia (odds ratio=67.239, $P=.02$). Myopic eyes with OAG showed lower macular steepness, higher temporal unevenness, lower superior-inferior asymmetry in steepness, and higher nasal-temporal asymmetry in unevenness (all $P<.05$). In myopic eyes, nasal-temporal asymmetry in fundus unevenness was associated with a higher risk of OAG (odds ratio=3.082 for every 100% increase, $P=.004$).

Conclusions: Region-specific fundus curvature alterations and peripapillary staphyloma are associated with OAG in myopia.

Abstract No.: 207067

Peripapillary Vessel Density as an Emerging Biomarker for Postoperative Monitoring Beyond the Structural Floor in Advanced Primary Open-Angle Glaucoma

First Author: Duyen PHAM

Co-Author(s): Yen DINH, Thanh DOAN, Quyen HUYNH

Purpose: To evaluate longitudinal changes in peripapillary vessel density (pVD) after trabeculectomy and explore its potential role as an adjunctive biomarker for disease monitoring in primary open-angle glaucoma (POAG).

Methods: This prospective longitudinal study included 36 eyes of 36 POAG patients undergoing trabeculectomy. Peripapillary vessel density was quantified by optical coherence tomography angiography (OCT-A), structural parameters were measured using OCT, and visual field function was assessed using Mean Deviation (MD). Measurements were obtained preoperatively and at 1, 3, and 6 months postoperatively.

Results: Mean intraocular pressure significantly decreased from 31.33 ± 7.08 mmHg to 12.12 ± 3.20 mmHg at 6 months. Despite effective pressure reduction, both pVD (from 38.79% to 38.23%; $p < 0.05$) and MD (from -19.81 dB to -20.35 dB; $p < 0.05$) exhibited significant declines over the follow-up period. Although both parameters decreased in parallel, no statistically significant correlation was found between the magnitude of pVD and MD change, suggesting that vascular and functional deterioration may occur through partially independent pathways. Retinal nerve fiber layer and ganglion cell complex thickness remained stable, indicating a structural floor effect in conventional OCT measurements.

Conclusions: Even with well-controlled intraocular pressure, disease progression may persist after trabeculectomy. The parallel decline in vascular and functional parameters, despite stable neural structural metrics, highlights pVD as an emerging objective biomarker for postoperative monitoring when conventional OCT parameters reach their structural floor. Integrating pVD with visual field testing may improve detection of progression and guide timely therapeutic decisions in advanced glaucoma.

Abstract No.: 202504

Peripheral Iridectomy With Goniosynechialysis and Goniotomy vs Trabeculectomy for Advanced PACG: A Randomized Clinical Trial

First Author: Fengbin LIN

Co-Author(s): Xiulan ZHANG

Purpose: To investigate the safety and effectiveness at 1 year of combining surgical peripheral iridectomy

(SPI) with goniosynechialysis (GSL) and goniotomy (GT) vs trabeculectomy in advanced primary angle-closure glaucoma (PACG) without cataract.

Methods: A total of 88 Chinese patients (88 eyes) with advanced PACG (no cataract) were enrolled. Mean (SD) age: 60.3 (7.3) years; 52 (59.1%) female. 43 randomized to SPI+GSL+GT, 45 to trabeculectomy; 86 (97.7%) completed 12-month follow-up. Primary outcome: 12-month IOP (noninferior margin: 4mmHg). Secondary outcomes: surgical success (IOP 5-18mmHg, $\geq 20\%$ baseline reduction, with/without antiglaucoma meds); postoperative complications/interventions, and antiglaucoma med count.

Results: At 12 months: SPI+GSL+GT mean (SD) IOP: 15.6 (4.0) mmHg vs trabeculectomy's 14.9 (4.2) mmHg ($P=.55$). Qualified success: 38/43 (88.4%) vs 42/45 (93.3%) ($P=.48$). However, complete success lower: SPI+GSL+GT 26 (60.5%) vs trabeculectomy 37 (82.2%) ($P=.03$). Postoperative complications: 8 (18.6%) vs 9 (20.0%) ($P=.71$). Postoperative interventions lower: 3 (7.0%) vs 25 (55.6%) ($P<.001$). Median (IQR) meds: SPI+GSL+GT 2(0-3) $\rightarrow$ 0(0-1); trabeculectomy 2(2-3) $\rightarrow$ 0(0-0) ($P=.004$).

Conclusions: SPI+GSL+GT was noninferior to trabeculectomy for IOP control in patients with PACG without cataract at 12 months postoperatively, with fewer postoperative interventions.

Abstract No.: 206997

Phacoemulsification Combined With Trabeculectomy for Secondary Glaucoma Associated With Pediatric Uveitic Cataract

First Author: Weiwei **WANG**

Purpose: To explore the effectiveness and safety of phacoemulsification combined with trabeculectomy for secondary glaucoma associated with pediatric uveitic cataract.

Methods: Retrospective analysis of preoperative and postoperative data in two pediatric patients with uveitis-associated cataracts and secondary Glaucoma.

Results: Child 1 had a 3-year history of bilateral uveitis, underwent bilateral LPI 2 years earlier, and left-eye cataract surgery 1 year earlier. Preoperatively, the right eye had a visual acuity of 0.2 and an IOP of 31.2 mmHg. Examination revealed peripheral band-shaped keratopathy, complete posterior synechiae of the iris, a laser iridotomy at the 6 o'clock position, and cortical lens opacity. Postoperatively, the visual acuity improved to 0.5, IOP decreased to 12.9 mmHg with no synechiae of the iris and a clear, well-positioned IOL. Child 2 had a 4-year history of bilateral uveitis and had undergone left-eye cataract surgery 2 years earlier. Preoperatively, the right eye had a visual acuity of 0.1 and an IOP of 49.4 mmHg, with no marked corneal edema, nearly complete posterior synechiae of the iris, and opacification of the lens. Postoperative

visual acuity improved to 0.5, IOP decreased to 13.0 mmHg with no synechiae of the iris and a clear, well-positioned IOL. Child 1 was followed for 1 year and Child 2 for 6 months; in both cases, postoperative IOP remained normal without any glaucoma medications, and no disease progression was observed.

Conclusions: Phacoemulsification combined with trabeculectomy is effective and safe for secondary glaucoma associated with pediatric uveitic cataract, but larger sample sizes and longer follow-up are needed.

Abstract No.: 200924

Postoperative Risks and Climate Exposure: A 10-Year Cohort Study of Incisional Glaucoma Surgery Outcomes

First Author: Tianhao **CHEN**

Co-Author(s): Yuan **LEI**, Xinghuai **SUN**, Yi **TIAN**, Yuyan **ZHANG**

Purpose: Incisional glaucoma surgery is an effective strategy for lowering intraocular pressure, yet postoperative fibrotic scarring frequently undermines long-term success. This study aims to characterize climatic determinants of surgical failure.

Methods: A total of 5,193 patients who underwent incisional glaucoma surgeries from January 2015 to July 2024 were included in this study. Individual-level clinical data were obtained from electronic medical records. Ambient temperatures were estimated using spatiotemporal bilinear interpolation. Multivariable-adjusted random-effects Cox proportional hazards models with restricted cubic splines and segmented regression were used to assess the temperature-outcome relation. To identify potential susceptible populations, stratified analyses were conducted. Multiple sensitivity analyses were performed to confirm robustness.

Results: Non-optimal temperature augmented the incidence of suboptimal surgical outcomes. A U-shaped, nonlinear association was observed between ambient temperature and risk of suboptimal outcomes (P for nonlinearity < 0.0001) within prolonged exposure windows (120 and 180 days), with the lowest risk at 3–26°C. The risk increased by 14.5% (95% CI: 11.5%–17.4%) for each 1°C decrease below this range, while each 1°C increase above the range was associated with a 31.9% (95% CI: 25.1%–39.0%) higher risk. Effects were more pronounced among older individuals and cases with primary open-angle glaucoma.

Conclusions: Ambient temperature significantly influences surgical outcomes following conjunctival incision glaucoma procedures. As climate change accelerates the frequency of heat and cold spells, integrating meteorological data into surgical planning and perioperative management may reduce risk, particularly in vulnerable populations.

Abstract No.: 206678

Predictive Factors for Ciliary Block After Cataract and Goniosynechialysis Surgery in Primary Angle-Closure and Primary Angle-Closure Glaucoma: A Multicenter Retrospective Study

First Author: Huijuan **WU**

Co-Author(s): Chao **DAI**, Sujie **FAN**, Shuning **LI**, Yao **MA**, Li **QIN**, Dajiang **WANG**

Purpose: To identify predictive factors for ciliary block (CB) following combined phacoemulsification, intraocular lens implantation, and goniosynechialysis (P+I+GSL) in patients with primary angle-closure (PAC) and primary angle-closure glaucoma (PACG).

Methods: This multicenter retrospective study analyzed 66 eyes from 66 patients who underwent P+I+GSL between February 2022 and December 2024. Patients were categorized into two groups: those who developed CB (n=33) and those who did not (n=33). Preoperative biometric parameters obtained from ultrasound biomicroscopy (UBM) and IOLMaster, along with intraoperative data, were analyzed. Univariable and multivariable logistic regression analyses were conducted to identify risk factors for CB.

Results: Compared to the non-CB group, patients who developed CB had shorter axial length, narrower anterior chamber width (ACW), and thinner lenses (LT) ($P < 0.05$) preoperatively. Multivariable analysis identified reduced ACW ($OR = 0.049$, $P < 0.05$), decreased LT ($OR = 0.007$, $P < 0.05$), and lack of preoperative mannitol administration ($OR = 0.025$, $P < 0.05$) as significant predictors of CB. The optimal cut-off values for predicting CB were 11.72 mm for ACW and 4.84 mm for LT, with area under the curve values of 0.861 and 0.863, respectively.

Conclusions: Shorter AL, narrow ACW, thin lenses, and lack of preoperative mannitol administration are significant risk factors for CB following P+I+GSL in PAC and PACG patients. These findings highlight the importance of preoperative assessment of ACW and LT, along with the use of mannitol, may help reduce the incidence of CB in high-risk patients.

Abstract No.: 208393

Preoperative and Intraoperative Characteristics of Zonulopathy in Patients With Acute Angle-Closure Glaucoma in Cataract Surgery: A Cross-Sectional Study

First Author: Rui **QIN**

Co-Author(s): Jiawei **CHEN**, Yiyun **LIU**, Hong **QI**, Xiaoyu **WANG**

Purpose: This study aimed to identify the zonulopathy in patients with acute angle-closure glaucoma (AACG) during cataract surgery and the preoperative biometric parameters related to zonulopathy.

Methods: A cross-sectional study of 80 eyes of 40 patients with one-eye AACG.

Results: All patients were one-eye AACG and 42.5 % of fellow eyes were diagnosed with primary angle-closure glaucoma (PACG), anterior capsule wrinkling demonstrated 70% sensitivity and 93% specificity for zonulopathy. Zonulopathy was diagnosed in 60% of AACG eyes. Zonulopathy eyes exhibited smaller ACD (2.01 ± 0.28 mm, $p = 0.025$), higher lens vault (1.25 ± 0.28 mm, $p = 0.007$), larger pupil diameter (4.33 ± 1.25 mm, $p = 0.048$), higher incidence of iris dechromation (50%, $p = 0.001$), greater cup-to-disc ratio (0.67 ± 0.15 , $p = 0.024$), and lower visual field index $66.35 \pm 33.95\%$, $p = 0.05$). Multivariate logistics analysis confirmed AACG as the sole independent risk factor ($OR = 3.733$, $P < 0.001$).

Conclusions: Intraoperative adverse events, particularly anterior capsule wrinkling, can help assess the severity of zonulopathy in AACG eyes. Zonulopathy was present in 60% of AACG eyes. The shallow ACD, dechromation of the iris, and increased C/D caused by AACG were associated with zonulopathy.

Abstract No.: 202112

Prognostic Factors Influencing the Outcomes of PEI Combined With Goniosynechialysis and Goniotomy in the Treatment of Primary Angle-Closure Glaucoma

First Author: Chukai **HUANG**

Purpose: To evaluate the effectiveness and safety of PEI plus GSL and GT for advanced PACG.

Methods: This was a cross-sectional study. IOP, BCVA, and the number of anti-glaucoma medications used in patients before surgery and at 1 day, 1 week, 1 month, and 3 months postoperatively were analysed. Quantitative assessment of changes in angle parameters was conducted using AS-OCT. Logistic regression analysis was employed to analyze the impact of multiple factors on the surgical outcomes.

Results: A total of 59 eyes of 59 patients were included. The mean preoperative IOP was 23.54 ± 11.14 mmHg, and the IOP at the end of follow-up was 14.00 ± 4.51 mmHg ($P = 0.001$), a decrease of 9.54 ± 10.72 mmHg (40.53%). The mean preoperative and the postoperative BCVA was 0.74 ± 0.85 and 0.53 ± 0.83 ($P = 0.007$). The number of anti-glaucoma medications was reduced from 3.12 ± 0.72 to 0.26 ± 0.74 . The complete success rate was 78.0%, and the qualified success rate 94.9%. At the 3-month postoperative follow-up, quantitative assessment of angle parameters showed significant increases compared to preoperative measurements ($p < 0.001$). Multivariate analysis revealed that a family history of glaucoma ($OR = 1.143$, 95%CI $2.295 - 135.075$, $P < 0.006$) and preoperative high intraocular pressure ($OR = 17.780$, 95%CI $1.040 - 1.241$, $P < 0.005$) were independent risk factors for prognosis.

Conclusions: PEI+GSL+GT is preliminarily effective and safe for advanced PACG. A family history of glaucoma and preoperative high IOP are independent risk of prognosis.

Abstract No.: 204749

Prospective Multi-Centre Evaluation of iStent Infinite as a Stand-Alone Procedure for Open-Angle Glaucoma With Up to 24-Months Follow-Up

First Author: Colin **CLEMENT**

Co-Author(s): Geoff **CHAN**, Hamish **DUNN**, Todd **GOODWIN**, Frank **HOWES**, Judy **KU**, Ridia **LIM**, David **MANNING**, Michael **SHIU**

Purpose: To evaluate the safety and efficacy of the iStent infinite trabecular micro-bypass system as a stand-alone procedure in eyes with open-angle glaucoma (OAG).

Methods: This prospective study included 78 eyes from 61 patients with OAG undergoing implantation of three iStent infinite devices as a stand-alone procedure. Patients were followed up to 24 months. Outcomes included intraocular pressure (IOP), glaucoma medication use, visual field mean deviation (MD), cup-to-disc ratio, retinal nerve fibre layer thickness (RNFL), and central corneal thickness. Multilevel mixed-effects linear regression was used to model IOP change, and Poisson regression for medication use, accounting for repeated measures nested within eye, patient, and surgeon. Surgical success was defined according to American Academy of Ophthalmology (AAO) criteria.

Results: Mean baseline IOP was 18.54 ± 6.24 mmHg on 2.5 ± 1.2 medications. At 12 months, mean IOP reduced to 13.72 ± 3.64 mmHg ($p < 0.001$), and to 14.68 ± 4.41 mmHg at 24 months, representing a ~21% reduction. Medication use decreased to 1.56 ± 1.55 at 12 months and 1.68 ± 1.55 at 24 months ($p < 0.001$). By 24 months, 39.4% of eyes achieved AAO-defined success (IOP < 21 mmHg and $> 20\%$ IOP reduction from baseline). Visual field MD, RNFL thickness, and cup-to-disc ratio remained stable, with no cases of hypotony or loss of light perception vision.

Conclusions: Standalone iStent infinite implantation produced significant and durable reductions in IOP and medication burden over 24 months in eyes with OAG, with stable visual function and a favourable safety profile. These findings support its role as an effective minimally invasive option for long-term glaucoma management independent of cataract surgery.

Abstract No.: 201936

Protective Role of Metformin in Glaucoma: Prospective Cohort Study, Meta-Analysis, and Drug-Target Mendelian Randomization

First Author: Can Can **XUE**

Co-Author(s): Miao Li **CHEE**, Ching-yu **CHENG**, Rachel **CHONG**, Raghavan **LAVANYA**, Hengtong **LI**, Zhi Da **SOH**, Nicholas **TAN**, Yih-chung **THAM**, Marco **YU**

Purpose: Metformin use may protect against glaucoma through multiple mechanisms, while previous studies reported mixed results. To clarify this association, we conducted a prospective cohort study, a meta-analysis, and a drug-target Mendelian randomization (MR) analysis.

Methods: In the UK Biobank, we examined the association between metformin use and incident glaucoma among 24,206 patients with diabetes using multivariable Cox regression. A random-effect meta-analysis was performed to synthesize existing human studies on the association between metformin and glaucoma. Biomarker (Hemoglobin A1c)-weighted drug-target MR was conducted using multiple MR models to estimate metformin's causal effect on primary open-angle glaucoma (POAG) and intraocular pressure (IOP), leveraging genetic variants near five metformin target genes as instrumental variables.

Results: A total of 841 patients developed glaucoma during a mean follow-up of 12.1 ± 2.8 years. Metformin use was associated with a 19% lower glaucoma risk (HR, 0.81; 95% CI, 0.69–0.97; $P = 0.018$), independent of glycemic control, IOP, diabetes duration, and other confounders. Random-effect meta-analysis of cohort studies showed a consistent protective effect (pooled RR, 0.81; 95% CI, 0.72–0.93; $P = 0.002$) of metformin on glaucoma incidence among subjects with diabetes. Drug-target MR indicated each standard deviation decrease in hemoglobin A1c via five metformin targets was causally associated with 33% lower glaucoma risk (OR, 0.67; 95% CI, 0.46–0.98; $P = 0.039$).

Conclusions: Our findings suggest metformin may reduce glaucoma risk in the diabetic population, supporting the need for randomized clinical trials to evaluate metformin's potential as a preventive glaucoma therapy.

Abstract No.: 200848

Quantitative Changes of the Ciliary Body and Their Association With Refractive Error After Phacoemulsification in Phakic Eyes With Malignant Glaucoma

First Author: Yu **YANG**

Co-Author(s): Jingjing **HUANG**

Purpose: To investigate ciliary body changes after phacoemulsification and their association with postoperative refractive errors in eyes with malignant glaucoma.

Methods: This retrospective study analyzed data of phakic eyes which underwent phacoemulsification combined with goniosynechialysis at Zhongshan Ophthalmic Center after failed trabeculectomy or laser peripheral iridotomy for primary angle-closure glaucoma between June 2022 and June 2024. Eyes were grouped by the diagnosis of malignant glaucoma, with additional anterior vitrectomy performed in the malignant glaucoma group. Ciliary body parameters were measured using ultrasound biomicroscopy, and pre- and postoperative values were compared between groups. Multivariate regression identified factors associated with postoperative refractive errors.

Results: Sixteen eyes with malignant glaucoma and 62 control eyes without malignant glaucoma were included. Preoperatively, eyes with malignant glaucoma showed thinner and more anteriorly rotated ciliary bodies ($P < 0.05$). Postoperatively, eyes with malignant glaucoma showed larger increases in ciliary body thickness ($P < 0.05$) and greater decreases in anterior rotation ($P < 0.05$), although their ciliary body thickness remained lower than that of controls. Greater myopic shifts were found in eyes with malignant glaucoma compared to controls (median: -1.19 versus -0.10 diopter; $P < 0.001$). Multivariate regression identified thinner preoperative lens thickness ($P = 0.028$), thinner baseline ciliary body thickness at the scleral spur ($P = 0.018$), and smaller trabecular-ciliary angle ($P = 0.003$) as being associated with greater myopic shifts.

Conclusions: In eyes with malignant glaucoma, although phacoemulsification combined with anterior vitrectomy partially restored ciliary body morphology, greater postoperative myopic shifts were found. Preoperative ciliary body assessment may help predict refractive errors in malignant glaucoma patients.

Abstract No.: 205996

Real-World Long-Term Efficacy of the Hydrus Microstent in Medication Reduction for Glaucoma Management: International Glaucoma Surgery Registry Analysis

First Author: Nathan **KERR**

Co-Author(s): Keith **BARTON**, Gok **RATNARAJAN**, Jing **WANG**

Purpose: To evaluate the real-world efficacy of the Hydrus Microstent combined with cataract surgery in reducing medication burden and maintaining intraocular pressure (IOP) control in patients with mild-to-moderate primary open-angle glaucoma (POAG), pseudoexfoliative glaucoma (PXFG), and pigment dispersion glaucoma (PDG).

Methods: An international, multicentre, registry-based study analysed 484 eyes from 361 patients who underwent Hydrus Microstent implantation with cataract surgery. Primary outcomes were changes in topical medication burden and IOP from baseline to

24 months. Secondary outcomes included medication-free status, complications, and secondary surgical interventions (SSI). Data were collected through the International Glaucoma Surgery Registry (IGSR.org) across centres in Australia, Canada, the United Kingdom, and the United States.

Results: At baseline, mean medications were 1.8 ± 1.4 , and mean IOP was 16.7 ± 5.4 mmHg. Visual field mean deviation was -5.83 ± 5.93 dB. At 12 months ($n = 205$), medications were reduced by 44% (1.8 to 1.0), IOP by 17% (to 13.8 mmHg), and 43% achieved medication-free status. At 24 months ($n = 187$), reductions were maintained: medications decreased 44% (1.0), 47% were medication-free, and IOP reduced by 20% to 13.3 mmHg (all $p < 0.001$). Complications were rare, with only 2 cases (0.4%) of hyphaema (>10% anterior chamber in 1 case). SSI occurred in 2.7%, mainly in filtration procedures. Outcomes compared favourably with the HORIZON trial.

Conclusions: In real-world practice, Hydrus Microstent with cataract surgery achieved sustained medication and IOP reduction with excellent safety, supporting its role as an effective minimally invasive glaucoma option.

Abstract No.: 203642

Relationship Between Long-Term Blood Pressure Fluctuations and Visual Field Progression in Primary Open-Angle Glaucoma

First Author: De-fu **CHEN**

Co-Author(s): Yuanbo **LIANG**

Purpose: This study aims to evaluate the association between long-term blood pressure (BP) fluctuations and visual field (VF) progression in patients with primary open-angle glaucoma (POAG).

Methods: Linear mixed models were used to assess associations between BP metrics and VF progression rates. BP variability (BPVR) and intraocular pressure (IOP) variability during the follow-up period were calculated as the standard deviation (SD) divided by the mean value. Correlated non-fluctuating BP metrics (baseline, mean, maximum, and minimum BP) were combined using principal component analysis (PCA) for systolic BP (SBP) and diastolic BP (DBP), respectively. Principal component 1 (PC1) was included as a covariate. The interactions between covariates and time from baseline were modeled to determine their effects on VF progression rates.

Results: A total of 157 eyes from 157 POAG patients were included, with a mean age of 56.9 ± 13.4 years at baseline. VF progression was observed in 74 eyes (44%). These eyes exhibited significantly higher DBPVR (0.10 ± 0.02 vs. 0.09 ± 0.03 mmHg, $P = 0.009$) and slightly higher SBPVR (0.08 ± 0.02 vs. 0.07 ± 0.02 mmHg, $P = 0.077$), though the latter was not statistically

significant. Notably, only SBPVR was significantly associated with VF progression rates (estimate: -12.57 dB/year [SE: 5.20 dB/year], $P = 0.0166$), while IOP and non-fluctuating BP metrics were not.

Conclusions: Blood pressure variability, particularly SBP variability, may be an independent risk factor for accelerated VF progression in POAG. Clinicians should carefully monitor BP variability in POAG patients to mitigate potential disease progression.

Abstract No.: 201492

Results of iTrack Global Data Registry to Support the Role of Canaloplasty for Treatment of Glaucoma

First Author: David **LUBECK**

Co-Author(s): Keith **BARTON**, Nathan **KERR**

Purpose: The iTrack Global Data Registry (iTGDR) was established to collect comprehensive real-world data on the efficacy and safety of canaloplasty. Key outcomes include intraocular pressure (IOP) reduction, medication use, endothelial cell count, adverse events, and procedure-specific parameters.

Methods: This is a prospective, multicenter, real-world study conducted in the USA, Canada, Europe, Asia, and Australia. Data were collected in a cloud-based registry and included patients with primary and secondary open-angle glaucoma undergoing canaloplasty. Only eyes with at least 12 months of follow-up and combined with phacoemulsification were included. Outcomes were assessed at baseline and post-op (last available follow-up). Success was defined as achieving criteria set by the American Academy of Ophthalmology.

Results: This study included 318 eyes of 237 patients up to May 2025. Mean baseline IOP and medication use were 17.2 ± 5.3 mmHg and 2.1 ± 1.1 , respectively, and were significantly reduced to 14.1 ± 3.9 mmHg and 1.3 ± 1.4 medications ($p < 0.001$) at the last available follow-up (mean: 20.4 ± 7.9 months). Medication-free eyes increased from 7.0% ($n=22$) at baseline to 42.8% ($n=134$) postoperatively. Success was achieved in 61.9% of eyes ($n=197$) at postop. Intraoperative complications occurred in 0.3% of cases ($n=1$), and postoperative complications in 2.2% of cases ($n=7$).

Conclusions: Canaloplasty performed via an ab-interno approach reduced IOP and medications in patients with primary and secondary open-angle glaucoma.

Abstract No.: 208341

Risk Factors for Visual Field Progression in Primary Angle Closure Disease Over 10 Years: The CUPAL Study

First Author: Ruyue **SHEN**

Co-Author(s): Poemen **CHAN**, Carol **CHEUNG**, Annie **LING**, Clement **THAM**

Purpose: To identify associated long-term risk factors of visual field (VF) progression among eyes of primary angle closure disease (PACD), including primary angle closure suspect (PACS), primary angle closure (PAC), and primary angle closure glaucoma (PACG).

Methods: PACD eyes with at least a ten-year follow-up duration were included. VF was tested every 6 months using a 24-2 pattern standard on the Humphrey Field Analyzer. The initial intraocular pressure (IOP) fluctuation and initial visual field index (VFI) slope were calculated based on the first-year follow-up data. Univariable and multivariable Cox proportional hazards regression models were calculated to determine potential risk factors associated with VF progression.

Results: Forty out of 129 (31.0%) eyes with PACD developed VF progression, including 2 out of 11 (18.2%) PACS eyes, 9 out of 52 (17.3%) PAC eyes, and 29 out of 66 (43.9%) PACG eyes. In multivariable Cox models, longer axial length (AL) at baseline, more advanced disease at baseline, higher initial IOP fluctuation, and steeper initial VFI slope were associated with VF progression in PACD eyes (all $P \leq 0.031$). Among PACG eyes, higher IOP fluctuation and steeper initial VFI slope were associated with glaucoma progression. Among PACS/PAC eyes, a steeper initial VFI slope was associated with VF progression ($P \leq 0.008$).

Conclusions: Larger initial IOP fluctuation, steeper initial VFI slope, longer baseline AL, and more advanced disease at baseline were associated with a higher risk of VF progression among PACD, highlighting the importance of tailored management strategies for patients with different severity and refraction.

Abstract No.: 201455

Serum Proteomic Profiles Associated With Inner Retinal Biomarkers and Intraocular Pressure: A Preliminary Proteomics Analysis From the UK Biobank

First Author: Ya Yuan Rachel **LEUNG**

Co-Author(s): Yonglin William **WU**

Purpose: Glaucoma is associated with intraocular pressure (IOP), which relates to inner retinal changes. We used an agnostic approach to identify proteins associated with IOP and inner retinal structural biomarkers associated with glaucoma.

Methods: We analyzed proteomic profiles linked to IOP (corneal compensated, $n=12,826$) and inner retinal biomarker (macular retinal nerve fiber layer

thickness (mRNFL, $n=5,263$), and macular ganglion cell inner plexiform layer thickness (mGCIPL, $n=5,263$), in the UK Biobank. Serum proteomic data ($n=2,923$ proteins), obtained using Olink technology and expressed as normalized protein expression units, were evaluated via multivariable-adjusted linear regression. Multivariable models were adjusted for demographic, biochemical, and clinical covariates. We used the linear mixed model testing method to adjust for multiple protein comparisons.

Results: Of ten proteins associated with IOP, five were related to extracellular matrix remodeling: opticin ($\beta=0.37$; CI: 0.22, 0.52), MMP12 ($\beta=-0.13$; CI: -0.45, -0.17), alpha-L-fucosidase1 ($\beta=0.19$; CI: 0.11, 0.27), stanniocalcin-2 ($\beta=0.67$; CI: 0.40-0.93), endothelin-converting enzyme1 ($\beta=0.48$; CI: 0.29, 0.68), and three were related to immune modulation: lymphotactin ($\beta=-0.27$; CI: -0.40, -0.15), KIR2DL3 (NK cell inhibitor; $\beta=-0.22$; CI: -0.32, -0.13), LILRB4 (inhibitory immune receptor; $\beta=-0.38$; CI: -0.54, -0.21). Of six proteins associated with mGCIPL and ten proteins associated with mRNFL, two shared proteins were related to immune regulation (SIGLEC9 (immunoregulatory receptor; mGCIPL $\beta=1.51$; CI: 0.87, 2.15; mRNFL $\beta=1.11$; CI: 0.63, 1.57)) and proteostasis (CREBZF (transcriptional regulator; mGCIPL $\beta=2.14$; CI: 1.16, 3.05; mRNFL $\beta=1.91$; CI: 1.21, 2.61)). Additionally, four other proteins were associated with immune regulation (TIMD4, BLNK, C1RL, and FGL1), and proteostasis (SUMF2, CSTB, CTSL, and PDIA3) respectively.

Conclusions: This study highlights proteins linked to IOP and inner retinal homeostatic mechanisms, which have the potential to serve as biomarkers that modulate genetic predispositions to glaucoma. Future protein set enrichment analysis could shed light on pathways associated with the identified proteins.

Abstract No.: 206715

Sleep Apnoea in Normal Tension Glaucoma Chinese Patients That Progressed Despite Achievements of Treatment Target Eye Pressure: A Case Series

First Author: Nancy Shi Yin **YUEN**

Purpose: To evaluate sleep apnoea in normal tension glaucoma patients with achieved target intraocular pressure reduction.

Methods: This study included normal tension glaucoma patients who showed visual field progression despite achieving a 25–30% target eye pressure with treatment. All patients were followed by the author, and detailed histories for systemic cardiovascular and other NTG risk factors revealed none. Full polysomnography was performed and reported by respiratory physicians or ENT specialists.

Results: Over 75% (25/33) of patients were diagnosed with moderate to severe obstructive sleep apnoea.

Most were non-obese, without daytime somnolence; only three reported snoring. A high proportion also had high myopia (23/33), suggesting increased optic nerve vulnerability in myopic patients.

Conclusions: Prevalence of moderate to severe obstructive sleep apnoea is noted to be very high in our series of Chinese Normal tension glaucoma patients with well-lowered intra-ocular pressure. Patients' history, symptoms, body build, and snoring history do not point to sleep apnoea. It is advisable to advise patients for a polysomnography in treating those NTG Chinese patients with progression before embarking on further invasive procedures to lower an already well lowered intra-ocular pressure. Besides, it is beneficial for these moderate or severe sleep apnoea patients too to lower their other cardiovascular disease risk with our help in picking them up and receiving OSA treatment which is well documented in medical literature.

Abstract No.: 205751

Sleep Pattern, Visual Field Loss, and Structural Damage in Older Adults With Glaucoma: Insights From EGSS China and NHANES 2005–2008

First Author: Jingjing **HUANG**

Co-Author(s): Zhonghua **LUO**

Purpose: To investigate sleep patterns in older adults with glaucoma and evaluate their associations with structural and functional glaucomatous damage.

Methods: We analyzed data from the Elderly Glaucoma and Sleep Study (EGSS) in China ($n = 200$) and the 2005–2008 National Health and Nutrition Examination Survey (NHANES) in the United States ($n = 3317$). All participants were aged 60 years or older and underwent ophthalmic and systemic assessments. Sleep patterns were evaluated using standardized questionnaires and wearable devices, and multivariable regression models were applied to examine associations between sleep disturbances and demographic, clinical, and ocular factors.

Results: In NHANES, older adults with glaucoma reported more frequent sleep disturbances than controls, including higher rates of sleep trouble (36.2% vs. 28.5%, $P = 0.014$), difficulty falling asleep (47.5% vs. 38.1%, $P = 0.003$), and difficulty maintaining sleep (51.1% vs. 46.9%, $P = 0.023$). In EGSS, patients with primary open-angle glaucoma (POAG) showed poorer sleep quality, longer and higher proportions of light sleep, and a lower 6-sulfatoxymelatonin/creatinine ratio than controls (all $P < 0.05$), while no significant differences were found for primary angle-closure glaucoma. In multivariable analyses, depressive symptoms, thinner peripapillary retinal nerve fiber layer, and reduced optic nerve head vessel density were independently associated with worse sleep outcomes in POAG.

Conclusions: Older adults with glaucoma, particularly those with POAG, exhibit a higher prevalence of sleep disturbances, including increased light sleep duration and altered melatonin metabolism. In POAG, poor sleep quality was closely associated with glaucomatous structural damage and visual field loss.

Abstract No.: 204559

Stereophotographic Assessment of Intraocular Pressure Reduction in Myopic Eyes With Glaucoma-Compatible Optic Neuropathy

First Author: Yang **ZHANG**

Co-Author(s): Ailing **BIAN**, Gangwei **CHENG**, Lue **LI**, Qi **ZHOU**

Purpose: To evaluate the clinical significance of intraocular pressure (IOP) reduction in patients with glaucoma-compatible optic neuropathy in myopia (GCON-M) and to determine whether optic disc and functional changes represent true glaucomatous damage or benign anatomic variants.

Methods: The eye with the worse baseline VF mean deviation received IOP-lowering treatment targeting a 30% reduction, while the fellow eye served as an untreated control. Participants underwent serial VF testing and stereophotographic imaging of the optic nerve head over a median follow-up of 48 months. Structural and functional progression was compared between the treated and control eyes.

Results: Among 82 eyes analyzed, 4 treated eyes (9.7%) and 5 control eyes (12.5%) showed progression. Although treated eyes achieved a mean IOP reduction of 31.1%, no significant differences in VF outcomes or optic disc morphology were observed between groups. IOP-lowering treatment was not associated with a significant reduction in the risk of visual field progression (HR = 1.04; 95% CI, 0.68–1.37; P = 0.88). Kaplan-Meier survival analysis indicated no significant difference in progression-free survival (P = 0.758), neither structural change (P = 0.496) nor disc hemorrhage (P = 0.524) significantly influenced progression-free survival.

Conclusions: In this cohort of young patients with GCON-M, no statistically significant differences were observed between treated and untreated eyes despite a substantial IOP reduction. These results should not be interpreted as evidence that IOP reduction is ineffective, but rather highlight the need for larger, prospective studies. The findings suggest that the natural history of GCON-M may differ from classical glaucoma and warrant cautious monitoring and individualized management.

Abstract No.: 206020

Subconjunctival Injection of Mitomycin C for Mitigating the Hypertensive Phase in Ahmed Glaucoma Valve Implantation

First Author: Shivam **GUPTA**

Co-Author(s): Devendra **MAHESHWARI**, Nimrita **NAGDEV**, Madhavi **PILLAI**

Purpose: To assess the safety and efficacy of postoperative subconjunctival injection of Mitomycin C for the hypertensive phase in Ahmed glaucoma valve implantation.

Methods: Sixty-three refractory glaucoma patients underwent Ahmed Glaucoma Valve (AGV) implantation. Thirty-two consecutive patients received subconjunctival 0.2 µg/mL Mitomycin C (MMC) injections at weeks 1 and 4 postoperatively (MMC group), compared to thirty consecutive patients undergoing standalone AGV (No MMC group). The primary outcome was the incidence of HP, defined as intraocular pressure (IOP) > 21 mmHg within 6 months postoperatively. Secondary outcomes included intraocular pressure (IOP), best-corrected visual acuity (BCVA), number of antiglaucoma medications (AGMs), complications, secondary interventions, and surgical success. All patients were evaluated on postoperative days 1, 7, and 1, 2, 3, 6 months.

Results: In this study, 37.5% in the MMC group and 53.3% in the No MMC group exhibited HP (p=0.21). In the MMC and No MMC groups, mean (SD) IOP reduced from 38.84 ± 11.12mmHg and 35.17 ± 12.56mmHg to 15.38 ± 3.25mmHg and 17.63 ± 5.53mmHg, respectively, by 6 months (p=0.256). AGM decreased from 2.97 ± 0.93 to 0.72 ± 0.68 and 2.83 ± 0.91 to 1.50 ± 0.94 in the MMC and No MMC groups, respectively, by 6 months (p<0.001). By criteria 1 (IOP reduction >20% from baseline and between 6 to 21 mmHg) and criteria 2 (IOP reduction >25% and between 6 to 18 mmHg), the success rate was 87.5 % and 75.0% in the MMC group and in the No MMC group, 70.0% and 60% respectively.

Conclusions: Post-operative subconjunctival MMC injection is associated with a lower incidence of hypertensive phase following AGV and decreases the need for antiglaucoma medications.

Abstract No.: 205937

Surgical Outcomes of Gonioscopy-Assisted Transluminal Trabeculotomy in High Myopia Versus Non-High Myopia With Open-Angle Glaucoma

First Author: Nimrita **NAGDEV**

Co-Author(s): Devendra **MAHESHWARI**, Madhavi **PILLAI**

Purpose: To compare the safety and efficacy of gonioscopy-assisted transluminal trabeculotomy in open-angle glaucoma associated with high myopia.

Methods: A prospective, interventional and comparative study included 36 high myopia (group 1) and 40 non-high myopia (group 2) patients with open-angle glaucoma. Combined gonioscopy-assisted transluminal trabeculotomy with phacoemulsification was performed in both groups. Baseline characteristics like Intraocular pressure (IOP), best corrected visual acuity (BCVA) and anti-glaucoma medications (AGMs) were compared. Data were collected at 2 weeks, 1 month, 3, 6 and 12 months. Surgical success was defined as IOP ≤ 21 / ≤ 18 / ≤ 15 mmHg with > 20%/25%/30% reduction from baseline, respectively (Criteria 1, 2 and 3). Complications, secondary interventions and surgical risk factors were also analyzed.

Results: The mean (SD) IOP (mmHg) decreased from 20.56 ± 4.71 to 13.32 ± 5.02 and from 19.33 ± 4.15 to 12.94 ± 3.48 in groups 1 and 2 respectively at the end of 12 months ($p < 0.001$). AGM reduced from 2.11 ± 0.89 to 0.36 ± 0.95 and 1.63 ± 0.87 to 0.06 ± 0.24 in group 1 and 2 respectively at 12 months ($p < 0.001$). Success rate was 84.0%, 69.3% and 43.5% by criteria 1, 2, and 3, respectively, in group 1. In group 2, it was 87.5%, 74.3% and 61.3%. Micro hyphemas were seen in 18 patients (8 in group 1, 10 in group 2), and macro hyphemas were seen in 7 patients (3 in group 1, 4 in group 2). 11 had IOP spikes (6 group 1, 5 group 2). AC was done in 4 patients (2 in each group).

Conclusions: Combined Gonioscopy-assisted transluminal trabeculotomy with phacoemulsification is a safe and effective procedure in open-angle glaucoma associated with high myopia. It showed similar outcomes in terms of IOP and AGM reduction to the control group at 12 months.

Abstract No.: 204604

Surgical Outcomes of Phacoemulsification Followed by KDB Goniotomy or Trabeculectomy in Patients With Moderate to Severe Primary Angle Closure Glaucoma

First Author: Xu **HOU**

Co-Author(s): Dan **HU**, Jing **WU**, Xiaxia **YANG**, Jian **ZHOU**

Purpose: This research was designed to compare the efficacy and safety of phacotrabeculectomy (phaco-trab) versus phacoemulsification combined with Kahook Dual Blade goniotomy (phaco-KDB) in patients with moderate to severe primary angle-closure glaucoma (PACG).

Methods: This single-center, non-randomized retrospective cohort study included 77 eyes from 74 PACG patients with concurrent cataract, who underwent either phaco-trab (40 eyes, 39 patients) or phaco-KDB (37 eyes, 35 patients). All patients had moderate-to-severe visual field (VF) defects and were using ≥ 2 topical intraocular pressure (IOP)-lowering medications preoperatively. Changes in best-corrected

visual acuity (BCVA), IOP, medication use, mean deviation (MD), progression of VF, and complications were compared between the two groups.

Results: The mean follow-up duration was 13.5 ± 4.1 months (phaco-trab) and 12.9 ± 3.9 months (phaco-KDB). Postoperative BCVA improved in both groups, with no significant intergroup difference. The baseline IOP was 30.29 ± 7.69 mmHg in the phaco-trab group, and 28.20 ± 4.70 mmHg in the phaco-KDB group, which decreased to 15.64 ± 3.22 mmHg and 17.55 ± 3.34 mmHg, respectively ($P = 0.041$), and the phaco-KDB group required more medications ($P = 0.027$) at the last follow-up. The qualified success rates were 87.5% (phaco-trab) versus 83.8% (phaco-KDB) ($P = 0.604$). No statistically significant progression of VF defects and no serious intraoperative or postoperative complications were noted.

Conclusions: Both KDB goniotomy and trabeculectomy, when combined with phacoemulsification, effectively improve visual acuity, reduce IOP, and stabilize VF. Phaco-KDB is an effective ab interno procedure that achieves a comparable success rate to phaco-trab. Its minimally invasive nature may delay or obviate filtration surgery, simplify the procedure, and offer faster visual rehabilitation.

Abstract No.: 201787

Surgical Outcomes of Trabecular Micro-Bypass Minimally Invasive Glaucoma Surgery in Eyes With High Myopia: A Multi-Centre Study.

First Author: Shi Qi, Natalie **WONG**

Co-Author(s): Bryan Chin Hou **ANG**, Rachel S **CHONG**, Hla Myint **HTOON**, Mitchell **LAWLOR**, Prasanna Venkatesh **RAMESH**

Purpose: To explore the outcomes of trabecular bypass minimally invasive glaucoma surgery in highly myopic (HM) patients.

Methods: A retrospective, observational multicentre study of HM eyes (phakic refractive spherical equivalent $\leq -6D$ or axial length $\geq 26mm$) with mild-moderate primary open-angle glaucoma or ocular hypertension that received iStent injects, or Hydrus Microstents was performed between January 2019 and December 2023.

Results: 252 eyes (207 subjects) across three tertiary ophthalmology centres were enrolled. At 24 months post-surgery, $\geq 20\%$ intraocular pressure (IOP) reduction from baseline with and without glaucoma medications was achieved in 35.8% and 13.4% of eyes in the Hydrus group, and 30.0% and 6.67% of eyes in the iStent group respectively ($p = 0.502$; $p = 0.223$); drop-freedom was achieved in 48.7% and 38.5% of eyes in the Hydrus and iStent groups respectively ($p = 0.248$). IOP $\leq 15mmHg$ with and without glaucoma medications was achieved in 55.2% and 28.4% of eyes

in the Hydrus group, and 63.3% and 21.7% of eyes in the iStent group, respectively ($p=0.391$; $p=0.408$). Kaplan-Meier analysis showed no significant difference between groups for time to failure of maintaining $\geq 20\%$ IOP reduction with (12-month cumulative risk: iStent=89.8%, Hydrus=83.1%, $p=0.0724$) and without glaucoma medications (iStent=92.2%, Hydrus=86.3%, $p=0.0998$). Surgical success, per American Academy of Ophthalmology criteria, was achieved in 61.2% of Hydrus eyes and 53.3% of iStent eyes.

Conclusions: The iStent inject and Hydrus Microstent may achieve lower IOP reduction in HM eyes with comparable complication rates to non-HM eyes. Outcomes appear similar between both implants.

Abstract No.: 206892

Surgical Outcomes of a Non-Valved Glaucoma Drainage Device Compared With Ahmed Glaucoma Valve in Malaysia

First Author: Suyi **SIOW**

Co-Author(s): Roslinah **MUJI**

Purpose: Aurolab Aqueous Drainage Implant (AADI), a prototype based on the Baerveldt Glaucoma Device (BGD), was introduced to Malaysia around 2018. The study aims to examine the efficacy and safety of AADI against Ahmed Glaucoma Valve (AGV) in the management of refractory glaucoma at one year.

Methods: Retrospective analysis of glaucoma patients who either underwent AADI or AGV from January 2021 to December 2022 in Hospital Kuala Lumpur and Hospital Selayang. Primary outcome measures were success rates (intraocular pressure; IOP 6 to 18mmHg) and numbers of post-operative antiglaucoma medications (AGM). Secondary outcome measures include early and late post-operative complications.

Results: Thirty-one patients underwent AADI, while 23 patients underwent AGV implantation. AADI patients were observed to have a significantly lower IOP at 3 and 6 months ($p<0.001$ and $p<0.003$). At 12 months, overall success was 90.3% in the AADI and 65.2% in the AGV group, respectively ($p=0.093$). The AADI group had a significantly lower number of AGMs at 12 months post-operation ($p=0.028$). There were no significant differences in early and late post-operative complications.

Conclusions: AADI is shown to have higher overall success rates while requiring a smaller number of AGMs as compared to AGV. They also have a similar safety profile.

Abstract No.: 205235

Sustained Intraocular Pressure Lowering With a Suprachoroidal Injection of Nanoliposomal Latanoprost in the Rabbit

First Author: Phey Feng **LO**

Co-Author(s): Joanna **BUSOY**, Shamira **PERERA**, Sai Bo **TUN**, Amutha Barathi **VELUCHAMY**, Tina **WONG**

Purpose: Sustained drug delivery allows for maintenance of optimal therapeutic concentrations, increasing bioavailability to targeted tissues, and addressing patient compliance. In glaucoma, the suprachoroidal space is an established anatomical space that can be utilised to lower IOP. Our study investigated the safety and efficacy of a latanoprost-loaded lipid nanoparticle system injected into the suprachoroidal space of a rabbit to lower IOP.

Methods: Dutch-Belt rabbits were randomised to receive a suprachoroidal injection of either a nanoliposomal latanoprost (150 μ l of 2mg/ml) or a blank liposomal nanocarrier. Baseline IOP was recorded before treatment and subsequently measured at set intervals until IOP returned to baseline. Anterior segment photographs, anterior segment optical coherence tomography (AS-OCT), OCT of the macula, and pattern electroretinography (pERG) were all done for monitoring.

Results: There was a 28.3% (5.1 ± 2.12 mmHg) decrease in IOP from baseline at 8 hours post nanoliposomal latanoprost injection, reaching a maximum of 40% (7.7 ± 2.3 mmHg) decrease on Day 5. Significant IOP lowering of at least 20% reduction ($p<0.01$) was sustained until Day 56 before gradually returning to baseline at Day 90. In comparison, eyes that received the blank liposome recorded a maximum IOP lowering of 7.7% (0.9 ± 0.9 mmHg) at Day 7 before returning to baseline by Day 28. Clinical monitoring did not show any adverse events in either group.

Conclusions: The suprachoroidal space is a feasible space that can be explored as an alternative anatomical placement for sustained drug delivery in the treatment of glaucoma.

Abstract No.: 204352

The Analysis of Angle Dysgenesis in Juvenile-Onset Open-Angle Glaucoma

First Author: Huaizhou **WANG**

Co-Author(s): Jinghong **SANG**, Weijia **ZHANG**

Purpose: The purpose of this study was to evaluate different types of angle dysgenesis and clinical features in juvenile-onset open-angle glaucoma patients in China.

Methods: This prospective study recruited consecutive patients diagnosed with JOAG. Patients were classified based on their iris and angle morphology. Age, age of onset, sex, IOP, visual field defect (MD), and vertical C/

D were analyzed and correlated with the gonioscopic features among JOAG patients. All statistical tests were performed using the software SPSS 20.0.

Results: Out of the 202 unrelated patients with JOAG, the study included 139 JOAG patients who had all the phenotypic characteristics required for the study. Only the right eye was included in the analysis. 68% patients had normal angles, while 21% patients had angle dysgenesis high iris insertion (HII), 11% patients had prominent iris processes (PIP). 50% patients had normal iris crypt (NIC), while prominent iris crypt (PIC) was seen among 32% patients, and absence of iris crypt (AIC) among 18% patients. Distribution proportions of the four JOAG clusters: Each cluster accounted for 14.4% to 45.3% of the cohort. Predictor importance analysis of the 4 variables revealed that iris features contributed more significantly to classification than gonioscopic patterns.

Conclusions: Some of the JOAG patients in China have angle dysgenesis and / or abnormal iris features. Cluster analysis extracted four subgroups of the JOAG phenotype that has clinical and prognostic significance and may potentially be helpful in treating JOAG patients in the clinics.

Abstract No.: 202712

The Effect of Epigallocatechin-3-Gallate (EGCG) on Matrix Metalloproteinase-3 (MMP-3) Expression and Fibroblast Migration in Human Tenon Fibroblasts as a Model of Post-Trabeculectomy Wound Healing In Vitro

First Author: Ruth **ANASTASIA**

Co-Author(s): Evelyn **KOMARATIH**, Yulia **PRIMITASARI**

Purpose: This study aimed to evaluate the effects of Epigallocatechin-3-Gallate (EGCG) on Matrix Metalloproteinase-3 (MMP-3) expression and fibroblast migration in human tenon fibroblasts (HTFs) as a model for post-trabeculectomy wound healing in vitro.

Methods: This in vitro true experimental study involved HTF cell cultures divided into four groups: a negative control group (untreated HTFs), a positive control group (treated with MMC 0.4 mg/mL), an EGCG group (treated with 50 μ M EGCG), and a combination group (treated with 50 μ M EGCG and 0.3 mg/mL MMC). Antifibrotic effects were assessed by measuring MMP-3 expression through immunofluorescence and analyzing cell migration rates using a scratch wound assay at 24, 48, and 72 hours.

Results: A significant difference in MMP-3 expression was observed among the four groups ($p < 0.001$). The combination group (50 μ M EGCG and 0.3 mg/mL MMC) showed the lowest MMP-3 expression (19305.54 ± 1630.63), followed by the MMC 0.4 mg/mL group (22876.45 ± 1263.72), the EGCG 50 μ M group (40182.18 ± 2498.39), and the control group (74654.72 ± 3269.02). There was a significant difference among

the four groups at 24, 48, and 72 hours of observation ($p < 0.001$). Migration analysis showed that the combination group had the largest remaining wound area (78.72%) at 72 hours, indicating the lowest fibroblast migration rate, followed by the MMC, EGCG, and control groups.

Conclusions: The findings suggest that both EGCG and MMC, individually and in combination, significantly reduce MMP-3 expression and inhibit fibroblast migration. The combination of EGCG and MMC demonstrated the greatest antifibrotic effect, supporting its potential as a safer alternative adjuvant therapy for reducing post-trabeculectomy fibrosis with minimized side effects.

Abstract No.: 200447

The Effectiveness and Safety of Kahook Dual Blade Assisted Ab Interno Trabeculectomy in Secondary Open-Angle Glaucoma

First Author: Xiang **FAN**

Co-Author(s): Lingling **WU**

Purpose: To explore the effectiveness and safety of Kahook Dual Blade (KDB) assisted Ab interno Trabeculectomy (ABiT) in secondary open-angle glaucoma (SOAG).

Methods: Uncontrolled SOAG patients were consecutively enrolled. KDB-assisted ABiT was performed, and phacoemulsification and intraocular lens implantation (Phaco+IOL) were combined for patients with cataract. Intraocular pressure (IOP) and types of anti-glaucoma medications at different times were compared by the Wilcoxon signed-rank test. Relative success rate was defined as IOP-reduction $\geq 30\%$ or type of anti-glaucoma medication's reduction ≥ 1 at 12 months postoperatively. Safety assessments included anterior chamber hemorrhage within 1 week, IOP Spike within 1 month, and other adverse events within 12 months postoperatively.

Results: 13 patients consisted of 3 pseudoexfoliation syndrome, 3 steroid-induced glaucoma, 3 herpes-zoster-induced SOAG, 2 Posner-Schlossman syndrome, 1 SOAG after silicone-oil-removal and 1 uveitic glaucoma had one-year-follow-up with 3.3 ± 0.2 type of medications and 33.3 ± 4.0 mmHg in IOP preoperatively. 9 patients underwent ABiT, 4 patients combined with Phaco+IOL. Average IOPs on postoperative day 1, week 1, month 1, month 6, and month 12 were 23.9 ± 3.8 mmHg, 17.4 ± 3.4 mmHg, 15.0 ± 1.7 mmHg, 17.8 ± 0.9 mmHg, and 14.4 ± 0.9 mmHg while average types of medications were 1.3 ± 0.1 , 2.3 ± 0.2 , 2.1 ± 0.3 , 1.6 ± 0.3 , and 1.7 ± 0.4 respectively, both significantly lower than preoperative ($p < 0.05$). With 100% relative success rates, there were not any complications except for 4 IOP spikes.

Conclusions: KDB assisted ABiT demonstrated well IOP reduction and could reduce the use of anti-glaucoma medication significantly in SOAG.

Abstract No.: 208346

The Efficacy and Safety of Ultrasound Cyclo Plasty in the Treatment of Secondary Glaucoma in Nanophthalmos

First Author: Yuxia YANG

Co-Author(s): Ming-ming YANG

Purpose: To investigate the efficacy and safety of Ultrasound Cyclo Plasty (UCP) in the treatment of secondary glaucoma in nanophthalmos that is uncontrolled by medication.

Methods: All eyes underwent UCP treatment (10 sectors). The mean preoperative intraocular pressure (IOP) was 45.7 ± 5.2 mmHg, with a mean of 5 types of IOP-lowering medications used. All patients subsequently underwent sequential secondary surgery, comprising phacoemulsification, intraocular lens (IOL) implantation, and goniosynechialysis, within 1-2 months after the UCP procedure. Patients were followed up for 6-24 months, with monitoring of visual acuity, IOP, anterior segment OCT findings, complications, and medication use.

Results: IOP: IOP dropped markedly on day 1 post-op, with a 100% control rate. Visual Acuity: Mean vision improved from the first day. Anterior Segment OCT: Showed clear chamber deepening and partial angle opening. Complications: Three transient choroidal detachments resolved spontaneously; two mild inflammations subsided within a week; three cases of pupil deformation occurred without lasting effects. Medication: Only one eye required one extra drug at six months; all others maintained normal IOP drug-free.

Conclusions: In nanophthalmic glaucoma, single UCP achieved complete IOP control without serious complications. Its non-invasive nature avoids the high risks of conventional surgery, making it ideal for these cases. Subsequent cataract surgery (phaco + IOL + GSL) provided markedly better outcomes than traditional methods.

Abstract No.: 201309

The Mechanism of Elevated Intraocular Pressure-Induced Retinal Ganglion Cell Necroptosis in Glaucoma via TRPV1-Mediated Regulation of RIPK1 Phosphorylation

First Author: Xiaoyu ZHUANG

Co-Author(s): Chenyu FU, Lin FU, Shumeng YAO, Qiaoping YOU, Yuanbo LIANG

Purpose: This study aimed to investigate the hypothesis that elevated intraocular pressure (IOP) induces

retinal ganglion cell (RGC) necroptosis through TRPV1-mediated, calcium-dependent RIPK1 phosphorylation.

Methods: Aimed to investigate the role of TRPV1 and downstream signaling pathways in glaucomatous neural injury by establishing both acute and chronic ocular hypertension animal models. IOP changes were monitored and compared between models. Parallel in vitro experiments involved an R28 retinal cell model subjected to high-pressure insult. Multiple techniques were employed, including immunofluorescence, Western Blot, qPCR, OCT, and ERG, to assess the expression and phosphorylation levels of key molecules such as TRPV1, CaMKII δ , and components of the necroptotic pathway (RIPK1, RIPK3, and MLKL).

Results: One week after induction of acute ocular AOH, a significant reduction in RGC density was observed in the AOH group compared to controls ($P < 0.05$), accompanied by significant microglial activation and proliferation ($P < 0.05$). Molecular analysis revealed a marked upregulation in the expression of TRPV1, CaMKII δ , and key necroptosis pathway proteins (RIPK1, RIPK3, and MLKL) in the AOH group ($P < 0.01$). Notably, treatment with TRPV1 and CaMKII δ inhibitors significantly downregulated the expression of necroptosis-related proteins and attenuated RGC loss. OCT imaging showed a reduction in the thickness of the INL and GCL in AOH retinas, which was significantly ameliorated by inhibitor treatment. Furthermore, ERG recordings indicated a pronounced decrease in response amplitude in the AOH group, with partial functional recovery following inhibitor administration.

Conclusions: We conclude that TRPV1-mediated RIPK1 phosphorylation is a key mechanism in pressure-induced RGC necroptosis, offering a promising new strategy for glaucoma neuroprotection.

Abstract No.: 202325

The Role of Scleral Structural Remodeling in Reducing Optic Disc Stress and Deformation Under High Intraocular Pressure and Its Optic Neuroprotective Mechanism

First Author: Liao LI

Co-Author(s): Duan XUANCHU

Purpose: To develop a rabbit eye finite element model for optimizing scleral excision-thinning parameters, establish hypertensive and scleral excision-thinning models to validate reduced optic disc stress and deformation, and analyze molecular mechanisms underlying scleral remodeling-mediated optic nerve protection, thereby proposing a novel glaucoma therapy.

Methods: A finite element model of the rabbit eye was developed using FEBio to simulate the biomechanical effects of various excision patterns. Chronic ocular hypertension was induced in New Zealand rabbits by anterior chamber injection of photocurable silk

fibroin hydrogel, with subsequent surgical excision-thinning of the scleral tissue. Intraocular pressure, lamina cribrosa depth, and photopic negative response (PhNR) were systematically measured and compared across experimental groups. Histological evaluation included TUNEL staining for apoptosis assessment, electron microscopy for ultrastructural analysis, and immunohistochemistry for detecting expression levels of FGF-2, MMP-2, TIMP-1, and TGF- β .

Results: Scleral excision-thinning significantly reduced IOP from 22.42 ± 5.62 mmHg to 15.42 ± 3.78 mmHg ($P < 0.05$), decreased lamina cribrosa depth, improved PhNR amplitude, and lowered scleral stiffness compared to the hypertension group. Structural improvements included more regular retinal cell arrangement, reduced axonal swelling, diminished myelin damage, and partial reorganization of scleral collagen fibers. Molecular analysis revealed significant downregulation of FGF-2 expression following excision-thinning, while MMP-2, TIMP-1, and TGF- β levels showed no statistically significant alterations.

Conclusions: Scleral excision-thinning effectively attenuates glaucomatous damage by reducing biomechanical strain on the optic disc and modulating extracellular matrix remodeling, representing a promising biomechanical intervention strategy for glaucoma management.

Abstract No.: 203171

The Role of eEF2 in Retinal Ganglion Cell Loss in a Glaucoma Model

First Author: Qiaoping **YOU**

Co-Author(s): Chenyu **FU**, Lin **FU**, Yuanbo **LIANG**, Yijing **PING**, Sen **WANG**, Shumeng **YAO**, Haiyang **ZHANG**, Xiaoyu **ZHUANG**

Purpose: This study aims to investigate the role of eukaryotic elongation factor 2 (eEF2) in retinal ganglion cell (RGC) loss under elevated intraocular pressure (IOP) in a glaucoma model. We hypothesize that eEF2 signaling pathway activation contributes to RGC degeneration.

Methods: Public single-cell RNA sequencing data of adult mouse RGC (GSM3177678, GSM3177677) were analyzed for eEF2 expression. An acute glaucoma model was established in mice by anterior chamber perfusion, achieving IOP >40 mmHg. Retinal function and visual behavior were assessed, along with eEF2 pathway protein and mRNA expression. RGC loss was evaluated via immunofluorescence staining and cell counting in retinal sections. The pathway was validated in in vivo models. Through the ocular hypertension model, RGC loss and activation of the eEF2-related pathway were observed.

Results: Single-cell RNA-seq analysis revealed various RGC subpopulations, all exhibiting strong eEF2 expression, with RGC subtypes displaying elevated

levels. Transcriptome sequencing results showed that compared to the control group, the eEF2 expression was up-regulated in the high-IOP model group, with a statistically significant difference. These findings are in agreement with immunofluorescence staining data. In the glaucoma model, RGC density was significantly reduced in the mid-peripheral and peripheral retina. qPCR and WB indicated elevated eEF2 mRNA and protein levels in the high-IOP group compared to controls.

Conclusions: eEF2 is consistently expressed in RGCs and is upregulated under high-IOP. In vivo models support the involvement of the eEF2 pathway in glaucoma-related RGCs loss. Targeting eEF2 signaling may represent a potential therapeutic strategy for neuroprotection in glaucoma.

Abstract No.: 202728

The Stiffness Changes of Optic Nerve, Retina and Peripapillary Sclera in Chronic Glaucoma Model Rats Were Observed by Atomic Force Microscopy

First Author: Xu **LIU**

Co-Author(s): Huan **DU**, Yuan **HE**

Purpose: Glaucoma is a chronic, irreversible, blinding eye disease. The change of biomechanical properties of intraocular tissues in glaucoma may cause optic nerve injury. The stiffness changes of optic nerve heads (ONH), retina and peripapillary sclera (PPS) in chronic glaucoma model rats were analyzed by atomic force microscopy (AFM) nanoindentation.

Methods: Glaucoma is a chronic, irreversible, blinding eye disease. The change of biomechanical properties of intraocular tissues in glaucoma may cause optic nerve injury. In this preliminary study, the stiffness changes of ONH, retina, and PPS in chronic glaucoma model rats were analyzed by AFM nanoindentation.

Results: The corresponding YME value of ONH showed that the average elastic modulus of the control sample was 140.5Pa, and that of the 2-week high IOP model eye was 226.2Pa, indicating that the elastic modulus of the optic nerve of the 2-week high IOP rats was increased ($P < 0.01$). The corresponding YME value of retina showed that the average value of the control sample was 53.1Pa, that of the 2-week high IOP model was 42.82Pa, that of the 4-week high IOP model was 22.4Pa, and that of the 6-week high IOP model was 33.76Pa. The elastic modulus of retina of rats with high IOP at 2, 4 and 6 weeks decreased significantly ($P < 0.01$). The corresponding YME value of PPS is displayed: The average elastic modulus of the control samples was 3.98kPa, the average elastic modulus of PPS for 4 weeks of IOP was 2.44kPa, and the average elastic modulus of PPS for 6 weeks of IOP was 7.50kPa. The elastic modulus of PPS in rats with IOP was decreased ($P < 0.01$), and the elastic modulus of PPS in rats with IOP was significantly increased ($P < 0.01$).

Conclusions: AFM can be used to characterize the stiffness of intraocular tissue, but further large-scale analysis is needed. Increased YME in ONH early in glaucoma implies increased resistance to deformability of ONH and decreased YME in retina, which may reflect its inherent tissue weakness, making the retina more vulnerable to damage from high intraocular pressure. The YME of PPS decreases in the early and middle stages and increases in the late stages, which may suggest that PPs exerts a protective effect on the optic nerve by adjusting its stiffness. This study may provide a new idea for the neuroprotection of glaucoma from the aspect of biomechanics.

Abstract No.: 205188

The Threshold Value for Predicting Diurnal Intraocular Pressure Variation in Patients With Suspected Normal-Tension Glaucoma

First Author: Pattawee **JONGYINGSIRI**

Co-Author(s): Sunee **CHANSANGPETCH**, Rath **ITTHIPANICHPONG**, Monchai **KOOAKACHAI**, Anita **MANASSAKORN**, Kitiya **RATANAWONGPHAIBUL**, Prin **ROJANAPONGPUN**, Visanee **TANTISEVI**

Purpose: To determine a threshold intraocular pressure (IOP) value that can predict diurnal IOP levels in patients suspected of normal tension glaucoma (NTG), with the goal of improving screening in resource-limited settings.

Methods: This retrospective study reviewed outpatient clinic (OPD) records and diurnal tension clinic (DTC) data collected between 2017 and 2025. Patients older than 40 years with suspected NTG were included if they had baseline IOP measured with a Goldmann applanation tonometer at the OPD and complete IOP data from a rebound tonometer (iCare®) recorded at five DTC time points. Exclusion criteria included previous glaucoma diagnosis, current glaucoma medication use or a washout period < 6 weeks, and previous glaucoma surgery or laser treatment. The optimal Goldmann applanation IOP threshold was identified using receiver operating characteristic (ROC) curve analysis with Youden's index. Logistic regression was performed to assess the association between IOP fluctuation and NTG diagnosis.

Results: A total of 125 eyes from 123 patients were analyzed. Based on diurnal IOP measurements, 109 eyes were diagnosed with NTG and 16 with primary open-angle glaucoma. ROC analysis identified a Goldmann applanation IOP cutoff of 17.0 mmHg for predicting diurnal IOP values ≤ 21 mmHg (sensitivity 77%, specificity 63%, area under the curve 0.70). Lower IOP fluctuation was significantly associated with an increased likelihood of NTG diagnosis (odds ratio 0.514, 95%CI 0.376-0.701; $P < .001$).

Conclusions: A Goldmann applanation IOP threshold of 17 mmHg may serve as a practical screening tool for predicting diurnal IOP values not exceeding 21 mmHg

in settings without access to DTCs, facilitating earlier NTG diagnosis and timely treatment.

Abstract No.: 202340

Time-Series Analysis of the Impact of Air Pollutants on Posner-Schlossman Syndrome Attacks in Hangzhou

First Author: Chenyu **FU**

Co-Author(s): Yuanbo **LIANG**, Zuowei **XIE**, Lin **FU**

Purpose: To investigate the potential association between air pollutants and the attack of Posner-Schlossman Syndrome (PSS) in Hangzhou.

Methods: Outpatient records of PSS patients from Zhejiang Eye Hospital (October 2018–October 2024) and concurrent air pollutant and meteorological data were collected. Generalized Additive Models (GAM) were employed to examine the relationship between pollutant concentrations and PSS attack counts, as well as pollutant lag effects; stratified analyses by season and gender were further performed.

Results: A total of 3,564 PSS-related outpatient visits were recorded, with 660 eligible cases (long-term Hangzhou residents with confirmed PSS onset and elevated intraocular pressure). The attack peak occurred from April to June (221 cases). The single-pollutant model showed: NO_2 had the highest risk, with significant positive correlations with PSS attack at single lags (lag0–5) and cumulative lags (lag01–07) (all $P < 0.05$), peaking at lag05 (RR=1.139, 95% CI: 1.048–1.238); O_3 was positively correlated at single lags (lag0–2) and cumulative lags (lag01–07) (all $P < 0.05$), peaking at lag04 (RR=1.065, 95% CI: 1.022–1.110); $\text{PM}_{2.5}$ and PM_{10} were positively correlated at lag2 (RR=1.074 and 1.040, respectively). For cumulative lags, $\text{PM}_{2.5}$ correlated at lag02–04, and PM_{10} at lag03. Stratified analysis revealed stronger impacts of NO_2 , $\text{PM}_{2.5}$, and PM_{10} on males, and a more pronounced effect of NO_2 in winter.

Conclusions: PSS has two annual attack peaks (April–June and October). Elevated NO_2 , O_3 , $\text{PM}_{2.5}$, and PM_{10} may be positively associated with PSS attack (with evident lag effects), among which NO_2 and O_3 show more prominent associations.

Abstract No.: 205449

To Determine the Target Intraocular Pressure That Needs to Be Achieved to Halt Disease Progression in Primary Angle Closure Glaucoma: The CUPAL Study

First Author: Alicia Hoi Ying **LIU**

Co-Author(s): Annie **LING**, Clement C. **THAM**

Purpose: To determine the target intraocular pressure (IOP) that needs to be achieved to halt disease progression in primary angle closure glaucoma (PACG).

Methods: PACG patients enrolled in the CUHK PACG Longitudinal (CUPAL) study with more than 8 years of follow-up were included in this analysis. IOP was documented every 6 months, and visual field (VF) was assessed with automated perimetry. As in the AGIS study for POAG patients, PACG subjects were categorised by the proportion of visits with IOP >18 mmHg: Group A (<20%, n=293 eyes), B (20-50%, n=86), C (50%-75%, n=24), and D (>75%, n=7). The primary VF outcome was mean deviation (MD), analysed as change from baseline. Independent-sample t-tests were used to compare VF progression between groups.

Results: A total 410 eyes from 205 PACG patients were analysed. Baseline mean age (65.25 years, p=0.247) and gender (male=29.3%, p=0.14) between < and ≥ 18 mmHg groups were insignificantly different. Over follow-up, VF stability of mean MD was observed in Groups A and B (p<0.001), while Groups C and D demonstrated progressive deterioration (Group B vs C, p=0.92; Group C vs D, p=0.06). Group-level mean IOP were 13.94, 17.05, 18.82, and 20.61 mmHg across Groups A to D, respectively. When IOP >18 mmHg in <50% of visits, VF in PACG is stabilised.

Conclusions: These findings may provide clinical guidance for long-term IOP targets in PACG.

Abstract No.: 206764

To Evaluate the Performance of a Bimodal Machine Learning Algorithm That Integrates Handheld Chromatic Pupillometry (HCP) Features With Standard Structural and Functional Clinical Metrics for the Detection of Early-Stage Glaucoma

First Author: Najiya **MEETHAL**

Co-Author(s): Eray **ATALAY**, Raymond **NAJJAR**, Mert Egemen **ÇALIŞKAN**

Purpose: To evaluate the performance of a bimodal machine learning algorithm that integrates handheld chromatic pupillometry (HCP) features with standard structural and functional clinical metrics for the detection of early-stage glaucoma.

Methods: Glaucoma patients (n=51, Age ± SD: 66.1 ± 5.9 years, 45% male) and age-matched controls (n=60, 66.4 ± 11.9 years, 55% male) were recruited for this cross-sectional study. In addition to a thorough clinical examination, participants underwent assessment with the Humphrey Field Analyzer (HFA), Optical Coherence Tomography (OCT), and HCP. Device-specific outcomes were extracted, feature importance evaluated with gradient-boosted trees, and logistic regression classifiers trained to construct single-modality (one device) and bimodal (two devices) models. Performance was assessed using the area under the receiver operating characteristic curve (AUROC), sensitivity, specificity, Akaike Information Criterion (AIC), and odds ratios (OR).

Results: Bimodal models outperformed single-modality classifiers. OCT+HCP achieved the highest performance (AUROC= 0.97, 95%CI: 0.95–1.00; sensitivity= 0.90, specificity= 0.93; AIC = 54.9). OCT+HFA yielded an AUROC of 0.93 (0.89–0.98), while HFA+HCP showed an AUROC of 0.87 (0.80–0.94). Key predictors in the OCT+HCP model were retinal nerve fibre layer thickness (OR: 0.66 (0.37–0.94)), vertical cup-to-disc ratio (OR: 6.2 (0.66–19.9)), and area under the post-illumination pupillary response ratio (OR: 0.76 (0.66–0.87)). Negative predictive values exceeded 0.99 across models, whereas positive predictive values, albeit low (0.33) due to disease prevalence, were highest in the OCT+HCP model.

Conclusions: Integrating HCP with conventional clinical modalities can improve the detection of early glaucoma. These findings underscore the potential of bimodal approaches as objective, non-invasive tools for early glaucoma stratification.

Abstract No.: 202136

Translating Neuroretinal Rim Width Into Progression Risk: A Deep Learning Framework for Normal-Tension Glaucoma

First Author: Tao **WANG**

Co-Author(s): Defu **CHEN**, Yuanbo **LIANG**

Purpose: To develop a high-precision automated model for optic disc and optic cup segmentation, establish a standardized neuroretinal rim width-based analysis system, and evaluate its value in tracking normal-tension glaucoma progression.

Methods: The TransUNet model segmented the optic disc and cup from 3,300 fundus images. Algorithm robustness was tested using coordinate transformation, rim width standard deviation, and test-retest reliability. Patients with visual field progression were classified by baseline mean deviation (MD) into early (MD>-6 dB) or moderate-to-advanced stages (MD ≤ -6 dB). Longitudinal rim width changes were quantified across eight quadrants.

Results: The model achieved cup segmentation sensitivity of 94.7% (Intersection over Union [IoU] 89.0%) and disc segmentation sensitivity of 94.2% (IoU 95.5%). Robustness testing showed a mean standard deviation of 2.64% after coordinate transformation and 1.20% on test-retest. Rim width reduction in early-stage disease was greatest in the temporal-inferior quadrant, while moderate-to-advanced disease showed significant reduction in nasal-inferior and temporal-inferior quadrants. Early-stage progression localized mainly to the temporal-superior and temporal-inferior quadrants, whereas later stages exhibited diffuse involvement. Among eyes with early visual field damage, 68.2% showed rim progression preceding functional loss, compared with 44.0% in moderate-to-advanced disease.

Conclusions: This TransUNet-based rim width analysis method for dynamic quantification of glaucomatous damage reveals distinct rim loss patterns in normal-tension glaucoma. Also, it shows structural changes often precede functional defects in early stages, offering a tool for precise diagnosis and early detection.

Abstract No.: 207272

Treatment Outcomes of Slow Coagulation Trans-Scleral Cyclophotocoagulation for Refractory Glaucoma

First Author: Shalini SHALINI

Co-Author(s): Salwa KAIDAKATH, Meena MENON

Purpose: To Evaluate the outcome and safety of slow coagulation transscleral photocoagulation (TSCPC) in patients with uncontrolled glaucoma.

Methods: Retrospective study of 58 eyes who underwent TSCPC using slow coagulation settings (power settings of 1300-1500 mW and a duration of 3500-4000 ms).

Results: The mean age was 53.86 years, and 62.1% were males. The indications for the laser included Neovascular glaucoma (34.5%), advanced. Primary open/angle closure glaucoma (19%), glaucoma secondary to vitreo-retina surgery (23.8%) or penetrating keratoplasty (23.8%). A statistically significant reduction in intraocular pressure (IOP) from 40.19 to 15.33 mmHg was noted at 6 months. Surgical success was achieved in 82.5 % at 6 months, and 75% in 26 patients followed up to 1 year. The mean antiglaucoma medications (AGM) reduced from 3.72 to 2.35 ($p < .001$). No drop in visual acuity seen in any patient. Some of the few post-procedural complications included sub-conjunctival hemorrhage, hyphema, scleritis which resolved with treatment. Hypotony was recorded in 1 patient and repeat laser was advised in 5 patients

Conclusions: Encouraging safety and efficacy were demonstrated by our study with a noteworthy decrease in IOP and AGM, with insignificant serious complications.

Abstract No.: 204575

Two-Year Outcome of Phacogoniectomy Versus Phacotrabeculectomy for Advanced Primary Angle-Closure Glaucoma With Cataract: A Randomized Controlled Trial

First Author: Yunhe SONG

Purpose: To investigate the two-year effectiveness and safety of phacogoniectomy versus phacotrabeculectomy among patients with advanced primary angle-closure glaucoma (PACG) and cataracts.

Methods: Multicenter, randomized controlled, non-inferiority trial. A total of 124 patients (124 eyes) with advanced PACG and cataracts were enrolled.

One hundred and twelve participants with 112 eyes completed the 2-year follow-up. Participants were randomly assigned in a 1:1 ratio to receive either phacogoniectomy or phacotrabeculectomy. The primary outcome was the reduction in intraocular pressure (IOP) from baseline to final visit postoperatively, for which a non-inferiority margin of 4 mmHg was evaluated. Complete success was defined as a postoperative IOP > 5 and ≤ 18 mmHg and a 20% reduction from baseline without the use of topical medications. Qualified success was similar to that of complete success, allowing the utilization of ocular hypotensive medications.

Results: After 2 years, phacogoniectomy demonstrated non-inferiority to phacotrabeculectomy in terms of IOP reduction, with mean IOP reductions of -24.9 mmHg and -24.8 mmHg ($P = 0.463$), respectively. Both groups experienced a significant reduction in the mean number of medications used postoperatively ($P < 0.001$). For surgery success, 81.4% and 84.6% patients achieved complete success in the phacogoniectomy and phacotrabeculectomy groups at 2 years, respectively ($P = 0.802$). The phacogoniectomy group had a qualified success rate of 94.9% (56 of 59 patients), whereas the phacotrabeculectomy group had a qualified success rate of 88.5% (46 of 52 patients) ($P = 0.301$). No additional adverse events or postoperative complications were observed in both groups.

Conclusions: Phacogoniectomy was non-inferior to phacotrabeculectomy in terms of IOP reduction for advanced PACG and cataracts in a two-year follow-up period. The extended 2-year follow-up results suggested that phacogoniectomy could be considered as a first-line treatment in these patients.

Abstract No.: 202491

Two-Year Outcomes of Gonioscopy-Assisted Transluminal Trabeculotomy (GATT) in Early Childhood Glaucoma in India

First Author: Anchal GERA

Co-Author(s): Sushmita KAUSHIK, Surinder PANDAV, Manik SARDANA, Vyshak SURESH

Purpose: To evaluate the safety and efficacy of Gonioscopy-Assisted Transluminal Trabeculotomy (GATT) in childhood glaucoma and compare outcomes between primary congenital glaucoma (PCG) and non-PCG eyes.

Methods: A prospective cohort study included 40 eyes of 32 patients (< 2 years) with glaucoma treated between January 2021–December 2023 at a tertiary centre in North India, with ≥ 24 months follow-up. Of these, 32 eyes had PCG and 8 had glaucoma associated with non-acquired anomalies. All underwent GATT with 5-0 polypropylene suture cannulation of Schlemm's canal. Surgical success was defined as IOP ≤ 21 mmHg (criterion A) or ≤ 18 mmHg (criterion B) with $\geq 20\%$ reduction from baseline, without additional surgery or

increased medications. Secondary outcomes included the extent of angle treated and complications.

Results: Mean age at surgery was 12.13 ± 14.04 months. Mean IOP reduced from 24.07 ± 9.8 to 15.96 ± 5.4 mmHg at 2 years (33.7% reduction), with medication use declining from 1.78 ± 0.8 to 0.92 ± 1.1 (45% reduction). In PCG eyes, cumulative success rates were 93.75%/87.5% at 1 year and 80.7%/76.9% at 2 years (criteria A/B). Complete 360° GATT achieved 100% and 95% success at 1 year. Non-PCG eyes showed significantly lower success (62.5% at 2 years); none achieved complete 360° treatment. Hyphema occurred in 52.5% and resolved spontaneously in 90.4%. No sight-threatening complications occurred.

Conclusions: GATT demonstrated high safety and efficacy, particularly in PCG. Outcomes correlated with angle extent, highlighting advantages over filtering surgery by preserving conjunctiva for future interventions.

Abstract No.: 203437

Two-Year Outcomes of Goniotomy Following Failed Surgery for Glaucoma: A Multicenter Study

First Author: Dilimulati **XIAOKAITI**

Co-Author(s): Zige **FANG**, Xiulan **ZHANG**

Purpose: To evaluate the two-year outcomes of goniotomy (GT) in patients with prior failed surgery for glaucoma.

Methods: This prospective multicenter study enrolled patients undergoing GT after previous failed glaucoma surgery. Outcome measures included intraocular pressure (IOP) change, medication use, treatment success rate, and postoperative complications over 24 months. Complete success was defined as an IOP of 6-18 mmHg with $\geq 20\%$ reduction from baseline, without medication. Qualified success required similar IOP control with medication. Logistic regression models identified factors affecting surgical success.

Results: A total of 61 eyes of 51 patients were included, with 20 eyes (17 patients) diagnosed with primary open-angle glaucoma and 41 (34 patients) with primary angle-closure glaucoma as their primary condition. The mean age was 60.6 ± 10.6 years, with 30 (58.7%) females. Among these, 26 (42.6%) achieved complete success, and 52 (85.2%) achieved qualified success. The mean IOPs dropped from 26.4 ± 6.2 mmHg preoperatively to 16.3 ± 4.8 mmHg at 24 months (35.8% reduction; $P < 0.001$). Anti-glaucoma medications decreased from 2.6 ± 1.2 to 1.4 ± 1.4 over 24 months ($P < 0.001$). The overall best-corrected visual acuity was stable during the follow-up period ($P = 0.987$). The primary complications observed included hyphema ($n=7$), IOP spikes ($n=6$), mild corneal edema ($n=3$), and shallow anterior chamber ($n=2$), all within the first postoperative month. Regression analysis

revealed that older age was positively correlated with both complete success (OR = 1.06; 95% CI, 1.00-1.12; $P = 0.044$) and qualified success (OR = 1.16; 95% CI, 1.05-1.28; $P = 0.004$). Conversely, the presence of POAG was negatively associated with qualified success rates (OR = 0.18; 95% CI, 0.04-0.84; $P = 0.029$).

Conclusions: GT proves to be a safe and effective procedure for patients with previous failed glaucoma surgery over the 24-month study period.

Abstract No.: 206182

Two-Year Results of the Paul Glaucoma Implant for Patients With Uncontrolled Glaucoma

First Author: Jyri-pekka **KOSKINEN**

Co-Author(s): Mohamed **GENEID**, Mika **HARJU**, Juha **VÄLIMÄKI**

Purpose: To evaluate the 1- and 2-year outcomes of the Paul glaucoma implant (PGI) as primary surgery in patients with uncontrolled glaucoma.

Methods: This prospective single-center study included 80 patients operated on by a single surgeon between January 2022 and September 2023. All cases used a tube ligature technique without intraluminal stenting or antimetabolites. Intraocular pressure (IOP), medications, visual acuity, and surgical success were assessed at 12 and 24 months. Complete success was IOP < 21 , < 18 , or < 15 mmHg with $\geq 20\%$ reduction from baseline without medications or further surgery; qualified success allowed medications.

Results: Baseline mean IOP was 33.4 ± 8.3 mmHg on 4.1 ± 0.9 medications. At 12 and 24 months, IOP was 12.8 ± 4.1 and 11.7 ± 4.4 mmHg with 0.8 ± 1.3 and 0.9 ± 1.1 medications (62% and 65% reduction, $p < 0.001$). Success rates at 12/24 months were 61%/52% (< 21 mmHg), 59%/48% (< 18 mmHg), and 43%/47% (< 15 mmHg) for complete success, and 94%/89%, 90%/82%, and 68%/72% for qualified success. Visual acuity remained stable (LogMAR 0.20 baseline, 0.46 at 12 months, 0.44 at 24 months). Complications occurred in 21 eyes (26%), most commonly choroidal effusion in 16 eyes (20%), of which 2 required drainage; tube erosion (2), tube occlusion by iris (2), and corneal decompensation (1) were rare.

Conclusions: In glaucoma eyes with useful vision, PGI with tube ligature without an intraluminal stent seems to provide significant and sustained IOP lowering with minimal vision-threatening complications through 2 years.

Abstract No.: 204480

Unconventional Inflammatory Markers (Serum Homocysteine, Vitamins B-6, B-12 and Folic Acid) in Prognostication of Primary Open Angle Glaucoma

First Author: Sangeeta **ABROL**

Co-Author(s): Nishi **SATISH**

Purpose: The purpose of this study is to determine if serum Homocysteine, vitamins B6, B12, and folic acid values are affected in primary open-angle glaucoma, to follow up and analyse if these values change according to the progression of POAG.

Methods: This is a prospective analytical study, done in two steps. The sample size statistically calculated was 200 patients with either or both eyes diagnosed as POAG. The duration of the study was 10 months, with the patient being diagnosed as POAG on the first visit. Once the patient was successfully diagnosed, a baseline value of all inflammatory markers was immediately evaluated. All patients were started on therapy and monitored on months 1, 3 and 6. Serum levels of inflammatory markers were taken on each visit and compared for patients who progressed vs patients who did not.

Results: Patients of all three grades were included in this study; the results were stratified according to severity. Patients who progressed according to visual field analysis or RNFL changes showed statistically lower levels of vitamin B12, B6 and folate. Serum Homocysteine levels were statistically higher, however not clinically higher.

Conclusions: With statistically higher levels of serum homocysteine levels and statistically lower levels of vitamin B6, B12 and Folic Acid at 6 months, these simple tests may prove useful for analysis and prevention of glaucoma progression. Awareness has to be created about these markers as they were not clinically significant levels and may be missed easily.

Abstract No.: 205080

Use of an Endoscope-Holding Robot (OQrimo) to Maintain Safe Tube-Endothelial Distance During Preserflo MicroShunt Insertion in Eyes With Opaque Anterior Chambers

First Author: Keisuke **ADACHI**

Co-Author(s): Kenta **ASHIKAGA**, Toshinari **FUNAKI**, Shintaro **NAKAO**

Purpose: Shorter tube-endothelial distance (TED) after Preserflo MicroShunt (PFM) implantation has been associated with decreased corneal endothelial cell density (Ibarz-Barbera et al., Ophthalmology and Therapy, 2022). In this study, we investigated whether using a robotically stabilized intraocular endoscope (OQrimo) enables safe PFM insertion while maintaining

a sufficient TED, even in porcine eyes with artificially induced anterior chamber opacity.

Methods: An experienced surgeon performed all procedures. PFM was inserted into both normal porcine eyes and porcine eyes with opaque anterior chambers using either the conventional blind technique or under visualization with a 25G intraocular endoscope (Machida Endoscope Co., Ltd.). In the endoscopic group, the endoscope was inserted at the 5 o'clock position and secured to visualize the trabecular meshwork. The insertion site and angle of the PFM were adjusted under direct endoscopic visualization. Opaque anterior chamber models were created by placing black-painted soft contact lenses on the cornea. Postoperative TED was measured using anterior segment optical coherence tomography (AS-OCT).

Results: The mean TED was significantly greater in the endoscope-assisted group compared to the non-endoscope-assisted group, both in normal eyes (1.96 ± 0.27 mm vs. 1.13 ± 0.40 mm, $P = 0.009$) and in opaque eyes (1.85 ± 0.32 mm vs. 1.12 ± 0.28 mm, $P = 0.015$).

Conclusions: OQrimo-assisted endoscopic visualization significantly increased TED during PFM insertion, even in eyes with opaque anterior chambers. This technique may contribute to reducing postoperative corneal endothelial cell loss.

Abstract No.: 204099

VEGFC-Mediated Neuroprotection Through Augmented Ocular Lymphatic Transport

First Author: Siting **WU**

Co-Author(s): Yiqing **LI**

Purpose: Recent studies have confirmed the existence of the ocular lymphatic system, but the relationship between glaucoma progression and ocular lymphatic drainage function remains to be characterized.

Methods: COH was induced in 6-8-week-old C57BL/6J mice via anterior chamber injection of in situ-crosslinking hydrogel. Two days prior to COH induction, mice received intravitreal administration of either sterile water or VEGFC (2 μ g). Time-course lymphatic drainage analysis using Evans Blue tracer (10-60 min pre-sacrifice) with subsequent sectioned or 3D optical clearing of ocular tissues and cervical lymph nodes. At 8 weeks after COH, the numbers of survival retinal ganglion cells (RGCs) were counted and stained by RBPMS. Concurrently, immunofluorescence staining was performed to evaluate the expression of GFAP, AQP4 and A β in the retina and optic nerve.

Results: In mice subjected to intracameral hydrogel injection, IOP was significantly elevated one week post-surgery and remained elevated for up to eight weeks. At 8 weeks post COH, VEGFC treatment markedly reduced Evans Blue accumulation in both the retina and optic nerve and enhanced its drainage to the

cervical lymph nodes compared to the injured group. VEGFC administration also significantly promoted RGCs survival. Immunofluorescence analysis revealed increased expression of GFAP and AQP4 in the retina and optic nerve of the injured group. Furthermore, VEGFC treatment partially preserved visual function in mice with chronic ocular hypertension.

Conclusions: Ocular lymphatic drainage was impaired in the mouse model of chronic ocular hypertension. VEGFC treatment enhanced Evans Blue clearance to the cervical lymph nodes, and significantly promoted RGC survival and preserved visual function.

Abstract No.: 204514

Validation of Smartphone-Based Gonioimaging Technique: Direct Imaging of Goniomirror by Smartphone (DIGS Pro)

First Author: Nilesh KUMAR

Purpose: Direct Imaging of Goniomirror by Smartphone (DIGS Pro) is a frugal, innovative slit-lamp device to obtain gonio-images. It utilises a gonio-mirror and a smartphone for the imaging. To validate the anterior chamber grading done on the images obtained with a 4-mirror gonio-lens using DIGS by comparing with the gold standard gonioscopy by Slit-lamp examination and imaging.

Methods: Gonioscopy was performed by a single masked physician. A sequential imaging of 70 eyes was done by the same physician for both DIGS Pro and Slit-Lamp Imaging in a masked fashion. The images were then compared to the gold standard slit-lamp gonioscopy by the same physician and graded in masked fashion by two physicians.

Results: Out of 280 images obtained, 250 were found to be of gradable quality. The intra-observer agreement (between DIGS Pro and Slit-Lamp Gonio-imaging) was 84.0% with Cohen's kappa 0.65, which signified substantial agreement. The interobserver agreement between two physicians for the grading of gonio-imaging using DIGS Pro was 92.4% with Cohen's Kappa 0.71, which signified substantial agreement.

Conclusions: The DIGS Pro technique provides a reliable, low-cost alternative for gonio-imaging without a slit-lamp. Substantial intra-observer and inter-observer agreement with conventional gonioscopy underscores its validity for anterior chamber angle assessment. Given its portability, affordability, and ease of use, DIGS Pro has the potential to enhance glaucoma screening and monitoring, especially in resource-constrained or outreach settings.

Abstract No.: 205779

Visual Impairment and Mortality in Older U.S. Adults: Roles of Physical Activity and Depression

First Author: Jingjing HUANG

Co-Author(s): Zhonghua LUO

Purpose: To examine the association between visual impairment (VI) and all-cause mortality in older U.S. adults and assess potential mediation by physical activity (PA) and mental health.

Methods: A prospective cohort of 2,154 adults aged ≥ 60 from NHANES 2007-2008 was analyzed. Participants were included and categorized by VI status based on self-reported visual function and objective visual acuity examination. Cox regression (adjusted for demographic, anthropometric, socioeconomic, and clinical factors), propensity score matching, and subgroup analyses assessed the association between VI and all-cause mortality. Mediation analyses evaluated direct and indirect effects via PA and mental health.

Results: The 2154 included participants represent a survey-weighted 51 million older U.S. adults. Over a median follow-up of 145.0 months, 399 (57.8%) deaths occurred in the VI group and 535 (34.6%) in the non-VI group. VI was associated with an increased risk of all-cause mortality after propensity score matching and adjusting for sociodemographic, clinical, and lifestyle factors (fully adjusted HR, 1.21; 95% CI, 1.04-1.41; $P = 0.012$). In subgroup analyses, subjective VI was significantly associated with mortality (fully adjusted HR, 1.33; 95% CI, 1.13-1.57; $P < 0.001$), whereas objective VI alone was not. Mediation analyses indicated that PA accounted for 9.4% of the association between VI and all-cause mortality, but depressive symptoms were not a significant mediator.

Conclusions: In this nationally representative cohort, VI was independently associated with higher all-cause mortality in older U.S. adults. Subjective VI appeared more predictive of survival than objective acuity loss. Reduced PA partially mediated this association.

Abstract No.: 201320

Visual and Surgical Outcomes of Mitomycin-C Augmented Combined Non-Penetrating Deep Sclerectomy and Phacoemulsification in Eyes With End-Stage Glaucoma

First Author: Jyotish Kumar KHILAR

Co-Author(s): Sharmila REDDY

Purpose: To report the surgical outcomes of MMC augmented NPDS and phacoemulsification in patients with co-existing cataract & end-stage glaucoma.

Methods: Retrospective analysis of 349 eyes of 320 patients who underwent combined NPDS+phaco surgery was included. Outcome measures BCVA, IOP, AGM (anti-glaucoma medication), and compared intra-

and post-operative complications and interventions were noted. Cumulative failure rate was defined as IOP >21 mmHg or not reduced by at least 20% below baseline; or IOP < 6mmHg on 2 consecutive follow-up visits, re-surgery for high IOP or a surgical complication, or loss of PL.

Results: Significant post-op reduction in mean IOP was noted from baseline of 17.54(5.43) to 15.10(5.34) & 16.23(6.87) mmHg at 6 months & 1 year, respectively. Number of AGM reduced significantly from 2.95(1.01) to 1.99(0.98) & 2.16(1.00) at 6 & 12 months respectively. Complications were seen in 17.8% patients, and most were related to poor IOP control (8.3%). 2(0.6%) patients underwent tube surgery & 3 (0.9%) underwent diode CPC for refractory high IOP. Cumulative surgical success was 91% and 84% at 1& 2 years, respectively.

Conclusions: This method is a safe & viable option for eyes with advanced glaucoma.

Abstract No.: 203301

$\gamma\delta$ T Cell-Mediated Neuroimmune Dysregulation in Glaucomatous Optic Nerve Injury

First Author: Jiahao XU

Co-Author(s): Xuanchu DUAN, Xiaoyu ZHOU

Purpose: Elucidating the intraocular pressure-independent neurodegenerative mechanisms is a key issue in glaucoma treatment. As an important subset bridging innate and adaptive immunity, the role of $\gamma\delta$ T cells in glaucoma remains unclear. This study aims to uncover the mechanism by which $\gamma\delta$ T cells mediate immune-neural interactions in primary open-angle glaucoma (POAG) and evaluate their potential as a therapeutic target.

Methods: A two-sample Mendelian randomization analysis was employed to assess the genetic associations between immune cells and POAG. Peripheral blood mononuclear cells (PBMCs) were isolated from three POAG patients and three age- and gender-matched healthy controls using Ficoll density gradient centrifugation, followed by high-throughput single-cell transcriptome sequencing on the SeekOne® microfluidic platform. Additionally, retinal tissues were collected from the DBA/2J spontaneous glaucoma mouse model during the normal intraocular pressure phase (4 months old) and the optic nerve degeneration phase (14 months old) for single-cell transcriptome sequencing.

Results: A total of 39 immune cell phenotypes associated with POAG pathogenesis were identified ($P < 0.05$), with T cell-related phenotypes being the most prevalent. Among these, $\gamma\delta$ T cells were identified as the most significant risk factor for POAG (OR = 1.089, $P = 6.78 \times 10^{-4}$). Single-cell transcriptome analysis revealed significant upregulation of GZMK expression in

peripheral blood $\gamma\delta$ T cells of POAG patients. This gene encodes granzyme K, which may be involved in vascular injury processes. In the animal model, 14-month-old DBA/2J mice exhibited significant disorganization of optic nerve axon structures and a reduction in retinal ganglion cell numbers compared to age-matched C57 mice and 4-month-old DBA/2J mice, along with increased $\gamma\delta$ T cell infiltration in the retina. CellChat cell communication analysis further demonstrated that both the number and intensity of signal interactions between $\gamma\delta$ T cells and microglia were significantly enhanced in the retinas of 14-month-old DBA/2J mice, with notable enrichment of the SEMA3 signaling pathway.

Conclusions: $\gamma\delta$ T cells may drive glaucomatous optic nerve injury through dual mechanisms: peripheral (GZMK-mediated blood-retinal barrier disruption) and central (SEMA3 signaling-triggered neuroinflammation). Targeting this signaling axis could provide a novel neuroprotective therapeutic strategy for glaucoma.

Intraocular Inflammation, Uveitis and Scleritis

Abstract No.: 207654

18 β -Glycyrrhetic Acid Reshapes Ocular Immunity and Attenuates Autoimmune Uveitis by Restraining Th1/Th17 Responses

First Author: Lin DU

Co-Author(s): Wai Kit CHU, Bo Man HO, Chi Pui PANG

Purpose: To test whether 18 β -Glycyrrhetic acid (GA) mitigates experimental autoimmune uveitis (EAU) by reducing pathogenic T-cell activity and remodeling ocular immune infiltration.

Methods: EAU was induced in C57BL/6 mice by immunization with hIRBP650-671 in CFA. Mice received oral GA (100 mg kg⁻¹, every other day, days 1–20) or vehicle. Longitudinal disease assessment included fundus/cSLO, OCT, and ERG. At days 11, 14, 17, and 20 post-immunization, ocular leukocytes were profiled by flow cytometry to quantify total CD45+ cells, retinal microglia (CD45intP2RY12+), and infiltrating immune subsets. CD4+ T-cell phenotypes and effector function were evaluated by intracellular staining for IFN γ and IL-17A. Absolute counts and proportional compositions were analyzed across timepoints.

Results: GA delayed clinical onset and reduced peak disease severity, with preservation of retinal function on ERG. GA lowered total intraocular CD45+ leukocyte burden from mid to late disease and blunted the expansion of CD4+ T cells that typically predominates after day 14. While microglial absolute numbers were largely unchanged, their relative proportion increased,

consistent with reduced recruitment of peripheral leukocytes. Frequencies of IFN γ + and IL-17A+ CD4+ T cells were decreased in GA-treated eyes, indicating suppression of canonical Th1/Th17 effector programs. Early myeloid dominance of the infiltrate was preserved, whereas GA tempered subsequent T-cell-driven amplification of inflammation.

Conclusions: GA ameliorates autoimmune ocular inflammation by restraining intraocular Th1/Th17 responses and reshaping the immune ecosystem, leading to reduced leukocyte burden and preserved retinal function. These findings support GA as a potential steroid-sparing immunomodulator; its activity is consistent with redox-linked, NF- κ B-modulating control of T-cell pathogenicity.

Abstract No.: 204286

A Case of *Pantoea ananatis* Endophthalmitis by Metagenomic Next-Generation Sequencing and 4-Year Follow-Up

First Author: Yuting **CAI**

Co-Author(s): Yun **LI**, Ziyang **LI**, Yingqian **PENG**

Purpose: To report the first documented case of *Pantoea ananatis*-induced endophthalmitis in a pediatric patient and highlight the role of metagenomic next-generation sequencing (mNGS) in pathogen identification, antibiotic sensitivity prediction, and clinical decision-making.

Methods: Case report of a 13-year-old girl initially managed as uveitis, diagnosed by aqueous humor mNGS analysis and confirmatory PCR and Sanger sequencing, cured by vitrectomy and antibiotics application.

Results: mNGS detected *Pantoea ananatis* (17,053 reads) in aqueous humor, revising the diagnosis to infective endophthalmitis. Targeted PCR (acxB, tssI, tssH) and sequencing confirmed pathogen identity. Despite its low virulence, the infection progressed insidiously following steroid therapy. Timely diagnosis and tailored treatment stabilized best-corrected visual acuity (BCVA) over a 4-year follow-up.

Conclusions: This represents the first report of *Pantoea ananatis* as an endophthalmitis pathogen. The case underscores diagnostic challenges in distinguishing inflammation from infection in an atypical, incooperative pediatric population. mNGS provides critical and rapid pathogen identification, guiding antibiotic strategies, and optimizing outcomes in complex ocular infections.

Abstract No.: 204074

A Computable Phenotype for HSV Anterior Uveitis: Operationalizing the SUN Classification Criteria Employing the OMOP Common Data Model

First Author: Brian **TOY**

Purpose: Uveitis Classification Criteria were developed in 2021 by the Standardization of Uveitis Nomenclature (SUN) Working Group. These criteria have the potential to be useful in the identification of patients for observational research. Real-life applications can be labor-intensive, and there is a current unmet need for efficient application of computable phenotypes for uveitis in real-world data. To streamline data integration and analysis across multiple databases, this study operationalized a computable phenotype for the SUN classification criteria for herpes simplex virus (HSV) anterior uveitis within the Observational Medical Outcomes Partnership (OMOP) Common Data Model (CDM) and applied it to two electronic health records (EHR) systems and one claims database.

Methods: Using the Observational Health Data Sciences and Informatics (OHDSI) ATLAS tool, we constructed a computable phenotype for HSV anterior uveitis, applied it to two electronic health records (EHR) systems for internal validation, and to Optum's Clinformatics® claims database for external validation.

Results: In EHR manual chart reviews, we identified 5,404 and 38 patients at two sites, achieving 70% and 90% accuracy, respectively, in a randomized validation sample. From the claims database, 10,858 (2.7%) patients met all criteria, consistent with previous literature. The most discriminatory inclusion criterion was a history of HSV keratitis.

Conclusions: Our results indicate that OMOP can accurately represent the SUN classification criteria for HSV anterior uveitis across disparate databases, suggesting potential utility for operationalizing other uveitis subtypes in observational research.

Abstract No.: 205514

Apolipoprotein A1 Modulates Teff/Treg Balance Through Scavenger Receptor Class B Type I-Dependent Mechanisms in Experimental Autoimmune Uveitis

First Author: Haixiang **HUANG**

Purpose: Experimental autoimmune uveitis (EAU) is a representative animal model of human uveitis. In this study, we investigated whether apolipoprotein A1 (APOA1) can alleviate EAU and explored its underlying mechanism.

Methods: Mice were immunized with interphotoreceptor retinoid-binding protein 1-20 and treated with APOA1 or vehicle. The retinas, draining lymph nodes (DLNs), and spleens were

analyzed. Isolated T cells were used for proliferation, differentiation, and function assays in vitro. Selective inhibitors and pathway agonists were used to study signaling pathways. The effect of APOA1 on peripheral blood mononuclear cells (PBMCs) from uveitis patients was also examined.

Results: Administration of APOA1 ameliorated EAU. APOA1 suppressed pathogenic CD4+ T cell expansion in DLNs and spleen, and decreased the infiltration of effector T (Teff) cells into the retina. APOA1 also inhibited T cell proliferation and T helper 1 cell differentiation in vitro and promoted regulatory T (Treg) cell differentiation. APOA1 restricted inflammatory cytokine production from lipopolysaccharide-stimulated PBMCs. Mechanistic studies revealed that the effect of APOA1 was mediated by scavenger receptor class B type I (SR-BI) and downstream signals including phosphatidylinositol 3-kinase/Protein kinase B (PKB, or Akt), p38 mitogen-activated protein kinase, and nuclear factor- κ B.

Conclusions: APOA1 ameliorates EAU by regulating the Teff/Treg partially through SR-BI. Our results suggest that APOA1 can be a therapeutic alternative for autoimmune uveitis.

Abstract No.: 206417

Association Between Glucose-6-Phosphate Dehydrogenase (G6PD) Deficiency and Systemic Autoimmune Diseases With Immunopathological Ocular Manifestations

First Author: Kit Fai **LAU**

Co-Author(s): Kam Lung, Kelvin **CHONG**, Ka Hei, Kenneth **LAI**, Chi Pui, Calvin **PANG**, Yi Ching **PO**, Chee Yung, Clement **THAM**

Purpose: To systematically review the potential association between glucose-6-phosphate dehydrogenase (G6PD) deficiency and systemic autoimmune diseases presenting immunopathological ocular manifestations. We aim to integrate the latest findings and bridge the knowledge gap between G6PD deficiency and eye-specific autoimmune complications.

Methods: Between June 2 and June 19, 2025, a literature search was conducted across four electronic databases: PubMed, Medline, Google Scholar, and Web of Science. Without restriction on the date of publication, only articles published in English were screened. In compliance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines, articles from all four databases were screened, retrieved, and assessed for eligibility. Articles were first screened independently by the two investigators, followed by a cross-checking process. Ultimately, this systematic review included only articles that were useful and relevant. An officially published record of this systematic review is available on Prospero (CRD420251073065).

Results: Among the 142 articles initially screened, 11 relevant articles documenting the relationship between G6PD deficiency and systemic autoimmune diseases that induce ocular manifestations were eventually included. There are two cohort studies, three case-control studies, two retrospective data analyses, one narrative review, one retrospective chart review, and two case reports.

Conclusions: It is reported that a positive correlation exists between G6PD deficiency and an individual's susceptibility to various systemic autoimmune diseases, which frequently manifest with secondary ocular complications due to dysregulated inflammatory responses that attack the eyes and ocular adnexa. However, there is currently no clear association between G6PD deficiency and primary idiopathic autoimmune ocular diseases.

Abstract No.: 205396

Bilateral Acute Panuveitis From Presumptive Ocular Tuberculosis in a Young Adult Woman With Antecedent Tuberculous Meningitis

First Author: Bryan Vincent **MESINA**

Co-Author(s): Josept Mari **POBLETE**

Purpose: Tuberculous uveitis is an uncommon manifestation of systemic tuberculous infection. Ocular involvement may occur through direct infiltration, hematogenous spread, or immune-mediated mechanisms.

Methods: We report a case of bilateral acute panuveitis in a young Filipino woman with antecedent tuberculous meningitis.

Results: A 32-year-old woman presented with a two-week history of headache, fever, dizziness, malaise, and vomiting. One week later, she developed sudden bilateral blurred vision with eye redness and floaters. Neuroimaging and cerebrospinal fluid analysis were performed, confirming tuberculous meningitis. Ocular examination revealed visual acuity of hand motions in both eyes, mild anterior chamber reaction, keratic precipitates, moderate vitritis, optic disc edema, and severe retinal vasculitis involving all retinal vessels. Extensive infectious and immunologic work-up supported a diagnosis of bilateral acute panuveitis from presumptive ocular tuberculosis. The patient was started on anti-tuberculous therapy with adjunctive systemic and topical corticosteroids. After four months of treatment, visual acuity improved to 6/12 in both eyes.

Conclusions: Definitive diagnosis of ocular tuberculosis remains challenging, particularly in resource-limited settings where specific testing is not readily available. This case highlights the importance of maintaining a high index of suspicion and performing comprehensive clinical and diagnostic evaluation to enable prompt

recognition and management of presumptive tuberculous uveitis.

Abstract No.: 205367

Bilateral Anterior Uveitis After Anti-Adhesion Agent Use in Obstetric and Gynecologic Surgery: A Case Series

First Author: Ivone **CAROLINE**

Purpose: We report a rare case series of bilateral anterior uveitis associated with Mediclore use, a thermo-sensitive anti-adhesion agent composed of poloxamer, gelatin, and chitosan, in Obstetric and Gynecologic Surgery.

Methods: Retrospective case series of patients from the Obstetrics and Gynecology service who developed acute anterior uveitis after intraoperative Mediclore use (April 2023–March 2024). Clinical data included demographics, surgery type, time to symptom onset, ocular findings, treatment, laboratory work-up, and one-week outcomes.

Results: Nine female patients (mean age 39.2 years; range 30–51) were included; five underwent Caesarean section and four underwent TAH/BSO (one with appendectomy). Ocular symptoms began on postoperative day 1–2 in all cases. Intraocular pressure was normal; inflammation was mild and anterior, often bilateral; initial visual acuity ranged 0.5–1.0. Management consisted of topical corticosteroids (dexamethasone, prednisolone acetate, or fluorometholone) with mydriatics when indicated; no systemic immunosuppression was used. Serologic screening excluded active infections (e.g., syphilis, toxoplasma, rubella, HIV, HBV/HCV, CMV). At one week, all patients showed resolution with visual acuity of 1.0 and no persistent inflammation. Causality assessment using the Naranjo Adverse Drug Reaction Probability Scale classified the association as probable (score = 6).

Conclusions: Postoperative, mild anterior uveitis with rapid, complete recovery was observed after Mediclore use, yielding a probable drug induced uveitis signal on standardized causality assessment. While outcomes were favorable with topical therapy, clinicians should recognize this potential association, ensure appropriate screening to exclude mimickers, and counsel patients accordingly.

Abstract No.: 204849

Characterization of Intraocular Microbiome-Immune Microenvironment in Age-Related Macular Degeneration

First Author: Yinhan **WANG**

Co-Author(s): Youxin **CHEN**, Qianyi **YU**, Xinyu **ZHAO**

Purpose: Emerging evidence supports the presence of an intraocular microbiome with disease-specific patterns, yet its contribution to age-related macular

degeneration (AMD) remains unclear. This study was designed to characterize the intraocular microbiome in AMD and elucidate its association with the local inflammatory microenvironment and clinical features.

Methods: A total of 41 treatment-naïve wet AMD (wAMD) patients and 33 cataract controls were enrolled. Aqueous humor samples underwent 5R 16s rDNA sequencing to profile the intraocular microbiome and identify differentially abundant microbial genera, which were correlated with clinical characteristics. Co-occurrence networks of high-abundance microbiota were constructed to investigate microbial interactions, while paired cytokine profiling assessed links to the inflammatory microenvironment.

Results: Both groups were dominated by Proteobacteria, Actinobacteria, Firmicutes, and Bacteroidetes, but exhibited distinct β -diversity and genus-level composition. wAMD was enriched in Bacteroides, Alistipes, Bilophila, Enterococcus, and Allobaculum, with Bilophila, Alistipes, and Allobaculum serving as key nodes in the microbial network. Bilophila abundance correlated negatively with IL-1ra (Spearman $r=-0.315$, $P=0.045$) and pigment epithelium detachment maximum diameter (Spearman $r=-0.620$, $P=0.010$), Enterococcus with MIP-1 α (Spearman $r=-0.359$, $P=0.021$), and Alistipes with central retinal thickness (Spearman $r=-0.700$, $P=0.004$). Both Bilophila and Bacteroides were enriched in type 2 macular neovascularization ($P=0.045/P=0.004$) and anti-VEGF treatment good responders ($P=0.041/P=0.030$).

Conclusions: wAMD is featured with a distinct intraocular microbiome linked to local inflammation and clinical phenotypes. Specific microbial genus, particularly Bilophila and Bacteroides, may represent candidate biomarkers for disease subtyping and treatment response. The relationship between Bilophila enrichment and reduced IL-1ra suggests a potential proinflammatory role, while further studies should be conducted to elucidate the mechanism.

Abstract No.: 205245

Clinical Efficacy of the 0.18 mg Fluocinolone Acetonide Intravitreal Implant for Non-Infectious Uveitis-Associated Macular Edema: A Real-World Study

First Author: Cong **CHEN**

Co-Author(s): Yanpng **SONG**, Ming **YAN**, Wenjing **ZHANG**

Purpose: To evaluate the clinical efficacy and safety of the 0.18 mg fluocinolone acetonide intravitreal implant (FAi) in Chinese patients with macular edema (ME) secondary to non-infectious uveitis (NIU).

Methods: This single-center, retrospective case series study included patients diagnosed with NIU-associated ME who received an intravitreal injection of the 0.18 mg FAi at our ophthalmology department between

January 2024 and September 2024. All patients were followed for at least 12 months. The main outcome measures included changes in best-corrected visual acuity (BCVA, converted to logMAR values), intraocular pressure (IOP), central macular thickness (CMT), and subfoveal choroidal thickness (SFCT) from baseline to 1, 3, 6, and 12 months post-injection. Rates of inflammatory recurrence and treatment-related adverse events were also recorded. Statistical comparisons were performed using repeated-measures analysis of variance.

Results: A total of 39 patients (50 eyes) with a mean age of 54.6 ± 14.8 years were enrolled. The mean baseline BCVA (logMAR) was 0.65 ± 0.33 , and the mean baseline CMT was 333.4 ± 108.6 μm . BCVA showed significant improvement from baseline at all postoperative time points ($P < 0.01$), decreasing to 0.48 ± 0.31 at 12 months. CMT demonstrated a continuous and significant decreasing trend post-injection ($P < 0.01$), reducing to 239.7 ± 54.4 μm at month 12. SFCT also decreased significantly compared to baseline ($P < 0.01$). A statistically significant increase in IOP from baseline was observed ($P < 0.01$); however, elevated IOP was effectively controlled with medication or laser/surgical intervention in the vast majority of cases (36%). The inflammatory recurrence rate within the 12-month follow-up period was 14% (7/50 eyes). Migration of the FAi into the anterior chamber occurred in one eye. No other serious ocular complications or systemic adverse events were observed.

Conclusions: In this real-world study, the 0.18 mg fluocinolone acetonide intravitreal implant effectively improved visual acuity, reduced macular edema, and attenuated choroidal inflammation in patients with NIU-associated ME. The primary risk was manageable IOP elevation, with an overall favorable safety profile. It represents an effective long-term treatment option for Chinese patients with this condition.

Abstract No.: 202940

Clinical Profile and OCT Characteristics of Optic Disc Toxoplasmosis

First Author: Dhwanee **AGARWAL**

Co-Author(s): Vishal Sanjay **JADHAV**, Anup **KELGAONKAR**, Anamika **PATEL**, Avinash **PATHENGAY**

Purpose: To characterize the clinical and OCT features of optic disc toxoplasmosis at presentation and study the associated pattern-based visual prognosis.

Methods: A retrospective, observational, cross-sectional single-center study at a tertiary eye center (September 2015- November 2024) included patients with clinically diagnosed ODT having baseline optic nerve head (ONH) OCT. The data included demographics, clinical findings, and OCT features at presentation.

Results: Thirty-two patients (mean age 31.87 ± 10.94 years; 17–62 years) were included: 21 primary, four recurrences, and seven reactivations; two were HIVpositive. Over 40% had anterior uveitis. Lesions were predominantly juxtapapillary (75%), unifocal (84%), and superotemporal (60%), with bright yellow coloration (34%) and illdefined margins (46%). Disc edema (71%) and skip vasculitis (68%) were frequent. OCT (30 patients) revealed fullthickness retinitis (96%), hyperreflective dots (83%), vitreous adhesions (86%), and neurosensory detachment (63%).

Conclusions: ODT resembles classic OT but shows characteristic changes at the vitreoretinal interface and macula on OCT at baseline. Recognizing these patterns helps in the diagnosis and management of ODT.

Abstract No.: 204263

Corticosteroid-First Versus QuantiFERON-Guided Upfront Anti-Tuberculosis Therapy in Presumed Ocular Tuberculosis: A Retrospective Cohort Pilot Study in BCG-Vaccinated, TB-Endemic Low-Resource Settings

First Author: Mayjane Joan **TUMULAK**

Purpose: To compare outcomes of QFT-guided upfront ATT versus corticosteroid-first followed by ATT in OTB, and to assess the impact of TST-QFT discordance in a BCG-vaccinated, TB-endemic, low-resource population.

Methods: We retrospectively reviewed 28 eyes from 21 QFT-positive OTB patients in a uveitis clinic. Eyes were grouped as upfront ATT ($n=16$) and Steroid-first $\rightarrow$ ATT ($n=12$). Outcomes included ≥ 2 line BCVA improvement, inflammation resolution, overall treatment response, and change in logMAR BCVA. TST-QFT discordance was defined as TST-negative but QFT-positive. Fisher's exact test, risk ratios with 95%CI, Mann-Whitney U, and Spearman's correlation were applied.

Results: Upfront ATT eyes showed higher ≥ 2 -line BCVA improvement (56% vs 33%) and universal inflammation resolution (100% vs 83%), though differences were not statistically significant. In the steroid-first eyes, referral delay (median 4.5 months) negatively correlated with visual improvement ($p=-0.59$, $p=0.044$). TST-QFT discordance was prevalent (82%). Discordant (TST-/QFT+) eyes responded robustly to ATT, with 100% inflammation resolution versus 60% in concordant eyes ($p=0.018$; RR 1.67; 95% CI 1.10-2.53).

Conclusions: In a BCG-vaccinated, TB-endemic, low-resource setting, TST frequently fails to detect OTB while QFT identifies cases that respond to ATT. Upfront QFT-guided ATT avoids harmful steroid delays and supports prioritising QFT access in diagnostic protocols.

Abstract No.: 204442

Costunolide Ameliorates Autoimmune Uveitis Through Inhibition of TRAF1 Deubiquitination and TNF- α -Induced Retinal Endothelial Inflammation by Targeting USP15

First Author: Yu **GAO**

Co-Author(s): Peizeng **YANG**

Purpose: The study aims to characterize the role of tumor necrosis factor- α (TNF- α) in inducing retinal endothelial inflammation and to identify an effective agent that can alleviate retinal endothelial dysfunction through screening of terpene compounds and to explore the specific mechanisms, providing new targets for the treatment of autoimmune uveitis.

Methods: Firstly, we used proteomics to profile the inflammatory response of human retinal microvascular endothelial cells (HRMECs) to TNF- α . A library of 336 terpenoids was screened to explore an effective compound alleviating retinal endothelial inflammation by immunofluorescence. Experimental autoimmune uveitis (EAU) was induced in mice to validate the therapeutic effect of the lead compound. Further, we used a 20K microarray to screen for a direct target of the lead compound. Finally, molecular docking, molecular dynamics, and lentivirus infection were performed to investigate the specific mechanism how the compound exerts its effects.

Results: TNF- α strongly triggers cellular inflammation in retinal endothelial cells. Costunolide (COS) is a potent suppressor of TNF- α -induced endothelial inflammation. In EAU mice, COS treatment improved clinical and histological scores, accompanied by reduced endothelial adhesion molecule expression and decreased T-cell infiltration. Mechanistically, directly targeting USP15, COS inhibited USP15-dependent deubiquitination of TRAF1 and TNF signaling in retinal endothelial cells.

Conclusions: COS plays a vital role in alleviating TNF- α -induced endothelial inflammation and autoimmune uveitis by suppressing USP15-dependent deubiquitination of TRAF1 and blocking T cell infiltration.

Abstract No.: 205881

Current Update on Clinical Spectrum, Diagnostic Challenges, and Management of Tuberculosis-Associated Ocular Surface Inflammation: A Systematic Review

First Author: Erica **WIDODO**

Co-Author(s): Tifanni **EXCELINDA**, Rina **LA DISTIA**, Ikhwanuliman **PUTERA**

Purpose: To systematically review the clinical spectrum, diagnostic challenges, and treatment outcomes of ocular surface inflammation associated with Mycobacterium tuberculosis (Mtb).

Methods: We searched PubMed/MEDLINE, Google Scholar, Epistemonikos, Cochrane Library, and ScienceDirect through February 22, 2025. Eligible studies reporting ocular surface inflammation in tuberculosis (TB) were included. Data on clinical presentation, systemic associations, diagnostic modalities, treatments, and outcomes were extracted and comprehensively analyzed.

Results: Thirty-four studies with 293 patients were analyzed. Ocular surface manifestations included keratitis/keratouveitis, keratoconjunctivitis, sclerokeratitis, scleritis/episcleritis, conjunctivitis, and sclerokeratoconjunctivitis. Diagnosis was primarily presumptive via tuberculin skin test or interferon-gamma release assay. However, a subset of patients at each anatomical site of involvement may have confirmed systemic TB or Mtb isolation from ocular specimens. Corneal involvement was aggressive and ulcerative during active TB, whereas immune-mediated keratitis was milder. Scleral disease had the highest microbiological confirmation rate, with necrotizing variants strongly linked to systemic infection. A full course of anti-tuberculous therapy (ATT) is fundamental, supplemented with topical and/or systemic corticosteroids based on disease severity and location. Recurrence of inflammation may occur in inadequately treated cases.

Conclusions: The clinical spectrum of TB-associated ocular surface inflammation is highly heterogeneous. Certain clinical features may increase the likelihood of active TB infection. A cautious and systematic workup is essential to detect active TB, and analysis of local ocular specimens should not be overlooked. Regarding treatment, ATT remains the cornerstone, with corticosteroids (local and systemic) tailored to disease severity and anatomical involvement.

Abstract No.: 201139

Demography, Risk Factors and Clinical Outcomes for Uveitic Glaucoma in a Multiethnic Malaysian Cohort – a Multicentric Study

First Author: Xu Kent **PEE**

Co-Author(s): Nor Azita **AHMAD TARMIDZI**, Nor Akmal **BAHARI**, I-ern **KOH**, Shelina **OLI MOHAMED**, Wendy Yen Nee **SEE**

Purpose: To study the prevalence, demographic characteristics, risk factors, and clinical outcomes of uveitic glaucoma in a multiethnic Malaysian cohort.

Methods: A retrospective, cohort study was conducted in tertiary hospitals in Kuala Lumpur and Sarawak, Malaysia. Clinical records were reviewed, and the cases were chosen based on the inclusion criteria.

Results: A total of 257 eyes (163 patients) were included. Mean age of uveitis onset was 37.3 $\pm$ 16.2 years with a slight female predominance. The

prevalence of hypertensive uveitis and uveitic glaucoma was 26.1% and 30.0% respectively. Multivariate analysis identified age of onset (Odds ratio [OR] 1.024; 95% confidence interval [CI] 1.003–1.044, $p = 0.023$), male gender (OR 1.970; 95% CI 1.046–3.709, $p = 0.036$), presence of posterior synechiae (PS) (OR 3.326; 95% CI 1.092–10.133, $p = 0.034$) or peripheral anterior synechiae (PAS) (OR 4.606; 95% CI 2.065–10.272, $p < 0.001$), and intraocular pressure (IOP) >21 mmHg at presentation (OR 1.077; 95% CI 1.039–1.117, $p < 0.001$) as risk factors of uveitic glaucoma. Steroid responsiveness occurred in 74/253 (29.2%) of corticosteroid-treated eyes. More than one-third (53/144, 36.80%) of eyes required at least one glaucoma incisional surgery, and chronic uveitis ($p = 0.004$) and presence of PAS ($p < 0.001$) were factors associated with a higher need for glaucoma surgery. Uveitic glaucoma, as the primary cause of visual impairment or blindness, occurred in 39/112 (34.8%) affected eyes.

Conclusions: Uveitic glaucoma is a potentially irreversible blinding complication. By understanding the risk factors, uveitic glaucoma can be prevented with targeted screening and timely intervention.

Abstract No.: 203523

Diagnostic Serum Biomarkers Associated With Acute Anterior Uveitis

First Author: Bo **GONG**

Co-Author(s): Huan **LI**

Purpose: Acute anterior uveitis (AAU) is the most common subtype of non-infectious uveitis and an important cause of vision-threatening ocular inflammation. However, its metabolic characteristics and potential diagnostic biomarkers remain largely unexplored.

Methods: Plasma samples from 21 AAU patients and 21 age- and sex-matched healthy controls (HCs) were analyzed using untargeted metabolomics based on ultra-performance liquid chromatography tandem mass spectrometry (UPLC–MS/MS). Differential metabolites were identified by univariate and multivariate analyses. Pathway enrichment and clustering analyses were performed to explore biological relevance. Predictive diagnostic models were constructed using random forest (RF) and least absolute shrinkage and selection operator (LASSO) regression.

Results: Among 995 detected metabolites, 76 showed significant differences between AAU and HCs (27 increased and 49 decreased; VIP > 1 , FDR < 0.05). Pathway enrichment highlighted perturbations in purine and pyrimidine metabolism, amino acid metabolism, and lipid metabolism. RF analysis achieved 95% predictive accuracy with an area under the curve (AUC) of 1.0. LASSO regression further retained 12 key metabolites, including phytanate, ursodeoxycholate, glycylvaline, p-cresol sulfate,

hexadecanedioate (C16DC), pyrrolidine, bilirubin (E,E), guaiacol sulfate, oleoylcholine, eicosenoylcarnitine (C20:1), oxindolylalanine, and fibrinopeptide A. These metabolites collectively provided excellent discriminative power, yielding an AUC of 0.990.

Conclusions: This study provides the first comprehensive plasma metabolomic characterization of AAU, identifying specific metabolic disturbances linked to systemic inflammation and immune regulation. The 12 metabolite panel demonstrates strong diagnostic potential and offers novel insights into the pathogenesis of AAU.

Abstract No.: 210363

Differentiating Vogt-Koyanagi-Harada Syndrome From Paraneoplastic VKH-Like Retinopathy: A Report of Two Cases

First Author: Jiabei **XIONG**

Co-Author(s): Jiayin **CAI**, Yongping **HU**, Jian **LI**, Yijia **ZHANG**

Purpose: To highlight the diagnostic challenge in distinguishing Vogt-Koyanagi-Harada (VKH) syndrome from paraneoplastic autoimmune retinopathy (p-AIR), which can present with nearly identical fundus features.

Methods: We report two patients with bilateral vision loss, macular edema, and serous retinal detachment. Case 1 was a 30-year-old male with a viral prodrome and fluorescein angiography (FFA) findings typical of VKH. Case 2 was a 65-year-old male with small-cell lung cancer and FFA characteristics indicative of p-AIR.

Results: Management diverged significantly. The VKH patient (Case 1) required systemic immunosuppression. The p-AIR patient (Case 2) improved with local retrobulbar steroids, avoiding systemic therapy that could interfere with his cancer treatment.

Conclusions: VKH and p-AIR are critical masqueraders in many cases. Accurate differentiation based on medical history and FFA is essential, as it dictates fundamentally different treatment strategies — systemic immunosuppression versus localized therapy — and directly impacts patient outcomes and oncological safety.

Abstract No.: 205379

Early Recurrence and Vision Outcomes in HLA-B27-Associated Uveitis: A Multicentre Asian Cohort with 12-Month Follow-Up

First Author: Gladys Sze Yee **LING**

Co-Author(s): Rupesh **AGRAWAL**, Carlos **CIFUENTES GONZÁLEZ**, Bernett **LEE**, William **ROJAS-CARABALI**

Purpose: HLA-B27-associated uveitis is common, yet early (12-month) predictors of recurrence and vision loss in Asian cohorts remain unclear, and published definitions of “recurrence” vary. The objective of our

study was to estimate 12-month recurrence and vision outcomes in HLA-B27-associated uveitis and explore baseline factors associated with early recurrence.

Methods: Multicentre cohort across Asia, including retrospective and prospective cases. Clinical charts of 172 HLA-B27-associated uveitis patients were reviewed. After exclusions, 94 participants were analysed. Exposures included baseline demographics, systemic disease, and anatomical diagnosis (predominantly anterior uveitis). Sixteen participants had a concurrent systemic disease; 88/94 (93.6%) had anterior uveitis, 1 had intermediate uveitis, and 5 had panuveitis.

Results: Across the first 12 months, 30/94 (31.9%) participants experienced ≥ 1 recurrence. Baseline age, sex, systemic disease, and anatomic class did not differ meaningfully between those with and without recurrence (all $p > 0.20$). 10/94 (10.6%) developed moderate-to-severe vision loss at 12 months. Vision loss occurred more often in participants with intermediate uveitis (1/10) or panuveitis (2/10) than among those without vision loss (0 and 3 cases, respectively); numbers were small and estimates imprecise.

Conclusions: In this Asian multicentre HLA-B27 cohort, about one-third recurred within 12 months, and one-tenth had moderate-to-severe vision loss. We did not identify baseline predictors of early recurrence. These findings support close early follow-up for newly diagnosed HLA-B27 uveitis and motivate prospective, time-to-event analyses to refine risk stratification.

Abstract No.: 207200

Efficacy and Safety of Topical Interferon Therapy in Inflammatory Macular Edema: A Large Retrospective Study

First Author: Raj HIRANI

Co-Author(s): Ankush KAWALI, Padmamalini MAHENDRADAS, Sai Bhakti MISHRA

Purpose: To evaluate the efficacy and safety of topical interferon (IFN) therapy in inflammatory macular edema (IME).

Methods: This is a retrospective study of patients with IME treated with topical IFN therapy. Case records of patients were evaluated for central macular thickness (CMT) on OCT scan at commencement of IFN therapy and its changes during the follow-up. The time taken for the complete resolution of IME was noted. IFN eye drops were administered in QID dose and tapered by 1 drop/month after resolution of IME.

Results: Eighty-five eyes of eighty patients with IME were studied. The leading cause of IME was post-operative inflammation (30), followed by uveitic cystoid macular edema (CME). Mean CMT at commencement of IFN was 486.2 μm (range: 277-762 μm , SD: 108 μm), and at 1 month was 381.7 μm (range: 222-769 μm , SD: 103.6 μm). The mean duration

for first complete resolution ($n=44$) was 13.4 weeks (range: 1.5 weeks- 90 weeks, SD: 16.5 weeks). Twenty-seven patients (29%) had relapse. Most common side effects seen were papillary conjunctivitis ($n=6$) and 1 patient with pre-existing endothelial decompensation showed worsening. No systemic side effects were noted clinically. Subgroup analysis was done for patients treated with only IFN ($n=19$) - mean CMT at commencement was 482.6 μm (range: 345-713 μm , SD: 93.7 μm), and at 1 month was 386.2 μm (range: 230-480 μm , SD: 61 μm).

Conclusions: This largest study on topical IFN therapy demonstrates that IFN can be a noninvasive, and safe therapeutic option in the treatment of IME.

Abstract No.: 205220

Flavoprotein Fluorescence as a Potential Biomarker of Mitochondrial Stress in Retinal Vasculitis

First Author: Ka Lam Janice WU

Co-Author(s): Amir AKHAVANREZAYAT, Dalia EL FEKY, Quan Dong NGUYEN, Mohammad Bagher RAJABI

Purpose: To evaluate flavoprotein fluorescence (FPF) patterns in patients with retinal vasculitis compared to healthy controls, and to explore the potential of FPF imaging as a non-invasive biomarker of mitochondrial stress in retinal vasculitis.

Methods: This cross-sectional case-control study included 66 eyes from patients with retinal vasculitis and 20 eyes from age- and sex-matched healthy controls. Flavoprotein fluorescence (FPF) imaging, which detects mitochondrial oxidative stress by capturing the autofluorescence of oxidised mitochondrial flavoproteins, was performed using the OCUMET® Beacon. OcuMet® imaging was performed at the macula, fovea, and optic nerve head. Proprietary software provided quantitative FPF parameters: mean signal intensity and signal heterogeneity. Images with suboptimal quality scores or incomplete outputs were excluded. Between-group comparisons were performed using non-parametric statistical tests.

Results: Cases demonstrated significantly higher mean FPF intensity in the macula and optic nerve head compared to controls ($p < 0.05$), indicating increased oxidative stress and mitochondrial dysfunction in retinal vasculitis. Macular signal heterogeneity was significantly lower in cases, suggesting a more uniform stress distribution, potentially due to anatomical buffering by the dual retinal and choroidal circulation. Optic nerve head heterogeneity was elevated in cases, reflecting localised stress near inflamed retinal vessels. Foveal signal heterogeneity did not differ significantly between groups, consistent with the avascular nature of the foveal region.

Conclusions: FPF imaging reveals region-specific increases in mitochondrial stress in retinal vasculitis,

particularly in the macula and optic nerve head. These findings support FPF as a sensitive, non-invasive biomarker of retinal vascular inflammation and highlight differences in vulnerability across retinal subregions, offering potential for more objective disease monitoring.

Abstract No.: 205417

From Atypical Optic Neuritis to Acute Zonal Occult Outer Retinopathy: A Longitudinal Diagnostic Challenge in a Young Adult Woman

First Author: Gabriel Angelo **MONTEMAYOR**

Co-Author(s): Bryan Vincent **MESINA**

Purpose: Acute zonal occult outer retinopathy (AZOOR) is rare condition affecting the photoreceptors and retinal pigment epithelium. Its mechanism remains unclear but is hypothesized to be autoimmune. It typically presents with photopsias or scotomas in the setting of a normal fundus, later progressing to retinal atrophy and mottling.

Methods: We describe a case of bilateral AZOOR initially misdiagnosed as atypical bilateral optic neuritis and treated with systemic corticosteroids eight years earlier.

Results: A 39-year-old woman initially presented with bilateral paracentral scotomas and blurred vision. Examination showed peripapillary atrophy in the right eye and grade 2 optic disc edema with peripapillary halo in the left. Fluorescein angiography demonstrated transmission defects in both eyes resembling chorioretinal atrophy, with peripapillary leakage on the left. She was treated with oral prednisone (1 mg/kg/day), resulting in partial symptomatic improvement and no recurrence for several years. At present, she reported enlarging scotomas despite visual acuity of 6/6 in both eyes. Fundus examination showed bilateral extensive peripapillary chorioretinal atrophy, while perimetry confirmed enlarged blind spots. Optical coherence tomography revealed outer retinal disorganization, while fundus autofluorescence demonstrated a trizonal pattern of hyper-, hypo- and normal autofluorescence, consistent with AZOOR. The patient opted for close observation rather than further corticosteroid therapy.

Conclusions: AZOOR remains an elusive diagnosis without established treatment guidelines. This case emphasizes the need for early recognition and comprehensive multimodal imaging to guide management and monitor progression in patients initially presenting with atypical optic neuritis that later evolves into AZOOR.

Abstract No.: 203332

Glymphatic System Dysfunction in Thyroid Eye Disease Associated With Disease Activity and Duration

First Author: Haiyang **ZHANG**

Co-Author(s): Xianqun **FAN**, *Xin Ning* **LEE**, *Yuting* **LIU**, *Huifang* **ZHOU**

Purpose: To investigate the alterations in the lymphatic system in patients with thyroid eye disease (TED) using diffusion tensor imaging (DTI) analysis along the perivascular space (ALPS) and to explore the correlation between the lymphatic system and clinical features of TED.

Methods: The study included 47 patients with TED, including 20 active TED patients (AP) and 27 inactive TED patients (IP), along with 24 healthy controls (HC). Imaging data, including DTI sequences, were acquired using a 3.0 Tesla scanner. ALPS values were calculated based on the diffusivity of the bilateral superior corona radiata and superior longitudinal fasciculus. Correlation analyses were thus performed between ALPS values and clinical characteristics.

Results: The DTI-ALPS analysis in the TED patient group collectively showed lower mean and left ALPS values compared to the HC, with statistically significant differences observed (mean ALPS: $P=0.0308$, left ALPS: $P=0.0032$). Among the TED subgroups, the IP had significantly lower left ALPS values than HC ($P=0.006$). Correlation analysis within the IP subgroup indicated that lower ALPS values were significantly associated with longer disease duration ($P=0.015$) and greater palpebral fissure height ($P=0.028$).

Conclusions: Glymphatic system dysfunction is evident in TED patients, with its extent influenced by disease activity and duration.

Abstract No.: 204409

High Serum Soluble Interleukin-2 Receptor Levels in Tubercular Uveitis

First Author: Ikhwanuliman **PUTERA**

Co-Author(s): Willem **DIK**, *Rina* **LA DISTIA NORA**, *Nicole* **NAGTZAAM**, *Saskia* **ROMBACH**, *P.Martin* **VAN HAGEN**

Purpose: To investigate whether serum soluble interleukin-2 receptor (sIL2R), a known biomarker for sarcoidosis, is elevated in tubercular uveitis (TBU) within a tuberculosis (TB)-endemic population, and to evaluate its diagnostic performance compared with other biomarkers.

Methods: Serum samples from 14 TB patients (2 with pulmonary TB [PTB] only, 4 with PTB and uveitis, and 8 with uveitis and positive QuantiFERON-TB Gold [QFT]) were analysed. Six of the latter fulfilled Standardization of Uveitis Nomenclature (SUN) criteria for TBU, and two were PCR-positive for Mycobacterium tuberculosis in ocular fluid. Comparisons were made with 76

patients with other infectious or non-infectious uveitis and 9 healthy controls. Serum sIL2R was measured, and diagnostic performance was assessed using receiver operating characteristic (ROC) analysis and Youden's index. A comparison of several biomarker combinations (sIL2R, CXCL9, BAFF, and QFT) was also evaluated.

Results: Median serum sIL2R was significantly higher in PTB patients than controls (449.5 vs 199.0 U/mL, $p=0.0004$). Among uveitis patients, TBU cases had higher sIL2R levels (359.0 vs 244.0 U/mL, $p=0.0341$). A cut-off of 310 U/mL yielded 75% sensitivity and 66% specificity for TBU (AUC=0.693, 95% CI: 0.526–0.860). sIL2R correlated positively with CXCL9, but adding sIL2R to CXCL9 and BAFF did not enhance diagnostic performance beyond the previously reported CXCL9–BAFF–QFT combination.

Conclusions: Serum sIL2R is elevated in TB and TBU, supporting its role as a general marker of granulomatous inflammation. However, its diagnostic utility in TBU is limited, and interpretation should be cautious, particularly in TB-endemic settings.

Abstract No.: 206628

Inter-Eye Correlation of Visual Acuity and Inflammatory Biomarkers in Bilateral Uveitis: Considerations for Statistical Modelling

First Author: Rupesh **AGRAWAL**

Co-Author(s): Carlos **CIFUENTES-GONZÁLEZ**, Alejandra **DE-LA-TORRE**, John **KEMPEN**, Bernett **LEE**, William **ROJAS-CARABALI**

Purpose: To evaluate inter-eye correlation of visual acuity (VA) and inflammatory biomarkers in patients with bilateral uveitis, to inform clinical assessments and statistical modelling in research and practice.

Methods: This retrospective observational study analysed standardized VA measurements (LogMAR and ETDRS) and inflammatory markers (anterior chamber cells, flare, and vitreous haze) from the Ocular Autoimmune Inflammatory and Infectious Disease (OASIS) registry, which includes data from tertiary uveitis centres. Only patients with bilateral uveitis and complete VA data for both eyes at the same visit were included. Spearman's rank correlation coefficients were used to assess inter-eye associations across different aetiologies and time points. Distribution patterns were examined using histograms and scatterplots with LOESS smoothing.

Results: At baseline, VA showed moderate inter-eye correlation ($\rho=0.53$), with stronger correlations in non-infectious ($\rho=0.60$) and idiopathic ($\rho=0.57$) uveitis compared to infectious cases ($\rho=0.45$). Inflammatory biomarkers demonstrated strong baseline inter-eye correlations, particularly for vitreous haze ($\rho=0.79$), which increased to nearly perfect levels at five years ($\rho=0.97$). Anterior chamber flare and cells showed moderate-to-strong correlations initially

but declined over time, indicating greater variability in anterior segment inflammation. Distributions of VA were skewed or bimodal, indicating heterogeneous disease severity.

Conclusions: Between-eye correlation in bilateral cases of uveitis for visual acuity and inflammatory biomarker varies by aetiology and inflammation site. Posterior segment markers exhibit greater symmetry over time, while anterior markers show declining concordance. These findings support the need for sophisticated, eye-paired statistical models in research and personalized assessment strategies in clinical settings.

Abstract No.: 204128

Interleukin-6 Inhibition With Vamikibart in Patients With Uveitic Macular Edema: Data From Phase-3 MEERKAT and SANDCAT Trials

First Author: Yih-shiou **HWANG**

Co-Author(s): Deanna **GALLOWAY**, Lyndell **LIM**, Lachlan **MACGREGOR**, Laura **STEEPLES**, Robyn **TROUTBECK**

Purpose: Vamikibart is a recombinant monoclonal anti-IL-6 (interleukin-6) antibody engineered for IVT (intravitreal) delivery. Two global, randomized, double-masked, sham comparator-controlled phase-3 trials, MEERKAT (study GR44277, NCT05642312) and SANDCAT (study GR44278, NCT05642325), are currently investigating the efficacy, safety, and pharmacokinetics/pharmacodynamics of IVT vamikibart in UME (uveitic macular edema) secondary to NIU (non-infectious uveitis).

Methods: Patients ($n=225$ per study) with UME and BCVA (best-corrected visual acuity) scores of 73–19 ETDRS (Early Treatment Diabetic Retinopathy Study) letters with active/inactive, acute/chronic NIU are randomized into three arms: vamikibart 0.25mg, vamikibart 1mg, and sham. Study treatment is administered 4 times every 4 weeks through Week 12, followed by as-needed dosing during Weeks 20–48. Predefined rescue criteria allow standard-of-care treatment for worsening BCVA, UME, or inflammation. The primary endpoint is the proportion of patients with ≥ 15 -letter BCVA improvement from baseline at Week 16. Secondary endpoints include changes in BCVA and central subfield thickness, rescue medication requirements, adverse events, and IL-6 and vamikibart concentrations in aqueous humor and serum.

Results: The trials are ongoing at the time of abstract submission. By the time of the proposed APAO presentation, primary endpoint data at Week-16, along with key secondary endpoints, will be available and presented.

Conclusions: MEERKAT and SANDCAT will evaluate Vamikibart's potential to address the unmet need for effective non-corticosteroid treatments in UME. Primary efficacy and safety data obtained from these

trials are expected to provide insights into vamikibart's potential role in UME treatment.

Abstract No.: 206589

Intracameral Bacteriophage As Prophylaxis of Staphylococcus aureus-Induced Endophthalmitis Following Lens Extraction Surgery in Rabbits

First Author: Herdina **RAMADHANI**

Co-Author(s): Muhammad Indra Mahardika Iridika **HUMERI**, Djoko **LEGOWO**, Annise **PROBONINGRAT**, Indri **WAHYUNI**, Ismi **ZUHRIA**

Purpose: Postoperative endophthalmitis is a severe complication following cataract surgery. The most common organism cause endophthalmitis is gram-positive bacteria, Staphylococcus aureus. This study aimed to demonstrate the prophylactic effect of intracameral bacteriophage administration in Staphylococcus aureus-induced endophthalmitis after lens extraction surgery in rabbits.

Methods: A total of 10 New Zealand rabbits were divided into 2 groups, consisting of 5 rabbits each. Postoperative endophthalmitis was induced by injecting intracameral S. aureus bacteria just after lens extraction surgery. The control group was rabbits that underwent extracapsular lens extraction surgery and were injected with S. aureus. The treatment groups as above, followed by simultaneously administering 2×10^9 intracameral Staphylococcal bacteriophage injection in 25 μ L of physiological saline. The expression of IL-1b, IFN-g, MPO, and ICAM-1 was evaluated using the ELISA method at 48 hours after surgery. Pathological changes in retinal tissues were observed using HE staining.

Results: IL-1b, IFN-g, and ICAM-1 levels in the treatment group ($8,4702 \pm 2,625$ ng/L; 16.086 ± 1.578 , 4 ng/L; and 9.0104 ± 1.4753 ng/L) were lower than the control group ($11,9021 \pm 3,508$ ng/L; 18.722 ± 1.113 , 1 ng/L; and 15.4895 ± 0.9845 ng/L) with $p=0.023$; $p=0.016$; and $p<0.001$. There was no difference in MPO levels between the treatment group and the control group ($p=0.521$). Histopathologic examinations showed disruption of the retinal layers and the presence of numerous S. aureus in the globe in control groups. In contrast, retinal structures are intact, and no S. aureus staining is found in bacteriophage-treated eyes.

Conclusions: Administration of intracameral bacteriophages into the rabbit after lens extraction surgery affect the levels of IL-1b, IFN-g, ICAM-1, however without any impact on MPO levels. These findings demonstrate the potential of bacteriophage therapy as an emerging treatment modality, offering a sustainable prophylactic alternative for endophthalmitis.

Abstract No.: 204167

Intraretinal and Subretinal Fluid Resolution With Vamikibart in Uveitic Macular Edema: Phase-1 DOVETAIL Exploratory Results

First Author: Iksoo **BYON**

Co-Author(s): Zeinab **BAREKATI**, William **HOLMES**, Andreas **MAUNZ**, Marina **MESQUIDA**, Kathryn **PEPPLE**

Purpose: To investigate the efficacy of intravitreal vamikibart on IRF (intraretinal fluid) and SRF (subretinal fluid) resolution in UME (uveitic macular edema) patients in DOVETAIL study.

Methods: DOVETAIL (NCT06771271) was a phase-1, open-label, multiple-ascending-dose trial of vamikibart in diabetic macular edema and UME (secondary to all noninfectious uveitis types). UME patients ($n=37$) were enrolled into three dose-groups (0.25-mg: $n=12$; 1-mg: $n=12$; 2.5-mg: $n=13$) and received vamikibart at W0 (Week), W4, W8, followed by off-treatment observation until W20 (2.5-mg) or W36 (0.25-mg, 1-mg). The primary endpoint was safety. In this exploratory analysis on retinal optical coherence tomography, IRF and SRF presence were evaluated by masked graders (central-reading center), and volumes were quantified via an automated deep-learning model.

Results: Across all doses, the proportion of patients with foveal IRF absence increased from baseline (40.5%) to W4 (74.3%), W8 (80.6%), and W12 (85.7%). Median IRF volume decreased from 129.0-nL at baseline to 5.2, 3.3, 3.8-nL at W4, W8, W12, respectively, in the Early Treatment Diabetic Retinopathy Study central 1-mm ring, and from 375.7-nL at baseline to 13.9, 7.4, 6.5-nL at W4, W8, W12, respectively, in the central 3-mm ring. Proportions of patients with foveal SRF absence increased from baseline (51.4%) to W4 (91.7%), W8 (97.2%), W12 (100%). For patients with baseline SRF >0 -nL in the central 3-mm ring ($n=20$), median SRF volume reduced from 12.4-nL at baseline to 0-nL at W4/W8/W12. IRF/SRF improvements were maintained during the off-treatment period.

Conclusions: Vamikibart led to rapid fluid resolution, with $>85\%$ patients achieving complete IRF resolution and 100% achieving SRF resolution by W12, highlighting Vamikibart's potential benefit as an effective treatment for UME.

Abstract No.: 203983

Iris Vascular Characteristics Changes in Non-Infectious Uveitis: A Wide-Field Swept-Source Anterior Segment Optical Coherence Tomography Angiography Study

First Author: Zihui **WU**

Co-Author(s): Liu **YANG**

Purpose: To quantitatively assess differences in iris vascular characteristics among patients with active non-infectious uveitis (NIU), inactive NIU, and healthy

controls using wide-field swept-source anterior segment optical coherence tomography angiography (SS-AS-OCTA), and to identify reliable imaging biomarkers for monitoring NIU.

Methods: This cross-sectional observational study involved 87 eyes from 48 participants, categorized into active NIU (28 eyes), inactive NIU (29 eyes), and healthy control (30 eyes) groups. Iris Vascular Characteristics were analyzed using wide-field SS-AS-OCTA. Iris vessel area density (VAD) and vessel length density (VLD) were measured in six regions of the iris: the inner one-third, outer two-thirds, and full range of both the nasal and temporal sides.

Results: The active NIU group showed significantly higher VAD values than the inactive NIU group in five iris regions (all $p < 0.001$), except for the nasal outer two-thirds ($p = 0.002$). Compared to the healthy controls, the active NIU group had significantly higher VAD ($p < 0.001$) and VLD ($p < 0.001$) across all six iris regions. Similarly, VLD was significantly higher in the active NIU group than in both the inactive NIU group and the healthy controls across all six iris regions (all $p < 0.001$).

Conclusions: Wide-field SS-AS-OCTA effectively detects iris vascular changes in active NIU. The VAD and VLD of the iris serve as sensitive, non-invasive imaging biomarkers, providing a quantitative method to monitor disease progression and evaluate treatment response, which enhances the clinical management of uveitis.

Abstract No.: 205965

Long-Term Visual Outcomes of Uveitis: A Real-World Study in China

First Author: Lingyu DAI

Co-Author(s): Guannan SU, Peizeng YANG

Purpose: To assess the long-term visual outcomes of uveitis in China, and to investigate demographic characteristics and diagnosis of this disease.

Methods: A retrospective review of clinical data from uveitis patients who were referred to the Uveitis Center of Chongqing Medical University First Affiliated Hospital between 2008 and 2022.

Results: A total of 1,380 subjects with third-year follow-up data were enrolled. The mean age at the first visit was 33 ± 15 years, with 46.3% females. The median duration of uveitis was 12.0 (3.0-35.0) months. There were 1,344 non-infectious uveitis patients (97.4%), with undifferentiated uveitis accounting for the largest proportion (33.0%). Furthermore, the most common specific types were Vogt-Koyanagi-Harada (VKH) disease (22.7%) and Behçet's disease (BD) (21.8%). Compared to baseline, significant improvements in visual acuity (VA) were observed in both male and female uveitis patients at 1, 2, 3, and 5 years after treatment (all $p < 0.001$). The overall percentage of eyes

with visual acuity (VA) $< 20/400$ was 17.5% at baseline and decreased to 13.9% at the third year. Notably, the proportion of eyes with VA $< 20/400$ in males was significantly higher than that in females (male: 20.3% at baseline and 18.5% at year 3; female: 14.3% at baseline and 8.7% at year 3). Among patients with VA $< 20/400$ in at least one eye at the third year, BD accounts for the largest proportion (37.0%), with 94.4% of BD cases being male.

Conclusions: Our study demonstrated that the most common specific uveitis subtypes were VKH disease and BD in China. The overall visual outcomes were improved after treatment. However, female patients had a superior long-term visual prognosis compared to male patients, possibly due to the refractory nature and poorer visual prognosis of BD and its higher prevalence in males.

Abstract No.: 204407

Metformin Reduces Intracellular M. tuberculosis Replication and Inflammation In Vitro: A Potential Host-Directed Therapy for Ocular Tuberculosis?

First Author: Ikhwanuliman PUTERA

Co-Author(s): Willem DIK, Rina LA DISTIA NORA, P.Martin VAN HAGEN

Purpose: To identify potential host-directed therapy (HDT) compounds for ocular tuberculosis (TB).

Methods: In silico drug discovery was conducted based on "anti-match" characteristics using a bioinformatics platform. In vitro assays to test HDT compound (metformin) efficacy were conducted with retinal pigment epithelial (RPE) cells and human retinal endothelial cells (RECs) that were infected with two different Mycobacterium tuberculosis (Mtb) strains (H37Rv and a hypervirulent clinical Beijing strain). Colony-forming unit (CFU) assays were conducted and cytokine levels were determined in culture supernatants.

Results: In silico analysis identified metformin as a potential HDT for ocular TB. Metformin (4 mM) treatment reduced intracellular Mtb replication in RPE cells 48 hours after Mtb-infection (median CFU: 2.4×10^5 CFU/mL in treated cells vs. 3.9×10^5 CFU/mL in untreated cells; $p = 0.019$). Metformin also significantly decreased the production of CCL2/MCP-1 and IL-6 in both Mtb-infected RPE cells and RECs and that of CXCL10/IP-10, CCL5/RANTES, and IL-8 in Mtb-infected RECs.

Conclusions: Metformin suppresses intracellular replication of Mtb in RPE cells alongside the proinflammatory cytokine production by RPE cells and RECs. This study provides the first evidence for metformin as a potential HDT for ocular TB.

Abstract No.: 205378

MicroRNA-Loaded Antioxidant Nanoplatfoms for Prevention and Treatment of Experimental Acute and Chronic Uveitis

*First Author: Siting SHENG**Co-Author(s): Haijie HAN, Jian JI, Wen XU, Huiling ZHAO*

Purpose: To address limitations of current uveitis treatments, this study developed a microRNA (miRNA)-loaded antioxidant nanoplatfom, polyethyleneimine (PEI)-modified polydopamine (PDA) carrying miR-132-3p (PEI/PDA@miR-132), for the prevention and treatment of experimental acute and chronic uveitis.

Methods: PEI/PDA was synthesized to load miR-132 via electrostatic interactions. Its characterization, in vitro anti-oxidative/anti-inflammatory activities, and in vivo therapeutic effects were evaluated using lipopolysaccharide (LPS)-induced acute uveitis rat models and inter-photoreceptor retinoid-binding protein 1-20 (IRBP 1-20)-induced chronic uveitis mouse models, with dexamethasone (DXM) as control. Safety was assessed via cytotoxicity, histology, and blood tests.

Results: PEI/PDA@miR-132 showed good stability, high miR-132 transfection efficiency, and concentration-dependent antioxidant activity. It scavenged reactive oxygen species (ROS), inhibited M1 macrophage polarization, downregulated nuclear factor-kappa B (NF- κ B) signaling, reduced pro-inflammatory cytokines (tumor necrosis factor- α (TNF- α), interleukin-1 β (IL-1 β)), alleviated uveitis symptoms better than controls, and exhibited superior retinal safety and excellent biocompatibility.

Conclusions: PEI/PDA@miR-132 effectively treats acute and chronic uveitis by targeting oxidative stress, inflammation, and apoptosis, promising a safe therapeutic strategy for such diseases.

Abstract No.: 206181

Multimodal Imaging of Uveal Effusion Syndrome Type 3 in Eyes in the Pachychoroid Spectrum

*First Author: Amala Elizabeth GEORGE**Co-Author(s): Muna BHENDE, Parthopratim Dutta MAJUMDER, Sudharshan SRIDHARAN*

Purpose: To report findings on multimodal imaging in eyes with uveal effusion syndrome Type 3 and pachychoroid.

Methods: Patients with Uveal effusion syndrome type 3 with normal axial length and scleral thickness, and pachychoroid were included. The diagnosis of pachychoroid was based on Optical Coherence tomography (OCT) and Fundus fluorescein angiography (FFA) in all patients. Details of Indocyanine green

angiography (ICGA) and OCT angiography (OCTA) were also reviewed when available.

Results: We included 21 eyes of 14 patients (1 female, 13 males); mean age was 45.2 (SD: 11.3) yrs. Bilateral disease was seen in 8 patients (57%) and unilateral in 5. Mean axial length was 22 mm (SD: 0.9). 5/21 eyes (24%) had best corrected visual acuity less than or equal to 6/60 at presentation. Mean sub-foveal choroidal thickness (SFCT) on OCT was 473(SD: 194) microns (Range: 260 to 793). OCTA showed dilated choroidal vessels in 3 patients. FFA did not detect any leaks in 8 patients. 4 eyes had leaks suggestive of central serous chorioretinopathy (CSCR) and 3 had pinpoint leaks during the course of their disease. Leopard spot patterns were noted in 11/21 eyes (51%) additionally. On ICGA (n=14) choroidal hyperpermeability was seen in 9 eyes.

Conclusions: In this largest series of eyes with Type 3 uveal effusion syndrome associated with pachychoroid spectrum, the most common finding was thickened choroid, leopard spot patterns, and choroidal hyperpermeability on ICG. 4 eyes had associated CSCR during the disease course. There was a strong male preponderance.

Abstract No.: 203499

NETs-CD44-IL-17A Feedback Loop Drives Th17-Mediated Inflammation in Behçet's Uveitis

First Author: Yi WU

Purpose: Behçet's uveitis (BU) is a severe ocular manifestation of Behçet's disease, a systemic immune disorder typically accompanied by abnormal neutrophil infiltration and hyperactivation. We aimed to investigate the underlying causes of excessive neutrophil extracellular traps (NETs) production in BU and to elucidate the mechanisms by which NETs contribute to the pathogenesis of BU.

Methods: Single-cell RNA sequencing (scRNA-seq) is used to investigate the heterogeneity of neutrophils in BU and to map the immune profile of experimental autoimmune uveitis (EAU) following NETs inhibition. The role of NETs in EAU was validated in vitro and vivo experiments.

Results: Circulating neutrophils from BU patients exhibited a higher propensity for NETs release compared to healthy controls. In EAU, neutrophils were observed to exert pro-inflammatory effects through NETs. Clearing NETs could inhibit T helper 17 (Th17) cells differentiation and significantly alleviate EAU symptoms. Both in vivo and in vitro experiments demonstrated neutralizing interleukin-17A (IL-17A), IL-17A secreted by Th17 cells markedly reduced neutrophil infiltration and NETs formation in EAU. ScRNA-seq confirmed CD44 plays a key role in mediating interactions between NETs and Th17

cells. Antagonizing CD44 significantly decreased the proportion of Th17 cells and NETs formation in both in vivo and in vitro experiments. Multiplex immunofluorescence and cell communication analysis demonstrated the interactions and colocalization between NETs and CD44highCD4+T cells in EAU.

Conclusions: NETs induce Th17 differentiation via upregulating CD44, and in turn Th17 cells secrete IL-17A to recruit neutrophils and promote NETs formation. Interrupting NETs-CD44-IL-17A feedback loop might be a potential therapeutic target for BU.

Abstract No.: 203264

Ocular Tuberculosis in Pediatric Population Visiting a Tertiary Eye Care Hospital: A Two-Year Retrospective Observational Study

First Author: Radhika **THUNDIKANDY**

Co-Author(s): Lisa **SUNNY**

Purpose: To report the clinical profile with radiological and immunological evidence of ocular tuberculosis in children.

Methods: Methods: Medical records of all pediatric patients diagnosed with ocular Tuberculosis from January 2023 to December 2024 were studied for ocular clinical features, Tuberculosis contact, Tuberculin skin test, radiological evidence of Tuberculosis, and history of previous systemic Tuberculosis.

Results: A total of 21 children were in the study. Mean age was 14 years (range 8-16). Posterior uveitis was most common which included choroiditis (4), retinal vasculitis (3), Tuberculous optic neuritis (1). Intermediate uveitis (4), phlycten (4), sclero keratitis (3), anterior uveitis (2). Only 5 patients had a history of tuberculosis contact. 18 out 21 patients had positive tuberculin skin test and 19 out of 21 children had radiological evidence of old Tuberculosis. No child gave a history of active systemic Tuberculosis in the past

Conclusions: Ocular Tuberculosis is an important cause for pediatric uveitis in an endemic country like India. It presents in a myriad ways and can cause morbidity if not recognized early and appropriately treated .As previous history of systemic tuberculosis was absent in all our patients the Tuberculin skin test and radiological evidence of old healed Tuberculosis are crucial adjuvants in the diagnosis of presumed ocular Tuberculosis.

Abstract No.: 202530

Optical Coherence Tomography (OCT) Biomarkers in Vogt Koyanagi Harada (VKH) Syndrome

First Author: Parima **JARENSIRIPORNKUL**

Co-Author(s): Wipada **LAOVIROJJANAKUL**, Kanpirom **TANGPONTIRAK**

Purpose: To evaluate associations between OCT features observed during the acute, active phase of VKH and late-stage best-corrected visual acuity (BCVA, logMAR) after inflammation is controlled.

Methods: Cross-sectional analysis of OCT images from patients with acute, active VKH. OCT features were graded for the presence/absence of subretinal septa (bacillary layer detachment), retinal pigment epithelium (RPE) folds, RPE clumping (subretinal drusen-like deposits), and hyperreflective foci (HRF), and for subretinal fluid (SRF) thickness and central subfield thickness (CST). Associations with late-stage BCVA were examined using generalized linear models.

Results: Ninety-five eyes from 95 patients were included (mean age 43.1 years). Median initial and late-stage BCVA were 1.00 and 0.18 logMAR, respectively. Median SRF and CST were 339.0 μ m and 578.5 μ m. HRF were present in 76 eyes (80.0%), RPE folds in 54 (57.4%), subretinal septa in 36 (37.9%), and RPE clumping in 26 (27.7%). In univariable models, RPE clumping showed a trend toward worse late-stage VA ($\beta=0.121$ logMAR; 95% CI -0.0046 to 0.2468 ; $p=0.059$), while subretinal septa showed a non-significant trend toward better VA ($\beta=-0.0758$; 95% CI -0.168 to 0.016 ; $p=0.107$). In a stepwise multivariable model, subretinal septa were independently associated with better VA ($\beta=-0.134$; 95% CI -0.265 to -0.003 ; $p=0.045$), whereas RPE clumping was associated with worse VA ($\beta=0.118-0.125$; $p=0.039-0.027$).

Conclusions: The presence of subretinal septa on OCT in active acute VKH was associated with better VA, while the presence of RPE clumping would predict the worse VA in the late stage of disease. These results identify OCT biomarkers that may aid prognostication and treatment plans.

Abstract No.: 206143

Rate of Intraocular Inflammation (IOI) Post-Intravitreal Brolucizumab: A 5-Year Clinical Audit at a Malaysian Tertiary Center

First Author: Xin Yee **CHONG**

Co-Author(s): Rajasudha **SAWRI RAJAN**

Purpose: To evaluate the rate of intraocular inflammation (IOI) following intravitreal Brolucizumab at a tertiary centre, compare with landmark studies, characterise affected cases, identify risk factors, and explore strategies to reduce inflammation.

Methods: This retrospective audit included patients who received at least one intravitreal Brolucizumab injection at HSAS, the main medical retina centre in Malaysia, between January 2021 and August 2025. Data from electronic records included demographics, ocular diagnosis, number of injections, IOI occurrence, clinical presentation, treatment, visual acuity changes, lens status, and history of IOI, uveitis, or allergy.

Results: Ninety patients were reviewed; 20 (22.22%) developed IOI, a higher rate than the 4.6% reported in the HAWK and HARRIER trials. The mean age of affected patients was 68 years, with equal gender distribution. Most were Malay and phakic, with polypoidal choroidal vasculopathy the most common diagnosis. IOI developed mostly after the second injection, with symptoms appearing on average 10.75 days after the last intravitreal Brolucizumab. Clinical presentations included anterior, intermediate, and pan-uveitis; 15% showed vasculitis on fluorescein angiography. Visual acuity worsened in 70% of IOI cases. Brolucizumab was discontinued in all affected patients and treated with topical steroids, where 65% also received oral steroids. No patients required intravenous steroids. IOI was more common among the Malay ethnicity, phakic eyes, and patients aged 60–70 years. No significant associations were found with gender, uveitis history, or systemic comorbidities.

Conclusions: The IOI rate in our study was higher than in clinical trials, highlighting the importance of careful monitoring and patient selection to enhance safety in real-world Brolucizumab use.

Abstract No.: 206813

Resurgence of Acquired Syphilitic Uveitis: Characteristics, Challenges and Outcomes

First Author: Devesh KUMAWAT

Co-Author(s): Shakha ., Shoryavardhan AZAD, Vinod KUMAR, Pradeep VENKATESH

Purpose: Syphilitic uveitis (SU) is a re-emerging cause of intraocular inflammation. This study aimed to characterize the clinical, imaging features, treatment modalities, and outcomes of SU at a tertiary-care center in North India over the last decade.

Methods: An ambispective observational study included SU patients between January 2016 and April 2025. Diagnosis was based on compatible clinical features, positive syphilis serology, and response to antibiotic therapy. Data on demographics, HIV status, ocular findings, imaging, treatment regimens, and outcomes were retrieved. Best-corrected visual acuity (BCVA) was assessed, with a favorable outcome defined as $BCVA \geq 20/30$. Statistical analysis identified factors associated with a favorable outcome.

Results: Twenty-six patients (44 eyes) were included, predominantly male (92.3%) with a mean age of 37.9 ± 12.1 years. Five patients presented before and

21 presented after the Coronavirus disease (COVID-19) pandemic. HIV co-infection was present in 50% of patients. Posterior uveitis (61.4%) and panuveitis (36.4%) were common forms. Characteristic placoid or confluent chorioretinitis patterns were noted, with punctate white dots in nearly one-third of eyes. 38.5% cases were misdiagnosed initially and empirically treated with corticosteroids. Definitive treatment included intravenous ceftriaxone/ aqueous penicillin with adjunctive corticosteroids in few cases. At median follow-up of 9 months, 93.2% eyes showed resolution, and 54.5% achieved $BCVA \geq 20/30$. Better initial vision, posterior uveitis (versus panuveitis), and treatment with aqueous penicillin were associated with a favorable outcome.

Conclusions: Syphilitic uveitis has resurged, particularly in the post-COVID era. Heightened awareness, due suspicion, and early recognition using multimodal imaging are vital for favorable outcomes. Aqueous penicillin may yield superior outcomes and merits further evaluation.

Abstract No.: 205328

Reticular Iris Pattern as a Potential Clinical Marker for Cytomegalovirus-Associated Posner-Schlossman Syndrome

First Author: Ba Dong Nhat HUYNH

Co-Author(s): Thi Uyen Duyen NGUYEN

Purpose: To evaluate reticular iris pattern as a clinical marker for cytomegalovirus infection in Posner-Schlossman syndrome through aqueous humor polymerase chain reaction analysis and correlation with clinical findings.

Methods: This cross-sectional study included 30 patients with active Posner-Schlossman syndrome. All underwent ophthalmologic examination and aqueous humor PCR for CMV, HSV, VZV, and EBV DNA. Clinical parameters, including iris morphology patterns, keratic precipitate morphology, intraocular pressure measurements, corneal endothelial cell density, and glaucomatous damage, were systematically correlated with PCR results.

Results: CMV DNA was detected in 14/30 (46.7%) patients, with EBV co-infection in 2 cases. Reticular iris pattern was strongly associated with CMV infection, occurring in 64.3% of CMV-positive versus 6.3% of CMV-negative eyes ($p=0.002$; $OR=58.5$). Additional CMV correlates included stellate keratic precipitates (85.7% vs 25.0%, $p=0.002$) and reduced endothelial cell density (1913 ± 629 vs 2357 ± 555 cells/ mm^2 , $p=0.049$). CMV-positive patients exhibited more frequent recurrent episodes and advanced glaucomatous damage ($p<0.05$). HSV and VZV were not detected.

Conclusions: Cytomegalovirus was the predominant viral pathogen detected in Posner-Schlossman syndrome, identified in nearly half of cases. Reticular

iris pattern appears to be a potential clinical indicator for CMV-associated disease. Clinical differences may exist between CMV-positive and negative cases, potentially helping clinicians identify patients who may benefit from aqueous PCR testing and targeted antiviral therapy. Further longitudinal studies are warranted to confirm these findings and establish their prognostic value.

Abstract No.: 205643

Retinal Pigment Epithelium Stress Following Intravitreal Ganciclovir: A Novel Insight From Clinical Spectrum

First Author: Kuifang DU

Purpose: The retinal toxicity of intravitreal ganciclovir (GCV) is contentious. Our study aims to describe new clinical findings following intravitreal GCV and propose a mechanism for the pathogenesis of those post-injection retinal changes.

Methods: A retrospective case series included 114 patients with cytomegalovirus retinitis (CMVR) receiving intravitreal GCV (2.5 mg/0.05 mL) combined with systemic therapy. Patients with presumed retinal toxicity following intravitreal GCV injection were enrolled. Clinical data, laboratory tests, ocular examination, and multimodal images of the retina were collected. Serial optical coherence tomography (OCT) was performed to monitor pre- and post-retinal changes.

Results: Five patients (7 eyes) ($4.4\% \pm 2.6\%$) with macular spared from CMVR lesions experienced acute vision loss and transient macular edema after the GCV injection; 1 patient ($0.9\% \pm 2.6\%$) with bilateral CMVR developed chronic and progressive retinal pigment epithelium (RPE) atrophy in the CMVR-spared areas of the eye receiving repeated GCV injections, contrasting with untreated contralateral eyes. Three of them were additionally diagnosed as cytomegalovirus-immune recovery retinitis. With OCT, all eyes showed intact Bruch's membrane and normal thickness of inner retinal layers. Seven eyes with acute vision loss showed outer retinal changes within 24 hours post-injection, including macular SRF (7 eyes), macular vertical hyperreflective foci (5 eyes), and ONL edema (4 eyes), and resolving spontaneously weeks later.

Conclusions: Intravitreal GCV treatment may trigger acute macular edema and chronic RPE degeneration in CMVR patients. We hypothesize that RPE dysfunction is the pivotal pathogenic mechanism orchestrating these clinical spectrums, potentially induced by multifactorial interplay, including chemical irritation, cumulative toxicity, systemic comorbidities, and CMVR-related inflammatory cascades.

Abstract No.: 204265

Role of Adjunctive Intravitreal Therapy in Intraocular Tubercular Granuloma – a Retrospective Case Series

First Author: Sudha GANESH

Purpose: To evaluate the role of intravitreal anti-VEGF with moxifloxacin in intraocular tubercular granuloma.

Methods: This retrospective study was conducted at a referral uveitis clinic between January 2022 and 2025. All patients who had received intravitreal anti-VEGF with moxifloxacin along with systemic anti-tubercular therapy (ATT) for intraocular tubercular (TB) granuloma were included.

Results: Eight eyes of eight consecutive patients with tubercular granulomas treated at our institution were analyzed. The median age of presentation was 33 years (range 18-44 years). The median duration of follow-up was 5 months (range 2 to 34 months). Five cases had TB choroidal granuloma, two had ciliary body granuloma, and one had both choroidal and ciliary body granulomas. All patients received intravitreal anti-VEGF and moxifloxacin along with systemic ATT therapy and oral steroids. Seven eyes had resolved granuloma at the last follow-up. One patient had persistent inflammation despite three intravitreal anti-VEGF injections along with moxifloxacin. The visual acuity improved in six patients.

Conclusions: Adjunctive intravitreal therapy with anti-VEGF with moxifloxacin, along with ATT, aided in the resolution of intraocular TB granuloma.

Abstract No.: 203712

Scleral Abscess- Review of Risk Factors, Clinical Features, Causative Organism, Management and Outcome in a Tertiary Eye Care Hospital

First Author: Radhika THUNDIKANDY

Co-Author(s): Lisa SUNNY

Purpose: To analyze the demographics, risk factors, causative organism, management, clinical features, and outcome of patients with exogenous infectious scleral abscess.

Methods: Retrospective observational study. The medical records of all patients diagnosed with scleral abscess from January to December 2024 were reviewed. 30 eyes of 30 patients were included in the study. The Ultrasound bio microscopy (UBM) findings were noted.

Results: Median age was 65 years. Males were more than females, 21:9. Trauma was the most common risk factor. Trauma with stick /stone 11, fall of insect 2, uncontrolled diabetes 6, fall of chemical 1, post-ocular surgery 5, immunosuppressed state 3, old age 8. Corneal involvement seen in 6 patients, hypopyon/ac reaction 3. Commonest site of abscess was temporal

10, followed by nasal 8. *Pseudomonas* was the commonest organism, followed by fungus. no growth by culture was seen in 19. All underwent incision and drainage except 1 patient due to scleral breach by UBM. Appropriate antimicrobials were given according to culture and sensitivity report when available. Pain was more than the clinical signs. Use of topical or oral steroids gave only temporary relief and there was delay in time to healing. Healing was faster following early debridement. All cases resolved with underlying scleral necrosis 1 eye went into endophthalmitis.

Conclusions: Careful history, clinical examination and UBM helped in early diagnosis of exogenous scleral abscess. Early debridement helped in faster resolution compared to medical management alone. Use of corticosteroids delayed healing and worsened the scleral abscess.

Abstract No.: 208059

Serum Metabolic Analysis Identifies Novel Biomarkers for Distinction Between Corticosteroids and Cyclosporin A Resistant and Sensitive Pediatric Idiopathic Uveitis Patients

First Author: Rui **CHANG**

Co-Author(s): Peizeng **YANG**

Purpose: To identify serum metabolic biomarkers capable of distinguishing corticosteroids and cyclosporin A (CS & CsA) resistant from sensitive pediatric idiopathic uveitis (PIU) patients.

Methods: Serum samples from 32 CS & CsA-sensitive and 24 CS & CsA-resistant PIU patients were analyzed for metabolic profiles using Ultra High Performance Liquid Chromatography-Orbitrap Exploris Mass Spectrometry (UHPLC-OE-MS). Bioinformatic analyses were performed to identify differential metabolites between the two groups, and machine learning (ML) algorithms were employed to develop a diagnostic model based on these metabolites. To assess the model's stability and generalizability, all serum samples were randomly split into a training set and a test set using ML-based random sampling.

Results: The metabolic phenotype of CS & CsA-resistant PIU patients showed significant remodeled compared with sensitive patients. Among the differential metabolites between the two groups, lipids were markedly dysregulated (72.47%). The ML-based multivariate selection approach, including Neural Network (NNET), Least Absolute Shrinkage and Selection Operator (LASSO), and eXtreme Gradient Boosting (XGBoost), identified 4 candidate metabolite biomarkers. Receiver operating characteristic (ROC) analysis revealed that MG 15:0, PI-Cer 28:0;3O, and SPB 20:0;2O yielded area under the curve (AUC) values of 0.934, 0.953, and 0.904, respectively, all of which were upregulated in resistant patients. In contrast, N-acetylaspatic acid, with an AUC of 0.934, was

downregulated in resistant patients. The combined diagnosis model of these 4 metabolites achieved an improvement in AUC values (AUC=1). Validation of the combined diagnosis model showed excellent efficiency with AUC=0.971 of NNET, 0.971 of LASSO, and 0.957 of XGBoost, respectively, in test sets.

Conclusions: We identified 4 previously unexplored but potentially valuable metabolic biomarkers that can effectively discriminate between CS & CsA-resistant and -sensitive PIU patients. These findings may provide critical guidance for the early stage of clinical medication decisions in order to avoid visual impairment of resistant PIU patients.

Abstract No.: 203092

Sestrin2 Exerts a Novel Protective Effect Against LPS-Induced Ferroptosis via the Nrf2-SLC7A11-GPX4 Signaling Axis

First Author: Jiawei **YIN**

Co-Author(s): Peiquan **ZHAO**

Purpose: Uveitis is a leading cause of visual impairment linked to systemic inflammatory diseases. Current corticosteroid treatments are limited by significant long-term side effects. Sestrin 2 (SESN2), a stress-responsive antioxidant protein, is implicated in the regulation of ferroptosis and inflammation. This study investigates SESN2's role in modulating inflammation and ferroptosis in endotoxin-induced uveitis (EIU) models, aiming to develop safer therapeutic alternatives for uveitis management.

Methods: C57BL/6 mice were subjected to EIU via intravitreal injection of lipopolysaccharide (LPS) with or without SESN2-overexpressing adeno-associated virus (AAV). Clinical evaluations, cytokine profiling, and ferroptosis marker assessments were conducted. Additionally, BV2 microglial cells were genetically modified to overexpress or silence SESN2, followed by analyses of inflammatory cytokine production, oxidative stress, ferroptosis-related pathways, mitochondrial function, and involvement of the Nrf2 signaling pathway.

Results: SESN2 expression was significantly reduced in vivo and in vitro following LPS treatment. AAV-mediated SESN2 overexpression suppressed inflammatory responses. Mechanistically, SESN2 inhibited ferroptosis by upregulating ferroptosis-resistant proteins (SLC7A11, GPX4) and reducing lipid peroxidation markers (4-HNE). In vitro, SESN2 overexpression reduced oxidative stress and ferroptosis, while SESN2 knockdown exacerbated these effects. SESN2's protective role was mediated by Nrf2 activation, enhancing antioxidant defenses and ferroptosis inhibition. Inhibition of Nrf2 reversed SESN2's protective effects, underscoring the importance of the p62/Nrf2/GPX4 axis in SESN2-mediated ferroptosis protection.

Conclusions: SESN2 plays a crucial role in protecting against inflammation and ferroptosis via the Nrf2 pathway, presenting a promising therapeutic target for uveitis management.

Abstract No.: 202548

Single-Cell Transcriptome Analysis Reveals Immune Cell Heterogeneity of Vogt-Koyanagi-Harada (VKH) Disease

First Author: Jingwen WANG

Co-Author(s): Ying LI, Shuai OUYANG, Jia QU

Purpose: This study aimed to reveal immune cell heterogeneity and cell-cell interaction signals in the immune microenvironment in the pathogenesis of VKH patients.

Methods: We utilized single-cell transcriptomics methods to explore immune cell heterogeneity of VKH.

Results: We revealed that major antigen-presenting cells CD14⁺ Monocytes and mDC cells function enriched in antigen-presenting, T, NK and NKT cells mainly involved in acute immune responses and immune activation functions, upregulated function of plasma cells and mast cell related to increased protein translation, synthesis and processing in VKH. Moreover, we uncovered VKH involves multiple immune cell-cell interactions increased and cell communication signals were dysfunction in VKH. In addition, we revealed that pro-immunity and inflammation transcription factors like USF2, IRF8, POU2F2 and JUN were activated while anti-immunity and inflammation transcription factors such as ETS2 and MXD4 were suppressed in the majority of cell types of VKH.

Conclusions: These findings provided a potential target cell population or target genes for immunotherapy and anti-inflammation treatments.

Abstract No.: 206380

Six-Month Versus Nine-Month Anti-Tubercular Therapy for Tubercular Posterior Uveitis: A Multicentric, Prospective, Randomised Controlled Study

First Author: Ronnie Abhishek TALLURI

Co-Author(s): Soumyava BASU, Anup KELGAONKAR, May Zun Aung Win, Somsiri Sukavatcharin

Purpose: The role of anti-tubercular therapy (ATT) in prevention of recurrent inflammation in ocular tuberculosis (TB) is well established. However, the optimal duration of ATT in ocular TB remains unclear. Here, we report a prospective, randomized, study, to compare the efficacy of 6-month versus 9-month ATT, for the treatment of clinically diagnosed tubercular posterior uveitis (TPU).

Methods: We conducted a multi-center, prospective, randomized, observer masked-study across three different centers in India, Myanmar and Thailand

respectively. We included patients with clinically diagnosed TB retinal vasculitis, serpiginous-like choroiditis (SLC) or multifocal choroiditis (MFC), based on SUN-diagnostic criteria, and no active pulmonary or extra-pulmonary TB. The primary efficacy outcome was persistent or recurrent inflammation, from the completion of ATT till one year follow up

Results: Sixty-four patients were randomized into the study, of which 14 were excluded due to incomplete follow up. Of the remaining 50 patients, 36% (n=18) were bilateral, 60% (n=30) male, with mean age of 38.4±12.1 years. The patients were equally divided (n=25 each) between six- and nine-month groups. Clinical phenotypes at presentation were retinal vasculitis (n=28, 56%), MFC (n=12, 24%), and SLC (n=10, 20%). Four patients (16%) from the six-month group, and none from the nine-month group had persistent (n=1, SLC) or recurrent (n=3, one each of SLC, MFC and retinal vasculitis) inflammation following completion of ATT. However, logistic regression analysis did not reveal any difference between the six-month and nine-month groups (p=0.91).

Conclusions: Six-months ATT was as effective as nine-months in the treatment of TB posterior uveitis.

Abstract No.: 202707

Studies on the Mechanism by Which Magnesium Regulates Mitochondrial Function Through NPTX1 in CD4⁺ T Cells of Vogt-Koyanagi-Harada Syndrome

First Author: Jing XU

Purpose: To clarify the role of magnesium in regulating mitochondrial function in CD4⁺ T cell of Vogt-Koyanagi-Harada syndrome (VKH).

Methods: Inductively coupled plasma mass spectrometry was conducted to evaluate trace element levels. Then we performed a magnesium supplement experiment in human peripheral blood CD4⁺ T cells and the EAU mouse model. Flow cytometry was used to measure the frequency of Th1, Th17, and Treg cells. Immunofluorescence and quantitative real-time polymerase chain reaction (RT-qPCR) were subjected to detect mitochondrial function. Then RNA sequencing-based transcriptomics was performed in vitro to screen potential molecules regulated by magnesium.

Results: We found the lower magnesium level in both serum and CD4⁺ T cell extracted from VKH syndrome patients compared with that from healthy controls. In vitro results showed that magnesium supplement could decrease the frequency of Th1 and Th17 cells, and improve the frequency of Treg cells. Furthermore, magnesium supplement could down-regulate ROS levels and mitochondrial DNA copy number. In vivo experiments demonstrate that magnesium supplement could alleviate the inflammation of the experimental autoimmune uveitis model mouse. Transcriptomics

analysis found that magnesium could influence mitochondrial function through NPTX1. RT-qPCR verified higher NPTX1 levels in healthy control and magnesium supplement subjects. And NPTX1 silencing could not invert the imbalance of Th1, Th17/Treg cells.

Conclusions: Magnesium could regulate mitochondrial function in CD4+ T cell through the activation of NPTX1 to alleviate disease progression. The study indicates that magnesium would be a novel insight and potential applications for the prevention and treatment of VKH syndrome.

Abstract No.: 205949

Suprachoroidal Proliferative Membrane in Uveal Effusion Syndrome With Nanophthalmos: Incidental Finding During Sclerectomy

First Author: Jingyi **SHI**

Co-Author(s): Yong **TAO**, Ying **TIAN**

Purpose: To report the identification and histopathological analysis of a suprachoroidal proliferative membrane in a patient with uveal effusion syndrome (UES) and nanophthalmos, highlighting its potential role in the pathophysiology of the condition.

Methods: A comprehensive ophthalmological examination, including fundus examination, IOL-Master biometry, and B-scan ultrasound, was performed on a 52-year-old female patient presenting with blurred vision. Sclerectomy was conducted, during which a white strand-like substance was extracted from the suprachoroidal space. Histopathological and immunohistochemical analyses were carried out to characterize the substance.

Results: The patient presented with hand motion visual acuity in the right eye and a best-corrected visual acuity of 0.4 in the left eye. Fundus examination revealed a spherical bulge of the retina in the right eye, and IOL-Master confirmed nanophthalmos with axial lengths of 18.2 mm (right) and 18.5 mm (left). B-scan ultrasound showed a retinal and choroidal detachment in the right eye. During sclerectomy, a 3 cm white strand-like substance was extracted from the suprachoroidal space of the right eye. Histopathological analysis identified it as a collagen-rich proliferative membrane, with immunohistochemical staining showing strong positivity for collagen type I and moderate positivity for CD68. Post-surgery, with topical corticosteroids, the uveal effusion resolved, the retina flattened, and visual acuity improved to 0.02 in the right eye.

Conclusions: The discovery of a suprachoroidal proliferative membrane rich in fibroblasts and macrophages in a patient with UES and nanophthalmos suggests an inflammatory component in the pathophysiology of nanophthalmic UES, providing new insights into its mechanism and potential therapeutic targets.

Abstract No.: 203806

Taming the Acute Storm: The Prognostic Influence of Early Systemic Immunosuppressive Therapy in Acute Uveitic Phase of Vogt-Koyanagi-Harada Syndrome

First Author: Asifa Tasnim **MOUTUBA**

Co-Author(s): Md.Dedarul **HASSAN**, Md.Zaman **SAKIB**

Purpose: Vogt-Koyanagi-Harada (VKH) disease is a bilateral, diffuse, idiopathic autoimmune condition and a major cause of severe vision loss. This study aims to assess the prognostic significance of initiating systemic immunosuppressive therapy early during the acute uveitic phase of the disease.

Methods: A prospective interventional study was conducted at Ispahani Islamia Eye Institute, Bangladesh (Aug 2024–Aug 2025). 80 eyes from 40 VKH patients were divided into two groups: early treatment (within 2 weeks of symptom onset) and delayed treatment (after 1 month). Treatment included intravenous methylprednisolone followed by oral prednisolone and immunomodulatory therapy. Outcomes measured over 3 months included best-corrected visual acuity (BCVA), intraocular pressure, central macular thickness, recurrence, and chronic disease development.

Results: A total of 80 eyes from 40 patients were analyzed. The mean age of the study population was 40 ± 11 years, with a male-to-female ratio of 1:2. Complete resolution of uveitis was observed in 23 patients (57.5%), while 12 patients (30%) developed a chronic course, and 4 patients (10%) progressed to chronic recurrent uveitis. Those who began immunosuppressive therapy within two weeks of symptom onset demonstrated significantly better visual outcomes, a notable reduction in central macular thickness, quicker resolution of exudative retinal detachment, and fewer instances of chronic recurrent disease and late complications such as sunset glow fundus.

Conclusions: Early immunosuppressive therapy during the acute phase of VKH improves long-term visual outcomes and lowers risk of chronic progression underscoring the need for prompt diagnosis and aggressive management.

Abstract No.: 202388

Targeted Delivery of Avacopan via Sortase A-Modified Extracellular Vesicles Attenuates Endotoxin-Induced Retinal Inflammation

First Author: Deixn **MENG**

Co-Author(s): Yidan **CHEN**, Cong **CUI**, Dawei **SUN**

Purpose: Uveitis is a prevalent ocular inflammatory condition and a major contributor to global vision impairment, impacting persons of all ages and genders. The inflammatory cascade activates the complement system, resulting in the production of C5a, promoting excessive neutrophil recruitment and reactive oxygen

species (ROS) bursts, thus intensifying tissue damage. In this study, we developed a targeted drug delivery system by conjugating small extracellular vesicles with the microglia-binding peptide MG1 using Sortase A. The C5aR1 antagonist CCX168 (Avacopan™) was loaded into the modified EVs via extrusion, resulting in the successful construction of a microglia-targeted therapeutic platform.

Methods: Using a lipopolysaccharide (LPS)-induced endotoxin-induced uveitis (EIU) model, we evaluated the effects of MG1-EVs/Ava on ocular inflammatory pathology, microglial migration, and retinal cytokine expression. In vitro assays were performed to assess the cytotoxicity of Avacopan as well as its impact on ROS generation and pro-inflammatory cytokine production. In addition, data-independent acquisition (DIA) proteomics analysis was conducted to explore the downstream signaling pathways involved in MG1-EVs/Ava-mediated therapeutic effects.

Results: Both in vitro and in vivo investigations indicated that MG1-EVs/Ava showed markedly improved transport efficiency relative to EVs/Ava and greater anti-inflammatory effects compared to Avacopan alone. In rescue experiments, siRNA-mediated knockdown of MAPK9 reversed the upregulation of C5aR1 and pro-inflammatory cytokines, further supporting its role in mediating the therapeutic effects of MG1-EVs/Ava.

Conclusions: The findings of this study demonstrate both the therapeutic efficacy and mechanistic basis of MG1-EVs/Ava, highlighting its potential as a promising treatment strategy for infectious uveitis.

Abstract No.: 207095

Tattoo-Associated Uveitis

First Author: Xuchuan WANG

Purpose: This paper elaborates on the clinical features of tattoo-related uveitis by presenting a well-documented case, analyzes the pathogenesis of this disease based on the tattoo history, and describes the treatment process.

Methods: Multiple tattoos were noted on the patient's body, with discoloration, stiffness, redness, unevenness, and slight skin damage on the left upper arm where a tattoo had been removed by laser six months prior. Five days after the laser removal, the patient developed decreased vision, eye redness, and photophobia in both eyes.

Results: In this case, the patient developed eye symptoms two weeks after laser tattoo removal. When laser is used to remove tattoos, it can break down pigment particles into smaller sizes, making them more easily captured by lymphocytes and triggering an immune response. At the same time, laser can also cause damage to normal skin tissue, leading to an inflammatory response and activating the immune

function. Generally speaking, local and systemic use of corticosteroids or immunosuppressants can treat patients of this kind. During the treatment, the ocular and skin symptoms often improve simultaneously. The patient in this case conforms to this situation.

Conclusions: Both tattooing and laser tattoo removal can cause panuveitis, but the mechanism remains to be further studied. With the popularity of tattoo culture, more cases of tattoo-related uveitis will emerge. All cases of uveitis with unknown causes should undergo inquiries and examinations regarding tattoos.

Abstract No.: 203237

The Risk Assessment of Uveitis After Monkeypox Diagnosis: A Multicenter Population-Based Study

First Author: Chun-ju LIN

Co-Author(s): Ning-yi HSIA, Alan Y. HSU, Hou-ting KUO, Bing-qi WU

Purpose: Human monkeypox (MPOX) infection is attributed to the MPOX virus. While details on ophthalmologic manifestations have been limited, some case reports of uveitis have also been documented. However, uveitis has not been extensively documented among MPOX patients. Therefore, we conducted a population-based study utilizing the TriNetX electronic health registry database.

Methods: This retrospective cohort study used the TriNetX database and recruited those with and without MPOX diagnosis from January 1, 2016, to December 31, 2023. The non-MPOX cohort consisted of randomly selected control patients, including age, gender, ethnicity, race, relevant comorbidities, previous medications, and the inflammatory marker C-reactive protein. Statistical analysis on uveitis risk included hazard ratios (HRs) and 95% confidence intervals (CIs) were calculated over 8 years (2016–2023). A separate analysis of the risk of uveitis among MPOX patients aged 20 years and older was also conducted.

Results: A total of 5449 MPOX patients of all ages (25.45% female; mean age 35.17 ± 15.70 years) and 5449 propensity-matched non-MPOX comparators (23.97% female; mean age 35.30 ± 15.91 years) were recruited. For both the overall MPOX patient population and the adult MPOX patients, the risk of uveitis was significantly higher. This increased risk mainly happened in patients with anterior uveitis. Specifically, the HR for uveitis in all MPOX patients was 2.59. Among MPOX patients aged 20 years or older, the HR for uveitis was 2.14.

Conclusions: There is a notable association between new-onset uveitis and patients with MPOX. Our real-world findings underscore the importance of being aware of the potential risk of anterior uveitis.

Abstract No.: 206625**Topical JAK-Inhibitor: A Possible Therapeutic Option for Ocular Inflammatory Diseases***First Author: Ngoc THAN**Co-Author(s): Amir AKHAVANREZAYAT, Jia-horung HUNG, Hareem KHAN, Caroline LU, Quan Dong NGUYEN, Wang SHEN, Albert TSAI*

Purpose: To investigate the potential of a selective topical JAK1/TYK2 inhibitor as a corticosteroid-sparing therapy in ocular inflammatory diseases, including postoperative inflammation and noninfectious anterior uveitis (NIAU). By targeting IL-12/IL-23 signaling, JAK1/TYK2 inhibitors suppress pro-inflammatory Th1 and Th17 responses, which play central roles in autoimmune and anti-inflammatory in uveitis.

Methods: Preclinical findings and early clinical experience with selective JAK1/TYK2 inhibitors were evaluated, with emphasis on anterior uveitis, postoperative inflammation, and ocular surface disease. Particular attention was given to cytokine modulation involving IL-12/IL-23 and Th1/Th17 responses, as well as the pharmacologic attributes of topical formulations engineered for ocular penetration.

Results: Topical JAK1/TYK2 inhibition demonstrated rapid and robust anti-inflammatory activity. In NIAU Phase 2 trials, both concentrations of topical JAK1/TYK2 inhibitor achieved a ≥ 2 -grade reduction in ACC in $>92\%$ of subjects by day 14, compared with 77.80% for prednisolone acetate ($p=0.048$). Rates of complete ACC resolution at Day 28 reached 85.71% with high-dose group versus 77.78% with prednisolone acetate. In postoperative inflammation, a significantly greater proportion of patients achieved complete resolution of anterior chamber cells (ACC=0) at day 15 compared to approved corticosteroids ($p<0.01$), accompanied by superior pain relief. Importantly, ocular adverse events were comparable to vehicle, with no evidence of steroid-related intraocular pressure elevation.

Conclusions: Topical JAK1/TYK2 inhibition represents a promising new therapeutic class for ocular inflammatory disease, combining efficacy comparable or superior to corticosteroids with a favorable safety profile. Its mechanism of targeting IL-12/IL-23-driven inflammation supports broad application across uveitis, postoperative inflammation, and ocular surface disease. This approach may redefine management of ocular inflammation while reducing reliance on corticosteroids.

Abstract No.: 204567**UveAltis: Development, Performance Evaluation, and Benchmarking of a Novel Uveitis Retrieval-Augmented Chatbot for Patients and Physicians***First Author: Elaine Marie TAN**Co-Author(s): Rupesh AGRAWAL, Carlos CIFUENTES-GONZÁLEZ, Alejandra DE-LA-TORRE, William ROJAS-CARABALI, Maxwell SINGER*

Purpose: Uveitis, a complex group of inflammatory eye conditions, poses significant diagnostic challenges that can lead to impaired visual outcomes. Accurate diagnosis and effective patient education are crucial for improving care. This study introduces UveAltis, an AI-based chatbot utilizing Retrieval-Augmented Generation (RAG) and GPT-4o, designed to enhance diagnostic accuracy and provide high-quality patient education for uveitis. This study assesses the diagnostic accuracy and patient education capabilities of UveAltis compared to traditional diagnostic criteria and other language models.

Methods: A validation study was conducted using simulated clinical scenarios to evaluate UveAltis's diagnostic performance. Comparisons were made with five large language models (ChatGPT4o mini, ChatGPT4o, Gemini 1.5 Flash, Meta Llama3.1, Claude Sonnet-3.5) and the Standardization of Uveitis Nomenclature (SUN) criteria. Patient-related queries were assessed using Likert scales for correctness, completeness, readability, helpfulness, and safety. Data analysis was based on a peer-reviewed literature dataset of 1,421 relevant uveitis articles. Independent ophthalmologists reviewed all cases and educational outputs.

Results: UveAltis achieved a diagnostic accuracy of 92% (23/25 cases), outperforming other models (range: 44%–88%). It demonstrated superior patient education capabilities, scoring higher in correctness, completeness, readability, and safety compared to online resources. Diagnostic task completion was 80% (20/25) for task 1 and 92% (23/25) for task 2. Statistically significant differences ($P < .05$) were observed in educational quality across multiple dimensions.

Conclusions: UveAltis, leveraging GPT-4o and RAG, serves as a translational bridge between AI innovation and clinical ophthalmology, significantly improving diagnostic support and patient education in uveitis. It represents a promising digital health tool for improving outcomes in complex ocular diseases, especially in settings with limited specialist access.

Myopia

A New Perspective on Myopia Control: The Causal Role of Depression and Anxiety

First Author: Xiao WANG

Co-Author(s): Zhipeng LAI, Zhouyue LI, Jinyi XU, Shengsong XU, Xiao YANG

Purpose: To investigate the bidirectional causal relationship between depression, anxiety, and myopia using a robust genetic approach.

Methods: We employed a bidirectional two-sample Mendelian randomization to examine the causal relationship between depression, anxiety and myopia, while accounting for potential confounding factors. Summary statistics from large-scale genome-wide association studies (GWAS) were utilized. Genetic variants (single-nucleotide polymorphisms, or SNPs) associated with depression were sourced from the FinnGen consortium, and those for anxiety were obtained from the Psychiatric Genomics consortium. The inverse-variance weighted (IVW) method served as our primary analytical tool, complemented by comprehensive sensitivity analyses, including MR-Egger regression and leave-one-out analysis, to ensure the robustness of our findings and detect potential pleiotropy.

Results: A total of 21, 10 SNPs were selected as instrumental variables for depression and anxiety, respectively. Based on the IVW analysis, both depression (OR = 1.010, 95% CI = 1.002-1.018, P = 0.016) and anxiety (OR = 1.083, 95%CI = 1.022-1.149, P = 0.008) increased the risk of myopia. After adjusting in the multivariable MR, the IVW and Egger methods indicated that depression (OR = 1.004, 95%CI = 1.000-1.008, P = 0.030) or anxiety (OR = 1.004, 95%CI = 1.001-1.008, P = 0.026) was still associated with elevated risks of myopia.

Conclusions: This study provides compelling genetic evidence of a direct causal link between mental health disorders, specifically depression and anxiety, and an increased risk of myopia. These findings highlight the importance of integrating mental health screening and support into strategies for myopia prevention and control. Future research should focus on the underlying biological mechanisms to inform more targeted clinical interventions.

Abstract No.: 206943

AI-Based Non-Cycloplegic Refraction Diagnosis and Multimodal Temporal Prediction of Myopia Risk

First Author: Yunyun SUN

Co-Author(s): Mengxian HE

Purpose: To develop and validate two artificial intelligence (AI) models: (1) a diagnostic model for accurate refraction assessment under non-cycloplegic conditions, and (2) a multimodal temporal model for individualized prediction of myopia onset and progression.

Methods: Subjects were recruited from the Beijing, Lhasa and Anyang Eye Study. Cycloplegia was achieved with two drops of 1% cyclopentolate and 1 drop of Mydrin P (Tropicamide 0.5%, phenylephrine HCl 0.5%). For the diagnostic model, data from over 30,000 individuals were used. Demographic, non-cycloplegic refraction, and ocular biometric parameters were integrated. Missing values were imputed with Hyperband-optimized learners, followed by ensemble learning to predict cycloplegic refraction and myopia classification, with a final neural network aggregator. For the temporal prediction model, longitudinal data with 6 years of follow-up) were analyzed, integrating refraction, axial length, corneal curvature, fundus imaging, genetic, and environmental factors. Multimodal and multi-time-scale modeling was performed, incorporating temporal variables. Model interpretability was assessed with SHAP analysis.

Results: The diagnostic model reduced unnecessary cycloplegia by 35% while maintaining 95% sensitivity, supporting reliable and cost-effective screening. The temporal model achieved high accuracy, with a one-year prediction error of 0.16D, clinically negligible. SHAP analysis identified temporal intervals as the most influential predictor, surpassing ocular biometry. Regional comparisons (plateau vs. plain populations) revealed limited cross-applicability, highlighting environmental and lifestyle effects.

Conclusions: AI-driven approaches enable accurate refraction diagnosis without routine cycloplegia and provide dynamic, multimodal prediction of myopia risk. These models improve screening efficiency, support personalized management, and emphasize the need for region-specific adaptation in global applications.

Abstract No.: 205112

Adjunctive Use of Eyelid Wipes Improves Ocular Surface Condition in Children Initiating Orthokeratology

First Author: Xiaoxiao ZHANG

Co-Author(s): Mansha HE

Purpose: To evaluate whether eyelid wipes improve ocular surface health and meibomian gland function

in children newly fitted with orthokeratology (Ortho-K) lenses.

Methods: Fifty-eight myopic children (mean age 10.2 ± 1.3 years) initiating Ortho-K were randomized to an eyelid-wipe group ($n = 31$, daily wipes for 1 month) or a control group ($n = 27$, no lid hygiene). Baseline and 1-month follow-up assessments included noninvasive tear breakup time (NITBUT), lipid layer thickness (LLT), tear meniscus height (TMH), meibomian gland expressibility (MGE), corneal fluorescein staining (CFS), Ocular Surface Disease Index (OSDI), and overnight lens-wear comfort.

Results: All participants completed follow-up with comparable baseline characteristics. After 1 month, NITBUT showed modest improvement in the eyelid-wipe group (6.8 ± 2.5 s to 7.4 ± 2.6 s) versus minimal change in controls ($P = 0.12$). LLT tended to increase with wipes while remaining stable in controls ($P = 0.07$). MGE improved significantly in the eyelid-wipe group (2.5 ± 0.9 to 1.9 ± 0.8) compared with controls ($P = 0.002$). CFS rose in both groups but was significantly lower with eyelid wipes ($P = 0.03$). TMH showed no significant change. Subjective outcomes favored eyelid wipes, with greater OSDI reduction ($P = 0.02$), better overnight comfort ($P = 0.04$), and reduced morning crusting/itching (48% vs. 19%, $P = 0.01$). No adverse events were observed.

Conclusions: Adjunctive eyelid wipes improved meibomian gland function, ocular comfort, and corneal staining outcomes in children beginning Ortho-K wear. Incorporating lid hygiene may enhance safety and tolerability in pediatric Ortho-K management.

Abstract No.: 206834

Advancing Myopia Care Through Generative AI-Enabled Non-Invasive Choroidal Vascular Fingerprinting

First Author: Danli **SHI**

Co-Author(s): Mingguang **HE**

Purpose: To non-invasively generate indocyanine green angiography (ICGA)-like choroidal vasculature from color fundus photography (CFP), establish a comprehensive vascular analysis system, and evaluate their clinical utility as biomarkers for myopia progression.

Methods: A generative adversarial network (GAN) was trained on paired CFP-ICGA images to synthesize ICGA-like choroidal vessels. Segmented ICGA vasculature served as ground truth. Segmentation performance was evaluated using the area under the receiver operating characteristic curve (AUC). From simulated images, five categories of choroidal metrics—caliber, density, complexity, branching angle, and tortuosity—were extracted. Associations with myopia were tested in 34,623 UK Biobank participants, while predictive value for progression was evaluated in 542 adolescents

from the Guangzhou Twin Eye Study over a median 4-year follow-up, using regression models adjusted for conventional risk factors with FDR correction.

Results: The GAN generated detailed choroidal vessel segmentations, achieving an AUC of 0.746 (95% CI: 0.704–0.787) from CFP input and 0.940 (95% CI: 0.929–0.950) from ICGA input. In UK Biobank, 84 and 85 of 102 choroidal parameters were significantly associated with spherical equivalent and prevalent myopia, respectively. In adolescents, models incorporating age, gender, and choroidal vessel metrics predicted axial length progression with an AUC of 0.888, compared to 0.852 for risk factors alone; for spherical equivalent progression, the corresponding AUCs were 0.844 vs. 0.805, with significant improvements when choroidal features were added.

Conclusions: Generative AI enables non-invasive reconstruction of ICGA-level choroidal vasculature from CFP. Quantitative choroidal vascular fingerprints significantly enhance the prediction of myopia progression, representing novel biomarkers with strong potential for personalized myopia management.

Abstract No.: 206871

Age Alone Predicts Myopia Progression From School Age to Early Adulthood

First Author: Yin **HU**

Co-Author(s): Xiaohu **DING**

Purpose: Each additional diopter of myopia confers a 20%-60% increase in the risk of varying sight-threatening complications. It is imperative to establish prediction models to identify children at risk of experiencing excessive cumulative myopia progression spanning the critical progression period and, accordingly, administer proactive intervention. This study aimed to develop and validate prediction models for cumulative myopia progression by early adulthood.

Methods: Prediction models were derived using data of a prospective, 12-year twin cohort in Guangzhou, China. Cumulative axial elongation by adulthood was defined as the change in axial length from the current visit to the last follow-up visit as an adult (≥ 18 years). Multilevel logistic regression models were built and validated to predict cumulative axial elongation of 0.4 mm or more. Age was used to develop a univariate model. Prior defined candidate predictors were selected to develop a multivariate prediction model. Discrimination and calibration were evaluated based on five-fold cross-validation.

Results: A total of 9782 visits from 1203 eligible participants (526 [43.72%] males; mean [SD] age and SE refraction at first recorded visit after myopia onset, 12.81 [2.23] years and -1.93 [1.60] D, respectively) were analyzed. An age-only-based model demonstrated excellent predictive discrimination (AUC [95%CI] of five-fold cross-validation, 0.96 [0.96, 0.97])

and calibration (Brier score [95%CI], 0.08 [0.08, 0.08]). Inclusion of other predictive variables did not improve model performance.

Conclusions: An age-only-based model demonstrated good predictive accuracy for cumulative myopia progression that needs proactive intervention. Future studies are needed to validate its clinical utility.

Abstract No.: 201308

Analysis of Gene Mutation Spectrum for Early-Onset High Myopia Based on Whole Exome Sequencing

First Author: Liyin **WANG**

Co-Author(s): Xingtao **ZHOU**

Purpose: This study aimed to identify the loci of gene mutations associated with high myopia (HM), analyse the genetic mutation spectrum characteristics for early-onset HM (eo-HM), and explore the application of polygenic risk scores (PRS) in predicting eo-HM.

Methods: Whole-exome sequencing (WES) and ophthalmic measurements were performed on participants with HM, and the mutation results were further verified by copy number variation sequencing, long-range PCR, and Sanger sequencing. Participants were classified into eo-HM (onset age <7 years, binocular spherical equivalent refraction <-6.0 dioptres [D]) and late-onset HM (lo-HM). PRS was calculated and assessed for eo-HM prediction accuracy through receiver operating characteristic (ROC) curve metrics.

Results: The participants comprised 100 patients with HM. WES identified 36 variants across 35 of 100 patients (35.00%), with the eo-HM group exhibiting a significantly higher detection rate (56.52%) than the lo-HM group (16.67%) ($p < 0.001$). COL2A1 c.1221+1G>A, ARR3 c.41T>C, GLRA2 c.1006G>A, ZEB1 c.1672C>T, and HDAC8 c.466A>G were recognized as denovo mutation loci in eo-HM. TCF7L2, AIPL1, INPP5E and promoter mutation of SALL4 were identified as novel potential pathogenic mutations for HM. Genetic mutations related to retinal diseases were more frequently observed in eo-HM group than in the lo-HM group ($p < 0.01$). ROC curve analysis signified that PRS could serve as a potential predictor for eo-HM, (area under the curve 0.70).

Conclusions: This study expands the eo-HM mutational spectrum and proposes novel HM pathogenic genes, while demonstrating PRS's potential as a predictive model for eo-HM.

Abstract No.: 200578

Association Between Relative Peripheral Refractive Error and Myopia Progression: A Preliminary Study Using Optical Path Difference Scans

First Author: Kai En **CHAN**

Co-Author(s): Marcus **ANG**, Joey Zi Ying **CHUNG**

Purpose: Myopia is one of the leading causes of irreversible visual impairment globally. The role of relative peripheral hyperopia in myopia onset and progression remains debated. This study evaluates the relationship between relative peripheral refraction (RPR) and myopic status using Optical Path Difference (OPD) scan data.

Methods: This cohort study included 660 patients (1320 eyes) from the AIM cohort who underwent cycloplegic OPD scans at follow-up. RPR was calculated as the difference between peripheral (6-8 mm optical zone diameter) and central (2-4 mm zone) refraction derived from OPD scan. Linear regression was used to assess associations between RPR and myopic status, while generalised estimating equations evaluated the association between RPR and myopic progression. Models were adjusted for age, pupil size, astigmatism and inter-eye correlation.

Results: Myopic eyes had significantly more hyperopic RPR compared to non-myopic (β : +0.16D, 95%CI: 0.07-0.25 D, $p = 0.001$) eyes. However, no significant difference was observed between low and moderate-high myopia. Eyes with relative peripheral hyperopia at follow-up were more likely to have shown myopic progression (RR: 1.13, 95%CI: 1.02-1.25, $p = 0.020$) from baseline.

Conclusions: Although RPR was measured at follow-up, eyes with relative peripheral hyperopia were more likely to have exhibited myopic progression from baseline. This association supports the relevance of RPR in myopia and highlights the potential of OPD-based measurements as an adjunctive tool in identifying eyes at risk of progression. Further prospective studies are warranted to validate its predictive utility.

Abstract No.: 202403

Association of Attention-Deficit Hyperactivity Disorder With Myopia Among School Children

First Author: Xiu Nian **CHEN**

Co-Author(s): Jason **YAM**

Purpose: To determine the relationship of attention-deficit hyperactivity disorder (ADHD) with myopia among school children.

Methods: Children aged six to eight years in Hong Kong were recruited through a stratified, clustered randomized sampling frame and subsequently invited to undergo cycloplegic autorefractometry and axial length

measurements between 2016 and 2021. ADHD diagnoses were made by qualified physicians according to ICD-10 criteria. ADHD symptoms were assessed using the SWAN Questionnaire.

Results: Totally 474 children with ADHD and 9950 control children were included. The age- and sex-adjusted myopia prevalence was lower in ADHD group (21%) versus controls (26%; $P = 0.02$). Multivariable regression analysis showed less myopia ($OR = 0.75$; $P = 0.03$), higher spherical equivalent refraction (SER) ($\beta = 0.13$; $P = 0.04$), and shorter axial length (AL) ($\beta = -0.07$; $P = 0.03$) in children with ADHD. Specifically, ADHD with oral MPH treatment had less myopia ($OR = 0.61$, $P = 0.04$), higher SER ($\beta = 0.36$; $P < 0.001$) and shorter AL ($\beta = -0.25$; $P < 0.001$) compared to controls. Each additional month of MPH treatment was associated with a higher SER ($\beta = 0.02$; $P = 0.01$) and shorter AL ($\beta = -0.01$; $P = 0.01$). For each one-point increase in attention-deficit scores, children were found to be less myopic ($OR = 0.88$, $P = 0.01$), having higher SER ($\beta = 0.07$; $P = 0.003$) and shorter AL ($\beta = -0.04$; $P = 0.001$). The prevalence of myopia among ADHD increased to 32% during COVID-19 pandemic compared with 23% before COVID-19 pandemic ($P = 0.04$).

Conclusions: This cross-sectional study found that ADHD is associated with reduced myopia prevalence, more hyperopic SER, and shorter AL.

Abstract No.: 200973

Association of Optic Nerve Head Metrics and Parapapillary Gamma Zone With Myopia Onset and Progression in Children: The Hong Kong Children Eye Study

First Author: Yi LI

Co-Author(s): Jason C. YAM, Xiu Juan ZHANG

Purpose: The purpose of this study was to evaluate the associations of optic nerve head (ONH) metrics and parapapillary gamma zone with myopia onset and progression in school children aged 6 to 8 years over 3 years.

Methods: The ONH was imaged by spectral domain-optical coherence tomography (SD-OCT) using an adopted scan protocol comprising 24 equally spaced radial B-scans.

Results: The study included 765 children (mean age: 7.69 ± 1.01 years). Significant differences were found in disc ovality index, gamma zone area, Bruch's membrane opening distance (BMOD), temporal border tissue angle (BTA), and optic disc-fovea distance (DFD) across different refractive status groups (all $P < 0.001$). Multivariable logistic regression analysis indicated that female sex ($OR = 1.74$; $P = 0.006$), longer axial length ($OR = 1.81$; $P < 0.001$), larger nasal BTA ($OR = 1.01$; $P = 0.005$), larger temporal BTA ($OR = 1.01$; $P = 0.019$), optic disc torsion ($OR = 2.12$; $P = 0.007$), and longer DFD at baseline ($OR = 3.39$; $P < 0.001$) were risk factors

of myopia onset, while presence of gamma zone at baseline was not. In multivariable linear regression analysis, baseline disc ovality index, BMOD, nasal BTA, temporal BTA, and DFD, as well as changes in BMOD, nasal BTA, temporal BTA, gamma zone area, and DFD were significantly associated with spherical equivalent (SE) progression over 3 years.

Conclusions: ONH parameters like nasal BTA, temporal BTA, disc torsion, and DFD may have predictive value for myopia onset and progression. As the myopic SE progresses, gamma zone enlargement coincides with the elongation of BMOD and DFD.

Abstract No.: 205013

Behavioral and Familial Risk Factors for Myopia Prevalence in Chinese Schoolchildren: A Latent Class Analysis

First Author: Hongmei ZHANG

Co-Author(s): Ruihua

Purpose: To identify high-risk behavioral patterns and family factors contributing to myopia prevalence among primary and secondary school students in China using latent class analysis (LCA).

Methods: This cross-sectional study analyzed data from 2,755 students aged 6-16 years, enrolled in the Tianjin Child and Adolescent Research of Eye (TCARE). Participants completed eye examinations and questionnaires assessing lifestyle factors such as physical activity, diet, near work, and screen time. LCA was used to classify students into distinct behavioral phenotypes. Multivariable logistic regression analyzed associations between these phenotypes and myopia risk, adjusting for parental myopia and education level.

Results: Three behavioral categories were identified: Healthy Behavior (44.6%), Eye Strain (24.6%), and Eye Strain with Unhealthy Diet (30.8%). Students in the Eye Strain and Unhealthy Diet category exhibited a 1.61-fold increased risk of myopia, while the Eye Strain category had a 1.89-fold increased risk compared to the Healthy Behavior category. Parental myopia and maternal education were also significant predictors of myopia risk.

Conclusions: Behavioral patterns, particularly those involving excessive screen time and insufficient physical activity, contribute significantly to myopia prevalence in Chinese schoolchildren. Our findings suggest that lifestyle modifications, including increased physical activity and reduced screen exposure, could be effective strategies for myopia prevention. The role of parental education highlights the importance of family-level interventions in mitigating myopia risk.

Abstract No.: 200768

Better Myopia Control of Orthokeratology Than Defocus Incorporated Soft Contact Lenses by Including the Modulation of Retinal Blood Flow

First Author: Yunjie ZHANG

Co-Author(s): Lin FU, Yijing PING, Shumeng YAO, Xiaoyu ZHUANG

Purpose: This study compares the effects of orthokeratology (OK) lenses and Defocus Incorporated Soft Contact (DISC) on retinal vessel density (RVD) and investigates the role of retinal microcirculation in myopia control.

Methods: A self-controlled clinical trial included 35 subjects (8-12 years) with myopia (-1.00D to -5.00D). Participants wore OK lenses or DISC in one eye, with the contralateral eye serving as the control. RVD was assessed using optical coherence tomography angiography, and axial length (AL) elongation was tracked. The 9 grids with the macula as the center and the 4-quadrant dividing method were utilized.

Results: After 12-month treatment, the AL elongation was significantly shorter in the OK group (0.17 ± 0.17 mm) compared to the DISC group (0.26 ± 0.15 mm, $P < 0.05$). RVD in the OK group initially decreased but rebounded to baseline values after 4 weeks off wearing, while the DISC group showed no significant changes. Baseline RVD parameters divided by the 9 grids method predicted AL elongation (AUC: 0.768-0.824, $P < 0.05$) in the OK group, whereas the RVD parameters from the 4 quadrants dividing method showed no correlation with the AL elongation.

Conclusions: The OK lenses showed better myopia control than the DISC lenses in this study, and this may be potentially mediated through retinal microcirculation modulation. This study further identifies RVD biomarkers from the 9-grid dividing method, predicting the myopia control effect of OK lenses. Therefore, more attention should be paid to the RVD changes by the 9-grid dividing method.

Abstract No.: 203496

Blue Light Suppresses Form-Deprivation Myopia in Mice via an Opn4-Mediated Pathway

First Author: Congying LI

Co-Author(s): Ying HUANG, Yuting KANG, Shi-ming LI, Xinyu LI, Tianli PENG, Meijun WANG, Ningli WANG

Purpose: The role of blue light in myopia development remains controversial. This study aimed to determine whether 480 nm blue light influences form-deprivation myopia (FDM) via intrinsically photosensitive retinal ganglion cells (ipRGCs) that express Opn4.

Methods: Monocular FDM was induced in C57BL/6J mice from postnatal days 21 to 63 (P21-P63),

maintained under a 12-hour light/12-hour dark cycle. Control mice were exposed solely to white light, while experimental groups received additional 480 nm blue light during one of the following intervals: 05:00-08:00, 17:00-20:00, 20:00-23:00, 08:00-20:00, or continuously ($n=10$ per group). The most effective interval for suppressing FDM was further tested in Opn4^{-/-} mice ($n=10$). Refractive error, axial length, and retinal Opn4 expression were evaluated at P63.

Results: Blue light exposure from 20:00-23:00 significantly suppressed FDM in C57BL/6J mice, resulting in reduced myopic shifts (-6.42 ± 4.08 D vs. -18.87 ± 9.66 D, $P = 0.007$), less axial elongation (0.014 ± 0.032 mm vs. 0.071 ± 0.017 mm, $P = 0.003$), and elevated Opn4 expression (0.79 ± 0.25 vs. 0.56 ± 0.10 , $P = 0.010$) compared with white-light controls. Other intervals did not yield significant protective effects. In Opn4^{-/-} mice, blue light exposure during this interval failed to suppress FDM, with refractive errors and axial elongation similar to those of wild-type controls under white light (-13.36 ± 3.62 D vs. -17.35 ± 4.31 D, 0.037 ± 0.014 mm vs. 0.030 ± 0.012 mm, all $P > 0.05$).

Conclusions: These findings identify Opn4 as an essential mediator in the suppression of myopia by blue light, highlighting its potential role in developing innovative light-based therapeutic strategies.

Abstract No.: 201033

CPNE1: A Novel Therapeutic Target for Myopia Progression – From Genetic GWAS Discovery to Functional Validation In Vivo

First Author: Lanbo JIA

Co-Author(s): Shan GAO, Guoge HAN, Yan WANG, Yining WANG, Pinghui WEI, Zitian XIA

Purpose: To identify novel regulatory genes associated with myopia and validate their functional roles in vivo using animal models.

Methods: We performed a fixed-effect meta-analysis of two large-scale genome-wide association studies (GWAS) comprising 41,468 cases and 817,202 controls to identify genome-wide significant loci associated with myopia. Potential functional myopia-associated genes were prioritized using summary data-based Mendelian randomization (SMR). Bayesian colocalization analysis, Mendelian randomization (MR) analysis, and validation in an independent cohort were used to verify the causal roles of the candidate genetic loci. DEGseq2 differential expression and machine learning-based LASSO feature selection, scleral transcriptomic analyses were investigated to strengthen the CPNE1 myopic prevention role. Single-cell RNA sequencing (scRNA-seq) and immunohistochemistry (IHC) were used to localize CPNE1 expression within ocular tissues. CPNE1 was overexpressed by adeno-associated virus (AAV) from the sclera in the lens-induced myopic (LIM) model, and its potential inhibiting eye axial progression role in scleral fibroblast was explored.

Results: The GWAS meta-analysis identified 35 genome-wide significant loci associated with myopia. Integrative SMR and colocalization analyses consistently prioritized CPNE1 (SMR: FDR < 0.05; colocalization: PP_{H4} = 0.988). MR analysis supports a causal protective role of CPNE1 in myopia (Wald [OR] = 0.97; IVW [OR] = 0.98). Transcriptomic profiling demonstrated significant downregulation of CPNE1 in myopic sclera (log₂FC = -7), and LASSO regression identified CPNE1 as a key feature gene. ScRNA-seq and IHF localized CPNE1 expression predominantly to scleral fibroblasts. In the LIM model, CPNE1 expression was significantly decreased, while AAV-mediated overexpression of CPNE1 attenuated axial elongation and refractive error progression. Mechanistically, CPNE1 overexpression was associated with upregulated α -SMA levels, suggesting a potential role in scleral remodeling.

Conclusions: These findings establish CPNE1 as a novel potential therapeutic target for myopia.

Abstract No.: 201438

Causes and Outcomes of Explantations of Iris-Fixated Phakic Intraocular Lenses in Patients With Corneal Endothelial Cell Loss

First Author: Jooye **PARK**

Co-Author(s): Yong-soo **BYUN**, So-hyang **CHUNG**, Hyun Seung **KIM**, Hye-yeon **YOON**

Purpose: To evaluate the risk factors contributing to corneal endothelial cell density (ECD) loss associated with iris-fixated phakic intraocular lenses (pIOLs) and to assess postoperative ECD changes until 1 year after explantation.

Methods: This retrospective study included 114 eyes (61 patients) that underwent explantation of Artisan (n=55) or Artiflex (n=59) pIOLs due to progressive ECD loss. Preoperative ocular parameters were analyzed, and ECD changes were tracked up to 1 year postoperatively. Receiver operating characteristic (ROC) curves were used to determine cutoff values for preventing significant post-explantation ECD loss at postoperative 1 year.

Results: The mean pre-explantation ECD was 1637 cells/mm² in the Artisan group and 1769 cells/mm² in the Artiflex group. The risk factors of decreased ECD were a small anterior chamber angle (ACA) and the distance of the nasal edge of the IOL to the endothelium in both groups. The difference in fixation length between temporal and nasal fixation in the Artisan group, and fixation length and iris pigmentation grading in the Artiflex group were additional risk factors. Cutoff values of preoperative ECD to minimize irreversible ECD loss were 1683.5 cells/mm² (Artisan) and 1648 cells/mm² (Artiflex).

Conclusions: Both anatomical and inflammatory factors contribute to ECD loss in eyes with iris-fixated pIOLs. Close monitoring of anterior segment changes

and ECD is essential to determine optimal timing for explantation and to prevent irreversible endothelial damage.

Abstract No.: 204471

Central Regulation in Myopia Development: Evidence From Optic Nerve Pathways in Myopic Mice

First Author: Xianghua **TANG**

Co-Author(s): Zhouyue **LI**, Xiao **WANG**, Jin-yi **XU**, Xiao **YANG**

Purpose: This study aimed to explore the regulating role of optic nerve conduction in refractive development in the murine model and its potential mechanism.

Methods: Optic nerve conduction in mice was blocked by optic nerve crush (ONC), with the Sham surgery (SHAM) group serving as the control. The 21-day-old C57BL/6 mice were divided into four groups: ONC group, SHAM group, optic nerve crush and lens-induced (ONC-LIM) group, and sham surgery and lens-induced (SHAM-LIM) group. The refraction was detected with retinoscopy after pupils dilated with compound tropicamide and ocular biological parameters were measured by optical coherence tomography in vivo at baseline and 2 weeks after the intervention. Bulk RNA-sequencing analysis was conducted with the mouse retina between the ONC group and the SHAM group.

Results: After ONC, 50% of the mice showed a myopic shift and 25% showed a hyperopic shift, and the changes of axial length (AL) were consistent with refraction. The ONC-LIM group did not show myopia shift and axial elongation similar to the SHAM-LIM group, suggesting that optical defocus could not induce a myopic shift in mice after ONC. RNA-seq analysis revealed several neural-related pathways, such as glutamatergic synapse, GnRH signaling, and long-term depression.

Conclusions: This study suggested that intact optic nerve conduction is required for murine emmetropization and lens-induced myopia. The potential mechanism may involve the central nervous system.

Abstract No.: 205336

Changes in Anterior Segment and Fundus Structure After ICL Surgery for High Myopia

First Author: Yifei **PENG**

Co-Author(s): Zheng **WANG**, Lu **XIONG**

Purpose: The study aims to investigate the effects of implantable collamer lens (ICL) implantation on intraocular pressure (IOP), anterior chamber angle, and fundus structure.

Methods: This prospective study enrolled patients with high myopia undergoing ICL implantation. IOP,

angle opening distance (AOD), angle recess area (ARA), trabecular-iris space area (TISA), trabecular iris angle (TIA), vault, disc RPC vessel density (DRVD), foveal avascular zone area (FAZ area), superficial vessel density (SVD) and deep vessel density (DVD) in the macular region were measured preoperatively, 1 day, 1 week and 3 months postoperatively. Paired t-tests, Mann-Whitney U tests, repeated-measures ANOVA, and Spearman correlation were performed, with significance set at $P < 0.05$.

Results: This study enrolled 63 eyes that completed follow-up. IOP peaked at one week and returned to baseline by 3 months. Postoperative anterior chamber angle parameters narrowed significantly ($P < 0.05$). At 3 months, nasal AOD750 and ARA750 increased, while selected TIA values showed further narrowing ($P < 0.05$). Parafoveal and paracentral SVD exhibited transient decreases in specific regions at 1 week, recovering to preoperative levels by 3 months. Similarly, DVD decreased significantly ($P < 0.05$) in the inferior parafoveal and temporal paracentral areas at 1 week and normalized by 3 months. DRVD dropped at 1 week and recovered. FAZ narrowed at 1 day ($P < 0.05$) and stabilized.

Conclusions: ICL implantation led to transient IOP and macular vessel density changes, which recovered by 3 months. However, a significant anterior chamber angle was narrowed, and a reduced FAZ area persisted.

Abstract No.: 207086

Comparative Evaluation of Different (Peripheral Defocus-Based) Spectacle Designs in Preventing Myopia Progression: 2-Year Results From a Double-Blinded Randomized Clinical Trial

First Author: Vinay GUPTA

Co-Author(s): Rebika, Swati PHULJHLE, Rohit SAXENA, Namrata SHARMA

Purpose: This study aimed to evaluate and compare the 2-year efficacy of different peripheral defocus-based spectacle designs [Defocus Induced Multiple Segment (DIMS), Highly Aspherical Lenslets (HALT), and Cylindrical Annular Refractive Element (CARE)] in controlling myopia progression.

Methods: This was a prospective, interventional, double-blinded, randomized clinical trial. Children aged 5-15 years, with myopia between -1D and -8D and documented myopia progression of $\geq 0.5D$ /year, were randomly assigned (1:1:1) to wear either DIMS, HALT, or CARE spectacles full-time. Ethical approval was obtained. Cycloplegic refraction and axial length measurements were recorded at baseline and 2-year follow-up. The primary outcome was the change in the rate of myopia progression. All analyses were performed based on the intention-to-treat principle.

Results: One Hundred Twenty participants (40 in each group: DIMS, HALT, and CARE) with a mean age of 10.1 ± 3.3 years (57% male) were enrolled. At the 2-year follow-up, the rate of myopia progression reduced by $0.4 \pm 0.12D$ /year (58.8%) for the DIMS-group, $0.39 \pm 0.11D$ /year (58.6%) for the HALT-group, and $0.33 \pm 0.13D$ /year (49.6%) for the CARE-group. The change in axial length was $0.18 \pm 0.1mm$ /year, $0.19 \pm 0.13mm$ /year and $0.22 \pm 0.12mm$ /year after 2 years of DIMS, HALT and CARE spectacles wear respectively. Inter-group comparisons showed a significant difference in the rate of myopia progression between DIMS and CARE ($P: 0.042$) and between HALT and CARE ($P: 0.047$). No significant differences were found between HALT and DIMS for any parameter. No adverse events reported with any design.

Conclusions: Spectacles incorporating peripheral defocus (DIMS, HALT, and CARE) were safe and significantly effective in reducing the rate of myopia progression. Among the three designs, DIMS and HALT exhibited comparable and significantly better efficacy than CARE spectacles at 2-year follow-up.

Abstract No.: 202589

Corneal Higher-Order Aberrations as Key Predictive Indicators of Axial Elongation in Myopic Children With Orthokeratology: A Single-Center Prospective Cohort Study

First Author: Ju ZHANG

Co-Author(s): Weiyun SHI

Purpose: This prospective study aimed to investigate changes in corneal higher-order aberrations (HOAs) in myopic children using orthokeratology (ortho-k) lenses and their relationship with myopia progression.

Methods: A total of 112 children aged 8-13 years were divided into group A (axial elongation ≤ 0.1 mm/y with ortho-k) and group B (axial elongation > 0.1 mm/y with ortho-k). At baseline, 1, 6, and 12 months following the initiation of lens wear, HOAs and corneal peripheral defocus were evaluated.

Results: Ninety-three patients completed the 1-year follow-up. The mean axial elongation was -0.07 ± 0.15 mm/y in group A, versus 0.32 ± 0.17 mm/y in group B. No statistical differences were observed in HOAs and corneal peripheral defocus at 1, 6, and 12 months ($F=0.653, 0.878; P > 0.05$). Multivariate linear regression showed axial elongation was negatively correlated with Δ HOAs, peripheral defocus, and Δ horizontal coma (standardized beta= $-0.331, -0.318, -0.209; P=0.006, 0.001, 0.010$, respectively) and positively correlated with the treatment zone diameter (standardized beta= $0.261, P=0.003$). Multivariate logistic regression identified Δ HOAs, peripheral defocus, Δ horizontal coma, and treatment zone as key factors distinguishing group A from group B (OR= $0.009, 0.455, 0.123, 12.172; P=0.036, 0.003, 0.032, 0.019$, respectively). The ROC

curve for Δ HOAs had an area of 0.803 with a cut-off value of 0.834 μm .

Conclusions: The Δ HOAs were more effective independent predictors of axial elongation than corneal peripheral defocus in children using ortho-k lenses. The Δ HOAs greater than 0.834 μm may lead to axial elongation ≤ 0.1 mm/y. These findings can be beneficial to fitting and optimizing ortho-k lenses.

Abstract No.: 204374

Correlations Between Photoreceptor Cell and Retinal Blood Flow Parameters in Low to Moderate Myopia by Adaptive Optics Scanning Light Ophthalmoscopy

First Author: Yingfan **WANG**

Co-Author(s): Manman **HUANG**, Changgeng **LIU**, Qian **LIU**, Yu **ZHANG**

Purpose: To study the association between photoreceptor cells and blood flow parameters of low to moderate myopia via novel adaptive optics scanning light ophthalmoscopy (AOSLO).

Methods: The 158 subjects were divided into three groups according to spherical equivalent. AOSLO was used to quantify the spatial characteristics of photoreceptor cell, including density, spacing, regularity, and dispersion; to measure fundus vascular blood flow, including vessel wall thickness (VW), lumen diameter (LD), vessel diameter (VD), the wall-to-lumen ratio (WLR), the cross-sectional area of the vascular wall (WCSA), and blood flow velocity; and to evaluate the association between cells and blood flow parameters using ANOVA and Pearson's correlation coefficients.

Results: With the increase of diopter, the significant difference of photoreceptor cell spacing increased gradually ($P < 0.001$), and was positively correlated with axial length (AL) and LD, it was negatively correlated with spherical equivalent (SE), cell density and WLR. The differences of LD, VD and WCSA increased with the increase of diopter ($P = 0.007$; $P = 0.008$; $P = 0.038$). There was a positive correlation between LD, AL, VW, VD, WCSA, blood flow velocity and velocity standard deviation. LD, VD and WCSA were negatively correlated with SE.

Conclusions: Photoreceptor cell spacing, LD, VD, and WCSA exhibited positive correlations with AL, while displaying negative correlations with SE. Cell spacing demonstrated a negative correlation with cell density. There was significant positive correlation between LD, VD, VW and WCSA, and they were positively correlated with blood flow velocity; whereas VD and WCSA were significantly positively with gender. The findings may help to understand the occurrence and development mechanism of myopia, and have potential value in clinical assessment of pathological changes in myopic retinopathy.

Abstract No.: 203690

Cry1 Deficiency Triggers Circadian Disruption and Evolutionarily Conserved Scleral Remodeling to Drive Myopia Pathogenesis

First Author: Tianli **PENG**

Co-Author(s): Congying **LI**, Shi-ming **LI**, Xinyu **LI**, Meijun **WANG**

Purpose: Circadian rhythm disruption caused by altered photoperiod is mechanistically linked to myopia pathogenesis, though core molecular determinants remain elusive. Cryptochrome 1 (Cry1), a pivotal circadian phototransducer, mediates light entrainment, yet its direct role in refractive development is undefined.

Methods: Using wild-type (WT) and Cry1^{-/-} mice under controlled photoperiods (LD: 12h light/12h dark; LL: 24h light; DD: 24h dark), we integrated longitudinal refraction, axial length (AL), corneal curvature, circadian behavior, scleral histomorphology, retinal transcriptomics, and cross-species scleral mechanotransduction assays.

Results: Compared to LD, LL induced myopia in WT mice (-1.69 ± 1.16 D vs. LD 5.06 ± 0.81 D; $P < 0.001$), accompanied by downregulated Cry1 expression ($P = 0.034$). Cry1^{-/-} mice exhibited severe circadian arrhythmia (free-running period: 22.48 ± 0.29 h vs. WT 23.89 ± 0.09 h; $P < 0.001$) and impaired photoreceptor function (reduced a-wave peak amplitudes under light adaptation: -9.38 ± 1.98 μV vs. WT -17.10 ± 1.45 μV ; $P = 0.012$; and delayed b-wave implicit times under dark adaptation: 30.22 ± 1.96 ms vs. WT 22.53 ± 2.31 ms; $P = 0.024$). Additionally, Cry1^{-/-} mice developed spontaneous myopia by week 9 (refraction: 2.42 ± 0.71 D vs. WT 8.55 ± 0.69 D; $P < 0.001$; AL: 3.11 ± 0.03 mm vs. WT 3.02 ± 0.02 mm; $P = 0.02$), with concomitant scleral thinning (17.83 ± 1.07 μm vs. 23.87 ± 0.95 μm ; $P = 0.014$). Crucially, LL elicited no refractive shift in Cry1^{-/-} mice ($P = 0.580$), establishing Cry1 as essential for photoperiod-dependent refractive regulation. RNA-seq analysis identified significant transcriptomic alterations in Cry1^{-/-} retinas, with pathways related to extracellular matrix (ECM) remodeling and stress responses being enriched. Notably, LL upregulated scleral cyclic adenosine monophosphate (cAMP) in WT mice ($P = 0.031$), while Cry1 deficiency also resulted in upregulated cAMP ($P = 0.012$). However, LL failed to further increase cAMP in Cry1^{-/-} mice, suggesting that LL induces myopia through the Cry1–cAMP axis. Additionally, Cry1^{-/-} mice exhibited increased Hif-1 α and α -smooth muscle actin (α -SMA) expression, indicative of myofibroblast transdifferentiation. This regulation was conserved in human scleral fibroblasts, where hypoxic exposure downregulated CRY1 expression at both transcriptional and translational levels.

Conclusions: Cry1 deficiency causes intrinsic circadian disruption that activates evolutionarily conserved

scleral remodeling program-encompassing oxidative stress, ECM dysregulation, and hypoxic signaling to drive myopia pathogenesis. This positions Cry1 as a master regulator of light-dependent ocular growth.

Abstract No.: 201338

Detection and Localization of Paravascular Abnormalities Using Dream OCT in Highly Myopic Eyes

First Author: Tomonari TAKAHASHI

Co-Author(s): Kyoko OHNO-MATSUI, Hiroyuki TAKAHASHI

Purpose: Paravascular abnormalities (PVA) are frequently observed in highly myopic eyes, but detailed investigations regarding their localization and associated factors remain limited. This study aimed to detect PVA using en face imaging with Dream OCT (Intalight®) and to evaluate its distribution and related factors.

Methods: We retrospectively analyzed 135 eyes of 72 highly myopic patients (17 men, 55 women) who visited the Institute of Science Tokyo, between December 2024 and June 2025. PVA was assessed on en face images obtained with Dream OCT. Eyes were divided into PVA-positive and PVA-negative groups, and associations with axial length, refractive error, and age were analyzed. PVA localization was classified into six regions relative to the optic disc: superior and inferior quadrants on the nasal side, papillomacular area, and temporal side.

Results: PVA was identified in 68 eyes (50.4%). The PVA-positive group had significantly longer axial length (29.24 ± 1.72 mm vs 26.99 ± 2.37 mm, $p < 0.001$) and greater myopic refractive error (-13.57 ± 3.91 D vs -7.78 ± 5.07 D, $p < 0.001$). PVAs were predominantly located in the papillomacular area, while nasal regions showed fewer PVAs ($p < 0.001$). PVA frequency increased with age, being observed in 23.5% of eyes under 40 years and 66.7% of eyes aged 40 years or older ($p = 0.0048$).

Conclusions: PVA is more prevalent in older patients with high myopia and primarily occurs in the papillomacular region. En face imaging with Dream OCT is a valuable tool for the detection and localization of PVA.

Abstract No.: 200316

Determining Safe Dosage Parameters for Red Light Photobiomodulation in Myopia Control: Mathematical Modeling and Animal Validation

First Author: Mengtian KANG

Co-Author(s): John PHILLIPS, Qianqian SONG, Ningli WANG, Wenjun XU

Purpose: Photobiomodulation (PBM) for myopia control has gained widespread attention, with increased choroidal perfusion as a potential therapeutic mechanism. This study investigated 650nm red laser retinal irradiance, dose factors, and safety thresholds through mathematical modeling, animal experiments, and molecular biology approaches.

Methods: A light propagation model incorporating optical parameters was established using the radiative transfer equation (RTE) and Henyey-Greenstein phase function. Ex vivo retinal irradiance was measured under 2mW, 5mW, 10mW, and 20mW conditions for model validation. Form-deprivation myopia models in chicks and guinea pigs received PBM treatment. RT-PCR, Western blot, immunofluorescence, electron microscopy, and TUNEL techniques assessed photoreceptor and RPE viability to determine damage thresholds. Axial length and refractive parameters were measured to evaluate myopia control efficacy.

Results: The mathematical model demonstrated predictable retinal irradiance calculations with relative differences of 0.0540-0.1075. Retinal irradiance increased non-linearly with greater laser power, shorter axial length, and larger pupil diameter. According to GB/T 7247.9-2016 MPE standards, safe parameters for human eyes (24.0mm axial length, 205mm source distance, 180s exposure) required pupil diameter ≤ 4.26 mm and power ≤ 2 mW. Animal experiments showed 2mW red light controlled axial elongation and myopic shift, but >10 mW induced structural changes in ONL and RPE with apoptotic cells and upregulated Bax/Bcl-2 pathways.

Conclusions: The RTE mathematical model validated through animal eyes can predict 650nm red laser retinal irradiance and determine safe exposure ranges. Red light demonstrates myopia control within safe limits but causes photoreceptor damage beyond safety thresholds, crucial for optimizing therapeutic benefits versus potential risks.

Abstract No.: 205208

Development and Validation of Predictive Models Based on the First-Month AL Change for the Long-Term Efficacy of Ortho-K in Myopic Children

First Author: Zhenbang **RUAN**

Co-Author(s): Wenlong **HAO**, Yin **HU**, Jinyun **JIANG**, Zhouyue **LI**, Chuqi **XIANG**, Xiao **YANG**

Purpose: Orthokeratology (ortho-k) is a widely used therapy to slow myopia progression, but individual responses to treatment often vary among myopic children. This study aimed to identify simple and practical predictors and develop predictive models for the long-term efficacy of ortho-k treatment in myopic children.

Methods: The training cohort data and external validation cohort data were collected from two separate prospective studies conducted at Zhongshan Ophthalmic Center, respectively. Baseline variables and first-month change in axial length (AL) were entered into logistic regression to develop predictive models to assess the 1-year efficacy of ortho-k treatment on retarding AL elongation. Nomograms and an online calculator were used to present the final models, while receiver operating characteristic (ROC) curves, calibration curves, and decision curve analysis (DCA). Internal validations, external validations were further used to assess the models.

Results: The training cohort comprised 150 myopic children, and the external validation cohort comprised 88 myopic children. Age and first-month AL change were included in the final predictive model for excessive myopia progression, with area under the ROC curves (AUC) above 0.84. Solely the first-month AL change was included in the final predictive model for rapid myopia progression with an AUC above 0.85. All the discrimination, calibration, and clinical net benefit performed excellently in training and external validation cohorts.

Conclusions: First-month AL change and age are simple and practical predictors for long-term efficacy of ortho-k treatment in myopic children. Predicting ortho-k efficacy after the first month will provide eye care practitioners with guidance to evaluate subsequent outcomes and adjust follow-up plans.

Abstract No.: 208123

Differential Effect of Outdoor Time on Myopia Prevention in Hyperopic and Premyopic Children

First Author: Ziyi **QI**

Co-Author(s): Jun **CHEN**, Xiaohu **DING**, Mingguang **HE**, Xiangui **HE**, Xun **XU**

Purpose: To assess whether time outdoors effectively prevents myopia in premyopic children.

Methods: This post-hoc subgroup analysis was nested in the Shanghai Time Outside to Reduce Myopia (STORM) study, a prospective, school-based cluster-randomized trial. Participants included 6 to 9-year-old schoolchildren who were all examined with cycloplegic refraction. Premyopia was defined as -0.50 diopters (D) $<$ spherical equivalence (SE) $\leq +0.75$ D. Findings were validated using the Guangzhou Outdoor Activity Longitudinal (GOAL) study. Participants were randomized into three groups: Control (usual outdoor activities), Test I (additional 40 minutes of daily outdoor time), and Test II (additional 80 minutes of daily outdoor time). Two-year cumulative incidences of myopia were the primary outcome. Adjusted relative risk (aRR) and relative reduction were assessed between intervention and control groups.

Results: The STORM study included 5067 participants, 3506 of whom were premyopia with a mean age of 7.4 years and 54.4% boys. Among premyopic children, the two-year cumulative incidences of myopia were 64.1% (Control), 55.6% (Test I), and 58.7% (Test II). aRRs were 0.87 (95% CI: 0.74-1.02) for Test I and 0.93 (95% CI: 0.79-1.10) for Test II, reflecting relative reductions of 13% and 7%, respectively. In hyperopic children, aRRs were 0.49 (95% CI: 0.36, 0.69) for Test I and 0.88 (95% CI: 0.66, 1.18) for Test II, indicating relative reduction of 51% and 12%, respectively. Consistent findings were observed in the GOAL study, with aRRs of 0.91 (95% CI: 0.75-1.10) for premyopic and 0.67 (95% CI: 0.46-0.96) for hyperopic children over two years, corresponding to relative reductions of 9% and 33%, respectively.

Conclusions: While increased outdoor time significantly reduced myopia incidence in hyperopic children, its effect was limited in premyopic children. These findings suggest that more intensive intervention strategies are needed for premyopic children to effectively prevent myopia.

Abstract No.: 201148

Effect of Optical Defocusing Frame Glasses on the Prevention of Myopia in Non-Myopic Children Aged 5–8

First Author: Yanhua **WANG**

Purpose: This study was to investigate the significance of preventing myopia using defocus spectacle lenses in non-myopic children aged 5-8.

Methods: The study included a total of 97 non-myopic children aged 5-8. All subjects were divided into two groups. One group (experimental group, 42 eyes) wore O.T.O.G.E. lenses, while the other group (control group, 55 eyes) wore no glasses. Refractive outcomes and axial length (AL) were measured in all subjects and then again six months and one year later for comparison. T-tests were used to compare the growth of spherical equivalent refraction (SE) and AL between the two groups.

Results: At the end of six months, the experimental group had less SE myopic shift and AL elongation than the control group ($0.01 \pm 0.20D$ vs. $0.32 \pm 0.38D$, $0.08 \pm 0.06mm$ vs. $0.19 \pm 0.09mm$, respectively) ($P < 0.01$). Moreover, at the end of one year, the experimental group had less SE myopic shift and AL elongation than the control group ($0.26 \pm 0.26D$ vs. $0.55 \pm 0.59D$, $0.21 \pm 0.09mm$ vs. $0.44 \pm 0.20mm$, respectively) ($P < 0.01$).

Conclusions: Wearing defocus spectacle lenses in non-myopic children aged 5-8 could slow the decrease in the degree of hyperopia and the growth of AL and delay the onset of myopia.

Abstract No.: 202767

Effects of Different Intervention Methods on Myopia Progression in Children

First Author: Sok Man **UN**

Co-Author(s): Iat Fan **LAI**

Purpose: To compare the efficacy of low-concentration atropine, defocus-incorporated multiple-segment spectacle lenses (DIMS), and low-concentration atropine combined with DIMS in the treatment of myopia in children.

Methods: A total of 85 children (166 eyes) with myopia aged 5-12 years old who were treated in Kiang Wu Hospital from April 2019 to April 2022 were included. The eyes were allocated into three groups: low-concentration atropine (54 eyes), DIMS (56 eyes), and the combined group (56 eyes). The spherical equivalent power (SE) and axial length were followed up for 1 year.

Results: At baseline, there were no significant differences in sex, age, or axial length, but there were significant differences in equivalent spherical power ($F=7.268$, $P < 0.001$). The combined treatment group ($-3.9 \pm 1.61 D$) was more myopic than the other groups. SE increased significantly over 1 year in the atropine group ($-0.41 \pm 0.47 D$), DIMS group ($-0.39 \pm 0.44 D$), and combined treatment group ($-0.38 \pm 0.44 D$); however, there were no significant differences ($P > 0.05$). Axial length increased significantly over 1 year in the atropine group ($0.24 \pm 0.19 mm$), DIMS group ($0.21 \pm 0.29 mm$), and combined treatment group ($0.17 \pm 0.16 mm$); there were no significant differences between the groups ($P > 0.05$).

Conclusions: There was no significant difference between low-concentration atropine, DIMS and low-concentration atropine combined with DIMS in the treatment of myopia in children. Compared with wearing single-vision glasses which was investigated in other epidemiological investigations, the three myopia treatment methods examined herein can control the progression of myopia.

Abstract No.: 202582

Efficacy and Safety of Low-Concentration Atropine Eye Drops Combined With Defocus Incorporated Multiple Segments for Moderate and High Myopia Control (LA-DIM Study)

First Author: Meinan **HE**

Co-Author(s): Ruihua Wei, Bei **DU**

Purpose: This paper reports a trial protocol aimed at evaluating the efficacy and safety of low-concentration atropine eye drops (0.02% and 0.04%) combined with defocus incorporated multiple segments (DIMS) for the control of moderate and high myopia in Chinese children.

Methods: A multi-centre, double-masked, non-inferiority, randomized trial was designed. 272 subjects aged 6 - 12 years with myopia ranging from $-3.00D$ to $-9.00D$ were enrolled. Participants were allocated in a 1:1:1:1:1 ratio (DIMS group, 0.02% atropine group, 0.04% atropine group, 0.02% atropine combined with DIMS group, 0.04% atropine combined with DIMS group) from four centres. Each participant was instructed to instil one drop of the assigned treatment into each eye daily and visit the research centre every 6 months.

Results: Currently, 210 participants have completed the 12-month follow-up. After 12 months, the axial length progression in the group treated with DIMS combined with 0.04% atropine was significantly less than that in other groups (DIMS vs. 0.02%A vs. 0.04%A vs. DIMS+0.02%A vs. DIMS+0.04%A: $0.29 \pm 0.14mm$ vs. $0.29 \pm 0.17mm$ vs. $0.29 \pm 0.20mm$ vs. $0.22 \pm 0.14mm$ vs. $0.17 \pm 0.18mm$, $p=0.045$). The spherical refractive progression was significantly different over the groups (DIMS vs. 0.02%A vs. 0.04%A vs. DIMS+0.02%A vs. DIMS+0.04%A: $-0.49 \pm 0.34D$ vs. $-0.53 \pm 0.49D$ vs. $-0.31 \pm 0.46D$ vs. $-0.29 \pm 0.44D$ vs. $-0.23 \pm 0.38D$, $p=0.038$).

Conclusions: The LA-DIM study will be the first to report on the efficacy of low-concentration atropine combined with DIMS for the control of moderate to high myopia in Chinese children. For the 12-month period, the combination of DIMS and 0.04% atropine demonstrated greater efficiency in axial length and spherical refractive control.

Abstract No.: 204873

Efficacy of Twice Daily 0.01% Atropine for Myopia Control: A Randomized Controlled Trial

First Author: Jin **ZHANG**

Co-Author(s): Jie **CHEN**, Xiaoman **LI**, Jianing **ZHANG**

Purpose: To evaluate the efficacy of twice daily 0.01% atropine eye drops for myopia control.

Methods: A one-year, prospective, randomized, controlled trial. A total of 207 children aged 6-12 years

(cycloplegic sphere diopters at least -0.50 diopter, astigmatism less than 1.50 D) were randomly assigned in a 1:1:1 ratio to three groups: 0.01% atropine twice daily (0.01% TD), 0.01% atropine once nightly (0.01% OD), and 0.04% atropine twice daily (0.04% OD). All the bottles were masked to subjects.

Results: After 12 months, the mean changes in spherical equivalent (SE) in the 0.01% TD, 0.01% OD, and 0.04% OD groups were -0.61 ± 0.42 D, -0.72 ± 0.52 D, and -0.39 ± 0.56 D, respectively (0.01% TD vs. 0.01% OD, $P = 0.250$; 0.01% TD vs. 0.04% OD, $P < 0.01$), with a respective mean increase in axial length (AL) of 0.33 ± 0.20 mm, 0.41 ± 0.19 mm, and 0.27 ± 0.22 mm (0.01% TD vs. 0.01% OD, $P = 0.033$; 0.01% TD vs. 0.04% OD, $P = 0.101$). Visual acuity, accommodation amplitude, and accommodative facility were not affected in each group.

Conclusions: Twice daily 0.01% atropine was more effective than once nightly in slowing myopia progression in myopic children, though it did not achieve the same efficacy as higher concentration atropine. All concentrations were well-tolerated with no adverse effects.

Abstract No.: 201479

Eight-Year Clinical Trial of Low-Concentration Atropine for Myopia Progression (LAMP1) Study: Phase 5 Report

First Author: Yuzhou **ZHANG**

Co-Author(s): Jason C. **YAM**

Purpose: To determine the optimal treatment cessation strategy on "how to stop treatment" to minimize rebound by evaluating the myopia progression of two treatment cessation approaches: Stop versus Taper.

Methods: Children aged 4–12 years originally from the Low-Concentration Atropine for Myopia Progression (LAMP1) study were followed up for 8 years. Subjects receiving atropine drops during Phase 4 (years 4 and 5) were recruited for follow-up for 3 years, including year 6 (pre-cessation period) and years 7 and 8 (cessation period). All recruited subjects were randomized into Stop and Taper groups at a 1:1 ratio. During the pre-cessation period, the Stop group received 0.05% atropine eye drops for a full year, while the Taper group received 0.05% atropine for 6 months and then 0.025% atropine for another 6 months. During the cessation period, all subjects stopped the treatment and were monitored for 2 years. Generalized estimating equations were used to compare the changes in spherical equivalent (SE) progression and axial length (AL) elongation between groups.

Results: A total of 180 (73.2%) of 246 children from the fifth year completed 8 years of follow-up. The SE progressions for stop and taper groups over 3 years were $-0.78\text{D} \pm 0.78\text{D}$ and $-0.54 \pm 0.68\text{D}$ ($P = 0.006$), and the AL elongations were $0.44 \pm 0.32\text{mm}$, and

$0.33 \pm 0.24\text{mm}$ ($P = 0.002$), respectively. Younger age and more myopic SE at pre-cessation were associated with SE progression (both $P < 0.001$) and AL elongation (both $P < 0.001$) over 3 years.

Conclusions: Taper approach achieved better treatment cessation efficacy than Stop approach.

Abstract No.: 201564

Evaluating the Effectiveness of Once Versus Twice Daily 0.01% Atropine Eye Drops in Myopia Control

First Author: Akila **RAMKUMAR**

Co-Author(s): Kayalvizhi N, Asha **THARSIS**

Purpose: To compare the efficacy of once daily versus twice daily application of low-dose atropine 0.01% (LDA) in controlling the progression of myopia.

Methods: This was an ambi-directional cohort study carried out in a tertiary eye care center. Children between 6 and 18 years of age with documented myopia progression of more than 0.50D and/or an increase in axial length by more than 0.2mm with once daily application of 0.01% atropine for between 6 and 12 months of starting treatment were considered as moderate responders. The study included these moderate responders, 24 children as controls who continued with a single daily application of LDA, and 24 in the interventional group who were started on twice daily LDA.

Results: The mean increase in spherical equivalent (SE) among those who received 0.01% atropine twice daily was 0.182 ± 0.266 . This was significantly lesser ($p < 0.01$) than the mean increase (0.398 ± 0.394) in spherical equivalent among those who continued with a single daily dose. The axial length elongation lesser than 0.2mm was 39.1% in the intervention group and 76.5% in the control group, although the difference was not statistically significant ($p = 0.27$).

Conclusions: Twice daily application of 0.01% atropine had better control in slowing the spherical equivalent and axial length elongation in children with progressive myopia. A larger study group and longer follow-up may be needed to substantiate the finding.

Abstract No.: 206665

Exploratory Clinical Study on the Effectiveness and Safety of Light Diffraction Frame Glasses in Controlling Myopia in Children

First Author: Wei **XU**

Co-Author(s): Xiaofeng **ZHU**

Purpose: This study evaluates the efficacy and safety of D.O.E spectacle frames in reducing the onset and progression of myopia, and compares them with conventional multifocal micro-lens spectacle frames.

Methods: This is a prospective, single-center, double-blind, randomized controlled exploratory clinical study. A total of 36 eligible children aged 6–8 years were enrolled, with best-corrected distance visual acuity of both eyes ≥ 0.8 and near visual acuity ≥ 1.0 . Subjects were randomly assigned to wear D.O.E (study group, $n=19$) or highly aspherical lenslets (H.A.L.T) frame glasses (control group, $n=17$). The right eye was used as the observation eye, with an observation period of 3 months. Measurements of best corrected visual acuity (BCVA), pre- and post-cycloplegic SER, axial length (AL), choroidal thickness (ChT), and other biological data were performed at baseline and at 1, 2, and 3 months after wearing the glasses. Subjective scores of wearing comfort were also collected.

Results: After 3 months of wearing, there were significant differences in SER and AL changes between the D.O.E group and the H.A.L.T group (SER: $[-0.07 \pm 0.30]D$ and $[-0.33 \pm 0.42]D$, $P=0.044$; AL: $[-0.06 \pm 0.12]mm$ and $[0.02 \pm 0.09]mm$, $P=0.039$). In addition, the mean ChT change in the D.O.E group was $29.28 \pm 26.66 \mu m$, and in the H.A.L.T group it was $16.88 \pm 17.18 \mu m$ ($P=0.114$). There were no significant differences in BCVA and subjective scores between the two groups.

Conclusions: D.O.E lenses effectively slow the progression of myopia in young children, providing a new perspective on myopia prevention and control that differs from traditional defocus theories, but further large-sample RCT studies are needed for evaluation.

Abstract No.: 201303

Fibroblast-Loaded Injectable Polysaccharide-Based Hydrogel for Scleral Remodeling to Prevent the Development of Myopia

First Author: Jingwen HUI

Co-Author(s): Quanhong HAN

Purpose: The innovative therapeutic strategy of utilizing injectable hydrogels loaded with scleral fibroblasts for posterior scleral reinforcement (PSR) aims to prevent myopia by strengthening the structural integrity of the sclera to resist axial elongation.

Methods: In this work, we develop a fibroblast-loaded carboxymethyl chitosan-aldehyde hyaluronic acid (CMCS-HA-CHO) injectable hydrogel for scleral remodeling. The CMCS-HA-CHO hydrogel is formed through simple mixing under mild conditions via Schiff base reaction between CMCS and HA-CHO.

Results: CMCS-HA-CHO hydrogel can be injected into the posterior sclera at low modulus, and its modulus increases with time, and the encapsulated fibroblasts can maintain good activity. Both hydrogel and fibroblast-loaded hydrogel were proven to be effective in shortening the axial length of myopic eyes in the guinea pig form deprivation model. Particularly, the fibroblast-loaded hydrogel has the best therapeutic

effect due to the synergy of cell therapy and physical compression, which always keeps the eye axis shortened within 4 weeks.

Conclusions: In conclusion, we prepared a fibroblast-loaded CMCS-HA-CHO hydrogel to prevent the development of myopia. In the guinea pig models, hydrogels and fibroblasts-loaded hydrogels effectively shortened the axial length of myopia. The fibroblast-loaded hydrogel group has a longer therapeutic effect, its sclera thickness becomes significantly thicker, and its tensile modulus is elevated, which proves the success of sclera remodeling. This fibroblast-loaded CMCS-HA-CHO hydrogel has the advantages of being minimally invasive and having good biocompatibility, and is a very promising option to prevent the development of myopia.

Abstract No.: 206880

Finite Element Analysis and Clinical Validation of Fluid Reservoir Thickness in Scleral Lens Fitting

First Author: Xuefei LI

Co-Author(s): Fan LU, Shenglong LUO, Meixiao SHEN, Junjie WANG

Purpose: To develop a finite element model (FEM) for predicting fluid reservoir (FR) thickness after scleral lens (SL) fitting and to validate its accuracy against clinical outcomes.

Methods: A total of 37 eyes (22 normal, 15 irregular corneas) were included. OCT-derived ocular geometries were used to construct subject-specific FEMs in ABAQUS. Simulated FR thickness was compared with clinical OCT measurements obtained 4 hours after stable SL wear. The FR was divided into three annuli: central, mid-peripheral, and peripheral. Paired t-tests and agreement analysis were used to assess consistency across regions. Correlation strength was quantified by the coefficient of determination (R^2), prediction error by root mean squared error (RMSE), and spatial distribution similarity by normalized cross-correlation (NCC).

Results: In both groups, only five regions showed statistical differences ($P < 0.05$), with minor central differences (normal: $10.85 \mu m$; irregular: $10.66 \mu m$). Agreement analysis demonstrated stronger consistency in the normal group, particularly in the center ($R^2 = 0.871$, RMSE = $42.35 \mu m$). In the irregular cornea group, the central annulus showed a mean prediction error within $100 \mu m$ (RMSE = $80.96 \mu m$). NCC analysis indicated high spatial similarity (mean NCC > 0.85 , with few cases below 0.8).

Conclusions: The personalized SL FEM accurately predicted FR thickness in both normal and irregular corneas. Simulated outcomes closely matched clinical OCT measurements after stable settling, supporting its

potential to guide individualized SL fitting and enhance fitting efficiency.

Abstract No.: 203133

Identification of IGFBP3 as a Key Gene in Myopia and Its Involvement in Crucial Biological Processes and the Microenvironment

First Author: Shichong JIA

Co-Author(s): Guoge HAN, Jie YU

Purpose: RNA methylation has emerged as a significant contributor to myopia progression. Here, we aimed to identify the key RNA methylation regulator and investigate its potential functions, as well as its associated immune characteristics, in relation to myopia.

Methods: First, we identified key RNA modifications related genes by weighted gene co-expression network analysis (WGCNA) based on the expression profile of RNA methylation-related genes in myopia using the dataset downloaded from the GEO database. CIBERSORT was used to infer the proportion of immune-infiltrating cells and analyze the correlation between gene expression and immune cell content. Drug-Gene Interaction database (DGIdb) was used to obtain the potential drug through the gene's drug network. Further validation of gene up-regulation in myopic cell model was conducted using RT-qPCR and Western blotting, while the role of IGFBP3 was assessed via knockout experiments.

Results: Utilizing WGCNA, we identified IGFBP3 as a key gene in myopia, demonstrating its predictive capacity for the disease's progression (AUC: 0.789). Using a hypoxic cell model of myopia, we demonstrated that hypoxia-induced human scleral fibroblasts (HSFs) had high IGFBP3 expression. Further analysis revealed its targeted genes were mainly enriched in the regulation of T cell activation and the MAPK signaling pathway. There were significant differences in Eosinophils, Macrophages M0, Mast cells activated, and NK cells activated between the control and the myopia group ($p < 0.05$). CIBERSORT further showed that it was positively correlated with macrophages M0 and mast cells activated and significantly negatively correlated with Mast cells resting and Tregs ($p < 0.01$). The knockdown reversed the hypoxia-induced elevation in apoptosis and the reduction in cell proliferation in HSFs. Moreover, IGFBP3 down-regulation resulted in a rise in protein levels of COL1A1 and a decrease in α -SMA, which is a classic biomarker for sclera remodeling. DGIdb showed that celecoxib is expected to be a targeted drug.

Conclusions: Our study uncovers significant alterations in IGFBP3 expression in myopia, offering novel insights that may pave the way for innovative diagnostic and therapeutic strategies in myopia management.

Abstract No.: 201168

Immediate Impact of Augmented Reality Visual Training on Choroidal Thickness and Accommodative Function: A Small Sample Study

First Author: Hongwei DENG

Purpose: The aim of this study is to evaluate the immediate effects of a single AR visual training session, integrated with a vision function restoration model, on ChT and AF.

Methods: Twenty healthy volunteers aged 6 to 13 years participated in the study. Participants were randomly assigned to an AR group ($n=11$) or a blank control group ($n=9$). A prospective self-controlled design was employed to assess changes in ChT before and after training using optical coherence tomography angiography. At the same time, AF was measured both before and after the training session. The AR group underwent a single session of visual training, with post-training metrics recorded within five minutes. The blank control group rested for 30 minutes before remeasuring the same metrics.

Results: Following a single AR visual training session, the AR group demonstrated a significant reduction in average ChT within the 0-1 mm zone, from $332.85 \pm 79.00 \mu\text{m}$ to $324.11 \pm 73.52 \mu\text{m}$ ($p = 0.007$). Additionally, AF significantly increased from $5.05 \pm 1.38 \text{ cpm}$ to $8.05 \pm 1.81 \text{ cpm}$ ($p = 0.004$). A positive correlation was observed between spherical equivalent and the change in ChT within the 0-1 mm zone ($r = 0.962$, $p = 0.009$).

Conclusions: A single AR visual training session combined with a vision function restoration model was associated with a short-term decrease in ChT and a significant improvement in AF. The integration of AR with DTx demonstrates potential for myopia intervention, suggesting a novel avenue for optimizing digital therapeutics.

Abstract No.: 205039

InNOut: A Perception-Aligned Machine Learning Model for Light-Based Indoor-Outdoor Classification in Myopia Research

First Author: Raymond NAJJAR

Co-Author(s): Daniella MAHFOUD, Zhiqun TANG

Purpose: To develop and validate a perception-aligned machine learning model (InNOut) utilizing real-life spectral light exposure data to objectively classify indoor and outdoor settings.

Methods: Spectral light exposure data (73,879 minutes) were collected from twenty-two adults (29.6 ± 4.5 years) using wrist-worn multi-channel sensors over 7 days. Participants labeled indoor and outdoor periods with an event button and diaries; these cross-referenced labels served as ground truth. InNOut was trained on

80% of the data using gradient boosting to classify indoor/outdoor environments, then tested on 20%. Performance was evaluated using receiver operating characteristic (ROC) curve analysis and compared to the conventional 1,000-lux threshold and to human perception derived from a survey of 400 participants (33.9 ± 11.3 years), including 17 light-and-health experts, who classified 183 real-world photographs paired with light data.

Results: InNOut achieved excellent performance (Area under the ROC curve [AUC] = 0.92; 95% CI, 0.92–0.93) with sensitivity of 73.9% (72.2–75.5) and specificity of 94.5% (94.1–94.9). It outperformed the conventional 1,000-lux threshold and showed high agreement with experts (83.5%) and the general public (80.8%). Both InNOut and survey participants reliably classified clear outdoor (balconies, bus stops, open walkways) and indoor settings, while ambiguous scenes (e.g., windowed spaces, inside vehicles) were usually labeled as indoor by participants but as outdoor by the model, reflecting spectral light properties.

Conclusions: InNOut provides a robust, perception-aligned framework to objectively classify indoor and outdoor environments based on light exposure. This enables accurate monitoring of outdoor time, supports behavior-changing applications, and may help disentangle the roles of light and viewing distance in myopia prevention.

Abstract No.: 206747

Investigating the Shared Genetic Architecture Between Myopia and Glaucoma: An Update in Methodology

First Author: Zuyi **YANG**

Purpose: Observational studies have shown that myopic eyes have a higher risk of primary open-angle glaucoma (POAG). Mendelian randomization (MR) analyses further confirmed a strong bidirectional genetic causal association between myopia and POAG. However, their shared genetic underpinnings remain unclear. A previous study using linkage disequilibrium score regression (LDSC) and polygenic risk score (PRS) failed to identify evidence of genetic overlap between myopia and POAG, yet such approaches may underestimate overlap, especially when genetic variants exert balanced concordant and discordant effects on the two phenotypes. Our study employed innovative methods, including MiXeR and cond/conjFDR analyses, to explore the genetic overlap between myopia and POAG.

Methods: We investigate the extent of polygenic overlap using the bivariate causal mixture model (MiXeR), leveraging summary statistics from recent large genome-wide association studies for myopia (Ncases = 65,574) and POAG (Ncases = 15,229). Additionally, we identify shared genomic loci through conditional/conjunctive FDR analyses.

Results: MiXeR showed a considerable polygenic overlap (Dice coefficient = 46.6%) between myopia and POAG. Among all shared variants, the proportion of variants with concordant effect directions was 71.9%. Subsequent conjunctive FDR analysis identified 31 distinct shared loci (conjFDR < 0.05) jointly associated with both traits. These shared loci are predominantly located in intergenic (15.8%) or intronic (63.1%) regions. The 139 protein-coding genes mapped by these shared loci have been implicated in ocular structure development and extracellular matrix metabolism.

Conclusions: By unraveling the shared genetic architecture between myopia and POAG, we identified several loci associated with both traits and provided insights into the molecular mechanisms underlying this complex relationship.

Abstract No.: 205219

Long-Term Outcomes of Myopia Control Strategies in Intermittent Exotropia: A Real-World Study of Myopia Control Spectacles and Orthokeratology

First Author: Mengya **HAN**

Co-Author(s): Yin **HU**, Stephen **VINCENT**, Xiao **WANG**, Xiao **YANG**

Purpose: This real-world study evaluated the effectiveness of myopia control spectacles (MCS) and orthokeratology (ortho-k) in slowing myopia progression and supporting binocular function in children with intermittent exotropia (IXT), highlighting treatment outcomes from routine clinical practice.

Methods: Clinical data were obtained from myopic children with IXT who completed at least two years of follow-up. After applying inclusion and exclusion criteria, 70 children were assigned to the MCS group. Using PSM, 82 and 76 children were included in the single-vision (SV) and orthokeratology ortho-K groups, respectively.

Results: After two years, both the MCS and ortho-k groups demonstrated significantly less axial elongation and myopia progression compared to the SV group (both, $P < 0.0001$), with no significant difference between MCS and ortho-k ($P > 0.05$). The MCS group also exhibited better preservation of distance and near stereoacuity than the ortho-k (both $P < 0.0001$) and SV groups ($P = 0.01$ and $P < 0.001$, respectively). For distance exodeviation, the MCS group showed a smaller increase than the ortho-k and SV groups ($P < 0.01$ and $P < 0.0001$, respectively), and the ortho-k group displayed less increase than the SV group ($P = 0.01$). A similar pattern was observed for near exodeviation, and the difference between MCS and ortho-k approached significance ($P = 0.05$).

Conclusions: MCS and ortho-K effectively slowed myopia progression in children with basic-type IXT. In

this high-risk population, MCS may additionally help preserve binocular function. These findings provide a foundation for future studies extending to broader IXT populations.

Abstract No.: 200639

Multidimensional choroidal changes after 0.01% atropine eye drops treatment for 2 years and prediction for the response: Results from 0.01% Atropine Eyedrops in Children with Myopia and Intermittent Exotropia (AMIXT)

First Author: Zijin WANG

Co-Author(s): Tianxi LI, Hu LIU, Xiaoxia ZUO

Purpose: To investigate multidimensional choroidal changes during 24-month 0.01% atropine treatment and develop prediction models for myopia control efficacy.

Methods: The secondary analysis of data from the AMIXT trial included 290 myopic children aged 6-12 years (195 atropine vs 95 placebo) with OCT/OCTA images. We longitudinally assessed one-dimensional (1D)/2D/3D choroidal parameters and choriocapillaris metrics (subfoveal choroidal thickness [SFCT], luminal area [LA], stomal area [SA], total choroidal area [TCA], luminal volume [LV], stromal volume [SV], total choroidal volume [TCV], choroidal vascularity index [CVI], 3D-CVI, and choriocapillaris flow deficit percentage [CcFD%]).

Results: Atropine-treated eyes exhibited transient choroidal thickening peaking at 4 months and experienced slightly decreasing thereafter, contrasting with progressive thinning in controls (between-group differences in SFCT change [Δ SFCT] = 11.22 μ m [95% CI, 3.21 to 19.23], $P=0.006$; Δ TCA within 3 mm perifoveal zone [Δ TCA_3] = 28.29 $\times 10^3 \mu$ m² [95% CI, 8.81 to 47.78], $P=0.004$; Δ TCV_3 = 53.68 $\times 10^6 \mu$ m³ [95% CI, 16.30 to 91.06], $P=0.005$). 3D parameters demonstrated superior predictive values, with 4-month Δ LV_3 showing moderate correlations to 24-month SE progression ($r=0.49$, $P<0.001$). The prediction model integrating baseline factors, 4-month Δ AL, and Δ LV_3 predicted 24-month Δ SE with an R^2 of 0.41, and the logistic model predicted atropine response (SE progression ≤ 0.50 D/year) with an AUC of 0.89 (95% CI, 0.83 to 0.96).

Conclusions: The 0.01% atropine induces transient choroidal expansion predictive of long-term myopia control, with 4-month LV change serving as a good predictive biomarker. The quantitative volumetric OCT parameter enables early treatment response monitoring and personalized prognosis estimation.

Abstract No.: 201857

Myopia Progression Associated With Atropine Therapy in Children: A 10-Year Retrospective Study

First Author: Eric JIN

Co-Author(s): David CHEN, Clement CHIA, Catherina GOENADI, Chae Eun LEE, Minxin LIU, Clifton LOH, Chen Hsin SUN

Purpose: To evaluate real-world myopia progression associated with atropine therapy in children at a tertiary hospital over a 10-year period.

Methods: This retrospective case-series included children treated with atropine at the National University Hospital, Singapore, between June 2015 and June 2024. Children aged < 16 years with > 2 manifest refractions or 3 axial length (AL) and had no previous intra-ocular surgeries were included. AL and refraction data were collected at baseline and follow-ups. Atropine therapy was individualised and adjusted based on progression. A multivariate linear regression model was used to identify factors associated with AL elongation.

Results: A total of 1,209 children (2,403 eyes; mean age: 8.65 ± 1.92 years old) were included, with a mean follow-up duration of 33.6 months. Most children were initiated on 0.01% atropine once nightly (ON) (92.3%), followed by 0.05% ON (5.3%). The mean refractive progression rate was -0.324 ± 0.439 D/year, and the mean AL elongation rate was 0.191 ± 0.185 mm/year, ranging from 0.400 mm/year (3 years old) to 0.049 mm/year (15 years old). Multivariate analysis showed that older age ($\beta = -0.037$, 95% CI = (-0.041, -0.033), $p < 0.001$) and longer baseline axial length at treatment initiation ($\beta = -0.019$, 95% CI = (-0.027, -0.011, $p < 0.001$) were significantly associated with slower AL elongation, while gender, race, and initial refraction were not ($p > 0.05$).

Conclusions: In a real-world clinical setting, atropine therapy was associated with low progression rates, with older age at initiation and longer baseline axial length linked to slower AL elongation.

Abstract No.: 207316

Noncycloplegic Methods for Screening Myopia and Pre-Myopia in Preschool Children

First Author: Jianfeng ZHU

Purpose: This study aimed to develop and evaluate noncycloplegic screening strategies for detecting both myopia and pre-myopia in preschool-aged children.

Methods: Uncorrected distance visual acuity (UDVA) was assessed using a logMAR chart. Refractive status was measured before and after cycloplegia using the Vision Screener SL-100. In addition, axial length (AL) and corneal curvature radius (CR) were obtained under

noncycloplegic conditions with the IOL Master-700. Logistic regression modeling was applied to formulate accurate screening protocols for myopia and pre-myopia without cycloplegia.

Results: The study enrolled 1,308 children with a mean age of 4.3 ± 0.9 years, including 640 girls (48.9%). Myopia (cycloplegic spherical equivalent [SE] ≤ -0.5 D) was identified in 2.8% ($n = 36$) of participants, while pre-myopia (cycloplegic SE > -0.5 D but $\leq +0.75$ D) was present in 21.9% ($n = 286$). Screening performance, as measured by the area under the receiver operating characteristic curve (AUC), was limited for UDVA alone in detecting pre-myopia (AUC = 0.52). Noncycloplegic SE yielded an AUC of 0.70, and AL alone achieved an AUC of 0.63. The combination of noncycloplegic SE with the AL/CR ratio produced the most favorable diagnostic accuracy with minimal assessments, yielding an AUC of 0.74 for pre-myopia and 0.94 for myopia. Incorporating UDVA did not enhance screening performance further.

Conclusions: Isolated UDVA measurement demonstrated inadequate accuracy for identifying myopia or pre-myopia in young children. Under noncycloplegic conditions, a combined metric incorporating SE and AL/CR ratio proved to be an effective strategy for screening both pre-myopia and myopia in the preschool population.

Abstract No.: 205045

Optic Nerve Head Changes Over 15 Years – From the Atropine Treatment Long-Term Assessment Study

First Author: Joey **CHUNG**

Co-Author(s): Marcus **ANG**, Ezekiel **CHEONG**, Leila **EPPENBERGER**

Purpose: To investigate optic nerve head (ONH) changes over 15 years in original participants of the Atropine for the Treatment of Myopia 2 (ATOM2) study.

Methods: A total of 148 myopic participants who were treated with 0.01%, 0.1% or 0.5% atropine eye drops from the ATOM2 trial were included. At three study visits (baseline, 5-year, 15-year), participants underwent cycloplegic autorefractometry, ocular biometry, and fundus photography. Additional optical coherence tomography (OCT) imaging was performed at recall. Fundus photographs were morphometrically examined for ONH ovality, torsion, parapapillary atrophy (PPA), disc-fovea distance, position of the central retinal vascular trunk (CRVT), angle kappa, and vertical distance between the arterial arcade (VDA). Bruch's membrane opening (BMOD), gamma zone, and Bruch's membrane overhang were measured in OCT images.

Results: Comparisons showed similar ONH characteristics across atropine treatment groups. Myopic refractive error increased from -4.54 ± 1.64 diopters (D) at baseline to -6.88 ± 2.4 D at 15 years

($p < 0.0001$). Axial length (AL) increased from 25.08 ± 0.89 mm to 26.31 ± 1.01 mm ($p < 0.0001$). Significant changes in ONH parameters after 15 years included PPA and position of the CRVT ratio (p -values < 0.0001). Age, AL, and spherical equivalent refraction (SER) were associated with optic disc changes ($p < 0.0001$). AL, SER, and PPA were associated with the BMOD area or the gamma zone (p -values < 0.0001). Age ($p < 0.0001$), PPA ratio ($p = 0.0017$), and disc-fovea distance ratio ($p = 0.0300$) were associated with a myopic progression of more than -2D during the 15 years of observation.

Conclusions: This long-term study suggests that myopic subjects showed increased PPA and nasal CRVT shift from childhood into young adulthood.

Abstract No.: 209422

Peripheral Refraction Dynamics in Myopic Teenagers: An In Vivo Analysis Post Cycloplegia

First Author: Lu **GAN**

Co-Author(s): Wentao **DENG**, Jifang **WANG**, Wuxiao **ZHAO**

Purpose: To investigate the effect of accommodation on peripheral refraction in children and adolescents with myopia.

Methods: One hundred and five teenagers with myopia were consecutively recruited in this study. According to their refraction, participants were divided into low, moderate, and high myopia groups. Peripheral refraction of each participant was captured before and after cycloplegia by multispectral refractive topography (MRT, Thondar, Shenzhen), Total relative defocus value (TRDV) and relative defocus values (RDV) at 15° (RDV- 15°), 30° (RDV- 30°), and 45° (RDV- 45°), together with quadrant-specific RDVs for the superior (RDV-S), inferior (RDV-I), temporal (RDV-T), and nasal (RDV-N) fields, were extracted from each participant's right eye for subsequent analysis. A paired t-test was employed to assess the differences in RDV between pre- and post-cycloplegia conditions. Additionally, a two-way ANOVA was conducted to examine the variations in RDV across the three groups.

Results: Cycloplegia induced significant changes in RDV of myopic participants. RDV- 15° remained stable, whereas TRDV, RDV- 30° , RDV- 45° , and all quadrant-specific RDVs (S, I, T, N) shifted significantly toward hyperopia (all $P < 0.001$). Moreover, the magnitude of change increased with retinal eccentricity: the farther the measurement from the fovea, the larger the post-cycloplegic hyperopic shift. Comparing pre- to post-cycloplegic RDV shifts across low, moderate, and high myopia revealed significant group differences in Δ TRDV and in Δ RDV at 45° , the inferior, and the nasal quadrants (all $P < 0.05$). Changes were consistently larger in low and moderate myopia than in high myopia, whereas low and moderate myopic eyes did not differ significantly from each other.

Conclusions: After cycloplegia, peripheral refraction shifted markedly toward hyperopia and grew increasingly eccentric with visual-field angle in myopic adolescents; the change was significantly larger in eyes with low or moderate myopia than in those with high myopia.

Abstract No.: 201471

Phenotyping Glaucomatous and Non-Glaucomatous Optic Neuropathy in High Myopia Using Lamina Cribrosa Depth Benchmarks

First Author: Maverick Wenhao WONG

Co-Author(s): Crystal CHONG, Rachel S CHONG, Samantha LOR, Lee Ching PHANG, Swati SHARMA

Purpose: To characterize optic neuropathy in high myopia (HM) using lamina cribrosa depth (LCD) benchmarks derived from normal HM eyes.

Methods: This cross-sectional study included 282 HM eyes (axial length ≥ 26.0 mm). Eyes were first classified as normal or abnormal (glaucoma or glaucoma suspect) based on clinical diagnosis. LCD thresholds from normal HM eyes (25th and 75th percentiles: 353.16 μ m, 513.96 μ m) were used to stratify abnormal eyes into presumed high myopic optic neuropathy (HMON, LCD < 353.16 μ m), mixed (LCD = 353.16–513.96 μ m), or presumed glaucoma (Glc, LCD > 513.96 μ m). Key parameters included ganglion cell complex (GCC) and retinal nerve fibre layer (RNFL) thickness, minimum rim width (MRW) derived from optic nerve head optical coherence tomography scans divided radially into octants; visual field mean deviation (MD) and papillomacular bundle (PMB) sensitivity.

Results: Comparing HMON eyes (n=41) with normal (n=80), significant GCC thinning was observed across all sectors; also RNFL thinning in all regions apart from superior and nasally. HMON GCC and RNFL thinning were most marked superonasal and inferonasal. Glc eyes (n=57) demonstrated GCC and RNFL thinning in all sectors compared to normal, apart from inferonasally, superonasally and nasally. MRW was thinner in all sectors in Glc but not HMON eyes compared to normal. The mixed group (n=104) showed GCC and RNFL thinning in all sectors except the nasal sector. HMON, Glc and mixed groups had significantly lower MD and PMB sensitivity than normal.

Conclusions: LCD-based stratification reveals distinct structural and functional phenotypes with HM that may differentiate HMON from Glc.

Abstract No.: 203779

Progression Patterns and Risk Factors of Axial Elongation in Young Adults With Nonpathologic High Myopia: Three-Year Large Longitudinal Cohort Follow-Up

First Author: Kangjie KONG

Co-Author(s): Fei LI, Xiulan ZHANG

Purpose: To investigate the progression patterns and risk factors of axial elongation in young adults with nonpathologic high myopia.

Methods: A total of 1043 eyes of 563 participants (3515 medical records) aged 18 to 50 years with nonpathologic high myopia (axial length [AL] ≥ 26 mm; myopic maculopathy < diffuse chorioretinal atrophy; without posterior staphyloma) were included from 1546 participants (6318 medical records). Annual axial elongation was calculated via linear mixed-effect models. The associated risk factors of axial elongation were determined by ordinal logistic regression analysis, with generalized estimate equations for eliminating an interocular correlation bias.

Results: Based on 5359 times of AL measurements, the annual axial elongation of participants (mean [SD] age 31.39 [9.22] years) was 0.03 mm/year (95% confidence interval [CI], 0.03–0.04; $P < .001$) during a 30.23 (6.06) months follow-up. Severe (>0.1 mm/year), moderate (0.05–0.09 mm/year), mild (0–0.049 mm/year), and nil (≤ 0 mm/year) elongation was observed in 122 (11.7%), 211 (20.2%), 417 (40.0%), and 293 (28.1%) eyes. The following risk factors were significantly associated with axial elongation: baseline AL ≥ 28 mm (odds ratio [OR], 4.23; 95% CI, 2.95–6.06; $P < .001$); age < 40 years (OR, 1.64; 95% CI, 1.18–2.28; $P = .003$); axial asymmetry (OR, 2.04; 95% CI, 1.26–3.29; $P = .003$), and women (OR, 1.52; 95% CI, 1.13–2.05; $P = .006$). Using antiglaucoma medications was a protective factor (OR, 0.46; 95% CI, 0.27–0.79; $P = .005$), which slowed 75% of axial elongation from 0.04 (0.06) to 0.01 (0.06) mm/y ($P < .001$).

Conclusions: Axial elongation continued in young adults with nonpathologic myopia. Risk factors included longer baseline AL and axial asymmetry, younger age, and woman. Topical use of anti-glaucoma medications may be useful to reduce ongoing axial elongation.

Abstract No.: 205028

Prospective Myopia Cohort Study in Singapore (PROMYSE)

First Author: Jia Ling LEE

Co-Author(s): Marcus ANG, Joey CHUNG, Leila EPPENBERGER

Purpose: High myopia is linked to severe complications such as retinal detachments and myopic macular degeneration (MMD). Despite these known associations, data on their prevalence and incidence are scarce.

Methods: This prospective observational study included Singaporean participants aged ≥ 16 years with a spherical equivalent refraction (SER) of ≤ -0.5 diopters (D) and without pre-existing eye conditions. Participants provided written informed consent and underwent comprehensive ophthalmological exams, repeated at one- and two-year follow-ups. Descriptive statistical analysis was performed.

Results: A total of 753 participants (mean age 36.5 ± 12.3 y; 60% male; 94% Chinese) were examined at baseline. The mean decimal best-corrected visual acuity (BCVA) was 0.97 ± 0.1 , the mean axial length (AL) of right eyes was 26 ± 1.6 mm, and the mean SER was -5.4 ± 3.6 D. At baseline, the prevalence of retinal tears was 0.4%, retinal detachment occurred in 0.1%, and staphyloma was present in 5%. Dome-shaped macula, intrachoroidal cavitations, or myopic traction maculopathy were found in 0.7% of right eyes (RE). Comparable results were noted for left eyes (LE). After two years, 45% of participants ($n=340$) returned for follow-up. AL and SER remained unchanged. MMD grade 1 in RE increased from 66% to 68%, and MMD grade 2 rose from 9% to 10%. There was a significant increase in peripheral lattice degeneration from 4% to 9% ($p=0.01$).

Conclusions: Over two years, AL and SER did not increase. Myopia-related complications were low. However, a significant rise in peripheral retinal changes was observed over two years. This dataset offers an overview of the prevalence of myopic macular degeneration and other complications in middle-aged Asian myopes.

Abstract No.: 202971

Quantification of Posterior Staphyloma Severity Using Scleral Curvature Analysis and Its Association With Anterior and Posterior Segment Alterations in High Myopia

First Author: Jie **WANG**

Co-Author(s): Lingling **BA**, Peiyao **HUANG**, Shuaixin **LU**, Simo **PAN**, Jing **SUN**, Kai **WEN**, Xiaohua **ZHANG**, Min **ZHOU**, Xinmiao **ZHOU**

Purpose: To develop a novel curvature-based method for quantifying posterior staphyloma (PS) severity and investigate its relationship with anterior and posterior segment parameters in highly myopic eyes.

Methods: A single-center, cross-sectional study included 385 eyes from 252 patients with high myopia (axial length AL ≥ 26 mm). All eyes underwent multimodal imaging: IOL-Master 700 (AL), CASIA 2 (anterior segment), B-mode ultrasonography (posterior scleral contour), and fundus/OCT (myopic maculopathy grading). PS Severity Index (PSI): Derived from posterior scleral curvature variations using AutoCAD segmentation. Calculated as: $PSI = [K - \max(K_1, K_2, \dots, K_n) - K] \times 100\%$, where K_i = segmental curvature. Anterior segment parameters: including anterior chamber

angle (AOD, ARA, TISA), iris volume, and lens metrics (decentration, volume). Myopic maculopathy: graded per international photographic classification.

Results: Mean PSI was 0.46 ± 0.262 , increasing significantly with AL ($P = .021$). PS severity distribution: mild (46.4%), moderate (33.8%), severe (17.5%), extreme (2.3%). Anterior segment associations: PS severity correlated with anterior chamber angle parameters (AOD250, ARA250, TISA250; all $P < 0.05$), iris volume ($P = 0.042$), and lens decentration ($P = 0.002$), but not AL or vitreous volume ($P > .05$). AL stratification (26–28/28–30/ ≥ 30 mm): Anterior chamber volume/iris volume remained stable ($P > .05$), while lens volume/vitreous volume increased significantly ($P < .05$). Anterior chamber angle widened with AL ($P = 0.002$). Myopic maculopathy (79.3% prevalence): Severity correlated with PSI ($P < .05$), AL ($P < .05$), and anterior angle parameters (TISA750, AOD500; $P < .05$).

Conclusions: This study establishes the first quantitative, curvature-based PS severity grading system, revealing significant links between PS biomechanics and anterior segment alterations—particularly anterior chamber angle widening. These findings underscore the eyeball as an integrated biomechanical system in high myopia, suggesting PS severity may serve as a biomarker for anterior segment remodeling and glaucoma risk.

Abstract No.: 204835

Repeated Low-Level Red-Light Therapy Combined With Orthokeratology for Myopia Control in Spain: A Randomized Controlled Trial

First Author: Fernando **FERNANDEZ-VELAZQUEZ**

Co-Author(s): Yuri **AUNG**, Maria Jose **FERNANDEZ FIDALGO**, Victoria D Ferigo **FERREL**, Lisa Zhuoting **ZHU**

Purpose: To evaluate the 12-month efficacy and safety of repeated low-level red-light (RLRL) therapy combined with orthokeratology (ortho-k) for myopia control in Spanish children.

Methods: In this single-site, randomized, parallel-group, non-blinded clinical trial (ClinicalTrials.gov identifier: NCT06899139), children aged 10–13 years with myopia ranging from -0.75 to -6.75 D were recruited and randomly assigned to either the combined RLRL plus ortho-k group (RCO) or the ortho-k-only group. Ortho-k participants wore lenses for ≥ 8 hours nightly, while RCO participants additionally received RLRL therapy twice daily (3 minutes per session, 5 days per week). Follow-up assessments were performed at 6, 9, and 12 months. The primary outcome was axial length (AL) change from baseline to 12 months; macular thickness (MT) was also assessed.

Results: A total of 26 children were enrolled (11 in RCO, 15 in ortho-k). After 12 months, the adjusted

mean AL change was -0.111 mm (95% CI, -0.142 to -0.080) in the RCO group versus $+0.104$ mm (95% CI, 0.074 to 0.133) in the ortho-k group, with a between-group difference of -0.215 mm (95% CI, -0.258 to -0.172 ; $p < 0.001$). The adjusted mean MT increase was greater in the RCO group ($+0.690$ μ m; 95% CI, 0.362 to 1.019) compared with the ortho-k group ($+0.199$ μ m; 95% CI, -0.112 to 0.510 ; $p = 0.033$). In the RCO group, 80% of children achieved AL shortening > -0.05 mm, while none in the ortho-k group did. No severe adverse events occurred.

Conclusions: RLRL therapy combined with ortho-k is effective and safe for slowing myopia progression in Spanish children. These findings support the generalisability of this synergistic approach across diverse ethnic groups.

Abstract No.: 201200

Shortening of Axial Length and Scleral Curvature Changes Following Repeated Low-Level Red-Light Therapy in Children With High Myopia

First Author: Naoki ISOMURA

Co-Author(s): Tae IGARASHI-YOKOI, Ahyoon LEE, Kyoko OHNO-MATSUI, Hiroyuki TAKAHASHI

Purpose: To identify factors associated with axial length (AL) shortening and fundus changes after 12-month repeated low-level red-light (RLRL) therapy in highly myopic children.

Methods: Highly myopic patients aged 8 to 18 years who underwent RLRL therapy at the Institute of Science, Tokyo, between October 2022 and August 2023 were included. Spherical equivalent (SE), AL, choroidal thickness in 9 ETDRS subfields, and posterior scleral curvature on optical coherence tomography (OCT) were evaluated at baseline and 12 months. Quantitative OCT analysis of scleral height was also performed. Analyses were conducted in the per-protocol population using right-eye data.

Results: Twenty-six patients (54% male; mean age, 11.2 ± 2.6 years; baseline SE, -9.4 ± 1.7 D; AL, 27.0 ± 1.0 mm) were analyzed. After 12 months, mean SE reduction was 0.28 ± 0.21 D, mean AL shortening was 0.01 ± 0.10 mm, and mean macular choroidal thickness increased by 26 ± 21 μ m. No significant interregional difference in choroidal thickening was observed, but 5 patients (19.2%) were subjectively assessed as having scleral curvature change. Multivariate regression identified macular choroidal thickening ($\beta = -0.68$) and scleral curvature change ($\beta = -0.27$) as significant predictors of AL shortening ($R^2 = 0.64$; $P < 0.01$). Quantitative OCT analysis demonstrated that eyes initially showing higher temporal and lower nasal scleral contour exhibited a temporal reduction and a significant nasal increase ($P = 0.011$) after therapy, consistent with posterior scleral flattening.

Conclusions: Axial shortening after RLRL therapy was associated with choroidal thickening and localized scleral curvature changes in highly myopic children.

Abstract No.: 201358

Shortening of Axial Length and Thickening of the Choroid Following Repeated Low-Level Red-Light Therapy in Adults With High Myopia

First Author: Junfuku LEE

Co-Author(s): Kyoko OHNO-MATSUI, Keigo SUGISAWA, Hiroyuki TAKAHASHI, Takeshi YOSHIDA

Purpose: To investigate the effects of 2-month repeated low-level red-light (RLRL) therapy on macular choroidal thickness (mCT) and axial length (AL) in adults with high myopia, and to evaluate changes in other biological parameters associated with RLRL therapy.

Methods: In this prospective interventional study, 30 adults (aged 21–64 years) with high myopia (spherical equivalent refraction [SER] ≤ -6.0 diopters) who visited the Institute of Science Tokyo Hospital between December 2023 and November 2024 were enrolled. Eyes with hereditary chorioretinal disorders were excluded. All participants underwent home-based RLRL therapy for 2 months. At baseline, 1 month, and 2 months, fundus autofluorescence (FAF), optical coherence tomography (OCT), and polarization-sensitive OCT were performed. SER, AL, and mCT were measured at each visit.

Results: Of the 30 participants, 28 completed RLRL therapy, while 2 discontinued due to personal preference. No adverse subjective symptoms or severe fundus abnormalities were detected in any participant. At 2 months, compared with baseline, significant improvements were observed: mean SER (-12.76 ± 3.66 D vs -13.07 ± 3.42 D, $P < 0.05$), AL shortening (29.17 ± 1.58 mm vs 29.23 ± 1.59 mm, $P < 0.05$), mCT thickening (103.35 ± 31.86 μ m vs 90.91 ± 27.71 μ m, $P < 0.01$), and choroidal polarimetric entropy decreasing (0.315 ± 0.15 vs 0.304 ± 0.16 , $P < 0.05$). Compared with baseline, 82.1% of eyes showed $>5\%$ increase in mCT, and 67.9% showed $>10\%$ increase.

Conclusions: RLRL therapy, previously reported to be effective for myopia control in children, also demonstrated a significant effect on biological parameters in highly myopic adults.

Abstract No.: 206858

Sleeping With Lights on Drives Childhood Myopia Independent of Sleep Duration: A Five-Year Cohort Study

First Author: Congying LI

Co-Author(s): Ying HUANG, Shi-ming LI, Ningli WANG

Purpose: To examine the association between sleeping with a light on and childhood myopia, and to explore whether sleep duration trajectories within light type influence myopia development.

Methods: In this 5-year cohort of 2,098 school-aged children, nighttime light exposure (on/off) and type (fluorescent vs. incandescent) were recorded annually, with six-year average fluorescent exposure categorized as low, medium, or high. Sleep duration trajectories within light type were classified using group-based trajectory modeling (GBTM). Incident myopia was defined as spherical equivalent refraction ≤ -0.50 D. Associations were estimated using multivariable logistic regression and generalized estimating equations, adjusting for demographic, behavioral, and familial covariates.

Results: Sleep duration trajectories were not independently associated with myopia (long vs. short: OR = 1.03, 95% CI: 0.82–1.30, $P = 0.792$). In contrast, sleeping with a light on significantly increased myopia risk (OR = 1.25, 95% CI: 1.01–1.57, $P = 0.048$). A clear dose–response was observed for fluorescent light exposure (medium vs. low: OR = 1.83, 95% CI: 1.01–3.35, $P = 0.050$; high vs. low: OR = 1.82, 95% CI: 1.15–2.87, $P = 0.011$). At 6 years, children exposed to nighttime illumination demonstrated greater myopic progression, longer axial length, higher AL/CR ratio, elevated intraocular pressure, and thinner lens thickness (all $P < 0.05$). Subgroup analyses by fluorescent exposure consistently confirmed that sleep duration did not influence myopia incidence or ocular growth (all $P > 0.05$).

Conclusions: Sleeping with a light on, particularly under higher fluorescent exposure, constitutes a modifiable risk factor for childhood myopia, whereas sleep duration trajectories within each light type appear to have no measurable effect. Limiting ambient nighttime illumination may provide a simple and scalable preventive strategy.

Abstract No.: 203867

Spectacle Lenses With Highly Aspherical Lenslets for Myopia Control in Children: A Systematic Review and Meta-Analysis

First Author: Safira Nurfadila HARAHA

Co-Author(s): Lissyantika HIDAYATULLAH, Ajeng Sekar KIRANA, Julsyawiah NOVTHALIA

Purpose: This study aimed to evaluate the efficacy of spectacle lenses with highly aspherical lenslets (HAL) in controlling myopia progression in children by assessing

changes in spherical equivalent refraction (SER) and axial length (AL).

Methods: This study employed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses. PubMed, Google Scholar, and ScienceDirect were searched for systematic reviews of randomized controlled trials (RCTs). Primary outcomes were changes in SER (diopters) and AL (millimeters). Risk of bias was assessed using the Cochrane risk assessment tool. Meta-analysis was performed using RevMan version 5.4.1.

Results: Three RCTs with 325 participants were identified. HAL lenses significantly reduced axial elongation compared to single-vision spectacle lenses (SVL) (MD = -0.22 mm; 95% CI: -0.33 to -0.10 ; $p < 0.001$; $I^2 = 96\%$). Similarly, HAL lenses significantly slowed the progression of myopia as measured by SER (MD = 0.51 D; 95% CI: 0.17 to 0.86 ; $p = 0.004$; $I^2 = 97\%$) compared to SVL. Funnel plots showed symmetrical distribution, suggesting low risk of publication bias. Despite high heterogeneity, consistent directional effects were observed across studies.

Conclusions: Spectacle lenses with highly aspherical lenslets are effective in slowing both axial elongation and myopia progression in children. These lenses represent a promising, non-invasive optical strategy for myopia control in children.

Abstract No.: 209751

Study on the Role of NF- κ B-Regulated Pyroptosis in Myopia

First Author: Qingwen YANG

Co-Author(s): Bo GONG, Man YU

Purpose: The rising global prevalence of myopia highlights the need to elucidate its molecular mechanisms. NF- κ B plays a crucial role in myopia progression, while pyroptosis is closely associated with various ocular diseases. However, the role of pyroptosis in myopia remains unexplored. Given that NF- κ B regulates pyroptosis, this study aims to explore whether NF- κ B influences myopia progression by modulating pyroptosis.

Methods: NF- κ B expression was knocked down in ARPE-19 cells and lens-induced myopia (LIM) mice using lentiviral shRNA. In vitro, LPS-treated ARPE-19 cells were assessed for viability (CCK-8), apoptosis (TUNEL), pyroptosis markers (NLRP3, caspase-1, GSDMD-N; qPCR/Western blot/immunofluorescence), and inflammatory cytokines (ELISA). In vivo, axial length, refractive error, and retinal structure (H&E staining) were evaluated, along with the levels of inflammatory cytokines and the expression of pyroptosis-related proteins and Lumican in the sclera.

Results: NF- κ B knockdown alleviated LPS-induced cytotoxicity and apoptosis in ARPE-19 cells, suppressed inflammatory cytokines (IL-1 β , IL-18, TNF- α), and

downregulated pyroptosis markers. In LIM mice, NF- κ B knockdown reduced axial elongation, decreased diopter values, improved retinal structure, and lowered the levels of inflammatory cytokines and pyroptosis markers.

Conclusions: This study provides evidence that NF- κ B promotes myopia progression by inducing pyroptosis, suggesting that targeting the pyroptosis pathway may represent a more precise and effective therapeutic strategy compared to NF- κ B itself for myopia intervention.

Abstract No.: 205077

TNF- α but Not IL-17 and IL-4 Promoted Myopic Retinopathy in BestCre-Lrp2fl/FL KO Mice

First Author: Jinyan **QI**

Co-Author(s): Xuexue **CUI**, Wen **DENG**, Jian **LIU**, Heping **XU**, Caijiao **YI**, Xiangling **YUAN**

Purpose: Inflammation is known to be involved in the pathogenesis of myopic retinopathy. Studies have reported high levels of inflammatory cytokines in high myopic patients. This study aimed to understand how the Th1, Th2, and Th17-type immune responses affect the progression of myopic retinopathy in the BestCre-Lrp2fl/fl KO mice.

Methods: 2-week-old BestCre-Lrp2fl/fl KO mice were treated intraperitoneally (i.p.) with TNF- α (75ug/g of body weight) or IL-4 (75/g of body weight) or IL-17A (25ug/g of body weight) twice a week for 8 weeks. Blood samples were collected at 6h and 72h after i.p. for the measurement of inflammatory cytokines. OCT was used to measure the axial length and retinal thickness. Retinal function was evaluated by ERG and optokinetic reflex. Eyeballs were collected and processed for immunofluorescent staining of retinal neurons, synaptic structures, Iba-1+ microglia, and phalloidin (for RPE cell structures).

Results: The serum levels of TNF- α , IL-4 and IL-17A increased significantly 6 h after i.p. treatment. TNF- α and IL-17A treatment reduced the population of CD11b+ monocytes, CD11b+LY6C+inflammation monocytes, but increased the population of B220+ B cells, CD11b+LY6C-monocytes in the blood and spleen in BestCre-LRP2fl/fl KO. IL-4 treatment increased the population of Ly6G+/CD11b+neutrophils, Ly6C-/CD11b+/ CD117+ mast cells, CD11b+ monocytes, DC, but decreased the population of CD4+ T cells and B220+ B cells. TNF- α , but not IL-17 or IL-4, treatment significantly reduced a-, b-, c-waves and Ops. Immunofluorescence staining showed that the BestCre-Lrp2fl/fl KO eyes had RPE cell dysmorphology, subretinal microglial accumulation, and reduced rod and cone cell numbers.

Conclusions: TNF- α promotes the progression of myopic retinopathy.

Abstract No.: 205169

The Association of Smart Watch Usage on Myopia Progression in Primary School Students: A 1-Year Prospective Observation

First Author: Runtong **MA**

Co-Author(s): Yin **HU**, Zhipeng **LAI**, Xiao **YANG**

Purpose: To explore the impact of smart watch usage on changes of refraction and axial length in primary school students.

Methods: A 1-year prospective, school-based, observational study. 661 students (Grade 5 at baseline, ages 11-13) were invited. The cycloplegic spherical equivalent refraction (SER), axial length (AL) and questionnaires were measured at baseline and 1-year visit.

Results: 526 participants (mean age, 11.31 ± 0.47 years; 52.3% male) completed the 1-year study, and were divided into three groups based on smart watch time (<0.5, 0.5-1, >1h/day). Participants with more daily smart watch usage (>1h/day) showed more significantly myopic shift in refraction (-0.95 D) and axial elongation (0.47 mm) compared to those with moderate (0.5-1h/day: -0.29 D and 0.25 mm) or low (<0.5h/day: -0.33 D and 0.28 mm) usage (both $p < 0.001$). The weekday time of the smart watch was strongly associated with SER ($r = -0.173$, $p < 0.001$) and AL changes ($r = 0.163$, $p < 0.001$). The generalized linear mixed model revealed that total screen time ($\beta = -0.07$ for SER change, $\beta = 0.03$ for AL change, both $p < 0.001$) and weekday smart watch usage ($\beta = -0.58$ for SER change, $\beta = 0.16$ for AL change, both $p < 0.001$) were significantly associated with myopic shifts in refraction and axial elongation.

Conclusions: Observational data indicate an association between total screen time (including smartwatches) and myopic shifts in refraction or axial elongation. These findings suggest that reasonable management of screen time may be needed.

Abstract No.: 205017

The Effectiveness of Red-Light Therapy on Myopia Control Depends on Its Direct Effect: A Mediation Analysis

First Author: Hongyu **WEI**

Co-Author(s): Qin **CHEN**, Ching-yu **CHENG**, Zhi Da **SOH**, Hua **ZHONG**

Purpose: To investigate whether alterations in subfoveal choroidal thickness and peripheral retinal refraction mediate the efficacy of repeated low-level red-light (RLRL) therapy for myopia control.

Methods: We conducted a mediation analysis within a multicenter, randomized controlled trial. A total of 300 myopic children were included in this analysis. Participants in the RLRL group wore single-vision spectacles and received red-light therapy twice daily for 12 months. The control group wore spectacles only,

without any additional myopia-control intervention. Axial length, spherical equivalent refraction, subfoveal choroidal thickness, and total refractive difference value were measured at baseline and at follow-up visits over 12 months.

Results: After 12 months, RLRL therapy significantly attenuated axial length and myopic shift in spherical equivalence compared with controls, accompanied by sustained increases in choroidal thickness and reductions in peripheral hyperopic defocus. Mediation analysis revealed that changes in choroidal thickness and peripheral refraction accounted for 24.83% and 6.79%, respectively, of the effect on axial length inhibition, and 28.79% and 5.97% of the effect on spherical equivalent control. The remaining effects were attributable to the direct impact of red-light (68.39% for axial length and 65.24% for spherical equivalence). Notably, choroidal thickening emerged as the predominant mediator within the first three months.

Conclusions: RLRL therapy exerted a predominantly direct effect on myopia control, while changes in choroidal thickness and peripheral defocus partially mediated its effectiveness.

Abstract No.: 200663

The Efficacy of Orthokeratology Lenses Combined With Diffusion Optical Technology for Myopia Control in Children With a Family History of High Myopia: Does It Alleviate Retinal Neural Adaptation?

First Author: Yujing LI

Co-Author(s): Kai WANG

Purpose: This study aimed to evaluate the efficacy of combining orthokeratology (Ortho-K/OK) lenses with Diffusion Optics Technology (DOT) lenses for controlling axial length (AL) elongation in myopic children with a family history of high myopia.

Methods: A prospective cohort study was conducted from June 2023 to June 2024. The participants were divided into OK lenses monotherapy (n=32) and OK+DOT combination therapy (n=32) groups. Patients in both groups wore only OK lenses for the first six months. Patients in the combination group were fitted with DOT lenses after demonstrating poor AL control (≥ 0.2 mm growth) during the first 6 months of wearing only OK lenses. AL was measured every 3 months over the 18-month follow-up.

Results: The OK+DOT group presented significantly greater AL growth at 3-6 months (0.12 ± 0.05 mm vs. -0.01 ± 0.19 mm, $p=0.001$) before DOT intervention. After combination, AL growth rates normalized to levels comparable to the OK lenses group (6-9 months: 0.06 ± 0.10 mm vs. 0.08 ± 0.09 mm, $p=0.309$). However, at 15-18 months, the combination group presented slightly greater AL growth (0.08 ± 0.06 mm vs. 0.05 ± 0.04

mm, $p=0.043$). Repeated measures analysis of variance revealed significant time-dependent changes in AL growth in the OK+DOT group (partial $\eta^2=0.153$, $p=0.005$).

Conclusions: The combination of OK and DOT effectively reduced AL growth in patients with inadequate response to OK lenses alone, suggesting that multi-mechanistic myopia control may require dynamic adjustments to maintain long-term efficacy.

Abstract No.: 201538

The Role of Ciliary Muscle Contraction in Myopia Onset Through Clinical, Animal, and Single-Cell RNA Sequencing Studies

First Author: Peng ZHOU

Co-Author(s): Zhao-yang MENG

Purpose: To investigate the biomechanical and cellular-molecular mechanisms by which ciliary muscle contraction contributes to the development of myopia.

Methods: Axial length was measured as an indirect approach to assess the tension transmission from ciliary muscle contraction along the eye wall. We compared cycloplegia (ciliary muscle relaxed) and non-cycloplegia (ciliary muscle contracted) groups to measure axial length in children and adolescents using a Nidek interferometer and in mice using a Topcon OCT. Post-mortem mouse eyes underwent single-cell transcriptomic sequencing for cellular analysis.

Results: Axial length increased by 0.0236 ± 0.0017 mm in 389 adolescent eyes (320 Chinese, 69 Caucasian) during muscle contraction ($t=28.80$, $P<0.001$), with similar increases of 0.0687 ± 0.0172 mm observed in mice ($t=4.46$, $P<0.001$). Analysis of 48,509 cells identified fibroblasts transitioned from subcluster 3 to 1, increasing sensitivity to mechanical stimuli, extracellular matrix secretion, and eye growth during ciliary muscle contraction. Cellchat analysis showed heightened activity in pathways related to immunity, cell adhesion, proliferation, and extracellular matrix composition.

Conclusions: Ciliary muscle contraction may initiate myopia by mechanically transmitting forces and involving inflammatory mediators and immune cells. These interactions trigger fibroblast differentiation and scleral extracellular matrix remodeling, underscoring the complex mechanisms underlying myopia onset and progression.

Abstract No.: 203974

The Shenzhen Model for Myopia Prevention: Artificial Intelligence – Empowered Strategies in a Super-Megacity of the Greater Bay Area

First Author: Haoxi ZHONG

Purpose: Myopia has become a global public health priority, particularly in East Asia's rapidly urbanizing

regions. Shenzhen, a super-megacity of over 20 million residents and a key hub of the Guangdong–Hong Kong–Macao Greater Bay Area, has pioneered an artificial intelligence (AI)–driven, citywide approach to childhood myopia prevention and control.

Methods: Since 2019, Shenzhen has implemented annual school-based myopia screening covering more than 1.8 million students aged 6–18 years. Over 20 million individual-level vision health records have been accumulated, forming one of the world's largest myopia databases. These data underpin digital vision health archives, predictive AI models (deep learning, time-series forecasting, survival analysis), and smart intervention platforms. Integration with wearable outdoor-activity sensors and mobile applications enables real-time feedback for schools, families, and healthcare providers.

Results: Universal coverage of school-aged children was achieved, enabling precise identification of high-risk subgroups and individualized prevention strategies. AI-powered prediction improved referral efficiency, reduced unnecessary clinic visits, and facilitated timely interventions. Early program evaluations show a measurable slowing of myopia progression in targeted cohorts. The initiative also fostered a regional alliance of >150 hospitals and schools, strengthening knowledge transfer across the Greater Bay Area.

Conclusions: The “Shenzhen Model” demonstrates that AI-powered, population-level myopia prevention is feasible in a super-megacity setting. Its integration of big data, artificial intelligence, and preventive public health offers a scalable framework for other global urban centers, contributing to equitable and sustainable eye health solutions.

Abstract No.: 205325

The Transition From Pre-Myopia to Myopia in School-Age Chinese Children: Not All Pre-Myopes Rapidly Become Myopic

First Author: Xiaohu **DING**

Co-Author(s): Wenjia **CAI**, Mingguang **HE**, Ian **MORGAN**

Purpose: To quantify the age-specific rates of conversion from pre-myopia to myopia in pre-myopic school children, and to identify risk factors associated with this conversion.

Methods: Data on subjects aged 7–15 at baseline from the Guangzhou Twin Eye Study (GTES), with 12 years of follow-up visits, were used for this analysis. Data on children aged 6 at baseline from the Guangzhou Outdoor Activity Longitudinal study (GOALS) were used for validation. Subjects were classified into 4 refractive categories based on spherical equivalent (SE): significant hyperopia ($SE \geq 2.0D$), mild hyperopia ($0.75 < SE < 2.0D$), pre-myopia ($-0.5 < SE \leq 0.75D$) and myopia ($SE \leq -0.5D$). Pre-myopes were split into two subgroups: incident myopes (IM) and remain not

myopic (RNM). Risk factors for incident myopia were examined.

Results: Among the 7 to 12-year-old pre-myopes, between 30% to 35% became myopic over the next year. After 12 years of age, the incidence rate dropped to 16.2% at 17 years old. Myopic shifts the IM subgroup have greater changes in SE than established myopes, while the RNM subgroup showed rates of change like those in the mild and significant hyperopes. Following an academic rather than vocational school pathway was a significant risk factor for the development of myopia in multivariate analysis. Similar patterns were seen in the GOAL data.

Conclusions: These results show that only a minority of pre-myopes are at risk of rapid development of myopia. Rates of myopic shift in SE and axial elongation in the IM group were higher than those in established myopes.

Abstract No.: 204200

The Trend Analysis: The Burdens of Refraction Disorders in Children and Adolescents From 2010 to 2021 in Global, Regional, and National

First Author: Yanxin **XU**

Co-Author(s): Zongyin **GAO**

Purpose: Exploring the burdens of refractive disorders among children and adolescents globally, regionally, and nationally between 2010 and 2021.

Methods: This was a population-based study using 2010–2021 data on the burden of refraction disorders from the Global Burden of Diseases, Injuries, and Risk Factors Study 2021 (GBD 2021). The burden of refraction disorders was evaluated in terms of case numbers, rates per 100,000 population, and average annual percentage changes (AAPCs) in prevalence rates and years lived with disability (YLDs). The burden was compared between 2010–2019 and 2020–2021.

Results: The AAPCs in prevalence and YLDs rates (both: -0.23 , 95% confidence interval [CI]: -0.25 to -0.20) decreased from 2010 to 2019, but the AAPCs did not show a significant downward trend between 2020 and 2021, with prevalence AAPC of -0.03 (95% CI: -0.10 to 0.02), YLD AAPC of -0.02 (95% CI: 0.09 to 0.04). Approximately two-thirds of regions exhibited an increasing trend between 2020 and 2021, which mainly concentrated in lower socioeconomic development regions. While East Asia shows a significant downward trend, with the most evident manifestation in China, with an AAPC of -2.97 . Moreover, only children under the age of 9 years exhibited an increased trend globally.

Conclusions: The burden of refraction disorders among children increased in most regions worldwide from 2020 to 2021 compared to the past decade. High sociodemographic index regions did not show an increased trend. We should adopt more effective

prevention and control measures to slow down the progression of refraction disorders, especially for younger children.

Abstract No.: 203919

Through Parents' Eyes: A Cross-Sectional Survey on Outdoor Time and Myopia in Singapore

First Author: Eric JIN

Co-Author(s): Pavithra ASHOK, Jermaine HAN, Daniella MAHFOUD, Najiya MEETHAL, Raymond NAJJAR

Purpose: This study aims to evaluate Singaporean parents' knowledge and perceptions regarding myopia and outdoor time, quantify their children's daily outdoor time, and explore perceived barriers to increasing time spent outdoors.

Methods: In this cross-sectional study, parents of Primary 1 to 3 students, from 42 public primary schools, completed a 22-item online questionnaire that captured baseline demographics, parental knowledge of myopia and outdoor time, children's outdoor habits and after-school activities, and barriers and parental commitment to increasing outdoor exposure. Chi-square/Fisher's exact tests analysed categorical variables, and Spearman's rank correlation assessed non-parametric associations.

Results: A total of 264 parents (40.9 ± 4.84 years) were included in this study. Children were on average 6.9 ± 0.81 years old, with 19.7% being myopic. Most parents (81.5%) rated their knowledge about myopia as good or very good, and recognized outdoor time as protective (89.8%). Only 5.7% of children spent >2h/day outdoors on weekdays, compared to 40.9% on weekends. Non-myopic children and those with parents not working full time were more likely to spend over 1h/day outdoors on weekdays (both $p < 0.05$). Key weekday barriers were academic demands (38.2%) and parental unavailability (34.9%), while weekend barriers included weather (29.5%), academics (26.9%), and enrichment classes (23.1%). Parental commitment strongly correlated with estimated children's outdoor time (weekday $p = 0.62$, weekend $p = 0.77$; $p < 0.001$).

Conclusions: Despite high parental awareness, most children fail to meet recommended outdoor durations for myopia prevention. Increasing time outdoors at schools, supporting working parents, and creating weather-resilient outdoor spaces may help translate awareness into action, lowering myopia risk in Singaporean children.

Abstract No.: 203702

Violet Light Enhances Adolescent Myopia Risk by Impeding the Development of Retinal VIP-Amacrine Cells During Critical Periods

First Author: Xuhong ZHANG

Co-Author(s): Ye SHEN, Jianping TONG, Xiaoyu WANG, Hong ZHU

Purpose: Drastic changes in the light environment significantly impact the visual health and even physical and mental health. While the role of light in early visual development is fundamental, the mechanisms behind its effects remain unclear. Myopia, characterized by an earlier onset and complex underlying mechanisms, is a critical condition affecting the visual health of adolescents worldwide.

Methods: We selected 400 nm violet light as our intervention. The critical exposure period was identified as postnatal days 14 to 28 (P14-P28). VIP::Ai14 mice were utilized to examine the impact of violet light on cellular development, morphology, and function. Patch clamp electrophysiology was employed to study the effects of violet light and virus on VIP-ACs. Immunoelectron microscopy was applied to detect changes in VIP-containing secretory vesicles.

Results: We demonstrate for the first time that exposure to short-wavelength violet light during the postnatal neuroplasticity window (P14~P28) in mice increases the risk of myopia by inhibiting the maturation of vasoactive intestinal peptide-expressing amacrine cells (VIP-ACs). Violet light suppresses dendritic arborization, graded potentials, and VIP secretion in VIP-ACs, and impairs retinal pathway function. Crucially, VIP derived from VIP-ACs exerts a predominant regulatory control over retinal development, thereby contributing to the pathogenesis of myopia. These findings identify violet light as a vital environmental trigger and VIP-ACs as spectral-sensitive modulators of retinal circuit formation. This links impaired neuropeptide signaling during a critical developmental period to increased myopic susceptibility.

Conclusions: This research underscores the impact of specific light wavelengths on visual nerve development and clarifies the underlying mechanisms.

Abstract No.: 204506

Association Between GLP-1 Receptor Agonist Use and Risk of Isolated Cranial Nerve Palsy in Patients With Type 2 Diabetes

*First Author: Sheng Chu **CHI***

*Co-Author(s): Hsin Ho **CHANG**, Hui-chen **CHENG**, Min-huei **HSU***

Purpose: To evaluate the association between GLP-1 receptor agonist (GLP-1RA) therapy and the time-dependent risk of isolated cranial nerve (CN) III, IV, and VI palsy in patients with type 2 diabetes mellitus (T2DM).

Methods: Using the TriNetX Research Network, a retrospective cohort of T2DM patients from 2006–2024 was identified. Patients prescribed GLP-1RAs were 1:1 propensity-score matched with those receiving non-GLP-1RA therapies, controlling for demographics, comorbidities, medications, and lab variables. Kaplan–Meier analysis and Cox proportional hazard models were used to assess time-dependent risks from 3 months to 5 years.

Results: After matching (702,886 patients per group), GLP-1RA users had significantly lower early cumulative risk of CN palsy at 3 months (HR 0.711; 95% CI, 0.581–0.869; $p=0.001$), 6 months (HR 0.743; 95% CI, 0.633–0.872; $p=0.086$), and 1 year (HR 0.857; 95% CI, 0.758–0.970; $p=0.014$). The protective effect declined at 2 years (HR 0.945; $p=0.258$) and was no longer observed by 5 years (HR 1.037; $p=0.359$). Subgroup analysis showed significantly reduced 3-month risk for CN III palsy (HR 0.693; $p=0.006$) and CN VI palsy (HR 0.735; $p=0.022$), but not for CN IV.

Conclusions: GLP-1RA therapy is associated with a significant, yet transient, reduction in risk of CN III and CN VI palsy in T2DM patients during the first year of treatment, suggesting a possible neuroprotective effect.

Abstract No.: 200144

Cellular Senescence Mediates Retinal Ganglion Cell Survival Regulation in Mice Post-Optic Nerve Injury

*First Author: Tsz Kin **NG***

*Co-Author(s): Xin **BIN**, Yao **YAO***

Purpose: Retinal ganglion cell (RGC) death is the critical pathological cause of irreversible visual impairment and blindness in optic nerve injury. We previously investigated the patterns of 11 modes of cell death in the mouse retina post-optic nerve injury. In this study, we aimed to identify additional signalling pathways regulating RGC survival in rodents post-optic nerve injury.

Methods: Retinal transcriptomes post-optic nerve injury were determined by RNA sequencing analysis. The expression of cellular senescence markers was evaluated in the retina post-optic nerve injury. Transforming growth factor receptor type II inhibitor (LY2109761) and senolytics (dasatinib and quercetin), counteracting cellular senescence, were applied to confirm the involvement of cellular senescence in RGC survival post-optic nerve injury.

Results: RNA sequencing analysis identified the upregulation of inflammation and cellular senescence-related genes in the retina post-optic nerve injury. Increased expression of senescence-associated β -galactosidase (SA- β gal) in RGCs and activation of microglia were also found. LY2109761 treatment suppressed p15 and p21 protein and SA- β gal expression and promoted RGC survival post-ON injury, while decreasing the expression of cell death markers in the retina. Consistently, dasatinib and quercetin treatments can promote RGC survival and alleviate the reduction of ganglion cell complex thickness and pattern electroretinography activity post-optic nerve injury, while reducing SA- β gal, p15, p21, microglial activation, and cell death marker expression.

Conclusions: This study revealed the activation of cellular senescence in the mouse retina post-optic nerve injury and contributed to RGC survival regulation. Targeting cellular senescence can promote RGC survival after optic nerve injury, suggesting a potential treatment strategy for traumatic optic neuropathy.

Abstract No.: 207131

Changes in Optic Nerve During Horizontal Eye Movements: A 3D MRI Study

*First Author: Hanwoong **LIM***

*Co-Author(s): Eun Hee **HONG**, Jin-ju **YANG**, Yeji **YEON***

Purpose: To investigate structural changes in the optic nerve (ON) induced by horizontal gaze using three-dimensional (3D) magnetic resonance imaging (MRI), and to analyze their associations with ocular parameters.

Methods: A cross-sectional study was conducted using orbital MRI scans of 48 healthy participants obtained during central and lateral gazes. The ON was segmented from the optic nerve head (ONH) to the optic chiasm using ITK-SNAP. We measured the length and diameter of the segmented ON, as well as various morphometric parameters (e.g., axial distance, eyeball volume) using Vascular Modeling Toolkit (VMTK). In addition, intraorbital ON length was specifically extracted using a self-developed MATLAB script to isolate the orbital segment from the full-length centerline. We compared the ON length, intraorbital ON length, and diameter between the central and lateral gaze positions, and analyzed correlations with ocular parameters. Statistical analysis was performed

using Python to assess the significance of observed differences and correlations.

Results: The ON was successfully segmented and extracted from MRI scans obtained during central and lateral gaze in all subjects. The total ON length was 49.33 ± 3.17 mm and the intraorbital ON length was 15.07 ± 2.74 mm, showing significant differences between the eyes (right, 49.10 ± 3.42 mm; left, 49.57 ± 2.92 mm; $P = 0.029$) and between sexes (male, 50.49 ± 3.46 mm; female, 47.71 ± 1.73 mm; $P < 0.001$). The total ON diameter was 4.87 ± 0.43 mm and the intraorbital ON diameter was 5.18 ± 0.67 mm, also showing significant differences between the eyes (right, 4.93 ± 0.40 mm; left, 4.82 ± 0.45 mm; $P = 0.028$) and between sexes (male, 5.00 ± 0.45 mm; female, 4.69 ± 0.31 mm; $P < 0.001$). The intraorbital ON length significantly increased during lateral gazes compared to central gaze (2.59 ± 0.85 mm in adduction and 2.27 ± 1.03 mm in abduction, $P = 0.004$), while intraorbital ON diameter significantly decreased (adduction, -0.20 ± 0.56 , $P < 0.001$; abduction, -0.26 ± 0.60 , $P < 0.001$). Age showed a significant negative correlation with intraorbital ON length change during lateral gaze (adduction, $r = -0.256$, $P = 0.012$; abduction, $r = -0.214$, $P = 0.037$), while no significant correlations were observed with other ocular parameters.

Conclusions: Horizontal eye movements induce significant elongation and thinning of the optic nerve. These findings suggest that the optic nerve undergoes elastic deformation. Further mechanical studies are needed to clarify the biomechanical implications of these changes.

Abstract No.: 208278

Chronic Alcohol-Consumption Related Effects on Pupillary Light Reflex and Eye Tracking (CARPET) – a Systematic Review

First Author: Ming Chi **CHOY**

Co-Author(s): Kam Lung Kelvin **CHONG**, Ka Hei Kenneth **LAI**, Chi Pui Calvin **PANG**, Chee Yung Clement **THAM**, Wing Lam Stephany **TAI**, Yiu Man Hanson **WONG**

Purpose: This systematic review aims to analyze findings of the effect of chronic alcohol abuse on Pupillary Light Reflex (PLR) and Eye Tracking (ET).

Methods: This systematic review was conducted in accordance with the PRISMA guideline. A search of the English literature was performed using the online databases including Scopus, Medline, PubMed, and Cochrane, as well as citation searching. Data extraction was conducted using predefined structural tables.

Results: Of 448 screened articles, 7 were selected. Regarding PLR, long-term alcohol misuse results in a shortened latency ($p < 0.05$) and a lengthened half-dilation time compared to baseline ($p < 0.05$), marking it role as a physiological marker. Furthermore, chronic alcohol abuse has been associated with a clear

pupillary response in healthy people. Study suggested that it predicts the prognosis of detoxified alcohol-dependent subjects ($n=2$), comparable to the results from Alcohol Use Questionnaire ($p < 0.05$) likely due to locus coeruleus-norepinephrine system dysfunction that is involved in attention and decision-making. Alternatively regarding ET, 3 studies show that alcohol abuse causes diminished oculomotor control in saccade velocity, fixation stability, and pupillary reactivity. Alcohol intoxication impairs visuo-motor functions, reducing cerebellar-related eye movement control, and inhibitory control of eye movements. ET serves as an objective physiological marker for alcohol intoxication and predicts relapse risk.

Conclusions: Future research directions include the detection of using wearables and portable devices. The development of pupillary reactivity and eye tracking biomarkers supports personalized treatment of alcohol use disorder and aids abstinence.

Abstract No.: 204880

Clinical Analysis of the Characteristics of Peripapillary Hyperreflective Oval Mass-like Structures in Adult Patients with High Myopia

First Author: Hashimoto **KINJI**

Co-Author(s): Yi **CAI**

Purpose: Objective: To characterize the clinical features of peripapillary hyperreflective ovoid mass-like structures (PHOMS) in highly myopic adults and to identify the key factors associated with their presence, height, and internal vascularity.

Methods: Methods: In this cross-sectional study, 199 highly myopic adults (398 eyes) were enrolled. Key parameters including axial length, spherical equivalent, and optic disc tilt were measured. The presence, height, and internal blood flow of PHOMS were determined using optical coherence tomography (OCT) and optical coherence tomography angiography (OCTA). Patients were divided into blood flow-positive subgroup and blood flow-negative subgroup according to the presence of internal blood flow in PHOMS. The correlations of age, equivalent spherical refraction, axial length, and optic disc tilt with the occurrence of PHOMS, as well as the correlation between internal blood flow of PHOMS and various factors, were analyzed. Multivariate logistic regression models were used to identify independent risk factors.

Results: Results: PHOMS were present in 93 of 398 eyes (23.4%). After multivariate adjustment, the presence of PHOMS was independently associated with longer axial length (OR = 1.392, 95% CI: 1.141–1.699, $P < 0.001$), greater myopic spherical equivalent (OR = 1.12, 95% CI: 1.013–1.254, $P = 0.028$), and greater optic disc tilt (OR = 1.169, 95% CI: 1.103–1.239, $P < 0.001$). PHOMS height was positively correlated with these three factors (all $P < 0.01$). Among the 93 PHOMS-

positive eyes, OCTA showed that 57 eyes (61.3%) had internal blood flow. Crucially, while multiple factors were associated with blood flow in univariate analysis, only greater optic disc tilt remained as an independent predictor in the multivariate model (OR = 1.246, 95% CI: 1.033–1.501, $P = 0.01$).

Conclusions: Conclusion: PHOMS are a common finding in highly myopic adults. A more negative spherical equivalent, longer axial length, and greater optic disc tilt are associated with a higher likelihood of PHOMS occurrence and greater PHOMS height. More significantly, optic disc tilt is the primary independent predictor for the presence of internal blood flow, suggesting that mechanical stress plays a key role in the vascular characteristics of these lesions.

Abstract No.: 209926

Clinical and Morphological Characteristics of Patients With Peripapillary Hyperreflective Ovoid Mass-Like Structure (PHOMS)

First Author: Damla **CULHA**

Co-Author(s): Hakan **ÖZDEMİR**

Purpose: To evaluate the clinical and morphological characteristics of eyes with peripapillary hyperreflective ovoid mass-like structures (PHOMS).

Methods: The clinical records, standard mode and enhanced depth imaging (EDI) mode spectral-domain optical coherence tomography (SD-OCT), fundus autofluorescence (FAF), and B-scan ocular ultrasonography (USG) of patients with PHOMS were retrospectively reviewed. The etiology of PHOMS, spherical equivalent (SE), integrity of the photoreceptor layer (PRL) below PHOMS, inversion of the retinal pigment epithelium (RPE) under PHOMS into the scleral canal, the lateral margin shape of PHOMS, and the outermost retinal layer observed at the highest point of PHOMS were evaluated.

Results: Seventy-two eyes of 42 patients with PHOMS were evaluated. The majority of patients were female (71.43%), under 18 years old (78.57%), and had myopic refraction (mean SE, -2.97 diopters). Optic disc drusen and optic disc edema were detected in 4 eyes each, and 64 eyes (37 patients) showed myopic tilted discs. Deterioration of the PRL under PHOMS was observed in all eyes. Inversion of the RPE was present in 55 eyes (76.39%). Oval-shaped margins were seen in 50 eyes (69.44%). PHOMS almost always exceeded the upper border of the outer nuclear layer.

Conclusions: PHOMS, which can occur due to various etiological factors, is more common in myopic females in the pediatric age group, almost always causes deterioration of the PRL, and may present with different margin characteristics.

Abstract No.: 202367

Comparison of the Effectiveness of Using Liquid Crystal Glasses “Srabo Glasses” and Transcutaneous Electrical Stimulation to Improve Visual Functions in Children With Partial Optic Nerve Atrophy

First Author: Igor **AZNAURYAN**

Co-Author(s): Karmen Artenian **ARTENIAN**, Satenik **AGAGULIAN**, Victoria **BALASANYAN**, Natalia **KURYSHEVA**, Alexander **LAVER**, Svetlana **RYCHKOVA**

Purpose: To compare the effectiveness of using liquid crystal glasses (LCG) and transcutaneous electrical stimulation (TES) in the functional treatment of congenital partial optic nerve atrophy in children.

Methods: We observed 99 school-age children with congenital PONA caused by perinatal pathology. Depending on the treatment, the children were divided into three groups: 1) 32 children who studied with LCG; 2) 35 children who underwent a course of classical TES; 3) 32 children who received combined treatment, including classes with LCG and TES. The study groups were comparable in terms of key clinical characteristics.

Results: A significant increase in visual acuity was observed in the better-seeing eye and the worse-seeing eye as a result of treatment in all three groups of children ($p < 0.001$). The improvement in visual acuity was more pronounced with combined than isolated use of TES and LCG ($p < 0.05$). As a result of using the LCG, alone or in combination with TES, we observed increases in the number of children with orthotropy and in the number of children with normal retinal correspondence ($p < 0.001$). After using TES alone, the number of children with normal fusion amplitude was comparable before and after treatment ($p > 0.05$).

Conclusions: Thus, the use of LCG alone or in combination with TES in children with congenital partial optic nerve atrophy, caused by perinatal pathology, allows for an increase in visual acuity, improved electrophysiological parameters, reduced the magnitude of deviation, improved fusion ability, and increased the number of children with binocular vision.

Abstract No.: 208435

Effect of Repeated Low-Level Red Light Therapy on Myopia Progression in Children and Adolescents: A Multicenter Randomized Controlled Trial

First Author: Ying **CHEN**

Co-Author(s): Jie **CHEN**, Hongyi **LI**, Xiaoman **LI**, Jia **QU**

Purpose: To evaluate the efficacy and safety of repeated low-level red light therapy (RLRL) in slowing myopia progression in children and adolescents.

Methods: This prospective, multi-center, randomized, open-label, parallel-controlled trial enrolled 200 eligible children aged 8–12 years with myopia

(spherical equivalent refraction, SER -0.75 to -6.00 D), anisometropia <1.5 D, and best corrected visual acuity ≥ 5.0 between January 2023 and June 2024. Participants were randomized to either the RLRL group or the control group. The primary outcome was axial length (AL) change at 12 months; secondary outcomes included SER, subfoveal choroidal thickness (SFCT), and accommodative flexibility (AF).

Results: A total of 177 children (92 in the RLRL group and 85 in the control group) completed the study. After 12 months, the mean change in AL was 0.03 ± 0.22 mm in the RLRL group versus 0.33 ± 0.18 mm in the control group ($P < 0.001$). The mean change in SER was 0.07 ± 0.48 D versus -0.63 ± 0.45 D, respectively ($P < 0.001$). SFCT increased significantly in the RLRL group ($18.52 \pm 31.74 \mu\text{m}$) but decreased in the control group ($-8.30 \pm 28.53 \mu\text{m}$, $P < 0.001$). Both groups showed improvements in AF from baseline. No adverse effects on vision or retinal structure were observed in the RLRL group.

Conclusions: Twelve months of RLRL therapy significantly slowed the progression of SER and AL in myopic children, with a favorable safety profile. These findings support RLRL therapy as a promising intervention for myopia control, although further studies are required to determine long-term efficacy and potential rebound after cessation.

Abstract No.: 202725

Implantable Self-Powered Composite Scaffold Based on Nanozyme Hydrogel: Promoting Optic Nerve Regeneration via Multiplex Synergistic Effects in Immunomicroenvironment Regulation

First Author: Jian **WU**

Co-Author(s): Ningli **WNG**, Jing **WU**

Purpose: To address the constrained regeneration of retinal ganglion cells (RGCs) and the impediment to optic nerve regeneration imposed by the inhibitory microenvironment.

Methods: A self-powered composite scaffold was engineered, incorporating an iron-zinc nanozyme hydrogel (reactive oxygen species scavenging), a micro self-powered battery (sustained electric field), and rutin-loaded electrospun fibers (anti-inflammatory activity).

Results: This biodegradable scaffold enables continuous trans-window electrical stimulation of transected optic nerves. Rutin is rapidly released to exert anti-inflammatory effects, while nanozymes potentiate ROS clearance. The three components synergistically drive macrophage polarization toward a pro-regenerative phenotype, suppress pro-inflammatory factors, and enhance RGC survival, proliferation, and migration.

Conclusions: The drug-loaded layer was fabricated via electrospinning, and the conductive nanozyme

hydrogel layer via a «one-pot» approach. Using commercial precursors (biodegradable Mo anode, high-specific-surface-area Zn cathode), the preparation is facile. The nanozyme-doped hydrogel exhibits 0.52 N cm^{-1} adhesiveness (ensuring stability). The scaffold has 78 % stretchability; its conductive layer maintains 2.48 S m^{-1} conductivity under stretching, facilitating signal transmission. The electrospun layer achieves 24.3 Mg g^{-1} drug loading (79% encapsulation), with 43 % rutin released within 3 days and sustained long-term release. Outputting 0.5 V stably, the scaffold regulates the microenvironment. Its adhesiveness/conductivity enables physiological signal detection (EEG, EOG, etc.). ABTS/TMB/DPPH assays validate antioxidant capacity. Cellular studies confirm it promotes RGC survival and axon regeneration via multi-mechanism microenvironment modulation, offering a novel optic nerve repair strategy.

Abstract No.: 205455

Metabolomic Signatures Across Leber Hereditary Optic Neuropathy, Dominant Optic Atrophy, and Wolfram Syndrome: A Large-Scale Comparative Analysis

First Author: Xuehao **CUI**

Co-Author(s): Patrick **YU-WAI-MAN**

Purpose: To perform the first large-scale metabolomic profiling across three inherited optic neuropathies (ION) — Leber hereditary optic neuropathy (LHON), dominant optic atrophy (DOA), and Wolfram syndrome (WS) — compared to healthy and Parkinson's disease (PD) groups, to identify disease-specific and shared metabolic signatures for potential diagnostic biomarkers or therapeutic targets.

Methods: Untargeted plasma metabolomics was performed in LHON ($n=56$), DOA ($n=75$), WS ($n=11$), PD ($n=40$), and healthy controls (HC, $n=55$). Patients were relatively young and male-skewed; mean onset ages were 25 ± 16 (LHON), 10 ± 10 (DOA), and 12 ± 3 years (WS). Visual acuity was poorer in LHON (logMAR 1.62 ± 0.56) compared with DOA (0.88 ± 0.48), and DOA-plus accounted for 24% of DOA cases. Genotypic stratification included three classical LHON mutations and the rare m.12719T variant. Statistical and multivariate analyses (Welch's t, ANOVA, sPLS-DA, $FDR < 0.05$) were combined with pathway enrichment. Machine learning classifiers (XGBoost, ANN, SVM, etc.) were built after LASSO feature selection, and SHAP was applied for interpretability.

Results: sPLS-DA showed clear separation of ION from HC and PD. Enriched pathways included upregulated creatine and glycine/serine/threonine metabolism and downregulated branched-chain amino acid, nicotinamide, and sphingolipid metabolism. Discriminating metabolites included guanosine, creatinine, 2-pyrrolidinone, and sphingosine-1-phosphate. A novel LHON m.12719T

subgroup (n=3) displayed profound accumulation of 3-methylglutaryl carnitine, implicating defective fatty-acid β -oxidation and correlating with more severe vision loss. The LASSO-XGBoost model achieved AUC 0.91 (test set) for four-class classification, with SHAP confirming amino acid and lipid metabolites as key drivers.

Conclusions: This multi-disease metabolomic study highlights shared and disease-specific metabolic abnormalities in ION, reflecting underlying mitochondrial dysfunction. These optic neuropathy-specific metabolic signatures, distinct from those in PD, suggest novel metabolite biomarkers for diagnosis and metabolic-targeted therapies.

Abstract No.: 210247

Modulating the Retinal Neuroimmune Microenvironment With an Engineered Exosome-Loaded Dehydroepiandrosterone Peptide Hydrogel

First Author: Zhuhong **ZHANG**

Purpose: Retinal ischemia-reperfusion (RIR) injury induces a neuroinflammatory microenvironment characterized by microglial activation and inflammatory responses. This study developed a multifunctional hydrogel system to specifically modulate this neuroinflammatory milieu and provide neuroprotection.

Methods: We constructed an engineered exosome-loaded self-assembling peptide hydrogel (BBR-hExos@DHEA-Pep), combining dehydroepiandrosterone with an IGF-1 mimetic peptide and exosomes from berberine-pretreated, hypoxia-exposed R28 cells. The system was evaluated in rat RIR models through intravitreal injection, with a comprehensive assessment of neuroinflammatory responses using transcriptomics, molecular assays, and immunohistochemistry.

Results: BBR-hExos@DHEA-Pep significantly attenuated neuroinflammation by reducing pro-inflammatory factors (IL-6, IL-1 β , iNOS) and promoting microglial polarization from M1 to M2 phenotype. It suppressed activation of neuroinflammatory pathways, including Wnt5a/NF- κ B and STAT3 signaling, while enhancing anti-inflammatory IL-10 expression. The hydrogel provided sustained neuroprotection, preserving retinal ganglion cells and visual function for 28 days with a single injection.

Conclusions: This engineered hydrogel system effectively modulates the neuroinflammatory microenvironment in RIR injury through multiple mechanisms, offering a promising therapeutic strategy for neuroinflammatory retinal diseases by simultaneously addressing microglial activation and neuronal damage.

Abstract No.: 205695

Multimodal Ocular Manifestations in Chinese Neurofibromatosis Type 1 Patients: Addressing the Unmet Need for Asian Population Data

First Author: Shipeng **GUO**

Co-Author(s): Haonan **MA**, Jie **PENG**, Mingyang **WANG**, Peiquan **ZHAO**

Purpose: To investigate the prevalence and multidimensional characteristics of various neurofibromatosis type 1 (NF1)-related ocular manifestations in the Asian population, based on a large Chinese NF1 cohort.

Methods: A total of 228 NF1 patients were consecutively enrolled. Visual acuity (VA) and intraocular pressure (IOP) were measured. Various NF1-related ocular signs were screened and assessed through slit-lamp biomicroscope examination, ultra-widefield fundus (UWF) photography, near-infrared reflectance (NIR) imaging, and optical coherence tomography (OCT).

Results: A total of 228 Chinese NF1 patients were enrolled. Lisch nodules were detected in 82.82% patients, and the prevalence increased with age by puberty. Positive correlation was revealed between the total number of Lisch nodules and age. A predilection for inferior distribution of Lisch nodules was observed, and darkening of Lisch nodules with age was primarily illustrated. Choroidal abnormalities were observed in 89.94% patients. Significantly higher prevalence of choroidal abnormalities, compared with Lisch nodules, was verified. Both the total number and total area of choroidal abnormalities showed a positive correlation with age. A predominance of distribution of choroidal abnormalities in the posterior pole was demonstrated, and the fundus regions involved expended with age. The prevalence of optic pathway glioma (OPG), retinal vascular abnormalities (RVAs), retinal astrocytic hamartomas (RAHs), and iris mammillations was 1.98%, 9.47%, 1.83%, and 8.37%, respectively.

Conclusions: This study reported the comprehensive ophthalmic clinical spectrum of Chinese NF1 population, estimated the prevalence of various NF1-related ocular manifestations, and described multidimensional characteristics of several NF1-related ocular signs, filling the critical gap in Asian population data on NF1-related ophthalmic manifestations.

Abstract No.: 204709

Optic Nerve Sheath Fenestration: A Decisive Surgical Step Against Visual Collapse

First Author: Usha **KIM**

Purpose: To evaluate the visual outcomes of optic nerve sheath fenestration surgery in patients with optic disc edema.

Methods: Retrospective analysis of 119 eyes from 93 patients who underwent optic nerve sheath fenestration surgery for vision-threatening optic disc edema was assessed for 5 years in our tertiary center. Demographic details, including age, gender, and laterality, were recorded. VA was assessed preoperatively, at postoperatively day 15, and at 3 months using the Log MAR scale. The Wilcoxon signal-rank test was used for statistical comparison.

Results: Ninety-three patients between 17 to 65 years of age were included in the study. Out of which 76% patients underwent unilateral and 26% underwent bilateral sequential surgery. The mean age of patients was 38.04 +/- 11.21 years. Of the total patients, 39.60% were male and 60.4% were female. There was a statistically significant improvement in VA on postoperative day 15 ($p < 0.05$). However, the change between preoperative and 3-month postoperative VA was not statistically significant ($p = 0.5057$). Based on final follow-up, VA improvement was noted in 37.25% of age, no change in 28.43% and worsening in 34.31%. patients who had defective color vision and central field, few showed a little improvement. For most of the patients, the fields remain defective until the last follow-up.

Conclusions: Optic nerve sheath fenestration is an effective modality for reducing optic disc edema in the treatment of unresponsive cases of intracranial hypertension, to other management options; hence, timely intervention can improve the quality of life. In our study, we have observed stabilization of vision post-ONSD with no further deterioration and marginal improvement of vision in the other eye in most cases, along with minimal improvement in Visual fields in a few cases, and patients felt symptomatically better in terms of quality of vision.

Abstract No.: 207203

Optical Coherence Tomography Angiography Parameters As Biomarkers for Preclinical Alzheimer's Disease

First Author: Narayanan **BALAKRISHNAN**

Purpose: To analyse the role of OCTA in the diagnosis of preclinical alzheimer's disease.

Methods: Sixty-two healthy individuals aged 60-93 were subjected to a positron emission tomography (PET) scan and OCTA. PET scans were visually rated for cortical amyloid-beta ($A\beta$) positivity. FAZ size and vessel densities for the inner and outer ring of the macular ETDRS grid and in a 3-6 mm ring around the optic nerve head (ONH) were measured. OCTA measures were associated with the visual $A\beta$ score.

Results: In 13 individuals who were amyloid positive, it was noted that they had higher vessel density than those who were amyloid negative in all regions, but did not differ in FAZ size.

Conclusions: This higher vessel density picked up by OCTA can serve as an easy, non-invasive, and reliable biomarker for preclinical AD.

Abstract No.: 203463

Plasma Proteomic Signature From the Retinal Photoreceptor Layer Predicts Diabetes and Multi-Organ Complications

First Author: Wei **WANG**

Purpose: To develop and validate a plasma proteomic signature, derived from photoreceptor layer thickness (PLT), that predicts incident type 2 diabetes (T2D), systemic complications, and mortality.

Methods: We analyzed 53,014 participants from the UK Biobank (median follow-up: 12.3 years) for discovery and internal validation, and 1,584 participants from the Guangzhou Diabetic Eye Study (GDES) for external validation. PLT was quantified by optical coherence tomography (OCT). Plasma proteomics was profiled using the Olink Explore platform. An elastic-net regression model generated a proteomic signature (Pro-PLT). Outcomes included incident T2D, microvascular and macrovascular complications, dementia, liver disease, and mortality.

Results: Cross-sectional analyses identified 91 plasma proteins significantly associated with PLT ($PFDR < 0.05$), enriched in inflammatory, vascular, and metabolic pathways. Pro-PLT mediated up to 59.9% of the association between PLT and diabetic outcomes. In longitudinal analyses, Pro-PLT significantly predicted 16 incident outcomes, including T2D ($HR = 2.23$), diabetic retinopathy ($HR = 2.94$), heart failure ($HR = 2.19$), dementia ($HR = 1.91$), and cardiovascular mortality ($HR = 2.32$). Incorporating Pro-PLT into existing risk models improved discrimination in 53 of 64 models (ΔC -index: 0.073-0.228) and enhanced net reclassification by an average of 31.5%. Predictive gains were consistent across genetic risk strata and validated externally in a multi-ethnic cohort.

Conclusions: Pro-PLT is a novel, minimally invasive biomarker that reflects systemic protein-driven pathways underlying retinal thinning. It enables early and precise risk stratification for diabetes and multi-organ complications, surpassing conventional models and supporting personalized prevention strategies.

Abstract No.: 202077**Prognostic Factors of Visual Outcomes, Relapse, and Multiple Sclerosis Conversion in Pediatric Optic Neuritis: A Systematic Review and Meta-Analysis***First Author: Angelina Riadi Alim* **SUPRAPTO***Co-Author(s): Angelina Patricia* **CHANDRA**, *Ametya* **MIRANDA**, *Syntia* **NUSANTI****Purpose:** To determine the prognostic factors of visual outcome, relapse, and conversion to multiple sclerosis (MS) in pediatric optic neuritis.**Methods:** The review protocol was registered in PROSPERO (CRD420251129139). Google Scholar, Science Direct, PubMed, Cochrane, Proquest, Wiley, and Scopus were searched for studies examining at least one predictive factor for visual acuity (VA), relapse, and conversion to MS. Meta-analysis was performed for factors that were reported in at least two studies to evaluate the pooled relative risk.**Results:** From 983 records, 33 studies involving 2070 patients were included. 82% studies were predominantly female and the mean proportion of children achieving final VA $\geq$ 20/40 or recovery to initial VA was 75%. Meta-analysis of 13 prognostic factors across 3 outcomes showed that age <10 years (RR 0.59, 95%CI 0.41-0.85; $p=0.005$) was significantly associated with better final VA. Male gender (RR 0.61, 95%CI 0.42-0.90; $p=0.01$), MOG-IgG (RR 2.59, 95%CI 1.13-5.95; $p=0.03$), and AQP4-IgG (RR 3.85, 95%CI 1.27-11.73; $p=0.02$) were significant predictors of recurrence, while MOG-IgG (RR 0.20, 95%CI 0.07-0.59; $p=0.004$), CSF oligoclonal bands (RR 5.05, 95%CI 3.89-6.55; $p<0.00001$), and brain MRI lesions (RR 7.38, 95%CI 3.50-15.58; $p<0.00001$) were significant predictors of conversion to MS.**Conclusions:** Age at onset, gender, MOG-IgG, AQP4-IgG, CSF oligoclonal bands, and brain MRI lesions are important prognostic factors of pediatric optic neuritis.**Abstract No.: 200485****Relapse-Independent Disease Activity in Neuromyelitis Optica Spectrum Disorder***First Author: Jae Ho* **JUNG***Co-Author(s): Jae Ryong* **SONG****Purpose:** To investigate relapse-independent disease activity (RIDA) through retinal structural progression in neuromyelitis optica spectrum disorder (NMOSD) patients and evaluate risk factors affecting ongoing retinal degeneration during relapse-free periods.**Methods:** This retrospective cohort study included AQP4-IgG-positive NMOSD patients over 18 years with longitudinal SD-OCT for ≥ 12 months. Baseline visit was the first examination ≥ 3 months after recent ON onset, with the index period [JJ1.1] being ≥ 12 months of relapse-free periods. OCT parameters, including

peripapillary retinal nerve fiber layer (pRNFL) and macular ganglion cell-inner plexiform layer (mGCIPL) thickness, were calculated using linear regression. Eyes were classified as affected or unaffected by ON history. Risk factors including demographics and early treatment (within 12 months after ON) were analyzed.

Results: 73 eyes from NMOSD patients were analyzed (29 affected, 44 unaffected). Both affected and unaffected eyes demonstrated progressive retinal thinning during relapse-free periods, with pRNFL thinning of -0.75 ± 1.60 $\mu\text{m}/\text{year}$ ($p=0.04$) and -0.55 ± 1.07 $\mu\text{m}/\text{year}$ ($p<0.01$), respectively. Similarly, mGCIPL thinning occurred in both groups (-0.30 ± 1.01 vs -0.13 ± 0.53 $\mu\text{m}/\text{year}$). B cell depletion therapy showed a protective effect against mGCIPL thinning (-0.07 ± 0.95 vs -0.30 ± 0.56 $\mu\text{m}/\text{year}$ in untreated, $p=0.06$), with early treatment being more effective than delayed treatment (0.27 ± 0.72 vs -0.27 ± 0.74 $\mu\text{m}/\text{year}$, $p=0.04$).**Conclusions:** NMOSD demonstrates significant RIDA with ongoing retinal structural degeneration occurring even during relapse-free periods. B cell depletion therapy provides significant protection against RIDA-associated retinal damage and successfully prevents progressive GCIPL thinning, achieving structural preservation.**Abstract No.: 200956****Relationships of Retinal Microvascular Changes and Biomarker-Based Alzheimer's Disease Diagnosis***First Author: Chunwen* **ZHENG***Co-Author(s): Carol Y.* **CHEUNG**, *Vincent C.t.* **MOK**, *Truong Xuan* **NGUYEN**, *Anran* **RAN****Purpose:** Previous studies have reported associations between retinal microvasculature and symptom-based diagnosis of Alzheimer's disease (AD). However, symptom-based diagnosis is limited by its non-specific clinical presentations, which delay AD-specific pathology detection at early stages. This study aims to identify associations between quantitative retinal vascular metrics measured from fundus photographs and AD defined by positron emission tomography (PET) biomarkers.**Methods:** A prospective cohort was recruited from Prince of Wales Hospital and the Chinese University of Hong Kong Eye Center. AD diagnosis was confirmed by significant amyloid-beta ($A\beta$) uptake on PET. Retinal vasculature was imaged with a fundus photograph. Vascular metrics were quantified using AutoMorph, an automated retinal vascular morphology quantification pipeline. Generalized estimating equations were used to identify differences between groups, accounting for inter-eye correlation. Multivariate analyses were used and adjusted for age, gender, hypertension, diabetes, dyslipidemia, stroke, heart disease, smoking, and axial length.

Results: A total of 82 patients underwent PET were involved, with 78 eyes in A β -positive and 86 eyes in A β -negative group. Arteriolar fractal dimension ($P = 0.010$) and arteriolar vessel density ($P = 0.010$) were significantly reduced in A β -positive group. Subjects with A β -positive were associated with lower arteriolar fractal dimension ($OR = 0.879$, 95% CI: 0.790 - 0.967, $P = 0.018$) and arteriolar vessel density ($OR = 0.886$, 95% CI: 0.803 - 0.965, $P = 0.018$).

Conclusions: Reduced arteriolar fractal dimension and arteriolar vessel density were associated with A β -positive status. The current study provides evidence to support using fundus photography as a non-invasive means of early AD detection.

Abstract No.: 202409

Retinal Nerve Fibre Layer and Ganglion Cell Layer Thicknesses in Children With Attention-Deficit/Hyperactivity Disorder

First Author: Xiu Nian **CHEN**

Co-Author(s): Jason **YAM**

Purpose: To investigate the association of retinal nerve fiber layer (RNFL) and ganglion cell layer (GCL) thicknesses with attention-deficit/hyperactivity disorder (ADHD) and its subtypes.

Methods: Peripapillary RNFL (p-RNFL), GCL (p-GCL) thickness, macular RNFL (m-RNFL), and GCL (m-GCL) were measured by Swept-source optical coherence tomography (SS-OCT). ADHD diagnosis and its subtypes, predominantly inattentive (ADHD-IA), predominantly hyperactive-impulsive (ADHD-HI), or combined type (ADHD-C), were made by psychiatrists based on ICD-10 criteria. Additionally, the parental version of the SWAN questionnaires was also used to assess symptoms of ADHD.

Results: Among 8174 children were included, comprising 363 (4.44%) children diagnosed with ADHD and 7811 children serving as controls. ADHD children have a thinner global p-RNFL ($110.46 \pm 13.53 \mu\text{m}$ vs $112.25 \pm 12.23 \mu\text{m}$, $P = 0.003$) and p-GCL ($42.78 \pm 4.43 \mu\text{m}$ vs $43.28 \pm 4.64 \mu\text{m}$, $P = 0.01$) thickness than controls. Thicknesses of p-RNFL, p-GCL and m-GCL in order from thickest to thinnest were ADHD-C type, ADHD-IA type, controls, ADHD-HI type, with significant P trend ($P = 0.001$, $P = 0.001$, $P = 0.002$, respectively). Among ADHD children, each one-point increase in attention-deficit scores were found to be thinner in p-RNFL ($\beta = -2.39$, $P = 0.01$), m-RNFL ($\beta = -0.55$, $P = 0.008$), p-GCL ($\beta = -0.62$, $P = 0.03$) and m-GCL ($\beta = -1.49$, $P < 0.001$).

Conclusions: A thinner p-RNFL and p-GCL thickness was observed in children with ADHD, particularly in ADHD-C subtype, which may be a potential biomarker to identify different subtypes of ADHD.

Abstract No.: 205660

Rolipram Reprograms Lipopolysaccharide-Induced Neurotoxic Activation of Astrocytes via the Cyclic AMP Signaling Pathway: Implications for Retinal Degenerative Diseases

First Author: Linglin **ZHANG**

Co-Author(s): Chaoqiang **GUAN**, Zhijie **LI**, Sudena **WANG**

Purpose: Astrocytes contribute to the pathogenesis of retinal neurodegenerative diseases, including AMD, DR, and glaucoma. The phosphodiesterase-4 (PDE4)/cAMP pathway has emerged as a potential therapeutic target. This study investigates whether modulating this pathway with Rolipram can reprogram neurotoxic astrocyte activation.

Methods: Primary mouse astrocytes were stimulated with LPS (80 ng/ml) in the presence or absence of Rolipram. Reactive and A1-type neurotoxic responses were assessed by qPCR (GFAP, LCN2, C3, IL-6, IL-1 β , IL-12B) and Western blot (p-STAT1, caspase-1). Morphology and LCN2 expression were evaluated via immunocytochemistry.

Results: LPS induced a robust reactive phenotype, characterized by hypertrophic morphology, increased branching, and upregulation of pro-inflammatory cytokines (IL-6, IL-1 β , IL-12B), A1 markers (LCN2, C3), and signaling molecules (p-STAT1, caspase-1). Rolipram treatment significantly reversed LPS-induced morphological hypertrophy and reduced LCN2-positive cells. At the molecular level, Rolipram selectively suppressed IL-1 β , IL-6, IL-12B, and activation of p-STAT1 and caspase-1, while C3 and GFAP mRNA levels remained largely unchanged.

Conclusions: Enhancing cAMP signaling with Rolipram does not merely suppress astrocyte activation but reprograms astrocytes away from a neurotoxic state. It selectively attenuates harmful inflammatory pathways (STAT1/inflammasome axis) and morphological reactivity while preserving certain activation markers. Fine-tuning astrocyte phenotype via the PDE4/cAMP pathway may represent a novel therapeutic strategy for retinal diseases characterized by chronic neuroinflammation.

Abstract No.: 200391

Senolytics Promote Retinal Ganglion Cell Dendrite and Axonal Regeneration in Mice After Optic Nerve Injury

First Author: Wen **YAO**

Co-Author(s): Xin **BIN**, Tsz Kin **NG**, Shuyi **ZHOU**

Purpose: To consolidate our previous findings on cellular senescence mediating retinal ganglion cell (RGC) survival regulation after optic nerve (ON) injury, we aimed to further determine the treatment

effect and mechanisms of senolytics (dasatinib and quercetin), which can specifically remove the senescent cells, on RGC dendrites and axons in mice post-ON injury.

Methods: C57BL/6 and Thy1-YFP mice were treated intragastrically with dasatinib and/or quercetin after ON injury. The number and morphology of dendrites and axons were analyzed. Microglia activation, cellular senescence, and cell death marker expression were evaluated. Retinal transcriptomics was applied to explore the mechanisms of dasatinib and quercetin.

Results: Dasatinib and quercetin treatments significantly reduced the number of senescent cells and cellular senescence marker expression in the ganglion cell layer post-ON injury. Both dasatinib and quercetin treatments significantly attenuated dendritic shrinkage and increased the number of regenerated axons after ON injury. Meanwhile, the P1-N2 amplitude of pattern electroretinography was significantly restored in the dasatinib and quercetin-treated mice. Microglia activation was significantly reduced upon dasatinib and quercetin treatments. RNA sequencing analysis showed that the differentially expressed genes in the dasatinib and quercetin treatment were associated with histone modification, mitochondria, and metal ion binding.

Conclusions: Dasatinib and quercetin can promote dendrite and axonal regeneration post-optic nerve injury. Targeting cellular senescence can be a potential strategy for ON injury treatment.

Abstract No.: 204628

Single-Cell RNA Sequencing Reveals the Ferroptosis Landscape and Identifies DUSP6 as a Therapeutic Target in Diabetic Retinal Injury

First Author: Xinlu **LI**
 Co-Author(s): Yan **MEI**

Purpose: Diabetic retinal neuropathy (DNR), an early and irreversible stage of diabetic retinopathy, is characterized by neuronal damage and glial apoptosis. This study aimed to investigate the role of ferroptosis in the pathogenesis of DNR and to explore potential therapeutic targets.

Methods: Single-cell RNA sequencing (scRNA-seq) was employed to delineate cellular heterogeneity and transcriptomic changes in a rabbit model of DNR. The neuroprotective effect of ferroptosis inhibition was assessed, and the function of Dual Specificity Phosphatase 6 (DUSP6) in modulating ferroptosis-related pathways was evaluated using both in vivo and in vitro models. In vivo experiments were conducted in alloxan-induced diabetic rabbits, while the in vitro system utilized primary mouse Müller cells exposed to high-glucose conditions.

Results: A comprehensive single-cell transcriptomic landscape of retinal injury in DNR was established.

The analysis revealed enrichment of ferroptosis-related pathways and gene expression in specific retinal cell subpopulations. Functional assays in both the diabetic rabbit model and high-glucose-treated Müller cells demonstrated that ferroptosis is a major pathological mechanism underlying DNR, and that its inhibition substantially mitigates retinal cell injury. Integration of scRNA-seq data with Mendelian randomization analysis identified DUSP6 as a pivotal anti-ferroptotic regulator in DNR. Mechanistically, DUSP6 exerted neuroprotective effects by activating the GPX4/DHODH/FSP1 axis, an important pathway for ferroptosis suppression.

Conclusions: Ferroptosis plays a significant role in the progression of DNR. Therapeutic upregulation of DUSP6 protects Müller cells from ferroptosis and attenuates retinal damage by promoting GPX4/DHODH/FSP1 inhibitory pathways.

Abstract No.: 201222

Single-Side Stimulation of Lateral Rectus for Congenital Nystagmus

First Author: Zequn **MIAO**
 Co-Author(s): Lejin **WANG**

Purpose: Congenital nystagmus (CN) is an ocular motor disorder leading to impaired visual function and quality of life. This study evaluates the safety and efficacy of lateral rectus neuromuscular stimulation (Lejin Procedure) as a novel treatment for CN.

Methods: A multicenter, prospective, single-group trial with a 6-month follow-up was conducted across three medical centers in China. Participants diagnosed with CN underwent implantation of a lateral rectus stimulator (i-NYS device, SuperVision Technologies). The outcomes included changes in Best Corrected Visual Acuity (BCVA), Nystagmus Acuity Function (NAFX), Foveation Period (FP), Nystagmus Frequency (NF), Nystagmus Amplitude (NA), and abnormal head posture (AHP).

Results: The study included 61 patients (26 children [8 to 18yr]; 35 adults [≥18 years]). At the 6-month follow-up, significant improvements were observed in all outcome measurements. All participants underwent successful implantation without major surgical complications. For the eyes that underwent surgery, 91.8% patients had improved BCVA with an average of 0.28 LogMAR (2.8 lines) improvement. Mean NAFX increased by 65.4% (from 0.433 to 0.716, $P < 0.001$). The FP increased by 587% (from 134.3 to 923.3 ms/s, $P < 0.001$). The mean NA and NF decreased by 84.1% ($P < 0.001$) and 79.4% ($P < 0.001$), respectively. AHP improved in 62.5% (5/8) of the patients. The procedure-related adverse events included only one case of conjunctival granuloma. There were no other adverse events during the 6-month follow-up period.

Conclusions: This study provides the first clinical evidence supporting lateral rectus neuromuscular stimulation as an effective therapy for CN.

Abstract No.: 206276

The Effect of Postmenopausal on Non-Arteritic Anterior Ischemic Optic Neuropathy Incidence

First Author: Antonia KARTIKA

Co-Author(s): Rusti HANINDYASARI, Dianita VEULINA GINTING, Prettyla YOLAMANDA

Purpose: To evaluate the effect of postmenopausal on non-arteritic anterior ischemic optic neuropathy (NAION) incidence.

Methods: This is a retrospective cross-sectional study designed to assess the impact of postmenopausal on the incidence of NAION. Sampling was conducted using a non-probability total sampling method, involving all subjects who met the inclusion criteria. The data used were obtained from medical records collected between January and December 2024.

Results: A total of 117 female patients with NAION were analyzed, with the majority (65.3%) being postmenopausal for more than one year. The most common comorbidities were hypertension (78.0%), followed by dyslipidemia (35.6%) and diabetes mellitus (33.1%). A total of 33.9% of patients experienced visual improvement after therapy, with a slightly higher proportion observed in the menopausal group. Chi-square test results indicated no significant association between postmenopausal status and the occurrence of NAION ($p=0.839$).

Conclusions: This study indicates that postmenopausal, characterized by reduced estrogen levels, is not significantly associated with the incidence of NAION.

Abstract No.: 206787

Utility of Freitag et al's Visual Field Criteria in Low-CAS Dysthyroid Optic Neuropathy

First Author: Kenneth Ka Hei LAI

Co-Author(s): Kelvin CHONG, Kervin DELLOSA, Alan LEE, Chiu Ming NG, Chi Pui PANG, Clement THAM, Marco VAN BOSWELL, Varan VONGSILPAVATTANA, Alvin YOUNG, Hunter KI YUEN

Purpose: Dysthyroid optic neuropathy (DON) represents the most vision-threatening manifestation of thyroid eye disease (TED). Diagnosis is often delayed in patients with low clinical activity score (CAS), where conventional inflammatory signs may be subtle or absent. Freitag et al's visual field (VF) criteria have been proposed as an objective method for diagnosing and monitoring DON, yet their role in low-CAS presentations remains insufficiently studied.

Methods: We conducted a retrospective cohort study of consecutive DON patients managed at the CUHK

between 2011 and 2025. Freitag et al's visual field (VF) criteria were interpreted by 2 ophthalmologists independently using Humphrey VF 24-2 testing. VF findings were evaluated against clinical and radiological parameters.

Results: Eighty-two patients (54 female; mean age 60 ± 10 years; 7 euthyroid; 17 smokers) were included. Stage 1b defects (isolated paracentral scotomas) were the most frequent, occurring in $n=39$ (47.6%). Stage 2a arcuate defects were the second most common, identified in $n=14$ (17.1%). Scatter defects were noted in $n=9$ (11.0%), while Stage 1a isolated central/paracentral depressions occurred in $n=8$ (9.8%). Less frequent were Stage 1c altitudinal changes ($n=4$, 4.9%), Stage 2b advanced arcuates ($n=2$, 2.4%), and Stage 3 generalized depression ($n=2$, 2.4%). Rare patterns included central/paracentral dense scotomas ($n=2$, 2.4%), superior altitudinal loss ($n=1$, 1.2%), and enlarged blind spot ($n=1$, 1.2%). Importantly, patients with Grade 2 or above (Stages 2a–3) were more likely to require surgical orbital decompression ($P<0.05$).

Conclusions: Freitag et al's criteria provide diagnostic and prognostic value in low-CAS DON. Grade 2 or higher strongly predicts the need for surgical decompression.

Abstract No.: 201366

"Decoding Diagnostic Dilemma"- Clinical Spectrum and Therapeutic Outcomes of Juvenile Double Seronegative Myasthenia Gravis

First Author: Deepti JOSHI

Purpose: To highlight clinical, serological, and neurophysiological features of juvenile double seronegative myasthenia gravis (DSNMG).

Methods: Fifteen children with clinical features suggestive of ocular myasthenia gravis and serologically tested as DSNMG were evaluated for extended antibody assay, including LRP4 and Cortactin. Additionally, RNST and response to therapy were noted.

Results: We assessed 15 children with double seronegative myasthenia gravis. 10 of 15 (66.6%) were positive for LRP4 and had an extremely good prognosis with sole Pyridostigmine. 3 (20%) were positive for cortactin antibody, of which 1 needed immunosuppressant therapy with azathioprine. 2 children had inconclusive antibody reports, and both needed immunosuppressant therapy. No generalisation/thymus involvement was noted. The repetitive nerve stimulation test was negative in 50% DSNMG. In such cases, single fibre electromyography was positive.

Conclusions: Juvenile double seronegative myasthenia gravis presents with mainly ocular symptoms with less generalization and with an extremely good prognosis with immunosuppressants. The dilemma is just

diagnosing them with extra suspicion and an extended antibody assay.

Ocular Imaging

Abstract No.: 203990

Advancing Prognostic Precision in Coats Disease: High-Definition OCT Biomarkers and Their Clinical Implications

First Author: Ziyi **ZHOU**

Co-Author(s): Guorui **DOU**, Manhong **LI**, Yusheng **WANG**, Zifeng **ZHANG**

Purpose: To evaluate the clinical utility of spectral-domain optical coherence tomography (SD-OCT) in detecting early morphological biomarkers associated with macular fibrosis, which is a critical determinant of irreversible vision loss in Coats disease, and to establish an imaging-guided prognostic framework for improved patient management.

Methods: This retrospective cohort study analyzed multimodal imaging data from 43 eyes of 43 patients with Coats disease (Stages 2A–3A2). OCT features such as intraretinal/subretinal fluid, exudation, hyperreflective foci (HRF), and epiretinal membrane were quantified.

Results: SD-OCT demonstrated superior sensitivity in detecting subclinical pathology compared to conventional modalities. It identified subretinal fluid in 48.8% of eyes, in which 12 were missed by FP and 3 by B-scan. Subretinal fluid (OR = 201.145, $p = 0.011$) and subretinal exudation were significantly associated with macular fibrosis development. HRF, suggestive of inflammatory activity, was observed in 16.3% of eyes. Stage 3A1 patients with subretinal fluid showed the highest fibrosis progression rate (46.2%). OCT also enabled layer-specific localization of hard exudates, predominantly within the inner nuclear (81.4%) and outer nuclear (76.7%) layers.

Conclusions: This study underscores the critical role of SD-OCT in transforming Coats disease management by enabling early detection of high-risk features which predict macular fibrosis, particularly subretinal fluid. Implementing routine OCT screening allows for risk stratification, timely intervention, and personalized treatment planning, ultimately mitigating poor visual outcomes. These findings advocate for the integration of OCT into standard protocols to guide clinical decision-making and improve long-term visual prognosis.

Abstract No.: 205981

Analysis of Corneal Biomechanical Indices Using the Standard Global Population Compared With the New Corneal Biomechanical Indices Optimized for the East Asian Population in Filipino Eyes

First Author: Maria Isabela **DE GUIA**

Co-Author(s): Keshia Lourdes **DUYONGCO-LENON**

Purpose: To evaluate whether corneal biomechanical indices optimized for East Asian populations provide improved diagnostic accuracy compared with globally standardized indices in Filipino eyes screened for refractive surgery.

Methods: The study included 180 Filipino patients (360 eyes) who underwent refractive surgery screening at a tertiary center from 2022 to 2024. Corneal tomography was performed with the Pentacam AXL, and biomechanical parameters were assessed using the Corvis ST. Corneal Biomechanical Index (CBI) and Tomographic and Biomechanical Index (TBI) derived from the global population were compared with their East Asian-optimized counterparts (cCBI and cTBI). Agreement was assessed using Bland–Altman analysis and Pitman’s test, while diagnostic performance was evaluated with receiver operating characteristic curves, sensitivity, specificity, and area under the curve (AUC) comparisons using DeLong’s test.

Results: Significant differences were observed between global and East Asian indices (mean differences: 0.314 for CBI vs. cCBI; 0.154 for TBI vs. cTBI; all $p < .001$). East Asian cCBI showed higher sensitivity (75.0%) but lower specificity (65.3%) than global CBI (50.0% sensitivity, 86.9% specificity). Global and East Asian indices achieved perfect discrimination in right eyes (AUC = 1.000). In left eyes, East Asian cTBI provided higher specificity (94.9% vs. 82.9%) while maintaining 100% sensitivity. No statistically significant AUC differences were found between global and East Asian indices.

Conclusions: Corneal biomechanical indices optimized for East Asian populations demonstrated enhanced sensitivity and specificity for Filipino eyes compared with global indices. These findings support the integration of ethnicity-specific thresholds into refractive surgery screening protocols to improve risk stratification and patient safety.

Abstract No.: 204363

Anterior Scleral Shape in Keratoconus and Its Spatial Relationship With Kmax Location

First Author: Qihao **SUN**

Co-Author(s): Mengyi **WANG**, Xiao **YANG**

Purpose: To investigate the characteristics of the anterior scleral shape in patients with keratoconus (KC), and to identify the spatial relationship between maximum keratometry (Kmax) location and anterior scleral shape.

Methods: In this prospective, cross-sectional study, 62 KC eyes and 116 control eyes were assessed using the Pentacam HR CSP module. Scleral sagittal height (SSH) was measured along eight semimeridians at 12–16 mm chord lengths. Kmax vector magnitude (Kvm) and angle (Kva) were computed to localize the steepest corneal region. ΔKva was defined as the absolute difference between Kva and 270° . Correlation and regression analyses examined associations between SSH, Kmax, and various factors.

Results: In controls, SSH increased from superior-temporal to temporal and decreased from inferior-nasal to nasal ($p < 0.001$). KC eyes exhibited a counterclockwise-shifted pattern, with elevations from superior to superior-temporal and declines from inferior to inferior-nasal. SSH was greater in KC eyes in the superior-temporal, inferior-temporal, and inferior meridians (all $p < 0.05$). Kvm correlated negatively with SSH in the superior-nasal, superior, inferior-nasal semimeridians ($r = -0.29$ to -0.251 , $p < 0.05$). ΔKva correlated positively with SSH in nasal, superior-nasal, inferior-temporal, inferior-nasal meridians ($r = 0.254$ to 0.421 , $p < 0.05$). Regression revealed larger ΔKva , older age, and male gender were associated with greater overall SSH. (all $p < 0.05$).

Conclusions: KC eyes exhibit a counterclockwise-shifted anterior scleral profile, with a steeper profile in the superior-temporal, inferior-temporal, and inferior meridians compared to the control group. Kmax location is spatially related to regional SSH, and a larger ΔKva is associated with greater global scleral sagittal height.

Abstract No.: 202520

Assessment of Photoreceptor Recovery and Visual Function Utilizing Adaptive Optics and Microperimetry in Patients With Surgically Closed Macular Holes

First Author: Jiayi **SONG**

Purpose: This study investigated the association between photoreceptor structural restoration and visual function outcomes in patients undergoing surgery for closed macular holes (MHs) using adaptive optics scanning laser ophthalmoscopy (AOSLO) and microperimetry.

Methods: A retrospective observational study was conducted involving 31 eyes from 28 patients who underwent vitrectomy with internal limiting membrane (ILM) peeling for idiopathic MHs. Postoperative monitoring (3 months to 2 years) included best-corrected visual acuity (BCVA), MH diameter and duration, optical coherence tomography (OCT), 4° retinal mean sensitivity (RMS), fixation rates, 68.2% binary contour ellipse area (BCEA) of microperimetry, and AOSLO-derived cone density. Based on OCT, patients were classified as type 1 (closed MH with no

foveal neurosensory defect) or type 2 (closed MH with foveal neurosensory defect).

Results: Type 1 closures showed significantly better photoreceptor recovery, with cone migration toward the fovea and dense islet formation, consistent with intact inner segment/outer segment on OCT. These patients had better BCVA and higher RMS, correlating with improved cone density. Type 2 closures exhibited sparse cone distribution and large, high-density cells, suggesting glial proliferation and exposed retinal pigment epithelium (RPE). MH size was the key predictor of type 1 closure, rather than duration or preoperative BCVA.

Conclusions: AOSLO reveals that type 1 closure facilitates cone migration and leads to better neuroretinal repair, BCVA, and retinal sensitivity. Type 2 closure shows limited photoreceptor recovery and more glial proliferation, resulting in poorer visual outcomes. Photoreceptor density and migration are critical for optimal visual recovery after MH surgery.

Abstract No.: 202167

Comparison between Diagnostic Accuracy of Two Non-Mydriatic Handheld Smartphone Fundus Cameras for Diabetic Retinopathy Screening: A Prospective Study

First Author: Arshad **MEHMOOD**

Co-Author(s): Muhammad **ABDUL REHMAN SIDDIQUI**, Arooba **HANNAN**, Altamash **SHAHRIYAR GHAZANFAR**

Purpose: Comparison between diagnostic accuracy, image quality and practical considerations between two handheld non-mydriatic fundus cameras- Eyer (Phelcom Technologies, USA) and Viva (Volk Optical, USA) as opposed to a traditional fundus camera (Triton, Topcon, Japan). We aimed to explore the potential of non-mydriatic handheld fundus cameras for DR screening.

Methods: This was a prospective study conducted between January and March 2025. We included adult diabetic patients presenting to our clinic with no past history of any treatment. Macula centred images with both Eyer and Viva cameras were taken before dilation. Images which were deemed ungradable were repeated after dilation. A macula centred image with a Topcon fundus camera was taken after dilation and this was treated as the reference-standard for this study. The images were graded for image quality and DR by two graders. Any disagreement was resolved upon consultation with a retina specialist.

Results: We included 903 images of 301 eyes of 165 patients. The mean age was 63.3 ± 11.8 years. There were 32 (10.8%) ungradable images with Eyer and 33 (11.1%) with Viva post-dilation. Sensitivity for referable DR was 79.0% and 76.5% for Eyer and Viva respectively. Specificity was 89.0% for Eyer and 95.2% for Viva. Both cameras had comparable image quality. There was

substantial inter-grader agreement with both Eyer ($k = 0.61$) and Viva ($k = 0.72$).

Conclusions: Both handheld fundus cameras showed promise, performing close to the required cutoff for DR screening. Further validation studies with staged mydriasis are needed in community settings to better evaluate their suitability for widespread DR screening.

Abstract No.: 206595

Cone Photoreceptor Damage and Reorganization in Laser-Induced Retinopathy: Evidence From Adaptive Optics Imaging

First Author: Dong **FANG**

Co-Author(s): Wei **CHI**, Shaochong **ZHANG**

Purpose: To investigate structural and functional changes of cone photoreceptors in laser-induced retinopathy (LIR) and to characterize their reorganization during recovery.

Methods: A longitudinal study was conducted on 15 eyes of 13 LIR patients and 38 control eyes. Participants underwent adaptive optics scanning laser ophthalmoscopy (AO-SLO), spectral-domain OCT, and microperimetry. Lesion morphology and cone metrics were analyzed at baseline and up to 6 months of follow-up.

Results: At baseline, AO-SLO revealed hyporeflective lesions with hyperreflective clumps (mean area: $97,128 \pm 107,478 \mu\text{m}^2$), along with reduced cone density, increased spacing, and irregularity compared with controls (all $P < 0.05$). Lesion size correlated with OCT ellipsoid zone defects ($r = 0.84$, $P < 0.001$) but not with retinal sensitivity. In 13 of 15 lesions (87%), a cluster of irregularly distributed bright cones was present at the lesion margin, which we term a «cone halo.» Over 6 months, 93% of lesions contracted significantly (to $27,560 \pm 26,901 \mu\text{m}^2$, $P = 0.031$). In 87% of cases, the perifoveal «cone halo» expanded (5092 ± 4264 vs. $16,169 \pm 16,771 \mu\text{m}^2$, $P = 0.02$). Cone density within halos increased ($27,942 \pm 6,970$ vs. $36,700 \pm 9,257$ cones/ mm^2 , $P = 0.01$) with reduced spacing ($P = 0.04$). Retinal sensitivity showed only marginal improvement ($P = 0.20$).

Conclusions: LIR causes pronounced cone disruption, while recovery involves a distinct perifoveal «cone halo» reflecting photoreceptor reorganization even in chronic adult lesions. These findings provide novel insight into intrinsic retinal repair mechanisms and the complex structure–function relationship in LIR.

Abstract No.: 206281

Correlation of Cone- and Rod-Derived Retinal Nonperfusion on Ultrawide Field Fluorescein Angiography With Diabetic Retinopathy Severity and Diabetic Macular Edema

First Author: Recivall **SALONGCAY**

Co-Author(s): Lizzie Anne **AQUINO**, Anna Karina **LEOPANDO**, Tunde **PETO**, Paolo **SILVA**

Purpose: To evaluate cone- and rod-specific nonperfusion indices (CPI, RPI) on ultrawide field fluorescein angiography (UWF-FA) and their correlation with diabetic retinopathy (DR) severity and center-involving diabetic macular edema (ciDME).

Methods: Sixty-nine eyes of 43 diabetic patients underwent UWF color photography (UWF-CP), UWF-FA, and macular optical coherence tomography (OCT). DR severity was graded by a masked reader on UWF-CP. UWF-FA images were segmented into posterior pole (≤ 10 mm from fovea), mid-periphery (10–15 mm), and far periphery (> 15 mm), and into the macula, within ETDRS fields, and extended peripheral fields. Ischemic areas were quantified using ImageJ to calculate nonperfusion index (NPI), CPI, and RPI. ciDME was determined on OCT. Correlations were analyzed using Pearson coefficients (r).

Results: DR severity correlated significantly with global NPI ($r = 0.56$, $p < 0.0001$) and across all retinal zones ($r = 0.35$ – 0.57). Both CPI (global: $r = 0.56$, $p < 0.0001$; zones: $r = 0.42$ – 0.59) and RPI (global: $r = 0.55$, $p < 0.0001$; zones: $r = 0.40$ – 0.59) showed similar associations. ciDME presence was also correlated with NPI (global: $r = 0.40$, $p = 0.0014$; zones: $r = 0.42$ – 0.54), CPI (global: $r = 0.47$, $p = 0.0001$; zones: $r = 0.32$ – 0.55), and RPI (global: $r = 0.46$, $p = 0.0002$; zones: $r = 0.33$ – 0.54).

Conclusions: Cone- and rod-related retinal nonperfusion strongly correlates with DR severity and ciDME. UWF-FA may help identify high-risk eyes and guide surveillance of ischemia-related progression. Further studies are needed to define ischemic thresholds predictive of vision-threatening complications.

Abstract No.: 205289

Determinants of Retinal Mitochondrial Redox Status in Young Adults With Myopia Free From Retinal Degeneration

First Author: Qiuruo **JIANG**

Co-Author(s): Shisong **RONG**, Chenfeng, Junfeng, Shihao, Zhanhao

Purpose: To evaluate the mitochondrial redox status of macular and optic-disc regions in myopic eyes without retinal degenerative changes, and to identify related ocular and lifestyle factors.

Methods: We conducted a hospital-based cross-sectional study at the Eye Hospital of Wenzhou

Medical University (April–June 2025). A total of 431 young adults with myopia (862 eyes) but no retinal degeneration completed questionnaires and underwent comprehensive ophthalmic examinations. Retinal metabolic stress was assessed using the OcuMet Beacon Imager, which quantifies flavoprotein autofluorescence (FPF) as an indicator of mitochondrial redox status. Associations were analyzed using linear mixed-effects regression, adjusting for age, sex, height, and weight. Ocular parameters (axial length [AL], AL/corneal radius [AL/CR], keratometry [Km], spherical equivalent [SE], cup-to-disc ratio [CDR]) and lifestyle variables were included.

Results: Participants had a mean age of 25.8 ± 7.2 years and a mean SE of -4.80 ± 2.08 D. Multivariable analyses revealed that more myopic refraction, longer AL, and higher AL/CR were significantly associated with lower macular and optic-disc FPF ($P < 0.001$), whereas higher Km were linked to higher FPF at both regions ($P < 0.001$). Larger CDR and anisometropia correlated with higher optic-disc FPF only ($P = 0.05$). Lifestyle factors, including longer outdoor time, more frequent exercise, and greater coffee consumption, were positively associated with FPF ($P < 0.05$).

Conclusions: The mitochondrial redox status of the healthy retina in myopic eyes is closely linked to myopia severity and optic-disc morphology, and is modulated by lifestyle behaviors. FPF may serve as a potential metabolic biomarker that complements structural measures in characterizing dynamic changes in myopia.

Abstract No.: 200379

Diagnostic Accuracy of a Smartphone-Based Device (VistaView) for Detection of Diabetic Retinopathy: A Prospective Study

First Author: Arshad **MEHMOOD**

Co-Author(s): Muhammad **ABDUL REHMAN SIDDIQUI**, Danish **SHABBIR**, Rida **SHAHZAD**

Purpose: This study compares the diagnostic accuracy of a smartphone-based VistaView camera to that of a desk-mounted fundus camera (Triton Topcon). We also compare the agreement between graders for DR screening between VistaView images and Topcon images.

Methods: This prospective study took place between December 2021 and June 2022 in Pakistan. Diabetic patients were imaged following mydriasis using both VistaView and Topcon cameras at the same sitting. All images were graded independently by two graders based on the ICDR criteria. Individual grades were assigned for the severity of DR and maculopathy. Diagnostic accuracy was calculated using the Topcon camera as the gold standard. Agreement between graders for each device was calculated as the intraclass correlation coefficient (ICC) and Cohen's kappa (k).

Results: A total of 1428 images were available from 371 patients with both cameras. After excluding ungradable images, a total of 1231 images were graded. The sensitivity of VistaView for any DR was 69.9% (95% CI 62.2–76.6%) while the specificity was 92.9% (95% CI 89.9–95.1%), and PPV and NPV were 80.5% (95% CI 73–86.4%) and 88.1% (95% CI 84.5–90.9), respectively. For VistaView, the ICC of DR grades was 78% between the two graders, and that of maculopathy grades was 66%. The Cohen's kappa for retinopathy grades of VistaView images was 0.61 (95% CI, $p < 0.001$), while that for maculopathy grades was 0.49 (95% CI, $p < 0.001$).

Conclusions: The VistaView offers moderate diagnostic accuracy for DR screening and may be used as a screening tool in LMIC like Pakistan.

Abstract No.: 206634

Diagnostic Performance of the Overall Superior-Inferior Peripapillary RNFL Thickness Symmetry for Early Glaucoma

First Author: Kunliang **QIU**

Co-Author(s): Qianqian **HE**, Lexi **HUANG**

Purpose: To evaluate the diagnostic performance of the overall symmetry of the superior-inferior peripapillary RNFL thickness (S-I symmetry score) in detecting early primary open-angle glaucoma (POAG).

Methods: This study included 100 early POAG [with visual field mean deviation (MD) ≥ -6 dB] and 104 normal control subjects, using Cirrus HD-OCT to obtain pRNFL thickness data. The overall superior-inferior RNFL thickness symmetry score (S-I symmetry score) was a quantitative parameter based on the normalized absolute pRNFL thickness difference between superior and inferior hemifields relative to their average. The two hemifields were divided by the disc-fovea line instead of the conventional horizontal line, with the major vascular components removed from the RNFL. Potential factors (e.g. age, disc area, and spherical equivalent) associated with the S-I symmetry score were assessed with regression analysis. The diagnostic performance was evaluated by receiver operating characteristic (ROC) curve analysis. Statistical analyses were performed using SPSS and MedCalc software.

Results: The S-I symmetry score was significantly higher in the control group ($95.81 \pm 3.01\%$) than in the POAG group ($82.38 \pm 12.31\%$) ($p < 0.001$). The S-I symmetry score was not significantly associated with age, spherical equivalent, and sex. The area under the ROC curve (AUC) for the S-I symmetry score was 0.918 (95% CI: 0.872 to 0.951), outperforming the average RNFL thickness (AUC: 0.814; 95% CI: 0.754 to 0.865). In the earlier-stage subgroup (MD ≥ -3 dB, $n=44$), the S-I symmetry score achieved an AUC of 0.954 (95%CI 0.905 to 0.982), better than in the later stage (MD < -3 dB, $n=59$) (AUC 0.895; 95%CI 0.834 to 0.939).

Conclusions: The novel overall intraocular S-I symmetry score showed good performance for the early diagnosis of POAG. It has the potential to better assist ophthalmologists in clinical practice after being integrated with OCT devices and further clinical testing.

Abstract No.: 206021

Enhance Diabetic Retinopathy Grading by AI-Assisted Vascular Biomarker Evaluation Using Ultra-Widefield Swept-Source Optical Coherence Tomography Angiography (UWF-SSOCTA)- DRIVE Study

First Author: Wenting **ZHOU**

Co-Author(s): Tai Yong **LOH**, Yue **QIU**, Wei Hing **SEAH**, Juling **SIA**, Wenjun **SONG**, Linyi **ZHUANG**

Purpose: To evaluate diabetic retinopathy (DR) biomarkers on ultrawide field swept-source optical coherence tomography angiography (UWF SS-OCTA) using a deep learning model, and to assess their correlation with clinical DR severity.

Methods: This prospective, cross-sectional study included 158 eyes from 120 patients across all DR stages, imaged with 29×24 mm UWF SS-OCTA. Key metrics included nonperfusion area (NPA) index (NPI = total NPA/gradable area), number of neovascularisations (NVs), and intraretinal microvascular abnormalities (IRMAs) in different regions using a self-developed extended ETDRS grid: central zone (≤9mm), mid-zone (9–18mm), and outer-zone (>18mm). All biomarkers were quantified using a custom-built deep learning model with manual refinement.

Results: Total NPI significantly increased with DR severity ($p < 0.001$). In PDR eyes, an NPI >10.9% yielded 77% sensitivity for predicting PDR. Higher NPI correlated with the presence of NVD ($p = 0.028$), increased NVE count ($p = 0.007$), and posteriorly located NVEs ($p = 0.02$). In early DR, NPI rose gradually from mid (0.9–2.9%) to outer (1.1–4.2%) zones, whereas in severe NPDR and PDR, NPI surged in the mid (13.2–21%) and plateaued in the periphery (14.2–26.7%). In comparison, the number of IRMAs peaked (80.3%) in the mid-zone from moderate NPDR onwards at the leading edge of ischemia.

Conclusions: UWF SS-OCTA enables rapid, quantitative, and comprehensive assessment of DR biomarkers. AI-enhanced OCTA-driven DR grading allows reproducible risk stratification. Quantitative biomarkers such as NPI and IRMAs are powerful predictors for DR progression and hold promise for objective endpoints in clinical trials.

Abstract No.: 204645

Hemoglobin Oxygen Saturation and Retinal Vascular Diameter in Myopic Eyes

First Author: Geng **WANG**

Co-Author(s): Kunliang **QIU**, Zixuan **XIAO**

Purpose: To evaluate the correlation of the retinal vascular diameter with retinal hemoglobin oxygen saturation in myopic eyes by scanning laser ophthalmoscope (SLO).

Methods: Sixty-one eyes from 61 patients were included. All subjects underwent SLO imaging with dual lasers (532 nm and 633 nm). The retinal arteries (DA) and veins (DV) were labeled, and the diameters of DA and DV were measured. The oxygen saturations of hemoglobin in arteries (SO_{2A}) and veins (SO_{2V}), and their differences (SO_{2AV}) were estimated from the optical densities of the vessels on the images at the two wavelengths.

Results: For vessel diameter, significant correlation of spherical equivalent (SE) with DA ($r = 0.32$) and DV ($r = 0.41$) was found ($P < 0.05$), while significant correlation was only observed between axial length (AL) and DV ($r = -0.41$, $P < 0.01$). For the retinal oxygen saturation, the SO_{2V} in the high myopia group ($73.21 \pm 21.42\%$) was significantly higher than that in the normal group ($55.81 \pm 21.69\%$) and the low and moderate myopia group (56.88 ± 13.83 , $P < 0.05$). The SE was significantly correlated with SO_{2A} ($r = -0.29$) and SO_{2V} ($r = -0.36$) ($P < 0.05$), and AL was also significantly correlated with SO_{2A} ($r = 0.27$) and SO_{2V} ($r = 0.30$) ($P < 0.05$). No significant correlations were found between SO_{2AV} and SE and AL ($P > 0.05$).

Conclusions: This study revealed a negative correlation of SO_{2A} and SO_{2V} with myopic diopters in younger adults. The retinal vascular diameter of myopic eyes decreases with the severity of myopia.

Abstract No.: 205722

Identification of Epiretinal Membrane-Prone Eyes and Feature Analysis From Optical Coherence Tomography by Deep Learning

First Author: Yi-ting **HSIEH**

Co-Author(s): Hsu-hang **YEH**

Purpose: To develop deep learning models using macular optical coherence tomography (OCT) to identify ERM-prone eyes and to elucidate relevant predictive features.

Methods: Macular OCT scans from a single institution were retrospectively reviewed. Eyes were included in the healthy group if both eyes showed no retinal diseases or macular abnormalities. Eyes were classified as ERM-prone if they appeared normal while the fellow eye exhibited idiopathic ERM. After age- and sex-matching, 606 eyes in the healthy group and 549 eyes in the ERM-prone group were included. Horizontal

B-scan OCT images centered on the foveal pit, superior foveal margin, and inferior foveal margin were used to train convolutional neural network (CNN) models.

Results: Among the single-scan models, the foveal pit-centered OCT achieved the best performance with an accuracy of $66.08 \pm 1.18\%$, recall of $60.84 \pm 8.49\%$, specificity of $70.62 \pm 9.30\%$, and an area under the receiver operating characteristic curve (AUROC) of $69.72 \pm 1.73\%$. The support vector machine model incorporating age and sex achieved the highest overall performance with an accuracy of $66.92 \pm 3.00\%$, recall of $61.96 \pm 7.56\%$, specificity of $71.13 \pm 7.21\%$, and AUROC of $71.64 \pm 2.36\%$. Heatmap analysis revealed that the vitreoretinal interface and foveal pit morphology were key discriminative regions, independent of posterior vitreous detachment status.

Conclusions: Deep learning models can differentiate between healthy and ERM-prone eyes with modest accuracy. Subtle structural changes at the vitreoretinal interface and in foveal pit morphology appear to be predictive features. These models offer valuable insights into early, preclinical structural alterations associated with ERM development.

Abstract No.: 203466

In Vivo Biomechanical Analysis of Ciliary Muscle Based on Digital Image Correlation Technology

First Author: Jingsong **WANG**

Co-Author(s): Fan **LU**, Shenglong **LUO**, Yilei **SHAO**, Junjie **WANG**

Purpose: To overcome the limitations of traditional static morphological analysis in ciliary muscle research, this study introduced Digital Image Correlation (DIC) technology into ciliary muscle biomechanical research, aiming to establish a quantitative analysis method for the dynamic strain of the ciliary muscle in vivo.

Methods: Two commercial swept-source optical coherence tomography (OCT) devices (CASIA2 and VG200D) were used. Through simulated deformation and ncorr algorithm analysis, the optimal device (CASIA2) and mode (R8) were screened out. A total of 2 participants were recruited in each of the three groups: low myopia, high myopia, and middle-aged to elderly. The Badal optical system was used to acquire ciliary muscle images in non-accommodated and 5D accommodation-induced states. The optimized ncorr algorithm was applied for DIC analysis to calculate displacement, strain, and average effective strain based on the von Mises formula.

Results: The ROI (Region of Interest) identification rate ranged from 81% to 92%, and displacement and strain in the non-accommodated state were close to zero. Under accommodation, the displacement and strain of the ciliary muscle in the three groups showed a trend of «low myopia group > high myopia group

> middle-aged to elderly group». The young myopic groups exhibited horizontal compression and vertical stretching, while the middle-aged to elderly group showed minimal changes.

Conclusions: This study successfully established the aforementioned analysis method, achieving sub-pixel level quantitative measurement, revealing differences in ciliary muscle mechanical responses among different populations, providing indicators for functional assessment, advancing research from static to dynamic, and facilitating the diagnosis and treatment of ocular refractive diseases.

Abstract No.: 203663

Inherited Retinal Diseases Observed by Multimodal Imaging Assisted by Adaptive Optics Scanning Laser Ophthalmoscopy

First Author: Wei **ZHOU**

Purpose: To investigate the differences in photoreceptors within the macular region of a group of inherited retinal diseases (IRD). The multimodal imaging change mechanisms and their impact on retinal structure and function were systematically analyzed.

Methods: Structural changes in retinal fundus autofluorescence (FAF) and optical coherence tomography (OCT) were observed in four patients with IRD from different families and subtypes with corresponding alterations of cone photoreceptor at the same locations examined by adaptive optics scanning laser ophthalmoscopy (AOSLO).

Results: In this study, morphological changes and density decreases of cone photoreceptors to varying degrees could be observed in all four different IRD patients. AOSLO can perform cell-level imaging of cone photoreceptor, and the morphology is highly correlated with vision. In AOSLO images, the dark areas are indicators of cone photoreceptor degeneration and apoptosis. Even if the outer layer changes of OCT are similar, the morphology of photoreceptors and the visual acuity and visual field manifestations of patients are the accumulation of different highly reflective materials in the macular region.

Conclusions: Compared with FAF and OCT, AOSLO images can directly show the structural damage of cone photoreceptor and are more consistent with the visual acuity and visual field manifestations of IRD patients.

Abstract No.: 204195**Interocular Differences in Retinal Curvature in Anisometropic Patients and Their Association With Myopic Degree Differences***First Author: Gongpeng SUN**Co-Author(s): Meixia ZHANG*

Purpose: To investigate regional differences in Gaussian retinal curvature (RC) between fellow eyes of anisometropic patients and their associations with interocular disparities in myopic parameters.

Methods: In this cross-sectional study, ultra-widefield swept-source optical coherence tomography (24 mm × 20 mm field) was performed in 121 anisometropic patients. Three-dimensional retinal morphology reconstruction based on Bruch's membrane was utilized to derive Gaussian RC. The retina was segmented into macular, peripheral, and six concentric annular regions (I-VI). Paired t-tests or Wilcoxon signed-rank tests were applied to evaluate interocular RC differences, with Spearman correlation analysis examining associations between RC variations and myopic parameter disparities.

Results: Mean interocular differences were 1.95 ± 0.95 D for spherical equivalent (SE) and 0.79 ± 0.46 mm for axial length (AL). The more myopic eye exhibited significantly steeper macular RC ($P < 0.001$) and flatter peripheral RC ($P < 0.001$) compared to the fellow eye. Macular/peripheral RC disparities demonstrated significant correlations with SE/AL differences (both $P < 0.05$). Region-specific analysis revealed positive correlations between AL and RC I-III differentials, whereas inverse correlations were observed for RC V-VI (all $P < 0.01$).

Conclusions: Anisometropic patients demonstrate biomechanical divergence characterized by macular steepening and peripheral flattening in the more myopic eye during axial elongation, suggesting region-dependent retinal adaptation mechanisms.

Abstract No.: 203580**Investigate the Interconnected Innervations of the Lacrimal Functional Unit in Terms of Changes in Lacrimal Gland Volume***First Author: Can YANG**Co-Author(s): Xuanwei LIANG, Kerui WANG*

Purpose: To investigate changes in LG volume in patients with unilateral LDO or prosthetic eye and to explore the neural link within the lacrimal functional unit.

Methods: CT images of both lacrimal glands were retrospectively reviewed for 11 patients with unilateral CNLDO, 40 patients with unilateral PANDO, 25 patients with unilateral prosthetic eye, and sex/age-matched healthy controls. Differences in the volume of the LG between the control subjects, the affected side,

and the contralateral healthy side were examined. Correlation analysis was used to assess the relationship between LG volume and disease duration.

Results: LG volumes in the CNLDO-affected side group were significantly reduced compared to the control group ($P = 0.019$). Similarly, the LG volumes in the PANDO-affected side group were significantly lower than those observed in the control group ($P < 0.001$) and similar to the non-PANDO side group ($P = 0.053$). 25 patients with a prosthetic eye were included. The anophthalmic group had significantly smaller LG volumes compared to the control group and the contralateral side group, with P-values of 0.021 and 0.041, respectively. Negative correlations were found between disease duration and LG volumes in both the PANDO ($r = -0.328$, $P = 0.019$) and anophthalmic ($r = -0.407$, $P = 0.044$) groups.

Conclusions: Compared to the control group, patients with unilateral LDO or prosthetic eye had smaller LG volumes on the affected side. Prolonged unilateral LDO and enucleation or evisceration are associated with reduced LG volume.

Abstract No.: 201786**Linking Endogenous Glucocorticoids to Fundus Alterations: An Ultra-Widefield Optical Coherence Tomography Angiography (UWF-OCTA) Study on Patients With Cushing's Syndrome (CS)***First Author: Linxin WEI**Co-Author(s): Youxin CHEN, Qing ZHAO, Xinyu ZHAO*

Purpose: To explore choroidal and retinal alterations in CS patients using UWF-OCTA and investigate their associations with endogenous glucocorticoids.

Methods: This prospective observational study enrolled 48 CS patients and 48 age- and sex-matched controls. 24×20 mm² UWF-OCTA images were analyzed to assess qualitative pachychoroid features and quantitative metrics including vessel flow density (VFD), retinal and choroidal thickness and volume, choroidal vascularity/stromal volume and index (CVV/CSV and CVI/CSI) across central, peripheral, and whole regions. Generalized estimating equations were utilized for inter-group comparisons and association analyses between OCTA parameters and hormonal levels.

Results: The CS group had a significantly larger proportion of eyes with pachyvessels, along with elevated choriocapillaris (CC)-VFD, choroidal thickness and volume across all the assessed regions than controls ($p < 0.05$). Conversely, large/medium choroidal vessel layer (LMCV)-VFD and CVI of the central and whole regions in CS eyes were significantly reduced ($p < 0.05$). Retinal alterations in CS eyes included increased peripheral superficial capillary plexus (SCP)-VFD, lower SCP-vessel length density, higher deep capillary plexus-VFD, thicker inner retinal

layers, and thinner outer retinal layers compared to controls ($p < 0.05$). Univariate association analyses revealed that total cortisol and 24-h urinary free cortisol negatively correlated with central CC-VFD and positively correlated with peripheral SCP-VFD ($p < 0.05$). Moreover, negative associations existed between adrenocorticotrophic hormone levels and LMCV-VFD across all the regions ($p < 0.05$).

Conclusions: CS represents an optimal model for investigating the effects of endogenous hypercortisolism on the choroid and retina.

Abstract No.: 206043

Longitudinal Treatment Response in Proliferative Diabetic Retinopathy (PDR) Tracked With Ultrawide-Field Swept-Source Optical Coherence Tomography Angiography (UWF SS-OCTA) -DRIVE PDR Study

First Author: Wenting **ZHOU**

Co-Author(s): Yusra **ASAD**, Wei Hing **SEAH**, Wenjun **SONG**

Purpose: To characterise six-month vascular and vitreoretinal interface changes after treatment in proliferative diabetic retinopathy (PDR) using Ultrawide-Field Swept-Source Optical Coherence Tomography Angiography (UWF SS-OCTA).

Methods: In this prospective longitudinal study, 42 eyes of 26 patients were imaged with 29×24 mm and 6×6 mm UWF SS-OCTA at baseline, 1, 3, and 6 months. Neovascularisations (NVs) size on vitreoretinal segmentation and non-perfusion area (NPA) on all-retinal-layer segmentation were quantified using customised AI algorithms with manual adjustment. Other key parameters include foveal avascular zone (FAZ), parafoveal vessel density (VD), and the status of posterior vitreous detachment (PVD).

Results: Baseline imaging confirmed NV in every eye and showed a moderate correlation between total NPA and FAZ size ($r = 0.465$, $p < 0.001$). Larger NPAs were linked to higher NV counts ($p = 0.007$) and more posteriorly located NV elsewhere (NVE) ($p = 0.02$). Mean NV size fell significantly after treatment, with the steepest decline at month 1; 33 eyes (78 %) showed regression, nine progressed. Adjunct anti-VEGF produced a larger, though non-significant, additional NV reduction ($p = 0.68$). Global ischaemic metrics - NPA Index (total NPA/total gradable area), FAZ, and VD—remained stable over six months ($p = 0.47$, 0.36 , 0.23). Partial PVD at NV sites was present in 12 eyes at baseline; three progressed, and two developed vitreous haemorrhage attributable to posterior hyaloid traction.

Conclusions: UWF SS-OCTA offers a rapid, repeatable, and quantifiable tool for monitoring PDR therapy, including tracking vascular response, detecting tractional risk, and guiding treatment decisions.

Abstract No.: 203303

Macrophage-Like Cells at the Vitreoretinal Interface as a Potential Imaging Biomarker of Inflammation in Myopic Macular Neovascularization

First Author: Yuchen **QIAN**

Co-Author(s): Li **ZHANG**, Ting **ZOU**

Purpose: Myopic macular neovascularization (mMNV) is a neurovascular complication of pathologic myopia, with growing evidence implicating inflammation in its pathophysiology. Imaging biomarkers capable of reflecting inflammatory activity could enhance mMNV management and elucidate disease mechanisms. This study explores the clinical utility of macrophage-like cells (MLCs) at the vitreoretinal interface as a potential inflammatory biomarker in mMNV, assessed via optical coherence tomography angiography (OCTA).

Methods: This retrospective, cross-sectional study included 86 eyes, which were categorized into three groups: non-high myopia ($n = 32$), simple high myopia ($n = 35$), and high myopia with mMNV ($n = 19$). En face OCTA images of the vitreoretinal interface were obtained to quantify the density and mean area of MLCs. Additionally, multiple ocular parameters were measured and analyzed, including best-corrected visual acuity (BCVA), axial length (AL), macular retinal thickness (MRT), choroidal thickness (ChT), choroidal vascularity index (CVI), as well as vessel densities of the superficial and deep capillary plexuses. Analysis of Variance and correlation analyses were conducted, and analysis of covariance (ANCOVA) was used to adjust for confounding factors such as age and to compare intergroup differences.

Results: Both MLC density ($p < 0.001$) and mean area ($p < 0.001$) were significantly increased in the mMNV group compared to the non-high myopia and simple high myopia groups, whereas no significant differences were observed between the two control groups. Further subregional analysis revealed that in patients with mMNV, MLCs not only increased in number but also showed a tendency to accumulate towards the foveal center. Correlation analysis indicated that MLC density and area were significantly correlated with multiple parameters, including age, axial length, best-corrected visual acuity, macular retinal thickness, choroidal thickness, choroidal vascularity index, and superficial and deep capillary plexus densities.

Conclusions: OCTA provides a non-invasive method to quantify MLCs at the vitreoretinal interface as a potential imaging biomarker of inflammation, holding promise for both monitoring mMNV progression and understanding the pathogenic role of inflammation in mMNV development.

Abstract No.: 204677

Multimodal Imaging Reveals Superior Sensitivity of Spectral-Domain OCT in Detecting Subclinical Retinal Astrocytic Hamartomas in Tuberous Sclerosis

First Author: Guorui **DOU**

Co-Author(s): Dongjie **SUN**, Jiaxing **SUN**, Yusheng **WANG**, Zi-yi **ZHOU**, Jinting **ZHU**

Purpose: To evaluate and compare the diagnostic performance of spectral-domain optical coherence tomography (SD-OCT) versus conventional fundus photography in detecting retinal astrocytic hamartomas (RAH) in patients with tuberous sclerosis complex (TSC), and to establish imaging-based criteria for early and subclinical lesion identification.

Methods: This cross-sectional study included 60 TSC patients (120 eyes). All participants underwent comprehensive ophthalmoscopic examination, fundus photography, and multimodal imaging with SD-OCT and infrared imaging. Lesion characteristics, including maximal thickness (MT), basal diameter (BD), reflectivity, and intraretinal features, were analyzed. ROC curve analysis was applied to determine optimal cut-off values for detecting lesions not visible on fundus photos.

Results: SD-OCT identified 117 RAHs in 45 patients (75%), whereas fundoscopy detected only 64 lesions in 33 patients (55%). Among these, 53 lesions (45.3%) were exclusively detected by SD-OCT. These subclinical lesions were significantly smaller in both MT ($205 \pm 133 \mu\text{m}$ vs. $423 \pm 26 \mu\text{m}$, $p < 0.05$) and BD ($1741 \pm 152 \mu\text{m}$ vs. $2475 \pm 134 \mu\text{m}$, $p < 0.05$). ROC analysis indicated that an MT threshold of $271 \mu\text{m}$ effectively discriminated lesions undetectable by fundoscopy (AUC = 0.84). SD-OCT further enabled detailed morphological classification and revealed novel features such as intratumoral cavities and vitreous seeding.

Conclusions: SD-OCT exhibits significantly higher sensitivity than fundoscopy in detecting RAHs, especially small or subclinical lesions (MT < $271 \mu\text{m}$). Incorporating SD-OCT into standard TSC ophthalmic screening may improve diagnostic accuracy, facilitate early intervention, and enhance systemic correlation studies supporting revised surveillance guidelines for TSC patients.

Abstract No.: 204269

Multimodal Imaging in Macular Telangiectasia Type 2: A Correlation Study Between Fundus Autofluorescence and Fluorescein Angiography

First Author: Dogukan **COMERTER**

Purpose: This study aimed to analyze the findings of spectral-domain optical coherence tomography (SD-OCT), fundus autofluorescence (FAF), and fluorescein

angiography (FA) in patients with idiopathic macular telangiectasia (MacTel) type 2.

Methods: This retrospective, cross-sectional study included 18 MacTel patients evaluated with SD-OCT (Spectralis). Fundus examinations consisted of color fundus photography, B-scan OCT, FAF, and FA imaging. OCT findings assessed included irregularities in the inner and outer retinal layers, loss of the outer nuclear layer and ellipsoid zone (EZ), intraretinal cavitation, intraretinal pigment proliferation, accumulation of retinal pigment epithelium (RPE) hyperplasia, presence of right-angled venules, and the internal limiting membrane (ILM)-drape sign. Hyperfluorescent areas detected with FA and FAF were manually measured using the “draw region” function, and the results from both imaging modalities were compared.

Results: A total of 34 eyes diagnosed with MacTel were evaluated. EZ loss showed the strongest negative correlation with best-corrected visual acuity (BCVA) ($p = 0.006^{**}$). RPE accumulation, intraretinal cavitation, and the presence of right-angled venules were also significant factors affecting BCVA ($p = 0.038$, $p = 0.043$, and $p = 0.027$, respectively). The ILM-drape sign showed no significant impact on vision. A significant correlation was found between hyperfluorescent areas detected with FAF and FA ($r = 0.897$; $p < 0.01$). The most common imaging pattern observed with both FAF and FA was “increased hyperautofluorescence” (94%). In only two eyes, hyperautofluorescence was detected with FAF without corresponding leakage on FA. A statistically significant difference was found between the hyperfluorescent areas measured on FAF and FA, with FA demonstrating larger leakage areas compared to FAF ($p = 0.0001$).

Conclusions: This study supports that FAF and OCT are more effective than FA in detecting vascular abnormalities before the onset of clinical symptoms. FAF findings became evident in the early stages, while FA did not demonstrate significant changes. As the disease progressed, hyperfluorescent leakage areas on FA were larger than those observed on FAF, reflecting a distinct change in disease course.

Abstract No.: 207757

Myopic Choroidal Neovascularization With Dilated Choroid Vessels Is Prone to Progression Into Subretinal Fibrosis Following Anti-Vascular Endothelial Growth Factor Therapy: A Retrospective Study

First Author: Xiangjun **SHE**

Co-Author(s): Yun **ZHANG**, Qiwei **CAI**

Purpose: This retrospective study aimed to identify risk factors for subretinal fibrosis (SF) and evaluate the response to anti-vascular endothelial growth factor (anti-VEGF) therapy in patients with myopic choroidal neovascularization (mCNV), with a specific focus on

the role of dilated choroidal vessels (DCVs) in disease progression.

Methods: In this retrospective study, patients with high myopia (spherical equivalent < -6.0 D, pathological myopia, Asian ethnicity) and active mCNV lesions, diagnosed between 2021 to 2023, were evaluated. The location of DCVs and mCNV was assessed, and macular thickness, submacular choroid thickness, best-corrected visual acuity, CNV area, and foveal density were measured at baseline and during follow-up. The presence of posterior staphyloma was evaluated at baseline. SF around the mCNV was evaluated lesions during follow-up. The time to SF detection was recorded using survival analysis. Risk factors for SF were analyzed using Kaplan–Meier and multivariable Cox regression analyses.

Results: A total of 46 eyes from 46 patients were included, with a mean age of 54.17 ± 14.37 years, and a baseline spherical equivalent of 12.36 ± 3.21 D. The logarithm of the minimum angle of resolution for the mean visual acuity was 0.70 (0.40–1.30), and the mean macular thickness was 313.11 ± 63.57 μ m at baseline. DCV was detected in 29 of the 46 eyes (63.0%), and the median time to detect SF was 43.41 [95% confidence interval (CI): 37.27–49.55] months. Multivariable Cox regression analysis identified submacular DCV [hazard ratio (HR): 14.93, 95% CI: 5.72–38.91, $P < 0.001$] and absence of posterior staphyloma (HR: 43.48, 95% CI: 12.15–156.32, $P = 0.002$) as independent predictors of SF. The presence of DCV under the fovea compared to the peripheral zone achieved a poorer therapeutic response and was prone to progress to SF after anti-VEGF therapy ($P = 0.041$).

Conclusions: Submacular DCV is associated with poor therapeutic response to anti-VEGF therapy and an increased risk of SF in patients with mCNV.

Abstract No.: 203510

Observational Study of Retinal Perivascular Spaces in Retinal Diseases Using an Adaptive Optics Scanning Laser Ophthalmoscope (AO-SLO)

First Author: Li ZHANG

Purpose: The glymphatic system contributes to central nervous system (CNS) homeostasis maintenance, and its function highly depends on the anatomy of perivascular spaces (PVS) and the physiological regulation of aquaporin-4 (AQP4). Studies have reported the existence of PVS around retinal vessels with high AQP4 expression, suggesting the retinal glymphatic system may be involved in intraocular homeostasis. Adaptive optics (AO) technology provides non-invasive observation of structures like retinal photoreceptor cells and vascular endothelial cells in vivo. This study aims to utilize an adaptive optics scanning laser ophthalmoscope (AO-SLO) to observe perivascular spaces.

Methods: A cross-sectional study was conducted using an adaptive optics retinal imaging system (AO-SLO; Mona Ila, Robotra Technologies) on participants with diabetic retinopathy (DR) and control subjects. Branch retinal arteries and veins at 2 disc diameters (PD) from the optic disc were measured.

Results: PVS were found around both retinal arteries and veins, exhibiting differences from cerebral PVS. The mean venous diameter was 108.0 μ m with a perivenous PVS of 25.1 μ m in DR patients, compared to 105.2 μ m and 27.7 μ m respectively in controls. The mean arterial diameter was 80.1 μ m with a perarterial PVS of 19.4 μ m in DR patients (Stage I-II), compared to 76.5 μ m and 25.4 μ m, respectively, in controls. Statistically significant differences in PVS were found around arteries and in controls.

Conclusions: This study utilizes high-resolution AO-SLO in vivo imaging to reveal retinal PVS in the physiological and pathological states of DR, suggesting glymphatic dysfunction may participate in the pathological processes of retinal inflammation and macular edema.

Abstract No.: 203687

Peripheral Ganglion Cell Complex Thickness and Retinal Microvasculature in Myopia Using Wide-Field Swept-Source OCT

First Author: Yinhang ZHANG

Co-Author(s): Fei LI, Deming WANG, Xiulan ZHANG

Purpose: This study aims to investigate the impact of axial elongation on ganglion cell complex thickness (GCCT) and retinal capillary density (CD) using wide-field swept-source optical coherence tomography angiography.

Methods: A retrospective cross-sectional analysis was conducted involving 506 eyes. Fovea-centered scans were obtained to assess the subregional GCCT and capillary density across the whole retina, the superficial capillary plexus (SCP), and the deep capillary plexus (DCP) among three groups: normal control, high myopia (HM) eyes with axial length < 28 mm, and HM eyes with axial length > 28 mm. Regional variations (central vs. peripheral, quadrants difference [superior, inferior, nasal, and temporal]) were analyzed.

Results: In HM eyes with axial length > 28 mm, GCCT and retinal CD exhibit a general decline in most regions ($P < 0.05$). In HM eyes with axial length < 28 mm, significant reductions were observed specifically in peripheral regions, as in the GCCT beyond the 3×3 mm² area and CD in the 9–12 mm whole retina, 9–12 mm superior SCP, and 6–12 mm DCP ($P < 0.05$). Maximum GCCT and retinal CD reduction with axial elongation was observed in subregions beyond 6×6 mm².

Conclusions: GCCT beyond the 3×3 mm² area and peripheral retinal CD beyond the 6×6 mm² area were more susceptible to axial elongation and are thereby

deserving of particular attention. It is necessary to evaluate different regions during the clinical assessment of the effect of myopia on the fundus and pay close attention to the peripheral retina.

Abstract No.: 200122

Presumed Retinal Micro(nano)plastics: A Bayesian Framework for Hypothesis Generation in Ocular Imaging

First Author: Aik Kah TAN

Purpose: Despite the known presence of micro(nano)plastics (MNPs) in multiple human tissues, they have never been documented in the retina. This study proposes a novel imaging-based hypothesis: that findings such as tiny discrete foci on fundus photography and hyperreflective foci on OCT may represent retinal MNPs. Using a Bayesian analysis, this work quantitatively evaluates the plausibility of this hypothesis, providing a rational foundation for the future development of MNP-specific retinal imaging tools.

Methods: A Bayesian model was constructed to evaluate the hypothesis under strong initial skepticism (prior probability $P(H) = 0.01$). Varying likelihoods of observed imaging evidence were analyzed under both null and alternative assumptions. Posterior probabilities and Bayes Factors were calculated to quantify hypothesis support and guide future imaging research.

Results: The model yielded a posterior probability of $P(H|E) = 0.023$ and a Bayes Factor of 2.33—representing weak but non-negligible evidence in favor of MNP presence. Despite a low prior, reproducible imaging features more than doubled the degree of belief. Sensitivity analysis showed the model was more influenced by priors than likelihoods, reinforcing the value of informed clinical suspicion in early hypothesis generation.

Conclusions: This hypothesis offers dual scientific value. If TRUE, it introduces environmental ophthalmology, impacting toxicology and public health. If FALSE, it uncovers the retina's nanoparticle barrier—a breakthrough in resilience biology and drug delivery. Either outcome reframes the retina as a paradoxical system, prompting high-impact inquiry at the intersection of environmental exposure, biological defense, and hypothesis-driven imaging science.

Abstract No.: 202558

Quantifying Edema and Fibrosis in Thyroid Eye Disease: The Role of Quantitative Synthetic MRI

First Author: Sien Ping CHEW

Co-Author(s): Duo Jin XIA, Haiyang ZHANG, Huifang ZHOU

Purpose: Edema and fibrosis are crucial factors in distinguishing disease activity in thyroid eye disease (TED). Accurate activity assessment of TED is essential for clinical decision-making but remains challenging with current subjective scoring systems. This study investigates the diagnostic value of synthetic MRI, specifically Magnetic Resonance Image Compilation (MAGiC), which combines quantitative T1, T2, and proton density (PD) mapping, for the objective evaluation of TED activity.

Methods: A total of 113 TED patients, including 49 with active and 64 with inactive disease, were included in the analysis. Patients underwent MRI using a 3T MRI scanner with MAGiC for simultaneous acquisition of T1, T2, and PD maps. Image quality was assessed based on spatial resolution, contrast, and legibility of key anatomical structures such as extraocular muscles and lacrimal glands, comparing MAGiC with conventional Dixon imaging. Diagnostic accuracy was evaluated using receiver operating characteristic (ROC) curve analysis.

Results: Synthetic MRI demonstrated high reproducibility with excellent ICCs (ranging from 0.755 to 0.985). The T1 + PD model showed the highest diagnostic accuracy, with significant associations between IR_T1 and IR_PD with TED activity. The T1 + T2 + PD model also demonstrated strong performance, although the inclusion of T2 provided only marginal improvements. The T1 + PD model was identified as the most reliable combination for evaluating TED activity, providing a robust and objective tool for clinical decision-making.

Conclusions: The T1 + PD model offers a clinically feasible method for assessing TED activity, which could improve disease staging and guide therapeutic decisions. These findings support the potential of MAGiC-based synthetic MRI in clinical practice, particularly for patients with borderline or ambiguous clinical features.

Abstract No.: 201490

Quantitative Assessment of Peripheral Choroidal Vasculature on UWF ICGA in Posterior Uveitis Using Advanced Imaging Processing Techniques

First Author: Ashish **MARKAN**

Co-Author(s): Airuddha **AGARWAL**, Rupesh **AGRAWAL**, Vishali **GUPTA**

Purpose: To quantitatively evaluate the peripheral choroidal vasculature in patients with posterior uveitis using UWF ICGA.

Methods: Retrospective study design. Patients, aged 18-50 years, registered in the uveitis clinic and diagnosed with posterior uveitis, were recruited as cases. Fellow eyes of the patients who underwent UWF FFA and ICGA for other ocular pathologies were recruited as controls. Early and mid-phase FFA ICGA images were used to analyze (using affine registration and advanced image processing techniques) various choroidal vascular parameters. We undertook a quantitative assessment of peripheral choroidal vasculature on UWF ICGA by leveraging image processing algorithms using the Python programming language. Choroidal vessel densitometry (CVD), asymmetry of choroidal outflow (ACO), the diameter of the prominent choroidal vessel, and the distance between the ampulla and optic nerve were assessed in eyes with posterior uveitis and the control group.

Results: A total of 31 cases and 14 controls were included. The choroidal vessel densitometry and diameter of inferior choroidal vessels were significantly altered in posterior uveitis as compared to the control group. Other parameters, like the asymmetry of choroidal outflow and the ampulla distance from the optic nerve, were comparable in both groups.

Conclusions: Quantifying choroidal vascular parameters can help clinicians monitor the disease progression and response to therapy. Our study also showed that CVD was markedly decreased, and the diameter of prominent choroidal vessels in the inferior quadrant was significantly increased in posterior uveitis as compared to the control group.

Abstract No.: 202524

Reducing Label Noise in Multi-Category Retinal Images Datasets: Data Cleaning Based on the CleanLab Framework

First Author: Yongleng **FANG**

Co-Author(s): Haoyu **CHEN**

Purpose: The study aims to verify the ability of CleanLab to identify label noise in ophthalmic public datasets, and provide more accurate retinal images.

Methods: The study used an open-source framework CleanLab to perform data cleaning on three multi-category datasets of fundus photography to identify

label issues, near-duplicates, and outliers. The results were independently authenticated by three experienced ophthalmologists.

Results: After data cleaning, the CleanLab framework detected label noise in all three public datasets. The ODIR-5K and Eye Diseases Classification datasets contained near-duplicates, but the MuReD dataset did not. Although the corrections of label issues proved only moderately reliable (28.6–45.8 %) across these three datasets, the CleanLab nonetheless detected 61–547 mislabeled and 4–19 out-of-distribution images in total. And the outlier detection across three datasets additionally identified 2–28 mislabeled images.

Conclusions: The CleanLab can identify the undiscovered label noise in ophthalmic multi-category public datasets. Although the CleanLab achieves only modest accuracy in label correction, its capacity to rapidly identify near-duplicate images and potentially mislabeled samples substantially alleviates the burden of data-cleaning efforts. This study substantiates a promising pathway to enhance the quality of publicly accessible datasets, which represents a meaningful contribution to the improvement of model performance in subsequent machine-learning research.

Abstract No.: 204918

Swept Source Optical Coherence Tomography Angiography (SS-OCTA) Assessment of Choroidal Structure in Vitreoretinal Lymphoma Patients and Their Changes During Intravitreal Methotrexate Chemotherapy

First Author: Xinyi **ZHOU**

Co-Author(s): Qing **CHANG**, Junxiang **GU**

Purpose: To evaluate choroidal structure changes in vitreoretinal lymphoma (VRL) patients during intravitreal methotrexate (MTX) therapy and quantitative characteristics of active VRL at the choroidal level using swept source optical coherence tomography angiography (SS-OCTA).

Methods: In this retrospective study, patients diagnosed with VRL who received intravitreal MTX chemotherapy from January 2022 to December 2023 were included, along with healthy volunteers of the same age range and sex ratio. Three-phase intravitreal MTX chemotherapy consisting of induction, consolidation, and maintenance was scheduled. SS-OCT/OCTA images obtained before intraocular chemotherapy and by the end of each phase of treatment were reviewed. Choroidal thickness (CT), choriocapillaris (CC) perfusion area, choroidal vessel volume (CVV), choroidal vascularity index (CVI), and choroidal stromal volume (CSV) were analyzed.

Results: Forty-four eyes of 29 VRL patients (15 males, 14 females) were enrolled in this study. CT, CVV, and CSV decreased significantly by the end of the induction

phase and maintained a continuous decrease during intravitreal MTX chemotherapy (all $P < 0.05$), while CC perfusion area and CVI remained statistically comparable. Comparative analysis demonstrated significantly lower CVI in VRL eyes versus normal controls across all measured regions (all $P < 0.05$), while CT, CVV, and CSV showed no intergroup differences.

Conclusions: VRL eyes demonstrated a decreased CVI, which reflected lymphoma-induced structural changes at the choroidal level. Following intravitreal MTX treatment, CT, CVV, and CSV all showed a significant reduction.

Abstract No.: 200680

The Role of En Face Imaging of Retinal Pigment Epithelium Alterations in Rapid Classification of Central Serous Chorioretinopathy Using Widefield Swept-Source Optical Coherence Tomography

First Author: Zhengwei **ZHANG**

Purpose: To investigate the role of widefield en face imaging of retinal pigment epithelium (RPE) alterations using swept-source optical coherence tomography (SS-OCT) for rapid classification of central serous chorioretinopathy (CSCR).

Methods: In this cross-sectional, single-center study, eyes diagnosed with unilateral CSCR were included. Volume SS-OCT scans (12-mm × 12-mm) were obtained for all the participants. High-quality structural en face images were automatically generated at the level of Bruch's membrane based on artificial intelligence to evaluate the RPE alterations.

Results: The study included 122 affected eyes from patients with unilateral CSCR, with a mean age of 46.3 ± 9.1 years. In 51 out of the 122 cases, fundus autofluorescence (FAF), fundus fluorescein angiography (FFA), indocyanine green angiography (ICGA), and en face imaging were assessed simultaneously. Among these, 17 eyes were categorized as complex CSCR. FAF exhibited the highest detection rate of RPE abnormalities (94.1%). En face imaging revealed RPE abnormalities in 15 out of 17 eyes (88.2%), while ICGA detected RPE abnormalities in 12 out of 17 eyes (70.6%). Only 6 out of 17 eyes (35.3%) showed RPE abnormalities in FFA. The RPE alterations in the remaining 71 eyes with CSCR were evaluated solely using en face imaging, wherein 17 eyes were designated as complex CSCR and 54 eyes were categorized as simple CSCR.

Conclusions: Evaluation of RPE alterations using widefield en face imaging has potential as a reliable, noninvasive approach to rapid classification of CSCR using the latest classification system.

Abstract No.: 205882

Thickness of the Eyelid Skin (Epidermis and Dermis) in Filipino Adults Using Ultrasound Biomicroscopy: A Preliminary, Descriptive, Cross-Sectional Study

First Author: Pauline Gabrielle **LACSAMANA**

Co-Author(s): Honeylen **TEO**

Purpose: Ultrasound biomicroscopy (UBM) provides high-resolution imaging of ocular structures and shows potential for eyelid skin assessment. No published data exist on epidermal and dermal eyelid thickness using UBM, and regional variability remains poorly characterized. Establishing normative values may aid oculoplastic and aesthetic practice. This study aimed to determine eyelid epidermal and dermal thickness in Filipino adults with Fitzpatrick Skin Phototype IV.

Methods: A descriptive cross-sectional study was conducted at St. Luke's Medical Center, Manila (July–August 2025). Sixty Filipino adults (30 males, 30 females) with normal eyelids and Fitzpatrick Skin Type IV were enrolled. Exclusion criteria included prior eyelid surgery, periocular trauma, disease, or hypersensitivity. Imaging was performed with the Sonomed Escalon VuMAX HD (50 MHz probe). Standardized upper and lower eyelid scans were obtained after topical anesthesia. Thickness was measured using device software, converted to micrometers, and analyzed descriptively.

Results: UBM was performed in 60 participants (10 per subgroup). In six young adults (18–39 years), the epidermis was uniformly thin (40–80 μ m), while dermal thickness showed regional variability. In the upper eyelid, thickness ranged from 540 μ m at the margin to 773 μ m beneath the brow; in the lower eyelid, from 650 μ m at the margin to 845 μ m at the lid–cheek junction. Dermal differences accounted for most variability.

Conclusions: UBM demonstrated regional heterogeneity in eyelid thickness, with thicker zones in peri-brow and lid–cheek regions. These baseline findings, which represent the first UBM data in Filipinos, are relevant for surgical planning, incision design, and device calibration, and support further age- and sex-specific studies.

Abstract No.: 202508

Towards In Vivo Cellular Visualization of Crystalline Lens With Full-Field Optical Coherence Tomography

First Author: Peng **XIAO**

Co-Author(s): Shang **HUANG**, Zhongzhou **LUO**, Jinze **ZHANG**

Purpose: To develop a non-invasive imaging technique capable of visualizing cells within the crystalline lens to advance our understanding of lens development and cataract formation.

Methods: We customized full-field optical coherence tomography (FFOCT) prototypes optimized for murine (NA=0.8) and human (NA=0.3) crystalline lens imaging. Utilizing spatial incoherent illumination ($\lambda=840\text{nm}$, $\Delta\lambda=30\text{nm}$), the effects of anterior ocular media aberrations on system resolution were mitigated when imaging the lens inside the eye. Simultaneous defocusing correction was conducted during in-depth scanning. Multi-plane en face image fusion strategy was adapted for larger field-of-view of curved lens epithelial cells (LECs) layer. Validation encompassed in situ and in vivo murine imaging, as well as first-in-human in vivo trials.

Results: The FFOCT systems achieved three-dimensional micron-scale resolution. Murine imaging visualized the anterior capsule as a hyper-reflective layer, while beneath it, the mosaic distribution of LECs. Murine LECs density exhibited biphasic decline from 25k to 6k cells/ mm^2 (from P0 to P30) followed by gradual stabilization ($\sim 6.5\text{k cells/mm}^2$ at P60). Concomitant cellular remodeling included initial hypertrophy (5.4 to 12.5 μm diameter, from P0 to P30) and subsequent compaction (10.9 μm at P60). Uniform rows of fiber cells, as well as suture structures and developmental voids, were then observed below the Murine LECs layer. Human imaging resolved distributions of LECs (10-15 μm), parallel arrays of cortical fiber cells, and Y-suture structures with micron-level details.

Conclusions: This study demonstrates the significant potential of FFOCT as a valuable tool to provide unprecedented cellular-level insights into the crystalline lens.

Abstract No.: 207160

Type 4 Macular Neovascularization (NV): A New Member of the Optical Coherence Tomography (OCT) Classification of NV Age-Related Macular Degeneration (AMD)

First Author: Hiok Hong CHAN

Co-Author(s): Gemmy CHEUNG, Alessandro FEO, David SARRAF

Purpose: To describe the clinical and multimodal imaging features of a novel form of macular neovascularization (MNV), designated Type 4 MNV, defined by mixed Type 1 and Type 2 neovascularization (NV), extensive intraretinal anastomotic NV, and central posterior hyaloid fibrosis (CPHF).

Methods: This multicenter retrospective observational case series included patients with neovascular age-related macular degeneration (AMD) exhibiting both Type 1 and 2 MNV and an overlying anastomotic intraretinal NV network. This was confirmed with OCT and OCT angiography (OCTA). Demographics, baseline visual acuity (VA), and OCT imaging biomarkers, including the hyperreflective oblique band (HOB)

sign, CPHF, epiretinal membrane (ERM), and OCTA NV subtype, were assessed.

Results: Eleven eyes from eleven patients (mean age: 76.9 years; 36.4% female) met the inclusion criteria. Baseline VA was logMAR 1.56 ± 0.45 ($\approx 20/630$), and 90.9% of subjects presented with severe visual loss. All eyes showed the HOB sign. CPHF was observed in 81.8% (9/11 subjects). ERM with radial traction was present in 81.8%. OCTA illustrated mixed Type 1 and 2 MNV with a prominent overlying intraretinal anastomotic network extending into the preretinal space.

Conclusions: Type 4 MNV represents a distinct AMD phenotype with aggressive anatomical features, including mixed Type 1 and 2 MNV, inner retinal and preretinal proliferation, anastomosis, and retinal disorganization. The visual prognosis is invariably poor with recalcitrance to anti-VEGF therapy. The recognition of this signature NV lesion subtype further refines the MNV classification system and can impact therapeutic strategies for neovascular AMD.

Abstract No.: 202977

Ultra-Widefield Fundus Fluorescein Angiography: Findings in Takayasu Arteritis

First Author: Manu SHARMA

Co-Author(s): Mohit DOGRA, Ramandeep SINGH, Basav TIGARI

Purpose: Takayasu arteritis is an uncommon vascular disorder. Fundus fluorescein angiography (FFA) plays a key role in staging and managing Takayasu retinopathy (TR). In this study, we assessed the utility of ultra-widefield FFA (UWF-FFA) in providing additional diagnostic information and influencing management decisions.

Methods: Retrospectively, Takayasu Arteritis (TA) patients with TR who underwent UWF-FFA were enrolled. Standard $7 \times 30^\circ$ ETDRS fields representing conventional imaging were superimposed over the UWF-FFA images. The extra information yielded by UWF-FFA and its advantages over standard $7 \times 30^\circ$ ETDRS fields were noted.

Results: Seventy-eight eyes of 39 patients (mean age: 31.31 ± 10 years; 34 females) were included. On UWF-FFA, 5(6.4%) eyes had stage 4; 33 (42.3%) stage 3, 11 (14.1%) stage 2, 7(9.0%) stage 1 and, 22(28.2%) eyes were normal. On conventional imaging, 4 (5.1%) eyes had stage 4, 1(1.3%) had stage 3, 17(21.8%) had stage 2, and 33(42.3%) had stage 1, and 23(29.5%) eyes were normal. Change in stage was seen in 41 (52.6%) eyes with $p \text{ value} < 0.05$, which was statistically significant. On UWF-FFA, peripheral capillary non-perfusion areas in 28 (35.9%) eyes, and neovascularization in 1(1.4%) eye.

Conclusions: UWF FFA helped to pick up extra information in 26(33.3%) eyes and perform sight-saving

treatment (laser) in 28 (35.9%) eyes. Hence, it should be the preferred imaging modality in TA patients.

Abstract No.: 205488

Widefield Indocyanine Green Angiography Evaluating Choroidal Vein Drainage Pattern and Choroidal Vein Alterations in Acute and Chronic Central Serous Chorioretinopathy

First Author: Xinlei HAO

Purpose: To access the distribution of choroidal vein drainage pattern and the choroidal vein alterations in choroidal vascular hyperpermeability (CVH) areas in eyes with acute and chronic central serous chorioretinopathy (CSC) using widefield indocyanine green angiography (WF-ICGA).

Methods: In this retrospective observational study, medical records and multimodal imaging of 127 patients (165 eyes) with CSC were reviewed. The number and location of dominant vortex veins and CVH areas on WF-ICGA images were evaluated. Choroidal vein alterations, including fusiform, bulbosity, sausageing, choroidal vein confluence, and intervortex venous anastomosis, were identified in CVH areas. The differences in choroidal features were compared between the acute and chronic groups.

Results: Sixty-three acute CSC eyes and 102 chronic CSC eyes were evaluated. In this study, 125 eyes (75.76%) exhibited an asymmetric pattern of choroidal vein drainage routes. The chronic CSC group had more CVH areas compared with acute CSC eyes in general ($P < 0.001$). Compared with chronic CSC eyes, CVH areas in acute CSC eyes were more likely to occur in the dominant vortex vein system ($P = 0.006$). Regarding the choroidal vein alterations, all kinds of anatomical changes were significantly more pronounced in chronic CSC eyes compared with the acute group ($P < 0.001$ for all), with sausageing and intervortex venous anastomosis more commonly observed in the chronic group ($P < 0.001$ and $P = 0.002$, respectively). The best corrected visual acuity (BCVA) of chronic symmetric CSC was significantly better than that of chronic asymmetric CSC cases ($P = 0.006$), with the BCVA showing a correlation with the frequency of sausageing dilations ($P = 0.032$). An increased number of sausageing dilation was associated with poorer visual acuity in chronic asymmetric CSC.

Conclusions: Choroidal vascular remodeling occurs throughout the entire course of the CSC, with the formation of an intervortex venous anastomosis creating a new drainage path that helps ameliorate choroidal vein congestion over time.

Windows to Memory: Pupillometry as a Specific Biomarker of Long-Term Memory

First Author: Agatha WONG

Co-Author(s): Lok Man Andy AU, Yu Yin Zenobia CHAU, Kam Lung Kelvin CHONG, Yiu Man Hanson WONG

Purpose: To systematically evaluate the utility of pupillometry as a non-invasive biomarker for long-term memory (LTM) retrieval, and to assess its potential as an accessible alternative to traditional neurophysiological methods.

Methods: Following the PRISMA guidelines, quantitative studies were identified via Scopus (1st January 2000–1st July 2025) using the search terms “pupillometry», “pupillary response (PR)”, and “long-term memory (LTM)”. Screening was conducted independently using Covidence. Studies were included if they examined the association between PR and any form of LTM retrieval and targeted healthy participants, while papers focusing solely on short-term memory were excluded. Static pupillometry data, namely pupil size, constriction, and dilation patterns, were extracted, with included studies stratified into episodic, semantic, and procedural memory for specificity.

Results: A total of 585 studies were identified using search terms, and 34 studies (1,732 patients) met the inclusion criteria. Twenty-one studies associate greater pupil dilation and baseline pupil size with successful LTM retrieval across all forms of LTM ($p \leq 0.01$), with the remaining 13 observing distinct pupillary patterns during the retrieval of LTM. Differences in pupil dynamics also reflect individual differences, age-related changes, and effort levels. On the other hand, dysregulated arousal, as indicated by inconsistent pupil responses, correlates with poorer memory performance.

Conclusions: Providing a low-cost, reproducible approach, infrared pupillometry holds potential for screening and self-monitoring of memory-related disorders, including mild cognitive impairment and Alzheimer's disease, by identifying distinct pupil dynamics linked to cognitive load, retrieval effort, and attentional regulation in LTR.

A Machine Learning Pipeline to Analyse Global Sentiment and Factors Influencing Retinoblastoma Treatment Hesitancy

First Author: Wai Chak CHOY

Co-Author(s): Lijia CHEN, Wai Kit CHU, Chi Pui PANG, Clement THAM, Emily Suhan WONG, Jason Cheuk Sing YAM, Yuzhou ZHANG

Purpose: The use of social media in cancer research, patient support, and information sharing has been well documented. Using retinoblastoma as a model, we utilise the abundance of information provided from Twitter to understand patients' treatment-seeking behaviour and barriers, as well as investigate its application in research and epidemiology.

Methods: Posts on retinoblastoma were extracted from Twitter. We trained Bidirectional Encoder Representations from Transformers models (BERT) to identify relevance and conducted sentiment analysis. The Hierarchical Dirichlet Process was trained to identify topics with BERTopic for sensitivity analysis. We enriched user profiles with OpenStreetMap-based geotagging and coreNLP-based occupation tagging. Retinoblastoma outcomes were obtained from a systematic review and meta-analysis, which covered articles published between January 1, 1981, and October 8, 2021.

Results: The dataset covered 2,382,511 posts from 797,870 Twitter users. Stronger negative sentiment towards enucleation ($\beta = -0.924$ [95%CI = -1.367--0.481]) but not chemotherapy ($\beta = -0.116$, [95%CI = -0.444--0.211], $P = 0.4763$) was associated with worse overall survival outcome. Active participation of clinical staff ($\beta = -0.105$, CI = -0.186--0.024, $P = .0111$) and academia ($\beta = -0.116$, CI = -0.208--0.252, $P = .0126$) correlated with lower enucleation hesitancy. Lack of disease understanding and the need for more support and counselling remained the most significant barrier to receiving treatment worldwide, as reflected by both intensity and number of tweets. The number of new posts per year related to treatment barriers and enucleation hesitancy showed exponential growth after 2016 ($\beta_{\log\text{-linear}} = 0.957$, $P = .0021$).

Conclusions: Social media is extensively used for retinoblastoma education and support, with positive sentiment on social media associated with better survival. Targeted information dissemination by trained personnel should improve acceptance in vulnerable zones and outcomes.

Abstract No.: 206682

Altered Mitochondrial DNA Copy Number and Biogenesis Gene Expression Correlates With Clinicopathological Features in Retinoblastoma Patients

First Author: Athang SAWANT

Co-Author(s): Bilal AHMED, Bhavna CHAWLA, Seema KASHYAP, Neiwete LOMI, Rachna SETH, Lata SINGH

Purpose: Retinoblastoma (Rb) is a common childhood cancer in India. The genetic foundation of the disease is well-documented; however, the subsequent metabolic adaptations, especially those related to mitochondria, are increasingly acknowledged as crucial in facilitating retinoblastoma progression and therapeutic chemoresistance. This study, therefore, aims to measure the mitochondrial copy number and expression of its biogenesis genes in Rb.

Methods: This was a prospective study which included 51 Rb patients. Mitochondrial DNA copy number (mtDNA) and biogenesis genes expression (PGC1- α , NRF1, NRF2, TFAM and POLRMT gene) were analysed using quantitative real-time PCR (qRT-PCR). Protein expression was evaluated by immunohistochemistry (IHC) and further validated using western blotting. Statistical analysis was performed to correlate their expression with clinicopathological parameters and patient outcome.

Results: There was a male preponderance (56%) and 17 patients were <2 years old. Histopathology revealed high-risk features in 50.98% cases, with necrosis and calcification in 43.13% and 50.98% cases, respectively. Poorly differentiated Rb (PDRB) was found in more than 90% of cases. qRT-PCR results showed significant upregulation of PGC1- α , TFAM, and POLRMT genes in more than 80% of cases. Western blotting and IHC results were consistent with qRT-PCR for PGC1- α and TFAM protein. The mtDNA copy number was significantly higher in primary Rb. On statistical analysis, PDRB and HRFs ≥ 1 were positively significant with PGC1- α , TFAM, and POLRMT expression.

Conclusions: This is the first of its kind study showing the evidence of differential expression of mitochondrial biogenesis genes and altered mtDNA copy number in Rb patients.

Abstract No.: 204554

An Unusual Variant of Eyelid Sebaceous Carcinoma With Central Squamous Differentiation

First Author: Maitha AL ASMI

Co-Author(s): Syed ALI RAZA RIZVI

Purpose: Sebaceous carcinoma of the eyelid is a rare and aggressive malignancy that often masquerades as benign conditions or mimics basal cell carcinoma. Histological variants with squamous differentiation are

exceedingly uncommon. Early recognition and accurate diagnosis are crucial for optimizing outcomes.

Methods: A 63-year-old male with a significant smoking history presented with a three-month history of progressive, painless right lower eyelid swelling. Examination showed an ulcerative lesion with malignant features, including madarosis, eyelid margin distortion, telangiectatic vessels, and a palpable preauricular lymph node. Excisional biopsy under frozen section with Hughes flap reconstruction was performed.

Results: Histopathology confirmed sebaceous carcinoma with rare squamous differentiation, demonstrating lobular growth, comedonecrosis, and deep invasion into muscle (9 mm), with intraepidermal and conjunctival extension. Surgical margins were free of tumor cells, and the tumor was staged as pT3NxMx (AJCC 8th Edition). Imaging revealed no definite metastasis apart from a nonspecific lung nodule. Despite advice for neck dissection and parotidectomy, the patient declined further surgery and opted for radiotherapy. On follow-up, eyelid reconstruction was stable with no evidence of recurrence.

Conclusions: Sebaceous carcinoma with squamous differentiation is an unusually rare histopathological variant with significant diagnostic and therapeutic implications. This case highlights the need for a high index of suspicion, comprehensive histopathological assessment, and multidisciplinary input in eyelid tumors. Awareness of such unusual presentations expands understanding of sebaceous carcinoma behavior and emphasizes the importance of individualized treatment planning.

Abstract No.: 204287

Characterization of Early Metastatic Subpopulations in Uveal Melanoma: Single-Cell Insights Into SPP1+ Cells and Their Interactions With Macrophages

First Author: Jingting LUO

Co-Author(s): Yang LI, Heng WANG, Wenbin WEI

Purpose: To identify highly invasive subpopulations of tumor cells that may be responsible for early uveal melanoma (UM) metastasis at the single-cell level and to analyze their interactions with immune cells.

Methods: Single-cell RNA sequencing was conducted on eleven samples from eleven UM patients who underwent primary enucleation. The patients were categorized into metastasis (M+) and non-metastasis (M-) groups based on whether metastasis occurred during the three-year follow-up. The results were validated using bulk RNA-seq data from 133 patients from our cohorts (n=53) and TCGA human UM patients (n=80). The clustering was confirmed by immunofluorescence. Cell proliferation and invasiveness were evaluated using CCK8 and transwell

assays. Apoptosis was analyzed using flow cytometry after Annexin V-FITC/PI staining. The relative expression levels of genes were assessed using RT-qPCR.

Results: A secreted phosphoprotein 1 (SPP1) + cluster that may be related to early metastasis and high invasiveness was identified by comprehensive bioinformatics analysis and confirmed by immunofluorescence in UM sections. In vitro experiments supported that SPP1 promotes UM cell proliferation, migration, and invasion. Moreover, CCL3+ macrophages were associated with poor prognosis, and the HMGB1-TIM-3 axis may serve as a potential immune checkpoint target. Consequently, SPP1+ melanoma cell populations will likely interact with CCL3+ macrophages, highlighting their possible role in the metastatic process.

Conclusions: Our study reveals early metastatic mechanisms in UM by identifying highly invasive SPP1+ melanoma cells and their interaction with macrophages, providing potential therapeutic targets for the metastatic process.

Abstract No.: 210221

Complete Regression of an Unusual Case of Reactive Retinal Astrocytic Tumor in the Posterior Pole of the Retina With Shortened Interval Anti-VEGF Injection

First Author: Luyun LIANG

Co-Author(s): Yiqin DUAN

Purpose: To explore the effective therapeutic options for Retinal Vasoproliferative Tumor (RVPT), describe a case of successful treatment of an unusual RVPT located in the posterior pole of the retina in a 16-year-old male patient.

Methods: To review the clinical manifestations, imaging features, and therapeutic regimen of a male patient diagnosed with RVPT in Changsha Aier Eye Hospital in September 2021.

Results: RVPT is a rare benign retinal glioma. Their development may be triggered by retinal ischemia and hypoxia, as well as the presence of inflammatory factors. However, the progression rate of these tumors is unpredictable. Once the primary intraocular lesion or inflammatory factors are activated, RVPT tends to induce extensive reactive retinal gliosis. The tumor mass can rapidly grow from a few millimeters to fill the entire vitreous cavity, leading to an extremely poor prognosis, also the treatment efficacy for RRAT has been reported to be relatively low in the literature. A 16-year-old male patient was diagnosed with the rare tumor RVPT due to a sudden decrease in vision over a short period of time, treated with shortened intervals between intraocular anti-VEGF injections and an increased frequency of laser treatments. Over the course of a ten-month follow-up, the tumor completely

regressed, and visual acuity in the right eye significantly improved.

Conclusions: Shortening the intervals between anti-VEGF injections and increasing the frequency of retinal laser treatments may provide a more effective approach for rapidly controlling RVPT growth and preserving vision. Compared with traditional vitrectomy, the treatment applied in this case greatly lessened patient suffering, effectively prevented enucleation, and offered a novel clinical approach for RVPT treatment.

Abstract No.: 205495

Diagnostic Yield, Safety and TCGA Risk Stratification of Transretinal Vitrector Biopsy in AJCC Stage 1–2 Choroidal Melanoma: A Retrospective Cohort Study

First Author: Adrian Fung

Co-Author(s): Svetlana Cherepanoff, Max Conway, Nikita Garg, Min Huang, Stephen Wong, Michael Zhang

Purpose: To evaluate the diagnostic yield, safety and TCGA molecular classification from vitrector biopsy in early-stage uveal melanoma and compare outcomes by clinical indication.

Methods: This single-centre retrospective study included patients with AJCC stage cT1–2 choroidal melanoma who underwent transretinal vitrector biopsy between 2019 and 2024. Demographics, tumour features, biopsy indication (diagnostic vs prognostic), and treatment details were recorded. Diagnostic yield was assessed using cytomorphology, BAP1 immunohistochemistry (IHC), and chromosomal microarray (CMA). TCGA risk classification was defined as Group A–D (CMA) or A/B (BAP1 retained) vs C/D (BAP1 aberrant). Post-biopsy complications were recorded up to 6 months.

Results: Twenty-nine eyes from 29 patients (mean age 58 years, range 18–95) were analysed. Cytological diagnosis was achieved in 27/29 cases (93%), CMA-based classification in 27/29 (93%), and BAP1 IHC in 22/29 (76%). Either cytology or CMA yielded diagnostic results in 28/29 cases (97%). All prognostic biopsies (11/11) yielded interpretable cytology, CMA, and BAP1 IHC. Diagnostic biopsies yielded cytology in 16/18 (89%), CMA in 16/18 (89%), and BAP1 IHC in 11/18 (61%). High metastatic TCGA risk profiles (Group C/D) were identified exclusively in T1/1a tumours. Two patients (6.9%) required vitrectomy for post-biopsy haemorrhage. No cases of tumour dissemination, endophthalmitis, or retinal detachment were observed within 6 months.

Conclusions: Transretinal vitrector biopsy is a safe, high-yield procedure for prognosis and diagnosis in early-stage choroidal melanoma. TCGA-based high-risk molecular profiles can be identified in low-stage

tumours, highlighting the limitations of AJCC staging alone and the utility of vitrector biopsy for personalised risk stratification.

Abstract No.: 204707

Distinct Genomic Signatures in Bilateral Ocular Mantle Cell Lymphoma

First Author: Usha Kim

Purpose: To analyze the genomic alterations in ocular adnexal lymphoma and look for the specific signatures in a unique case of bilateral ocular mantle cell lymphoma.

Methods: Whole-exome and transcriptome sequencing were done on 19 and 13 lymphoma tumors, respectively. The integration of exome and transcriptome data was performed to identify the key altered pathways.

Results: We identified ROS1 as a novel, recurrently mutated gene in 26% of cases, in addition to known mutations in EP300 (26%), TNFAIP3 (21%), and TBL1XR1 (11%). Patients with mutant ROS1 had shorter progression-free survival. Among the recurrent mutations, TNFAIP3 alterations were significantly correlated with recurrence, and IGLL5 mutations with dissemination. Analysis of both eyes in a bilateral ocular mantle cell lymphoma showed ATM and KMT2D mutations in one eye, while the other displayed ROS1 and BIRC3 mutations.

Conclusions: Significant genetic alterations at both the genomic and transcriptomic levels provide a comprehensive insight into the molecular characteristics of Ocular lymphoma. This integrated approach of clinical and genetic analyses suggests new avenues for targeted clinical interventions in Ocular lymphoma.

Abstract No.: 206917

Evolution of Intra-Arterial Chemotherapy Technique and Outcomes in Retinoblastoma: A 15-Year Retrospective Study From a Tertiary Referral Center

First Author: Nattarat Tang-Ananchai

Co-Author(s): Thanaporn Kritfuangfoo, Duangnate Rojanaporn

Purpose: To evaluate the efficacy of intra-arterial chemotherapy (IAC) for intraocular retinoblastoma through a 15-year retrospective review.

Methods: This retrospective study included all patients with intraocular retinoblastoma treated with primary or secondary IAC at a tertiary referral center in Thailand. IAC techniques and drug protocols were revised across two periods (Period 1: 2009–2017 and Period 2: 2018–2023). Globe salvage and visual outcomes were assessed by patient and tumor characteristics.

Results: A total of 63 eyes from 60 patients with intraocular retinoblastoma were included. IAC was administered as primary treatment in 46.0% and secondary treatment in 54.0% of eyes. The overall globe salvage rate was 71.4%, with significantly higher success in eyes receiving primary IAC (86.2%) compared to secondary IAC (58.8%, $p = 0.025$). Salvage outcomes improved markedly in Period 2 (91.7% vs. 44.4%, $p < 0.001$), alongside increased use of triple-drug regimens and improved catheterization success (93.5% vs. 77.3%, $p = 0.002$). Group E tumors had the lowest salvage rates, but subclassification revealed that some E1 eyes remained salvageable. Multivariable analysis identified retinal detachment (HR, 6.54; $p = 0.023$) and secondary IAC (HR, 12.93; $p = 0.020$) as independent predictors of treatment failure. For visual outcomes, macular involvement was associated with poorer final visual acuity. Although no variables remained significant in multivariable analysis, retinal detachment was associated with worse vision in univariable analysis.

Conclusions: IAC is an effective treatment for intraocular retinoblastoma, with improved globe salvage over time, particularly in primary IAC and triple-drug regimens. Early intervention and individualized treatment approaches are key to optimizing both globe preservation and visual outcomes.

Abstract No.: 204843

Exome Sequencing of Basal Cell Carcinoma of the Eyelids in Japanese Patients Characterizes Distinct and Shared Mutation Profiles Across Populations and Identifies New Oncogene

First Author: Masato **AKIYAMA**

Co-Author(s): Yuya **FUJII**, Noriko **HIMORI**, Yusuke **SANO**, Mika **TANABE**

Purpose: To elucidate the genetic landscape of basal cell carcinoma (BCC) of the eyelids in the Japanese population.

Methods: We conducted exome sequencing analyses in 46 patients with eyelid BCC who underwent surgical resection at two university hospitals in Japan. Sequence libraries for tumor- and blood-derived DNA were prepared using the SureSelectXT Library Prep Kit and sequenced on a NovaSeq 6000. The sequence reads were analyzed following the best practice of Mutect2. Gene-level statistical significance was estimated by dNdScv. The results were compared with those from a large-scale analysis conducted in the Western cohort (Bonilla et al., Nat Genet 2016).

Results: We successfully sequenced all samples. The tumor mutation burden was 8.6 ± 9.5 mutations/Mb (mean $\pm$ standard deviation), which was much lower than that reported in the previous study (65 mutations/Mb). Seven recurrently mutated genes (PTCH1, PTPN14, TP53, ARID1A, SLC25A3, KMT2D, and SMO) were identified at a false discovery rate $< 5\%$. Among them, SLC25A3 has not been previously reported.

Recurrent mutations ($N \geq 4$) were found in SMO and SLC25A3. Comparison of mutation frequencies in each gene with the previous study showed a significant positive rank-correlation ($\rho = 0.62$, $P = 4.52 \times 10^{-3}$); however, mutation frequencies of PTCH1 (50%) and TP53 (26%) in Japanese BCC were lower than those in the previous study (PTCH1: 79%; TP53: 61%).

Conclusions: While the genetic landscape of BCC in Asian patients is similar to that in Western patients, the mutation burden and the frequencies of mutated genes may differ across populations.

Abstract No.: 206769

Eyelid Malignancies in Indonesia: Insights From a Multicenter Study on Clinical Features and Outcomes

First Author: Mutmainah **MAHYUDDIN**

Co-Author(s): Neni **ANGGRAINI**, Raden Angga **KARTIWA**, Delfitri **LUTFI**, Purjanto Tepo **UTOMO**

Purpose: Eyelid malignancies are relatively common and treatable if detected early. In Asian populations, sebaceous gland carcinoma (SGC) is as frequent as basal cell carcinoma (BCC), while Indonesian single-center studies have reported inconsistent findings. Diagnosis is further complicated as eyelid malignancy can mimic benign conditions, often leading to misdiagnosis, recurrence, and even metastases. This study aimed to present the clinical characteristics and outcomes of eyelid malignancies in Indonesia.

Methods: This retrospective descriptive study utilized medical records of patients with histopathologically confirmed eyelid malignancies who underwent surgery in eleven referral hospitals across nine Indonesian provinces from January 2016 to December 2022. A consecutive sampling method was applied. Data collected included clinical characteristics, treatments, and outcomes. Statistical analyses were performed using IBM SPSS.

Results: A total of 574 patients were included, with females comprising 58.0%. The mean age was 59 ± 15 years and 35.5% presented within six months of disease onset. Basal cell carcinoma was the most frequent malignancy (45.5%), followed by SGC (20.2%) and squamous cell carcinoma (15.0%). Surgery was the primary treatment in 94.9% of patients, predominantly wide excision. Based on AJCC classification, 61.3% presented with stage T3a or higher. Although metastases were infrequent, recurrence occurred in 22.6% of patients and SGC showed the highest recurrence rate.

Conclusions: Eyelid malignancies in Indonesia are frequently diagnosed at advanced stages, with BCC as the most common subtype and SGC showing the highest recurrence rate. This underscores the need for early histopathological confirmation to improve outcomes.

Abstract No.: 204525

High Single-Treatment Success Using Plaque Radiotherapy for Vasoproliferative Tumors

First Author: Hung-da CHOU

Co-Author(s): Amit ARORA, Guy NEGRETTI, Mandeep SAGOO, Ian STOKER

Purpose: To review the outcomes of vasoproliferative tumor (VPT) following brachytherapy.

Methods: A retrospective case series in a national referral center. Clinical features were assessed by multimodal imaging. Single-treatment success was defined as a regression of the tumor or tumor activities without recurrence. Data are presented as median (Q1, Q3).

Results: Twenty-five eyes were analyzed. Brachytherapy was given with an apex dose of 80 Gy in all except one eye and a median tumor base dose of 181 Gy (145, 260 Gy). After 32 months of follow-up, single-treatment success was observed in 24/25 eyes (96%), and 16/25 eyes (64%) showed significant thickness regression of 0.5 mm or more. In a multivariate regression model, older age ($\beta = 0.472$; 95% CI, 0.005, 0.024; $P = 0.005$), poorer baseline VA ($\beta = 0.467$; 95% CI, 0.028, 0.155; $P = 0.007$), and baseline foveal hard exudates ($\beta = 0.469$; 95% CI, 0.191, 1.055; $P = 0.007$) were predictors of less VA improvement. A higher tumor base radiation dose, adjusted by baseline diameter, predicted significant tumor shrinkage (adjusted OR = 1.025; 95% CI, 1.001-1.059; $P = 0.04$), and the receiver operation curve analysis showed 183.5 Gy scleral dose has the best cut-off value to achieve tumor shrinkage (73% sensitivity, 90% specificity).

Conclusions: Ruthenium-106 brachytherapy has a high single-treatment success for VPT. An adequate tumor base radiation dose should be considered. Early treatment before exudation reaches the fovea is more likely to result in VA improvement.

Abstract No.: 201948

Hippo Pathway-Mediated Cytokine Dysregulation Drives Immune Evasion in Uveal Melanoma

First Author: Nikhil KUMAR

Co-Author(s): Seema KASHYAP, Neiwete LOMI, Seema SEN, Lata SINGH, Mithalesh Kumar SINGH

Purpose: Uveal melanoma (UM) frequently metastasizes despite effective local control. Oncogenic GNAQ/11 mutations dysregulate Hippo signaling, leading to YAP/TAZ activation that may alter cytokine networks and immune evasion. We investigated the association between Hippo pathway activity, cytokine expression, and aggressive features in UM.

Methods: We quantified plasma cytokine levels (IL-6, IL-1 β , IL-17, IFN- α , IFN- γ) in 70 UM patients using ELISA at baseline and 3-month postoperative follow-up.

These were correlated with histopathology, immune infiltration, and YAP/TAZ nuclear localization.

Results: Patients were predominantly male, >40 years, and presented with advanced-stage UM. High-risk tumors (epithelioid morphology, high mitotic index, BAP1 loss) showed strong nuclear YAP/TAZ expression and elevated IL-6 and IFN- γ levels. At follow-up, IL-6 and IL-1 β decreased, whereas IFN- γ and IL-17 increased. Hippo pathway dysregulation significantly correlated with aggressive histology, immune infiltration, and poor outcomes (15 metastases, 7 deaths). In contrast, low-risk tumors exhibited intact Hippo signaling and a less inflammatory cytokine profile.

Conclusions: Hippo pathway dysregulation promotes cytokine-driven immune modulation in UM and is linked to aggressive tumor behavior. Therapeutic targeting of Hippo-cytokine crosstalk may provide novel immunotherapeutic strategies for high-risk UM patients.

Abstract No.: 205257

IgG4-Positive Ocular Adnexal Extranodal Marginal Zone Lymphoma as an Aggressive Clinical Subtype

First Author: Rong LU

Purpose: To investigate the distribution and clinicopathological characteristics of IgG4-positive ocular adnexal lymphoma (OAL).

Methods: A retrospective single-center cohort study was conducted, enrolling 377 patients diagnosed with OAL between October 2014 and October 2024. Medical records of all patients were comprehensively reviewed to assess the distribution of IgG4-positive cases. Clinical features (e.g., local orbital structure involvement, T-stage, systemic involvement), histopathological indicators (e.g., Ki-67 index, IgG4-positive plasma cell count), and follow-up outcomes (e.g., recurrence time, reoperation rate) were compared between IgG4-positive and IgG4-negative groups. The main outcome measures were baseline differences in local/systemic involvement and recurrence risk during follow-up.

Results: IgG4-positive cases were most common in extranodal marginal zone lymphoma (EMZL, 23.3% [75/322]). Compared with IgG4-negative EMZL, IgG4-positive EMZL had higher involvement of eyelid, lacrimal gland, optic nerve and other orbital structures (all $P < 0.05$), more T3-T4 stages and systemic involvement, higher Ki-67 index (20.08 ± 6.56 vs. 14.13 ± 5.03 , $P < 0.0001$), and positive correlation between IgG4-positive plasma cells and T-stage/Ki-67 (all $P < 0.001$). IgG4-positive patients had earlier recurrence (2.04 ± 1.21 vs. 3.71 ± 1.23 years), higher reoperation rate (31.3% vs. 15.7%, $P = 0.023$), lower recurrence/reoperation-free survival (all $P < 0.01$), and IgG4-positive EMZL was associated with higher recurrence risk (HR=2.04, 95%CI:1.07-3.91, $P = 0.031$).

Conclusions: IgG4-positive EMZL represents a more aggressive clinical subtype. Additionally, IgG4 positivity may indicate increased recurrence risk and higher likelihood of systemic involvement, thereby warranting intensive follow-up and comprehensive evaluations.

Abstract No.: 206842

Intravitreal Dexamethasone Implant in Radiation-Induced Macular Edema

First Author: Ekaterina **MALAKSHINOVA**

Co-Author(s): Vera **YAROVAYA**, Andrey **YAROVVOY**

Purpose: To present the results of intravitreal dexamethasone (ID) in patients with macular edema after plaque radiotherapy of UM.

Methods: ID was performed in 130 patients (130 eyes) with ME, which developed after RT. Among them, 39 (30%) patients were men, 91 (70%) were women. The average age of patients was 53 years (from 14 to 70 years). The average visual acuity (VA) before treatment was 0.21 (range from 0.002 to 0.7). According to optical coherence tomography, the average value of central macular thickness (CMT) before intravitreal injections was 330 ± 86 microns, the average value of volume cube (VC) – 12 ± 2 . The average amount of intravitreal injections was 3 (from 1 to 10)

Results: The average VA after was 0.4. Based on the data of changes in VA, 14% patients had stabilization of the process, 57% showed improvement. According to optical coherence tomography, the average CMT value after ID was 251 ± 95 microns ($p < 0.001$), and the average VC value was 8 ± 4 ($p < 0.001$).

Conclusions: The single centre experience of ID has shown its effectiveness in reducing the height of CMT and improving or stabilizing visual acuity, which makes their use in radiation retinopathy reasonable.

Abstract No.: 201722

Level of Oxidative Stress Before and After Systemic Chemotherapy in Patients With Sebaceous Gland Carcinoma of the Eyelid

First Author: Rajendra **MAURYA**

Co-Author(s): Priyanka, Sanjay **BOSAK**, Asha **DEVI**

Purpose: To evaluate serum expression of Superoxide Dismutase (SOD) & Malonaldehyde (MDA) before and after anticancer chemotherapy and to find out its impact on response of chemotherapy (CT).

Methods: Thirty-two histopathologically proven cases of Sebaceous Gland Carcinoma (SGC) of the eyelid and 16 sex matched controls were studied for serum SOD & MDA. Serum biomarkers of oxidative stress were estimated before and after neoadjuvant chemotherapy (Cis-platin & 5FU). Response to chemotherapy was evaluated according to the WHO criteria.

Results: The majority (22, 68.8%) of cases were in the advanced stage. The histopathological

grading was well differentiated type in 9;28.1% cases, moderately differentiated in 11;34.3% and poorly or undifferentiated in 12; 37.5% cases. Overall response (CR+PR) of CT was 68.8% while in 18.8% cases there was no response, and the rest 12.5% had progressive disease. Level of sSOD was significantly increased after chemotherapy (mean $\pm$ SD 3.4275 ± 0.37256 Vs 4.2519 ± 0.17029), and level of MDA was markedly reduced after chemotherapy (Mean $\pm$ SD 5.5712 ± 0.32779 Vs 4.5146 ± 0.23209). sSOD was significantly reduced in patients having lymph node metastasis in comparison to those without lymph node metastasis (p value < 0.001). Post-chemo level of sMDA increased more in the advanced stage (5.8407 ± 0.20212) than the early stage (5.3608 ± 0.17753). There was no significant difference in the post-chemo level of both biomarkers, as histopathological differentiation was considered.

Conclusions: Serum MDA & SOD can be important biomarkers of oxidative stress, which significantly affect the response to chemotherapy.

Abstract No.: 203622

Licorice Extracts Inhibit Uveal Melanoma Progression by Suppressing the Nucleocytoplasmic Translocation of High Mobility Group Box 1

First Author: Haowen **LI**

Co-Author(s): Yuning **CHEN**, Zhaoxun **FENG**, Yang **LI**, Yueming **LIU**, Jingtong **LUO**, Wenbin **WEI**

Purpose: Uveal melanoma (UM), the most prevalent primary intraocular malignancy in adults, exhibits poor post-metastatic survival after metastasis. Licorice extracts demonstrate significant tumor-suppressive activity via high mobility group box 1 (HMGB1) targeting. This study aims to elucidate the mechanistic role of HMGB1 in UM progression and the therapeutic potential of licorice extracts.

Methods: HMGB1 expression was modulated by siRNA-mediated knockdown or cDNA plasmid overexpression. RNA sequencing of UM cell lines facilitated signaling pathway enrichment prediction. Proliferation, invasion, and apoptosis were assessed using CCK-8, colony formation, transwell assays, and flow cytometry. UM cells (C918, OCM1A, OMM2.3) were treated with glycyrrhizin (GL), 18β -glycyrrhetic acid (18β -GA), or diammonium glycyrrhizinate (DG). Tumor growth in vivo was evaluated in BALB/c-nu immunodeficient mice inoculated with UM cells.

Results: Elevated HMGB1 expression was associated with worse prognosis, advanced pathological classification, and increased tumor stage. HMGB1 knockdown suppressed UM cell proliferation, migration, invasion, promoted apoptosis, and inhibited tumor growth in vivo. Licorice extracts (GL, 18β -GA, and DG) similarly reduced proliferation, migration, and invasion of UM cells and induced

apoptosis. These extracts specifically impeded HMGB1 nucleocytoplasmic translocation without affecting total expression. Gene Set Enrichment Analysis revealed HMGB1 downregulation dysregulated autophagy. HMGB1 knockdown suppressed autophagy, while its overexpression promoted autophagy. HMGB1-Beclin-1 interaction was confirmed by co-immunoprecipitation. Licorice extracts additionally inhibited tumor cell autophagy and promoted DNA damage.

Conclusions: HMGB1 contributes to tumor invasiveness in UM patients by regulating autophagy and DNA damage repair. Licorice extracts may impede UM progression by inhibiting HMGB1 nucleocytoplasmic translocation and disrupting autophagy/DNA damage repair pathways.

Abstract No.: 204529

Metabolic Reprogramming Driving Extraocular Invasion of Retinoblastoma

First Author: Rong LU

Co-Author(s): Yaoming LIU, Junjie TANG, Zhihui ZHANG

Purpose: Retinoblastoma (RB) is the most common intraocular malignant tumor in children. During its vitreous seeding and extraocular invasion stages, the tumor microenvironment exhibits characteristics of hypoxia and nutrient deprivation. This study aimed to investigate the molecular mechanism by which metabolic reprogramming drives RB invasion.

Methods: Single-cell metabolic profiles of RB were mapped based on single-cell RNA sequencing to identify key factors in energy metabolism pathways. In vitro models, the effects of key molecules on cellular functions were explored by gene modulation, and changes in metabolic pathways were analyzed by combining transcriptomics and metabolomics. An orthotopic intraocular xenograft model of RB in nude mice was established to evaluate the in vivo intervention effect of targeting key metabolic targets.

Results: The lactate transporter MCT1, glutamine transporter ASCT2, and key glycolytic enzyme ALDOA were specifically highly expressed in invasive cell subsets. In vitro experiments demonstrated that inhibition of MCT1 led to lactate accumulation in RB cells; inhibition of ASCT2 interfered with glutamine uptake by RB cells; knockdown of ALDOA disrupted glycolysis and ATP synthesis, thereby inhibiting tumor invasive ability. In vivo experiments showed that inhibition of ALDOA, blocking of lactate transport, or glutamine transport could all significantly delay the invasive progression of intraocular tumors in mice.

Conclusions: RB exhibits significant metabolic heterogeneity. The lactate transporter MCT1, glutamine transporter ASCT2, and key glycolytic enzyme ALDOA are specifically highly expressed in invasive subsets and serve as key pro-invasive metabolic targets. Targeted

inhibition of these key metabolic targets can effectively suppress the progression and invasion of RB.

Abstract No.: 203391

Metastasis-Essential Genes Define Prognostic Subtypes and Therapeutic Targets in Uveal Melanoma

First Author: Chen HOU

Co-Author(s): Meixia ZHANG

Purpose: To elucidate the molecular determinants underlying uveal melanoma (UM) progression and to establish clinically relevant subtypes, biomarkers, and therapeutic candidates for advanced disease.

Methods: We integrated genome-wide CRISPR-Cas9 knockout screening data with transcriptomic profiles from TCGA and GEO cohorts. Molecular subtypes were identified based on metastasis-essential genes, followed by clinicopathological correlation, genomic and immune profiling, and drug sensitivity analysis. Functional validation of the candidate compound 5Z-7-oxozeaenol was performed in vitro using UM cell lines and in vivo in mouse models. A prognostic gene signature was constructed and validated across independent datasets.

Results: We identified 26 metastasis-essential genes enriched in cell cycle regulation, mRNA stability, and mitotic control, which stratified UM patients into three robust molecular subtypes with distinct outcomes. The high-risk subtype, validated in external cohorts, exhibited chromosome 3 monosomy, SCNA cluster D, epithelioid histology, advanced stage, and poor survival. This subtype showed enrichment of immune cell migration, interferon signaling, epithelial-mesenchymal transition, metabolic reprogramming, immune checkpoint activation, and genomic instability, reflecting an aggressive and immunosuppressive phenotype. Drug screening highlighted 5Z-7-oxozeaenol as a potent inhibitor of proliferation, migration, and invasion, while inducing apoptosis in UM cells. In vivo, the compound suppressed intraocular tumor growth and liver metastasis without systemic toxicity. Furthermore, a five-gene prognostic signature (PSMD14, NOP58, PSMA4, PAFAH1B1, EPRS) was established, demonstrating robust predictive power for survival across datasets.

Conclusions: The identified molecular subtypes provide insight into UM heterogeneity, the five-gene signature offers a clinically applicable prognostic biomarker, and 5Z-7-oxozeaenol represents a promising therapeutic candidate for advanced UM.

Abstract No.: 202793**Microneedle Scleral Patch: A Transscleral Drug Delivery Study for Retinoblastoma***First Author: Vishal RAVAL**Co-Author(s): Vamsi Krishna VENUGANTI*

Purpose: We aimed to design, fabricate, and evaluate the pharmacokinetic properties of topotecan loaded with a microneedle scleral patch (MSP) in the rabbit eye.

Methods: The MSP was fabricated using a 3D-printed mastermold. MSP was fabricated using a high-molecular-weight sodium hyaluronate biopolymer containing 90 conical microneedles in a 15x6 array format (10 x 5 x 0.2 mm). MSP was loaded with 100 µg of topotecan to study its pharmacokinetics across the choroid-retina complex.

Results: The dimensions of microneedles (MN) were uniform across the array, measuring 555 +/- 4 µm length, 342 +/- 3 µm width, and 23 µm tip diameter. In the ex vivo goat eye model, the required insertion force was 0.026 Newton per needle, which was 50 times lower than the compression strength of 1.27 N per needle. The MNs were inserted up to a depth of 225 µm. MNs were completely dissolved in phosphate buffer (pH 7.4) within 25 s. The average amount of topotecan HCl in 15 MSP was 99.39 ± 12.45 µg. In the in vivo rabbit model (9 eyes, choroid-retina complex), topotecan levels peaked at 1 hour (2.75 ± 2 µg/ml) and decreased at 2 hours (0.64 ± 0.3 µg/ml), attaining 200 times the therapeutic target level. At 8 hours, the drug level was undetectable (0.02 ± 0.01 µg/ml). The patch completely dissolved within 2-4 minutes without fundus changes.

Conclusions: MSP fabricated using sodium hyaluronate has the physical attributes required for transscleral drug delivery in clinical applications. Topotecan-loaded MSP achieved therapeutic target levels for retinoblastoma. MSP offers a promising alternative drug delivery route for treating RB.

Abstract No.: 206664**Mitochondria-Driven Pro-Ferroptotic and Anti-Ferroptotic Genes in the Progression of Intraocular Childhood Cancer***First Author: Lata SINGH**Co-Author(s): Bilal AHMED, Bhavna CHAWLA, Seema KASHYAP, Nikhil KUMAR, Neiwete LOMI, Rachna SETH*

Purpose: Retinoblastoma is the most common intraocular tumour that occurs in children. Mitochondrial dysfunction and increased reactive oxygen species have been found in cancerous cells, including Rb. Mitochondria play a diversified role in the process of ferroptosis, iron metabolism, the OXPHOS pathway, etc. Therefore, the aim of the study is to investigate the expression of mitochondrial-mediated ferroptosis genes in Rb patients.

Methods: This prospective study includes 71 Rb cases (50 primary and 21 chemoreduced Rb cases). Real-Time PCR was performed to assess the mRNA expression levels of mitochondrial genes (BAX, ACSF2, LONP1, CISD1, SOD2 & MFRN1/2) along with anti-ferroptosis, GPX4 gene. Immunoexpression of GPX4 was also determined, followed by western blotting. The expression levels of these genes were correlated with clinicopathological parameters.

Results: There was a male preponderance in this study. In 50 primary Rb cases, high mRNA expression of Bax was observed, followed by LONP1. While MFRN1/2, SOD2, and CISD1 were moderately expressed, and ACSF2 was downregulated. GPX4 was upregulated in our cases. Post-laminar optic nerve and optic nerve head invasion were observed in 22% and 40%, respectively. In 21 chemoreduced cases, although we observed similar levels of gene expression for MFRN1/2, BAX, CISD1, LONP1, and SOD2, GPX4 was downregulated, and ACSF2 was upregulated.

Conclusions: Our findings revealed dysregulation of mitochondrial genes involved in oxidative stress and apoptosis, which may have a potential role in tumour progression of Rb. Further studies could provide a better insight into these genes in the prognostication of Rb patients.

Abstract No.: 202267**Molecular Basis for Cavitory Retinoblastoma***First Author: Peiwei CHAI**Co-Author(s): Jiayan FAN, Renbing JIA*

Purpose: Cavitory retinoblastoma (CRB) represents a unique variant of retinoblastoma (RB) distinguished by the presence of translucent cavities, which are discernible through ophthalmoscopic examination. The present study was designed to elucidate the clinical implications and molecular signatures of CRB, thereby enhancing our understanding of this distinct subtype of RB.

Methods: A multicentric, nested case-control, retrospective cohort study combining spatial proteomic analysis.

Results: In a longitudinal study encompassing 1360 RB patients, conducted over a 13-year timeframe from June 2008 to February 2022, cavitory spaces were detected within the tumors of 48 eyes of 46 patients. A control cohort of 180 eyes from 138 age-matched patients with non-CRB was selected, maintaining a 1:3 case-control ratio. Laser-captured spatial proteomic analysis was conducted to explore the pivotal molecular changes within this specific subtype. Cavitory RB was linked to enhanced metastasis-free survival ($P = 0.007$) and overall survival ($P = 0.03$), as well as an increased proportion of well-differentiated status ($P < 0.001$) and a reduced incidence of vitreous seeding ($P = 0.02$). Spatial proteomic analysis, immunofluorescence,

and immunohistopathology revealed a lower MYCN expression in CRB than in non-CRB. Silencing MYCN in patient-derived xenografts using AAV recapitulated these phenotypes of CRB, including the formation of translucent cavities and the emergence of cone-like rosettes.

Conclusions: This study establishes a novel genetic-phenotypic association, revealing that diminished MYCN expression induces the formation of translucent cavities. This phenotype is indicative of a less aggressive, well-differentiated CRB subtype with a more favorable prognosis.

Abstract No.: 206913

Ocular Complications of Brachytherapy in Patients With Uveal Melanoma

First Author: Ekaterina MALAKSHINOVA

Co-Author(s): Vera YAROVAYA, Andrey YAROVVOY

Purpose: To evaluate the incidence and spectrum of complications following brachytherapy for uveal melanoma.

Methods: A retrospective analysis was performed on a cohort of 800 patients with uveal melanoma treated with Ruthenium-106 plaque brachytherapy at S. Fyodorov Eye Microsurgery Federal State Institution between 2018 and 2025. Patients were followed for a mean period of 28 months. The primary outcomes were the development and time to onset of radiation-related complications.

Results: In our series, the most frequent complications were radiation retinopathy (24%), cataract (26%), and maculopathy (19%). Neovascular glaucoma, a vision-threatening complication, developed in 1% of cases. A notable observation from our data was a significant correlation between scleral dose greater than 761 mm and an increased risk of radiation macular edema ($p < 0.001$) and radiation-induced cataract ($p=0.001$).

Conclusions: Our clinical observations confirm a high burden of radiation-induced complications following brachytherapy for uveal melanoma, consistent with existing literature. These findings underscore the necessity for close, long-term monitoring and the proactive management of sequelae. Personalized risk assessment based on tumor dimensions and location is crucial for predicting and mitigating visual loss.

Abstract No.: 201161

Ophthalmic Manifestations and Treatment Outcomes in Leukemia: A Comparative Analysis of Clinical Spectrum, Visual Prognosis and Predictors of Disease Remission Across Subtypes

First Author: Dhwanee AGARWAL

Co-Author(s): Rajeev Reddy PAPPURU, Vishal Ramesh RAVAL, Mudit TYAGI

Purpose: To conduct an analysis of ophthalmic manifestations in leukemic patients and evaluate their impact on visual outcomes and disease remission.

Methods: This retrospective, comparative study included 244 patients (378 eyes) diagnosed with leukemias between January 2016 and 2024. Data included demography, leukemia type, ophthalmic manifestations, imaging modalities, treatment modalities (ocular and systemic), treatment outcomes (relapses or remission), and final visual acuity. Univariate and multivariate regression analysis were performed to identify correlations and predictive features associated with visual outcomes.

Results: The mean age of patients was 34.9 ± 22.1 years (range, 1-88 years). ALL was the most common subtype (58%). Acute forms manifested earlier in life and were more aggressive. The presence of posterior segment manifestations (64%) was more than that of anterior segment manifestations (52%). Myeloid leukemia types were more often associated with hemorrhagic manifestations, whereas lymphoid types were associated with non-hemorrhagic manifestations. Univariate regression analysis showed that the presence of ERM (OR 0.110, 95% CI: 0.012-0.951, $p=0.04$), submacular hemorrhage (OR 0.091, 95% CI: 0.010-0.763, $p=0.027$) and type of leukemia-AML (OR 3.195, 95% CI: 1.697-6.012, $p<0.000$), or CML (OR 6.39, 95% CI: 3.130-13.041, $p<0.000$) had significant association with poor visual outcome. Multivariate regression analysis revealed AML (OR 2.769, 95% CI: 1.392-5.507, $p=0.004$) and CML (OR 7.313, 95% CI: 3.326-16.074, $p<0.000$) as independent predictors of poor visual outcome.

Conclusions: Ophthalmic manifestations are major diagnostic and prognostic clues for leukemias. Pattern recognition facilitates timely recognition, risk stratification, and disease remission prediction.

Abstract No.: 204706

Our 25 Years of Retinoblastoma Care in a Tertiary Eye Care Centre

First Author: Usha KIM

Purpose: To evaluate the outcome of our treatment strategies for life-saving, globe salvage, and vision preservation, and genetic methods to predict and prevent retinoblastoma in the last 25 years.

Methods: A study was conducted on 1,100 patients diagnosed with retinoblastoma from 1998 to 2024. The clinical, demographic, and genetic data of the patients were collected and evaluated for the outcomes in terms of their survival, preservation of the globe, and vision. Genetic testing was done to find out the risk of RB in family members, and counselling was done.

Results: During the last 25 years, 1,100 patients were treated with multimodal treatments, focal therapy, chemotherapy, and enucleation. Patients from multiple districts of Tamil Nadu and other Indian states, along with 36 from other countries, were given treatment. Among them, 80% have completed the treatment and are still under regular follow-up. Family history of retinoblastoma and other cancers was found in 8.25%. De novo germline and somatic mutations were found in 38% and 20% of bilateral and unilateral patients, respectively. Among the 244 eyes preserved, a good visual outcome was found in 129 (6/6 vision), and it could be preserved in 53 patients of Groups D and E.

Conclusions: Retinoblastoma management has evolved from lifesaving enucleation to preserving eyes and vision through early diagnosis, targeted therapies, and a better understanding of genetics. Identifying germline mutation now plays a key role in guiding treatment, surveillance, and family counselling.

Abstract No.: 203918

Pegylated Interferon Alpha 2a for the Management of Ocular Surface Squamous Neoplasia

First Author: Murtuza **NURUDDIN**

Co-Author(s): Rifat **AKHTER**, Soma Rani **ROY**

Purpose: Here we report our experience in the management of Ocular Surface Squamous Neoplasia (OSSN) with Pegylated Interferon Alpha 2a (Peg-interferon Alpha 2a) instead of Interferon alpha 2b, which is an effective immunotherapeutic agent to treat OSSN. We have used Peg-Interferon Alpha 2a instead of Interferon Alpha 2b because of the ease of availability. There is a structural difference in respect of amino acid at position 23 between these two agents. The addition of Peg (Polyethylene Glycol) increases the half life.

Methods: Seven eyes of seven patients were diagnosed as having OSSN clinically. Three patients underwent histopathological confirmation as well. All patients treated with Peg-interferon Alpha 2a (36 microgram/milliliter). Three patients received 0.2 milliliter (72 microgram) intralesional injection of peg-interferon alpha 2a twice at one-month intervals. Topical therapy was prescribed for 4 to 6 months and continued for at least one month even after complete resolution.

Results: All patients showed complete resolution without any significant side effects. It was well tolerated by every patient. No recurrence was observed for a minimum period of 6 months up to 4 years.

Conclusions: Peg-interferon alpha 2a is a safe and effective alternative for the management of OSSN.

Abstract No.: 206511

Proteomic Profiling of Aqueous Humor and Blood in Uveal Melanoma: Biomarker Discovery and Brachytherapy-Induced Changes

First Author: Heyan **LI**

Co-Author(s): Wenbin **WEI**

Purpose: To investigate proteomic alterations in aqueous humor (AH) and blood samples from patients with uveal melanoma (UM), and to evaluate the potential impact of brachytherapy through comparative proteomic analysis.

Methods: AH samples were obtained during brachytherapy or cataract surgery, while blood samples were collected prior to treatment. Differential expression protein analysis, Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analyses were performed. Diagnostic models were developed using the Least Absolute Shrinkage and Selection Operator (LASSO) algorithms. Model performance was assessed using receiver operating characteristic (ROC) curves.

Results: A total of 4,184 proteins were identified in blood samples, with 1,275 differentially expressed proteins (DEPs) between UM patients and controls. In AH samples, 2,459 proteins were identified, among which 531 DEPs distinguished UM patients from controls, and 113 DEPs differentiated pre- and post-brachytherapy samples. Enriched pathways in blood included cytoplasmic translation and neurodegeneration-related pathways, while complement activation and humoral immune response were prominent in AH. Post-treatment AH samples showed enrichment in leukocyte migration, and IL-17-related inflammatory pathways. Notably, S100A family members (S100A2, and S100A8/9) exhibited significant expression changes after therapy. Specifically, CD209 showed a significant expression level decrease after the surgery. Machine learning models highlighted fibrinogen genes (FGA, FGB, and FGG) as a potential biomarker capable of distinguishing UM patients from healthy controls in both AH and blood, with AUC reaching 0.792.

Conclusions: Proteomic profiling changes may not only reveal the molecular landscape in UM, but deepen the understanding of the effects of brachytherapy treatment.

Abstract No.: 204032

Rapamycin-Loaded Tumor-Derived Exosomes Inhibit Melanoma B16-F10 Cell Proliferation and Induce Apoptosis

First Author: Yuxin LI

Co-Author(s): Yuntao HU

Purpose: To evaluate the effects of rapamycin-loaded tumor-derived exosomes (Exos-RAPA) on melanoma B16-F10 cell proliferation, apoptosis, and ocular safety.

Methods: Exos-RAPA were generated from murine melanoma B16-F10 cells. Uptake by B16-F10 cells was visualized by confocal microscopy, and proliferation inhibition was assessed by CCK-8 assay. An orthotopic uveal melanoma model was established by suprachoroidal injection of B16-F10 cells in C57BL/6 mice, followed by treatment with Exos-RAPA, rapamycin in dimethyl sulfoxide (RAPA-DMSO), or PBS. Tumor progression was monitored by in vivo imaging and color Doppler ultrasound. Apoptosis was evaluated by apoptosis assays and TUNEL staining.

Results: Exos-RAPA were successfully constructed and efficiently internalized by B16-F10 cells. Exos-RAPA inhibited proliferation with an IC50 of 53.95 nM. In vivo imaging showed significantly smaller tumors in the Exos-RAPA group versus controls at day 14 ($P < 0.01$). Doppler ultrasound revealed reduced vascular density in Exos-RAPA-treated tumors. In ARPE-19 cells, apoptosis was significantly higher in the RAPA-DMSO group compared to Exos-RAPA and PBS ($P < 0.001$). Retinal tissues in the RAPA-DMSO group showed more TUNEL-positive cells, confirming the superior safety of Exos-RAPA.

Conclusions: Exos-RAPA effectively suppressed B16-F10 proliferation and induced apoptosis, while demonstrating improved ocular safety compared to free rapamycin. These findings suggest Exos-RAPA as a promising targeted therapy for uveal melanoma.

Abstract No.: 201112

Retinoblastoma Management and Outcomes: The New Zealand Experience Over 23 Years

First Author: Hannah NG

Co-Author(s): Cheefoong CHONG, Yvonne NG, Karen TSUI

Purpose: This nationwide study of retinoblastoma patients examined the epidemiology, diagnosis, evolution of management, and outcomes over time.

Methods: A retrospective review of all retinoblastoma patients referred to and managed at the Department of Ophthalmology, Auckland District Health Board, Auckland, between 2000-2023. We examined demographics, timing of diagnosis to treatment, grading and staging, treatment modalities, visual outcomes, and survival rates.

Results: Seventy-two patients (101 eyes) were diagnosed during the study period. Among them, 37 (51%) were of European ethnicity, 19 (26%) NZ Māori, 7 (10%) Asian, 4 (6%) Pacific, and 5 (7.5%) others. 15% were familial and 9 of these patients were diagnosed within the first month of birth. 85% of patients had sporadic disease with at least one eye showing group D or E disease (IIRC). Primary enucleation was the most common treatment modality in 54 out of 101 eyes (53%), with 24 (44%) of these eyes showing high-risk features on histology, warranting adjuvant intravenous chemotherapy. Intravenous chemoreduction with focal laser or cryotherapy was performed in 30 eyes (30%), with focal treatment only in 14 (14%). Intravitreal (5%) and intra-arterial (2%) chemotherapy were delivered as secondary treatments. Of the 29 (40%) bilateral cases, the binocular best corrected visual acuity was 6/12 or better in 22 (76%). The remainder had worse than 6/30 due to involvement of the macula. 2 were bilaterally enucleated. The survival rate was 100%.

Conclusions: This study presents an up-to-date dataset of retinoblastoma patients and their management from a New Zealand perspective.

Abstract No.: 206100

SPP1+ Neutrophils Mediate Resistance to Immune Checkpoint Blockade in BAP1-Inactivated Tumors Through the CCL2-CCR2 Axis

First Author: Jiahao SHI

Co-Author(s): Yixiong ZHOU

Purpose: BAP1 inactivation is the key driver event of uveal melanoma (UM) and is observed in other cancers. It is associated with resistance to immune checkpoint blockade (ICB) and poor prognosis. This study aimed to elucidate the mechanisms by which BAP1 loss induces an immunosuppressive tumor microenvironment (TME) and confers ICB resistance.

Methods: Using BAP1-knockdown (KD) murine cancer cell lines and human UM cell lines, we evaluated ICB response in vitro/vivo. Single-cell RNA sequencing (scRNA-seq) of tumor-infiltrating immune cells, flow cytometry, and ex vivo co-culture assays were employed to characterize immune cell dynamics. Proteomic and transcriptomic analyses were used to identify key secreted factors.

Results: Here, we show that BAP1 inactivation promotes an immunosuppressive tumor microenvironment (TME), marked by increased M2-like macrophage and Neutrophil infiltration. Single-cell transcriptomic analysis revealed an expansion of SPP1+ neutrophils in ICB-treated, BAP1-inactivated tumors. These SPP1+ neutrophils display a pro-tumorigenic phenotype and confer resistance to anti-PD-1 therapy by engaging with cytotoxic T cells via PD-1/PD-L1 signaling. Notably, depletion of neutrophils but not macrophages restored sensitivity to ICB in BAP1-

inactivated tumors. Mechanistic investigations revealed that BAP1 loss significantly upregulated chemokine (C-C motif) ligand 2 (CCL2) secretion, driving neutrophils to polarize into the SPP1+ subset, delaying neutrophil apoptosis, and promoting ICB resistance. This resistance can be significantly mitigated by targeting the CCL2-CCR2 axis.

Conclusions: Our findings underscore the role of BAP1 in modulating the immune landscape and suggest that targeting CCL2-CCR2-mediated neutrophil polarization may overcome ICB resistance in BAP1-inactivated tumors.

Abstract No.: 204369

Secondary Vitreoretinal Lymphoma: A Single-Center Retrospective Analysis of Clinical, Pathological, and Molecular Characteristics

First Author: Qing **CHANG**

Co-Author(s): Shixue **LIU**

Purpose: This study aimed to investigate the clinical characteristics, pathological manifestations, and prognostic factors of secondary vitreoretinal lymphoma (SVRL).

Methods: A retrospective, single-center study was conducted on patients diagnosed with SVRL between December 2013 and January 2025. Clinical data were analyzed using descriptive statistics and survival analysis.

Results: Twenty-three patients with SVRL were included. The median age at ocular symptom onset was 56.3 years, with a higher female proportion (74.4%). The most frequent primary tumor sites were lymph nodes (26.1%) and the nasopharynx (21.7%). The most common pathological diagnoses were diffuse large B-cell lymphoma (DLBCL) (57.9%) and NK/T-cell lymphoma (26.3%). The median interval from ocular onset to diagnosis was 47 months. Common ocular manifestations included vitreous opacities (88.9%) and retinal lesions (47.1%), with a cytology positivity rate of 92.3%. The MYD88 L265P mutation was detected in 63.6% of patients. Patients who were MYD88 mutation-negative or had received targeted therapy demonstrated shorter progression-free survival (PFS) and overall survival (OS). Intraocular fluid circulating tumor DNA (cfDNA) analysis revealed high mutation frequencies in MYD88, CD79B, PIM1, ETV6, PRDM1, and ARID1B.

Conclusions: SVRL predominantly affects middle-aged women, frequently originating from lymph nodes or the nasopharynx, with DLBCL being the primary histological subtype. Both cytological and molecular testing, including cfDNA analysis, are valuable for diagnosis. The MYD88 mutation status and prior targeted therapy are significant prognostic factors, underscoring their importance for patient survival outcomes.

Abstract No.: 200561

Sentinel Lymph Node Biopsy for Sebaceous Gland Carcinoma and Ocular Adnexal Malignant Melanoma in Chinese Patients: A 14-Year-Cohort

First Author: Venice Sze Wai **LI**

Co-Author(s): Jason **CHAN**, Karen Kar Wun **CHAN**, Kelvin Kam Lung **CHONG**, Kenneth Ka Hei **LAI**, Eddy **WONG**, Alvin Lerrmann **YOUNG**, Hunter Kwok Lai **YUEN**

Purpose: To evaluate the diagnostic and prognostic values of sentinel lymph node biopsy (SLNB) in Chinese patients with sebaceous gland carcinoma (SGC) and ocular adnexal malignant melanoma (MM).

Methods: We conducted a retrospective review of all patients with SGC or ocular adnexal MM (including conjunctival melanoma and MM of eyelid) who underwent SLNB from January 2011 to May 2025 across 3 hospitals in Hong Kong. Outcomes measures included lymphoscintigraphy detection rate, SLNB positivity, false-negativity, recurrence, metastasis, disease-free (DFS), and overall survival (OS).

Results: Eleven patients (mean age 62.8 ± 18.5 years, 8 females) were included. Seven (64%) had ocular adnexal MM, and four (36%) had SGC. SLNB detection rate on lymphoscintigraphy was 90.9% (10/11). Positive SLNB rate was 18.2% (2/11), all in recurrent MM (histologically confirmed regrowth post-treatment). False-negative rate (nodal recurrence or distant metastasis after negative SLNB) was 22.2%. Over a mean follow-up of 35.8 months (SD 41.5), local recurrence, nodal, and distant metastases rates were 18.2% (2/11), 27.3% (3/11), and 18.2% (2/11), respectively, exclusively in MM. No SGC patients experienced recurrence or metastasis. Median DFS and OS were 19.5 and 30 months, respectively, with no significant differences between primary pathologies or SLNB status. T staging $\geq 2b$, and presentation or development of recurrence or metastasis, had significantly shorter DFS (both $p < 0.05$).

Conclusions: SLNB is technically feasible with minimal morbidity. In our cohort, SLNB can identify occult nodal metastasis in recurrent ocular adnexal MM, representing a high-risk subgroup. Absence of metastasis in SGC patients suggests a more limited role, warranting further investigation. SLNB status and T-stage were significant predictors of survival.

Abstract No.: 203519

Shifting Clinical Characteristics of Uveal Melanoma in an Aging Population: A 20-Year Chinese Cohort Study

First Author: Haowen **LI**

Co-Author(s): Yuning **CHEN**, Yang **LI**, Yueming **LIU**, Yangxu **TAO**, Wenbin **WEI**

Purpose: This study aimed to summarize the evolving characteristics and prognostic trends of uveal

melanoma (UM) patients treated at Beijing Tongren Hospital in the context of population aging.

Methods: A single-center retrospective study was conducted, including UM patients treated in the Ophthalmology Department of Beijing Tongren Hospital from January 2004 to March 2025.

Results: A total of 2,578 UM patients were included, with a median follow-up of 31.0 months (IQR 13.0–53.0). The median age at diagnosis was 49.0 years (IQR 40.0–57.0), with 1,323 males (51.3%) and 1,255 females (48.7%). The median basal tumor diameter was 12.1 mm (IQR 10.1–14.4), and the median tumor height was 7.0 mm (IQR 4.9–9.3). Metastases occurred in 354 patients (13.7%), and 245 deaths (9.5%) were recorded. Annual patient volume generally increased from 2004 to 2019, declined in 2020, and subsequently rebounded. The mean age at diagnosis exhibited an upward trend over time, and the median basal tumor diameter increased significantly, whereas the median tumor height showed no consistent trend. Survival analysis revealed longer MFS in the 2004–2014 group compared to the 2015–2025 group ($p < 0.001$), though OS did not differ ($p=0.15$). Significant differences in MFS existed among the 2004–2011, 2012–2018, and 2019–2025 groups ($p=0.005$), with the 2004–2011 cohort demonstrating the best MFS and the 2019–2025 group the worst. The 2019–2025 group had superior OS compared to the 2004–2011 and 2012–2018 groups ($p=0.002$ and $p<0.001$, respectively), while OS between the 2004–2011 and 2012–2018 groups showed no significant difference ($p=0.052$).

Conclusions: This study identified evolving disease characteristics in UM patients in the context of population aging, marked by increasing age at diagnosis, larger tumor dimensions, and elevated metastatic risk.

Abstract No.: 210362

Sonidegib: Efficacy and Safety in Treatment of Basal Cell Carcinoma

First Author: Jian LI

Co-Author(s): Jianguang ZHONG

Purpose: To explore the efficacy, safety, and clinical practice strategies of sonidegib in the treatment of eyelid basal cell carcinoma.

Methods: A retrospective analysis was conducted on 6 patients with locally advanced eyelid BCC (stage T3 or higher) admitted to our hospital from 2023 to 2025. All patients received oral sonidegib at 200 mg/day, with treatment continued until disease progression or intolerable toxicity. The objective response rate (ORR), progression-free survival (PFS), and drug-related adverse events (AEs) were evaluated.

Results: Among the 6 patients, 4 (66.67%) achieved partial response (PR), and 1 (16.67%) had stable disease (SD). The median PFS was 14.2 months. The

average reduction in tumor volume was 62.3% (per RECIST 1.1 criteria). All 6 patients (100%) avoided orbital exenteration, with preservation of the eyeball and visual function. Common AEs included muscle spasms (53.3%), dysgeusia (40%), and alopecia (33.3%), all of which were grade 1–2. One patient had a temporary treatment interruption due to elevated creatine kinase and resumed treatment after.

Conclusions: Sonidegib significantly improves the tumor control rate and organ preservation rate in locally advanced eyelid BCC, providing an effective alternative for patients at high risk of surgery. Individualized management of muscle spasms and metabolic toxicities should be emphasized. Future studies with larger sample sizes are needed to verify long-term efficacy and explore the synergistic mechanisms of combination with radiotherapy and immunotherapy.

Abstract No.: 204952

Spontaneous Bilateral Vitreous Hemorrhage: A Rare Initial Presentation in Trilateral Retinoblastoma

First Author: Alex SUA

Purpose: To demonstrate a rare case of retinoblastoma where vitreous hemorrhage was an early and significant sign.

Methods: Case report of a one-year-old child presenting with acute bilateral visual loss secondary to vitreous hemorrhage.

Results: A previously healthy 17-month-old male, born full-term, sought consultation because of mild peri-orbital erythema on his left eye. There was no history of ocular trauma, significant medical or family history of bleeding disorders, retinal vascular disease, or eye tumor. Anterior segment examination was unremarkable. He was treated with antibiotics, but similar symptoms occurred in the contralateral eye. His condition worsened with a decrease in vision to hand motion and the appearance of vitreous hemorrhage in his left eye, followed by the right. No evidence of a solid intraocular tumor was demonstrated on B scan ultrasonography. Despite vitrectomy, recurrent hemorrhages and subsequent retinal detachments occur. Cytopathological analysis of the vitreous samples showed hemorrhages, inflammatory cells, cellular debris, and fibro-cellular membranes suggestive of proliferative retinal vascular disease. He presents two weeks post-operatively with a bulging left eye necessitating enucleation, which showed diffuse infiltrating retinoblastoma with high-risk features including choroidal, optic nerve, and subarachnoid invasion. MRI imaging revealed a contralateral intraocular tumor requiring enucleation and a synchronous midline pineal mass. The patient underwent intensive chemotherapy with radiotherapy and remained disease-free two years post-treatment.

Conclusions: This case highlights the importance of considering retinoblastoma in the differential diagnosis of unexplained pediatric vitreous hemorrhage. It underscores the need for vigilance and thorough diagnostic workup when confronted with unusual signs, as timely intervention can significantly impact outcomes.

Abstract No.: 205883

Thermotherapy for Retinoblastoma: Approaches and Long-Term Results

First Author: Denis VOLODIN

Co-Author(s): Vera YAROVAYA, Andrey YAROVVOY

Purpose: to retrospectively evaluate the long-term results of laser thermotherapy for retinoblastoma and determine the predictors of treatment success.

Methods: We retrospectively reviewed the clinical records of 251 patients (306 eyes, 1635 tumors) treated with laser thermotherapy for intraocular retinoblastoma between March 2011 and April 2023. The median age at the time of thermotherapy was 12 months (from 1 to 78 months). For the vast majority of tumors, thermotherapy was used as the second-line treatment (n=1587, 97%); primary thermotherapy was used for small tumors of group A (n=48, 3%). The median tumor thickness was 0.7 mm (range, 0.3-4.2 mm), the median tumor base – 1.5 mm (range, 0.6-13.4 mm). Most of the tumors (n=942, 58%) were located in the preequatorial zone, while 588 tumors (36%) were in the postequatorial zone. 6% of tumors (n=105) had central localization. Thermotherapy using near-infrared radiation (810 nm) was delivered via transpupillary or transscleral routes. Approaches included conventional thermotherapy for small postequatorial tumors, «step-by-step» repeated thermotherapy for resistant «cavitary» tumors, transpupillary thermotherapy with simultaneous scleral depression, and transscleral thermotherapy for preequatorial tumors. The median follow-up period was 68 months (range, 6-168 months).

Results: Complete tumor regression was observed in 1510 tumors (91,5%). In 18 tumors (1%), we observed incomplete tumor regression. Tumor progression or recurrence was observed in 140 tumors (8%). Multivariate statistical analysis identified tumor thickness ≤ 0.8 mm ($p<0.0001$), tumor basal diameter ≤ 1.5 mm ($p<0.0001$), pre- and postequatorial tumor location ($p=0.0145$), dark and medium fundus pigmentation ($p<0.0001$), and number of treatment sessions ≤ 2 ($p=0.0391$) as statistically significant predictors of thermotherapy success. ROC-analysis demonstrated 3 and more predictors to be a statistically significant «cut-off» value for thermotherapy success ($p<0.001$, AUC=0.851) and relative risk for thermotherapy application in tumors having < 3 predictors of success made up 11.6926. Complications of laser thermotherapy occurred in 12 eyes (4%). The most frequent complications were focal iris atrophy

and lens opacity (n=6), preretinal/pretumoral vitreous hemorrhage (n=5). Eye retention was achieved in 93% of the treated eyes (n=285). Twenty-one eyes (7%) were enucleated after thermotherapy because of tumor progression (n=14), inability of adequate tumor monitoring (n=2), phtisis bulbi (n=5).

Conclusions: Thermotherapy is a highly effective method of small Rb treatment with a low complications rate, that, however, requires a careful patients' and tumors' selection with systemic and multifactor analysis.

Abstract No.: 204546

Three SS-OCT Flags to Spot Malignant Choroidal Tumors Fast: A 5-Year, 305 Eyes, Single-Center Study From China

First Author: Yitong LI

Co-Author(s): Wenbin WEI

Purpose: Early recognition of malignant choroidal tumors is challenging, and head-to-head comparisons of swept-source optical coherence tomography (SS-OCT) features across tumors and mimics are limited. This single-center study from Beijing Tongren Hospital (China) sought a concise, clinically applicable SS-OCT rule for malignancy triage in Chinese patients.

Methods: We retrospectively analyzed 305 eyes from 298 consecutive patients with clinically or histopathologically confirmed choroidal tumors between July 2019 and March 2024 at Beijing Tongren Hospital. Univariable and multivariable logistic regression identified independent malignancy indicators; diagnostic performance was estimated with bootstrapped 95% CIs.

Results: The cohort comprised 133 malignant eyes (melanoma 113, lymphoma 11, metastasis 9) and 172 benign/mimic eyes (hemangioma 92, nevus 39, osteoma 32, others). Multivariable analysis identified three independent indicators of malignancy: complete loss of overlying choriocapillaris (OR=52.3, 95%CI: 4.85–552.7), optical shadowing (OR=104.1, 95%CI: 5.33–2028.8), and subretinal fluid extending >3 mm beyond the tumor margin (OR=24.2, 95%CI: 2.14–274.0). Diagnostic performance: choriocapillaris loss—sensitivity 0.962 (95%CI: 0.926–0.992), specificity 0.750 (0.682–0.816), negative predictive value (NPV) 0.962 (0.927–0.992); subretinal fluid >3 mm—sensitivity 0.714 (0.639–0.788), specificity 0.831 (0.776–0.884); presence of any of the three features—sensitivity 0.985 (0.960–1.000), NPV 0.976 (0.938–1.000). Subgroup analyses showed choriocapillaris loss distinguished melanoma from nevus (sensitivity 0.923, specificity 0.973). In amelanotic lesions, choriocapillaris loss or subretinal fluid >3 mm achieved 100% sensitivity for malignancy detection.

Conclusions: Three SS-OCT features—complete choriocapillaris loss, optical shadowing, and subretinal

fluid >3 mm beyond the margin—constitute a simple, high-sensitivity triad for rapid identification of malignant choroidal tumors, supporting early triage in primary and referral settings.

Abstract No.: 205021

Ultrathin Choroidal Cutter Biopsies for Lesions 1.5 mm or Thinner and Thin Biopsies for Lesions 1.6–2.5 mm Thick

First Author: Hung-da CHOU

Co-Author(s): Sarah COUPLAND, Antonio ELEUTERI, Heinrich HEIMANN, Rumana HUSSAIN, Helen KALIRAI

Purpose: To review the outcomes and complications of thin choroidal biopsies.

Methods: Medical records of patients with lesions 1.5 mm or thinner (“Ultrathin Group”) and 1.6 mm – 2.5 mm thick (“Thin Group”) who had a transretinal cutter-biopsy were reviewed. Diagnostic biopsy success was defined as having either a definitive diagnosis or a tentative diagnosis that included lesions suggestive of a nevus. Prognostic biopsy success was defined as obtaining the chromosome 3 status.

Results: One hundred and thirty-four biopsies in the Ultrathin Group and 281 biopsies in the Thin Group were analyzed. The mean follow-up was 4.1 ± 4.0 years. Diagnostic biopsy success was obtained in 85% (46/54) for the Ultrathin Group and in 96% (121/126) for the Thin Group. Prognostic biopsy was successful in 75% (60/80) for the Ultrathin Group and 79% (123/155) for the Thin Group. Moderate-to-severe biopsy-related complications were documented in 8.2% (Ultrathin) and 4.3% (Thin) Groups. Thicker lesional thickness and biopsy done during the second 10 years were associated with prognostic biopsy success (β [95% CI], 0.530 [0.211, 0.848]; p -value = 0.001 and β [95% CI] 1.240 [0.926, 1.560]; p -value <0.0001, respectively), but not with diagnostic biopsy success or complications.

Conclusions: In most patients, ultrathin or thin transretinal cutter biopsy assisted with clinical management in eyes with atypical lesions and provided genetic prognostication.

Abstract No.: 206848

Uveal Melanoma: Treatment Approaches and Prognostic Outcomes Based on the American Joint Committee on Cancer (AJCC) Staging in a Tertiary Referral Center

First Author: Thansit SRISOMBUT

Co-Author(s): Thanaporn KRITFUANGFOO, Duangnate ROJANAPORN

Purpose: This study aims to comprehensively evaluate the clinical characteristics, treatment outcomes, and prognosis of uveal melanoma (UM) based on the 8th

edition of the American Joint Committee on Cancer (AJCC) staging system.

Methods: A retrospective analysis was conducted on patients diagnosed with UM at a tertiary referral center in Thailand between 2010 and 2024. Data on clinical presentation, diagnostic methods, treatment approaches, and long-term outcomes were systematically reviewed and analyzed.

Results: A total of 106 patients were analyzed, with a mean diagnostic age of 51.6 years (range 16–86). Most tumors arose in the choroid (94.3%), with fewer in the ciliary body (3.8%) and iris (1.9%). Staging (AJCC 8th edition) showed T1 (18.9%), T2 (17.9%), T3 (48.1%), and T4 (15.1%). Treatments included enucleation (53.8%), Ruthenium-106 brachytherapy (29.2%), endoresection with brachytherapy (16.0%), and exoresection (0.9%). At a median 37.3-month follow-up, globe salvage was 44.3%. Kaplan-Meier estimates revealed 5- and 10-year distant metastasis rates of 22%, with overall survival rates of 78% and 71%. Melanoma-related death incidence was 3.4 per 100 person-years, varying by stage: 1.4 (T1), 3.5 (T2), 4.1 (T3), and 9.6 (T4). Multivariate analysis identified distant metastasis as the sole independent prognostic factor for overall survival (HR 50.6, $p < 0.001$).

Conclusions: In conclusion, UM prognosis in this Southeast Asian cohort is strongly influenced by distant metastasis, emphasizing the critical importance of early detection, accurate staging, and individualized treatment to optimize long-term survival outcomes.

Ophthalmic Epidemiology and Prevention of Blindness

Abstract No.: 200864

A 31-Year Overview of Presbyopia Trends and Regional Variations (1990–2021)

First Author: Tianyu WANG

Co-Author(s): Xianyao PENG, Yinan WU, Xiaoping XU

Purpose: To provide an assessment of the prevalence and disability-adjusted life years (DALYs) associated with presbyopia from 1990 to 2021.

Methods: In this cross-sectional study, epidemiologic data were gathered from the Global Burden of Disease (GBD) database, covering persons of all ages with presbyopia in 204 countries and 21 regions from January 1, 1990, to December 31, 2021; data analysis was completed on 30 September 2024.

Results: In 2021, global presbyopia cases reached 1.16 billion (95% UI, 0.88–1.51 billion), a 169.91% increase (95% UI, 151.49%–187.12%) since 1990. Associated DALYs rose from 4.32 million (95% UI, 1.94–8.41) to 11.65 million (95% UI, 5.21–22.42). The prevalence

rate increased from 9,788.66 to 13,436.18 per 100,000, while the DALY rate rose from 98.26 to 135.52 per 100,000. The middle SDI region had the highest DALYs in 2021. South Asia saw the largest prevalence increase (EAPC 2.37, 95% UI, 2.03–2.71). South Africa had the highest prevalence rate (28,268.53 per 100,000), and Southern Sub-Saharan Africa had the highest DALY rate (251.60 per 100,000). Aging populations and limited vision care access drove the rising global burden.

Conclusions: This study highlights significant regional disparities in the burden of presbyopia, indicating that the global burden of presbyopia has risen significantly, with marked regional, age, and gender disparities. Low- and middle-income countries bear a disproportionately high burden. These data provide useful references for healthcare professionals, policy makers, and researchers to strengthen and consolidate management strategies.

Abstract No.: 203287

A Cohort Analysis Focus on the Relationship Between Follow-Up Adherence and Corneal Graft Rejection

First Author: Ting **ZHANG**

Co-Author(s): Hua **GAO**, Shuhan **GUO**, Jinhui **LIU**

Purpose: Regular postoperative surveillance plays a critical role in allograft survival after penetrating keratoplasty (PK). This retrospective cohort study analyzed the clinical characteristics of PK cases and investigated the relationship between follow-up compliance and corneal graft rejection.

Methods: Data of patients undergoing PK from June 2018 to January 2022 were analyzed. The patients were divided into two groups (normal group vs. rejection group) using keywords as designated terms for the computer to flag rejection events. Logistic regression was employed to analyze the association between specified follow-up intervals and allograft rejection risk.

Results: Analysis of 635 patients (540 normal vs. 95 rejection eyes) revealed no significant baseline differences between groups in demographics or clinical factors. Farmers were the predominant occupation in both groups (50.5% vs. 51.9%). Fungal keratitis was the primary PK indication (40.7% vs. 34.7% rejection). Other common indications included corneal ulcer perforation, keratitis, corneal leukoplakia, and bullous keratopathy. The median graft survival time was 308 days with an overall rejection rate of 15.0%. Additionally, male patients exhibited significantly higher rejection rates compared to females (17.3% vs. 10.3%, $P = 0.018$). The rejection group had a shorter routine follow-up interval than the normal group before rejection onset (21.5 vs. 32.5 days, $P < 0.0001$). Paradoxically, its follow-up interval before rejection was longer than the routine interval (82.0 vs. 21.5 days, $P < 0.0001$). The results indicate a positive correlation between follow-up intervals and rejection risk. For

each increase in monitoring interval category (e.g., <1 month $\rightarrow$ 1-2 months $\rightarrow$ 3-4 months $\rightarrow$ 5-6 months $\rightarrow$ >6 months), the odds of rejection occurrence increase by approximately 3.88 times (OR = 3.88, $p < 0.001$).

Conclusions: The results indicate a positive correlation between prolonged follow-up intervals and rejection risk. Measures to improve follow-up adherence are helpful for reducing corneal graft rejection.

Abstract No.: 201355

A Proteomic Profile of the Ocular Phenome: Systemic Signatures, Predictive Value, and Causal Insights Across 131 Ocular Diseases and Traits

First Author: Duanke **LIU**

Co-Author(s): Li **CHEN**, Hanruo **LIU**, Ningli **WANG**

Purpose: To test whether systemic plasma proteins can capture intraocular pathology and enable early detection, risk stratification, and therapeutic targeting of major eye diseases.

Methods: To systematically evaluate the relevance of the plasma proteome to ocular phenotypes, we profiled 2,920 circulating proteins in 53,016 UK Biobank participants across 80 clinically defined eye diseases and 51 quantitative ocular traits. We integrated association analyses, protein-based prediction models, Mendelian randomization, and unsupervised clustering to uncover predictive, causal, and mechanistic insights.

Results: We uncovered $>5,800$ protein-phenotype associations, with the strongest signals in diabetic retinopathy, intraocular pressure, and ISOS-RPE thickness. Plasma proteins such as GDF15, VSIG4, and PLAUR were consistently associated across phenotypes, implicating inflammation, vascular leakage, and complement signaling as convergent mechanisms. Proteome-based models outperformed clinical predictors in multiple conditions (e.g., AUC = 0.913 for diabetic retinopathy) and identified distinct risk gradients. Mendelian randomization supported causal roles for 144 proteins, including therapeutically actionable targets. Hierarchical clustering of 80 ocular phenotypes revealed six proteome-defined ocular modules, linking anatomically diverse traits through shared systemic biology and suggesting a new molecular taxonomy of eye health.

Conclusions: Circulating proteins capture key features of ocular pathology, enabling noninvasive risk assessment and molecular subtyping. Plasma proteomics may serve as a practical tool for early detection and therapeutic targeting in ophthalmology.

Abstract No.: 205756

Accuracy Assessment and Cost-Effectiveness Analysis of Visual Screening for Primary School-Aged Children in Nakhon Pathom by Primary Care Unit Comparing With Optometrist at Metta Pracharak (Wat Rai Khing) Hospital

First Author: Thanwarat **CHAIPHO**

Co-Author(s): Arpha **PORNSETH**, Kulawan **ROJANANUANGNIT**, Phantaraporn **TANGTAMMARUK**, Fahsiri **TAVONVUNCHAI**

Purpose: To evaluate the diagnostic accuracy and cost-effectiveness of two community-based vision screening models—teacher-led and public health officer (PHO)-led—for primary school children in Thailand, using optometrist screening as the gold standard.

Methods: This cross-sectional study enrolled 402 students aged 6–12 years in Nakhon Pathom. Visual acuity screenings by teachers and PHOs were compared against comprehensive examinations by a licensed optometrist. Diagnostic performance was assessed using sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV). A cost-effectiveness analysis was also performed.

Results: A total of 402 children were enrolled (51.0% male, 49.0% female), with a mean age of 9.01 ± 1.63 years (range 6–12). The prevalence of refractive error was 27.4%. Compared to the optometrist reference, teacher-led screening demonstrated high sensitivity (83.8%) but lower specificity (76.3%), with a PPV of 57.4% and NPV of 92.5%. Conversely, PHO-led screening yielded lower sensitivity (70.3%) but higher specificity (92.1%), with a PPV of 77.2% and NPV of 89.0%. Both community-based models proved to be economically viable alternatives to screening conducted by an optometrist.

Conclusions: The findings indicate a clear trade-off between the two community-based screening models. Teacher-led screening showed higher sensitivity, making it more effective at identifying children with visual impairment, though at the cost of lower specificity. Conversely, screening by public health officers demonstrated a higher specificity, reducing false positives, but had a lower sensitivity. Both methods are feasible and economically viable alternatives to optometrist-led screening for the early detection of visual impairment in this population.

Abstract No.: 203215

Artificial Intelligence-Assisted Community-Based Ocular Screening Integrated Into Primary Healthcare for Older Adults in China: Design and 2-Year Follow-Up Results

First Author: Gu **ZHENG**

Co-Author(s): Xinting **LIU**, Fan **LU**, Meixiao **SHEN**, Cong **YE**

Purpose: To describe the design, objective, and application effect of a pioneering community-based eye exam and healthcare study that investigated to improve the provision of ocular services to the elderly.

Methods: In this prospective study, comprehensive eye examinations were incorporated into annual physical assessments at community health centers, leveraging cutting-edge automation, digital documentation, and real-time data transmission technologies. Participants aged ≥ 60 years underwent four key tests: presenting distance visual acuity, autorefractometry, intraocular pressure measurement, and non-mydriatic fundus photography, enabling efficient detection of prevalent age-related eye diseases. To ensure diagnostic precision, a dual-validation system combining artificial intelligence-driven analysis with on-site expert confirmation was implemented for high-risk case identification. Additionally, a tiered management strategy featuring expedited referral pathways was established to facilitate timely tertiary care access.

Results: Among 3,785 eligible residents, 3,459 (91.4% response rate) completed initial screening, with an average examination duration of 4–8 minutes. Following expert validation, 1,466 participants (42.4%) required advanced hospital-based evaluation. Substantial unmet ophthalmic needs were uncovered, with prevalence rates of uncorrected refractive error (14.6%), cataract (22.7%), age-related macular degeneration (19.8%), glaucoma suspect (12.4%), and diabetic retinopathy (4.6%). Longitudinal analysis at 2-year follow-up demonstrated significant visual health improvements, particularly in younger cohorts (60–69 years), whereas the older subgroup (80–84 years) exhibited progressive decline.

Conclusions: This investigation establishes a transformative model for geriatric vision care, demonstrating exceptional feasibility, scalability, and effectiveness through its synergistic integration of technological innovation and community health infrastructure. The paradigm holds substantial promise for nationwide implementation, offering a blueprint for enhancing primary ophthalmic healthcare delivery across aging populations.

Abstract No.: 208374**Associations of Long-Term Joint Exposure to Multiple Ambient Air Pollutants With the Incidence of Age-Related Eye Diseases***First Author: Yingan LI*

Purpose: The associations between long-term joint exposure to low levels of multiple air pollutants and the incidence of common age-related eye diseases (AREDS), including cataract, glaucoma, and age-related macular degeneration (AMD), remain underexplored.

Methods: We conducted a prospective cohort study using UK Biobank data from 441,567 participants without cataract, glaucoma, or AMD at baseline. An air pollution score was constructed to assess the combined effect of multiple air pollutants, including PM_{2.5}, PM_{2.5-10}, PM₁₀, NO₂, and NO. Cox proportional hazards models were used to evaluate associations.

Results: Over a median follow-up of 14.41 years, 55,104 participants developed cataract, 11,940 glaucoma, and 9,060 AMD. A relatively stronger association was observed between combined exposure to multiple pollutants and AREDS incidence compared to exposure to individual pollutants. For every interquartile range increase in the air pollution score, the risk of incident AREDS increased by 4-5% (cataract, HR [95% CI], 1.05 [1.04-1.06]; glaucoma, 1.04 [1.02, 1.06]; AMD, 1.04 [1.01, 1.07]), suggesting the potential additive or synergistic effects of exposure to pollutant mixtures. Compared to individuals in the lowest exposure quartile, those in the highest had a 13%, 9%, and 14% greater risk of developing cataract (1.13 [1.10-1.16]), glaucoma (1.09 [1.03-1.15]), and AMD (1.14 [1.07-1.22]), respectively.

Conclusions: Long-term joint exposure to multiple air pollutants, even at low concentrations, is associated with an increased risk of AREDS incidence, suggesting that reducing air pollution levels could improve human ocular health. These findings provide a more comprehensive understanding of air pollution's impact on ocular health in the real world.

Abstract No.: 205664**Astigmatism Trends in the Hong Kong Adult Population From 2015 to 2024: The Hong Kong Children Eye Study.***First Author: Anakin Chu Kwan LAI**Co-Author(s): Li Jia CHEN, Ka Wai KAM, Jason Cheuk Sing YAM, Alvin L YOUNG*

Purpose: Astigmatism is the most common refractive error in both children and adults. Our study revealed significant increases in the prevalence and severity of child astigmatism from 2015. This study aims to examine trends in refractive (RA) and corneal astigmatism (CA) in the Hong Kong adult population during the same period.

Methods: We analyzed parents of children recruited in the Hong Kong Children Eye study (HKCES), a population-based cross-sectional study. Astigmatism was measured with an autorefractor and an IOL Master. RA was defined as ≥ 1.0 diopter (D) of cylindrical power, while CA was defined as a ≥ 1.0 D difference between the steepest and flattest corneal meridians. The annual prevalence of RA and CA was age-standardized according to the census data and served as the primary outcomes.

Results: A total of 28,330 participants were included, comprising 10,037 males (35.4%), aged 20-59 years. The age-standardised prevalence rate (ASR) for RA increased from 32.0% (95%CI: 28.9, 35.3) in 2015 to 34.1% (95%CI: 30.1, 37.9) in 2024, ($p > 0.05$); For CA, the ASR rose from 39.6% (95%CI: 36.2, 43.6) in 2015 to 48.5% (95%CI: 44.6, 52.8) in 2024, ($p < 0.05$). Regression showed increases of 0.096D ($p < 0.001$) for RA and 0.086D ($p < 0.01$) for CA after adjusting for age and gender.

Conclusions: In 2024, one-third of adults in Hong Kong had at least 1D of RA, and nearly half had at least 1D of CA. The prevalence of CA increased significantly over the past decade, while the rise in RA was minimal, suggesting potential compensation by internal astigmatism.

Abstract No.: 205825**Astigmatism Types Effects on Internal Astigmatism and Compensation in Children: Hong Kong Children Eye Study***First Author: Ka Wai KAM**Co-Author(s): Arnold CHEE, Li Jia CHEN, Erica SHING, Jason YAM, Alvin YOUNG*

Purpose: Astigmatism is highly prevalent among schoolchildren in Hong Kong. Children demonstrate distinct patterns of internal astigmatism (IA) to compensate for corneal astigmatism (CA). This study aims to investigate the associations between astigmatism subtypes, IA, and compensation factors (CF) in schoolchildren with a minimum of 0.5 dioptre (D) of refractive astigmatism (RA).

Methods: RA in children was assessed following cycloplegia and classified into simple myopic (SMA), compound myopic (CMA), mixed (MA), simple hyperopic (SHA), and compound hyperopic astigmatism (CHA) based on the location of the focal planes. IA was calculated through vector components J0 and J45. CF were determined by dividing IA by CA in respective vectors. Generalized linear models were used where variances were unequal.

Results: 4,027 children with a mean age of 7.6 ± 1.0 years were analysed. CMA was associated with male sex ($p = 0.019$), older age ($\beta = -0.143$, 95%CI -0.201 to -0.085, $p < 0.001$), longer axial length ($\beta = -0.143$, 95%CI -0.158 to -0.129, $p < 0.001$) and deeper anterior

chamber ($\beta = -0.019$, 95%CI -0.022 to -0.015, $p < 0.001$). CHA possessed the greatest mean IA value of 0.61D whereas CMA and SMA had the least of 0.55D. 56.1% of CHA displayed over-compensation as opposed to 7.9% and 7.6% in CMA and SMA respectively. On the contrary, 55.6% and 52.9% of CMA and SMA under-compensated their astigmatism, compared to 8.2% in CHA.

Conclusions: Children with hyperopic astigmatism over-compensate their corneal astigmatism, whereas children with myopia are more likely to suffer a greater amount of astigmatism as a result of lower IA and under-compensation in myopic astigmatism.

Abstract No.: 201499

Availability and Accessibility of End-to-End Diabetic Eye Care Services in Indonesia: A Spatial Analysis

First Author: Rima Afifah **POTRI**

Co-Author(s): Fariza Rahma **SAFIRA**, Muhammad Bayu **SASONGKO**, Firman Setya **WARDHANA**, Felicia **WIDYAPUTRI**

Purpose: Indonesia is among the countries with the fastest-growing diabetes and diabetic retinopathy (DR), with the annual increase of DR-related vision-threatening and blindness being 24.5 and 8.33/1000 individuals with diabetes. These data suggest the lack of diabetic eye care services in the country. This study aimed to assess the availability and accessibility of DR care from screening (DRS) to treatment facilities in Indonesia.

Methods: This was a comprehensive descriptive study comprising data review on national and local DR care resources, guided interviews with diabetic eye care stakeholders, and spatial analyses of DRS and treatment facilities access from each district in Indonesia. Availability was defined as the presence of DR care service in each province, while accessibility was the distance between the closest population cluster and the nearest DR care services (km).

Results: Of over 25,000 primary health centers across 38 provinces, none actively performed DRS. Although all provinces had DRS, only 26 (68.42%) had DR treatment facilities. Approximately 2.8 million (8.65%) individuals with diabetes had access to DRS facilities within 50 km, whilst 30.4 million (91.35%) had to travel 50-692 km to obtain DRS. More importantly, 2.2 million (6.65%) had DR treatment facilities within 100 km, while 31.0 million (93.35%) were at least 100-1,400 km away.

Conclusions: Our study suggests that disparities in DR care existed, and that a large proportion of individuals had a lack of access to DRS and DR treatment. These data strongly highlight the need to improve the availability of DR care in Indonesia.

Abstract No.: 201845

Bidirectional Relationship Between Myopia and Mental Disorders

First Author: Dan-lin **LI**

Co-Author(s): Chen-wei **PAN**

Purpose: Myopia and mental disorders share common environmental and behavioral risk factors. Previous studies have been inconsistent regarding the association between them; this systematic review and meta-analysis aim to explore the association between myopia and mental disorders.

Methods: Databases including PubMed, Web of Science, Wiley online library, and Cochrane Library were searched for eligible publications from January 2000 to July 2024. Studies assessing the relationship between myopia and any one of the mental disorders were identified. Pooled odds ratios (ORs) and their corresponding 95% confidence intervals (95% CIs) were estimated using random-effects models.

Results: We identified 15 articles (2 cohort studies and 13 cross-sectional studies) examining the impact of myopia on mental disorders, involving 2841653 participants from 7 countries. Pooled results indicated that myopia was significantly associated with an increased risk of mental disorders (OR = 1.43, 95% CI 1.25, 1.61). Besides, a significant relationship was observed between the mental disorders and myopia (OR = 1.15, 95% CI 1.01, 1.29) through 8 articles, including 1942855 participants from 5 countries. Subgroup analyses showed that the association of myopia with both anxiety and depression was significant, with ORs of 1.49 and 1.21, respectively.

Conclusions: Myopia and mental disorders may influence each other, with each condition potentially exacerbating the risk of the other. These findings help to explore the possible interplay between mental disorders and myopia.

Abstract No.: 201244

Bridging the Gaps in Refractive Error Services in Malaysia: Insights From the National Eye Survey III and the Way Forward With SPECS 2030

First Author: Wan Radziah **WAN NAWANG**

Co-Author(s): Norasyikin **MUSTAFA**, Mohamad Aziz **SALOWI**, Siti Nurhuda **SHARUDIN**

Purpose: To report key indicators, including effective Refractive Error Coverage (eREC) among adults aged 50 years and older in Malaysia, based on the 2023 population-based eye survey.

Methods: The National Eye Survey III was a cross-sectional study employing the World Health Organization (WHO)-recommended Rapid Assessment of Avoidable Blindness (RAAB) methodology, conducted in Sarawak and the Eastern Region of Malaysia.

Individuals with refractive error were identified, and uncorrected and corrected (pinhole) visual acuities were measured. Refractive Error Coverage (REC) and eREC were calculated.

Results: Of 10,184 individuals enumerated, 9,709 were examined. Refractive error prevalence was higher in Sarawak (21.4%) than in the Eastern region (15.4%). Spectacle use for distance and near vision was consistently higher among females. eREC in the Eastern region was 42.7% in females and 34.1% in males, while in Sarawak, it was slightly higher in males (48.8%) than in females (47.6%). The quality gap was wider in the Eastern region (12.7%) compared with Sarawak (8.7%). Although the unmet need for distance correction was proportionally higher in Sarawak, the overall burden was greater in the Eastern region.

Conclusions: Regional differences in prevalence, spectacle use, and eREC highlight the need for targeted strategies. In line with WHO's SPECS 2030, Malaysia is initiating a nationwide program to bridge these gaps, ensure universal access to affordable, high-quality, people-centred refractive error services, and to achieve a 40-percentage point increase in eREC by 2030.

Abstract No.: 203755

Burden and Depression in Caregivers of Patients With Visual Impairment

First Author: Kavita BHATNAGAR

Purpose: Caregivers devoted to their patients often neglect their own needs, resulting in burden and depression.

Methods: A cross-sectional observation study of 270 caregivers for 109 permanent visually impaired patients, from category III onwards. Caregiver burden was measured using the Caregivers Burden Scale while depression levels were assessed using the Centre for Epidemiologic Studies Depression Scale.

Results: The mean caregiver age was 38.3 years (SD $\pm$ 14.34), and the majority (56.66%) belonged to a lower socioeconomic status according to the Kuppuswami scale 2021. Moderate to severe burden was found in 115 [42.59%] caregivers, while severe burden was found in 9 [3.33%]. The possibility of major depression was found in 32 [11.85%]. Noteworthy findings were higher burden and depression levels with increasing duration of caregiving ($p < 0.0000001$), female gender (burden p -value= 0.01614 and depression p -value= 0.01246), parents or spouse as caregivers had higher burdens ($p < 0.0002334$), and nuclear families had higher levels of depression ($p < 0.006499$). Illiterates had an elevated burden ($p < 0.001708$). A positive linear correlation between Caregivers Burden Scale scores and Centre for Epidemiologic Studies Depression scores in caregivers was found [R is 0.6479, $P < 0.00001$].

Conclusions: These findings underscore the need for tailored support interventions addressing the specific

needs of caregivers of visually impaired individuals, particularly those facing heightened burden and depression.

Abstract No.: 200149

Cataract Global Burden of Adolescents and Young Adults Between 1990 and 2021: Analyses of the Global Burden of Disease Study 2021

First Author: Zijing LI

Purpose: To investigate the trend of cataract burden in individuals aged 15 to 39 years from 1990 to 2021.

Methods: This cross-sectional study leveraged data from the Global Burden of Disease Study 2021. The analysis included prevalence and disability-adjusted life years (DALYs) rates, along with the associated estimated annual percentage changes (EAPCs), assessed at the global level and categorized by sex, sociodemographic index (SDI), geographic region, and country.

Results: In 2021, the global age-standardized prevalence rate (ASPR) was 51.095 per 100,000. From 1990 to 2021, the ASPR decreased by 5.615%, with an EAPC of -0.379. The age-standardized DALYs rate (ASDR) in 2021 was 5.541 per 100,000, decreasing by 20.498%, with an EAPC of -0.959. The reductions in EAPC for ASPR and ASDR were more pronounced in males than in females. The high-SDI region exhibited the greatest increase in the EAPC of ASPR and generally remained stable in the EAPC of ASDR. However, the low-middle-SDI region showed the greatest decrease in ASPR (EAPC: -1.246) and ASDR (EAPC: -1.889). Central Europe had the sharpest rise in both ASPR and ASDR among the 21 geographic regions, while South Asia saw the steepest decline. At the country level, the Central African Republic exhibited the largest increase, while Equatorial Guinea showed the greatest decrease in both ASPR and ASDR.

Conclusions: Over the past 32 years, the global burden of cataracts among adolescents and young adults has decreased; however, it remains a significant public health concern worldwide. Cost-effective and targeted strategies are needed to alleviate this burden.

Abstract No.: 207191

Characterization and Risk Factors of Astigmatism Among Children and Adolescents Aged 3-20 Years in Northwestern China

First Author: Lu YE

Co-Author(s): Yiming GUO, Yijin HAN, Jiaqi WANG, Junhan WEI

Purpose: To investigate the prevalence, severity, types, correction status, and associated risk factors of astigmatism among children and adolescents in Shaanxi Province, China.

Methods: A cross-sectional study was conducted involving 236,397 children aged 3-20 years from 641 schools across Shaanxi Province using multistage stratified cluster random sampling. Astigmatism was defined as $|\text{cylinder diopter}| \geq 0.5\text{D}$. Demographic information was collected via questionnaires. Refractive measurements were performed using an autorefractor without cycloplegia.

Results: The overall astigmatism prevalence was 73.81%, increasing with age (63.17% in 3-5-year-olds to 81.70% in 18-20-year-olds) and education level (62.08% in kindergarten to 82.71% in high school). Males had a higher prevalence (74.44%) than females (73.13%). Northern Shaanxi showed the highest prevalence (80.52%), followed by Central (73.18%) and Southern Shaanxi (69.21%). With-the-rule astigmatism (92.63%) and compound myopic astigmatism (63.00%) were predominant. Only 30.73% of astigmatic children received correction, with rates increasing with age (2.19% in 3-5-year-olds to 64.66% in 18-20-year-olds) and education level. In multivariate regression analysis, age, education level, male gender, Northern Shaanxi residence, and non-Han ethnicity were significant risk factors.

Conclusions: Astigmatism prevalence among children in Shaanxi Province is considerably higher than previously reported in other Chinese regions, with significant variations across demographic factors. The low correction rate, particularly among younger children, highlights the need for enhanced early screening and timely intervention programs to prevent visual function impairment.

Abstract No.: 201777

Chronotype, Age-Related Macular Degeneration and Outer Retinal Structure: Insights From the UK Biobank

First Author: Zihan **SUN**

Co-Author(s): Mahantesh **BIRADAR**, Paul **FOSTER**, Anthony **KHAWAJA**, Yue **LENG**, Robert **LUBEN**

Purpose: Chronotype—whether an individual is a «morning lark» or «night owl»—reflects the timing of their internal biological clock and is associated with various health outcomes. Genetic studies have identified chronotype-related loci that are enriched for genes expressed in retinal tissue, but epidemiological evidence remains limited. We therefore investigated the associations between chronotype, age-related macular degeneration (AMD), and retinal structure in the UK Biobank.

Methods: Chronotype was assessed via a self-administered questionnaire and categorized into extreme morning, moderate morning, moderate evening, and extreme evening types. The primary outcome was AMD, identified through a combination of self-reported diagnosis, hospital admission records, and manually graded retinal images. Secondary

outcomes included outer retinal layer thicknesses measured with OCT. Multivariable analyses were adjusted for sociodemographic, lifestyle, systemic, and ocular factors.

Results: Of the 443,404 UK Biobank participants included in the primary analysis, 16,916 had AMD. Compared to the extreme morning type, moderate morning (OR 1.05, 95% CI 1.01-1.09, $P = 0.02$), moderate evening (OR 1.06, 95% CI 1.01-1.10, $P = 0.008$), and extreme evening (OR 1.14, 95% CI 1.07-1.21, $P = 2.8 \times 10^{-5}$) groups all showed significantly higher odds of prevalent AMD. In 39,547 participants with retinal imaging, extreme eveningness was associated with thinner photoreceptor layers and thinner RPE-Bruch's membrane complex.

Conclusions: Eveningness, particularly extreme evening preference, is associated with increased odds of AMD and thinner outer retinal layers. Our findings suggest chronotype may be a novel risk factor for AMD, underscoring the importance of circadian rhythm in retinal health.

Abstract No.: 200434

Comparison of the Efficacy and Clinical Applications of Three Different Myopia Control Methods: RLRL, 1% Atropine, and OK Lens in Adolescent Children

First Author: Yunyun **WANG**

Purpose: To compare the efficacy and clinical application of repeated low-level red light (RLRL), 1% atropine gel, and orthokeratology lenses for myopia in adolescent children.

Methods: This study investigated 600 children aged 8–16 years with a spherical equivalent (SE) of -0.50 to -7.00 diopter (D) in the past 1 year. They were divided into four groups. In the RLRL group, the adjustable settings were 3/6/9, corresponding to powers of 0.35/0.65/0.95 mW. The other three groups were 1% atropine, orthokeratology lens (OK group), and control (single-vision spectacles [SVS]).

Results: After 1 year, the AL of the four groups increased by 0.05 ± 0.21 , 0.07 ± 0.16 , 0.25 ± 0.19 , and 0.41 ± 0.18 mm. When the OK group was compared with the RLRL, 1% atropine, and SVS groups, the difference was statistically significant ($P < 0.05$). In the RLRL group, the difference between 0.35 mW and 0.95 mW was statistically significant ($P < 0.05$). The KI (flat K) and K2 (steep K) in the four groups. The differences were statistically nonsignificant ($P > 0.05$). After 1 year, the four groups showed SE increases. The differences between the OK, RLRL, and 1% atropine groups and the SVS group were statistically significant ($P < 0.05$).

Conclusions: RLRL and 1% atropine exhibited better outcomes than OK lenses in controlling AL and SE increase. RLRL was effective at controlling myopia progression at powers of 0.35, 0.65, and 0.95 mW.

Abstract No.: 206449**Effective Refractive Error Coverage (eREC) and Its Determinants: The Ural Eye and Medical Study***First Author: Giulli KAZAKBAEVA**Co-Author(s): Mukharram BIKBOV, Jost JONAS, Songhomitra PANDA-JONAS*

Purpose: Uncorrected refractive error (URE) is a leading cause of global vision impairment. Effective Refractive Error Coverage (eREC), the proportion of individuals with a refractive error who have and use appropriate correction, is a key metric of health system performance. This study aimed to determine the eREC and identify its key sociodemographic determinants in a Russian population.

Methods: The Ural Eye and Medical Study (UEMS) is a population-based, cross-sectional study of participants aged 40+ years from urban and rural areas of the South Urals region. All participants underwent a comprehensive ophthalmological examination. eREC was calculated per the WHO definition, requiring possession of spectacles or contact lenses and achieving a presenting visual acuity of $\geq 6/12$. Sociodemographic and barrier data were collected via standardized questionnaires.

Results: Among 5,389 participants, the prevalence of refractive error requiring correction was 68.2%. The overall eREC was 55.4% (95% CI: 53.8–57.0). eREC was significantly lower in females than in males and demonstrated a progressive decline with increasing age after 50. Multivariate regression analysis confirmed that older age (particularly ≥ 50 years), female gender, lower income, rural Residence and lack of awareness about refractive correction were independent predictors of inadequate eREC.

Conclusions: Despite a high need, effective refractive error coverage in the Ural region is suboptimal and characterized by significant sociodemographic disparities. Public health strategies must prioritize affordability, health literacy, and equitable access, with targeted interventions for older adults, women, and rural communities to bridge this gap and eliminate preventable vision impairment.

Abstract No.: 208287**Evolution of Diabetic Retinopathy Screening Models in Central India: Transition From Manual to Offline AI-Based Detection Under Project C.A.R.E.***First Author: Gajendra CHAWLA**Co-Author(s): Aashul CHAWLA, Carol Y. CHEUNG, Chunwen ZHENG*

Purpose: To compare three sequential models of diabetic retinopathy (DR) screening implemented over 17 years in Central India—manual, teleophthalmology, and artificial-intelligence (AI)—based screening—and

to evaluate accuracy, cost, and acceptability of the AI model.

Methods: A retrospective descriptive cohort (2008–2024) with an embedded prospective arm (2025) was analyzed. Manual and teleophthalmology data comprised 16,428 diabetic subjects screened across 282 camps. The 2025 Project C.A.R.E. cohort included 490 diabetics screened using offline Medios AI integrated into a non-mydriatic fundus camera. Outcome measures included DR and vision-threatening DR (VTDR) detection, AI sensitivity/specificity, screening time, cost per VTDR detected, and patient–physician acceptability.

Results: DR prevalence was comparable across models: 22.6% (manual/tele) vs 23.4% (AI). VTDR among DR-positive cases was 20.1% and 21.1%, respectively ($p > 0.05$). AI sensitivity and specificity were 91% and 87% ($\kappa = 0.82$). Average screening time decreased from 45–50 min to 5.6 min, and cost per VTDR detected dropped from ₹10,960 to ₹3,480. Follow-up compliance improved from 34% to 52%. Acceptability was high—85% of patients and 76% of physicians endorsed AI screening for routine triage.

Conclusions: Offline AI-assisted screening significantly reduced screening time and cost while maintaining diagnostic accuracy and high acceptability. Project C.A.R.E. demonstrates a scalable, cost-effective framework for diabetic eye screening in resource-limited settings.

Abstract No.: 205800**Exploring Barriers to Cataract Surgery Uptake in Eastern Zone of Malaysia: Trends and Insights From the National Eye Surveys***First Author: Siti Nurhuda SHARUDIN**Co-Author(s): Fei Yee LEE, Norasyikin MUSTAFA, Mohamad Aziz SALOWI, Wan Radziah WAN NAWANG*

Purpose: This study examined shifts in barriers to cataract surgery uptake among adults 50 years and above in the Eastern Zone of Malaysia by comparing data from the 2014 and 2023 National Eye Surveys.

Methods: A population-based survey was conducted in 2023 using the RAAB methodology with multistage cluster sampling. Participants underwent standardized visual assessments and structured interviews on perceived barriers. Logistic regression identified factors associated with poor vision to assess temporal changes.

Results: In 2023, operable cataract prevalence was 15.9% lower than 21.3% in 2014. “Need Not Felt” remained the most cited barrier but declined from 55.8% to 38.9%. “Fear of Surgery” persisted at 16%, while “Local Reasons” rose from 10.6% to 21.9%. Predictors of poor vision shifted: in 2014, older age and “Need Not Felt” were strongest (AOR: 1.042, 95% CI 1.014, 1.070, $p=0.003$ and AOR: 4.288, 95% CI

2.644, 6.954, $p < 0.001$), respectively. While in 2023, “Fear of Surgery” (AOR: 2.205, 95% CI 1.190, 4.084, $p = 0.012$), “No Access” (AOR: 3.003, 95% CI 1.324, 6.810, $p = 0.008$), and “Local Reasons” (AOR = 2.650, 95% CI 1.497, 4.689, $p = 0.001$) significantly increased the likelihood of poor vision.

Conclusions: Traditional barriers, such as “Felt surgery not needed,” have declined, but emerging challenges, including cost, limited awareness, and accessibility, persist. Public health interventions addressing both longstanding and new barriers are essential to improve surgical coverage and reduce preventable blindness in the Eastern Zone of Malaysia.

Abstract No.: 208443

Female Predominance and Socio-Demographic Inequalities in Global Near Vision Loss Burden: Projected Trends and Disparities From 1990 to 2035

First Author: Guodong TANG

Co-Author(s): Hongsheng BI, Xiaoqi GONG, Jing LI, Jike SONG

Purpose: Near vision loss (NVL), a hallmark of aging populations, imposes a growing global health burden, exacerbated by demographic shifts and socioeconomic disparities. Despite its profound impact on productivity and quality of life, comprehensive analyses that integrate aging, socioeconomic development, and sex-specific disparities remain limited.

Methods: Using the Global Burden of Disease (GBD) 2021 dataset spanning 204 countries and territories (1990–2021), we evaluated the NVL burden through prevalence, disability-adjusted life years (DALYs), and sociodemographic index (SDI). Advanced methodologies included decomposition analysis to disentangle demographic and epidemiological drivers, Bayesian age-period-cohort (BAPC) modeling for projections, and frontier analysis to quantify SDI-linked inequities. Gender-stratified and age-specific trends were analyzed using joinpoint regression analysis.

Results: Global NVL prevalence surged from 428 million to 1.155 billion cases (1990–2021). Females exhibited a higher age-standardized prevalence (16,588 vs. 14,718 per 100,000 in 2021). South Asia had the highest burden (age-standardized DALYs: 208.0), whereas the Gulf Cooperation Council reported the lowest (93.8). Socioeconomic inequities widened: The DALY gap between high- and low-SDI regions expanded from 10.19 to 31.96. Population growth (65.3%) and epidemiological shifts (39.2%) drove DALY increases, offset marginally by aging (−4.4%).

Conclusions: NVL burden escalated disproportionately in low-SDI regions and among females, fueled by population growth and systemic healthcare gaps. Aging, while a minor contributor globally, critically affects the high-income Asia-Pacific region. Policymakers must

prioritize sex-sensitive refractive care programs, expand optical subsidies in underserved areas, and address digital near-work hazards to mitigate the premature onset of NVL.

Abstract No.: 206455

Forty Years of Global Retinopathy of Prematurity Management Outcomes: A Systematic Review and Meta-Analysis of Associations With Socioeconomic and Health-Care Factors

First Author: Wai Chak CHOY

Co-Author(s): Li Jia CHEN, Allan Wang Yee CHU, Yuen Tsing Adeline HO, Michelle Yuen-ching NG, Calvin Cp PANG, Noel PANG, Clement THAM, Emily WONG, Jason Cheuk Sing YAM, Yuzhou ZHANG

Purpose: Retinopathy of prematurity (ROP) is an important cause of childhood blindness. We aimed to investigate trends in global ROP anatomical and visual outcomes during the past 40 years. and investigate the association with socioeconomic and healthcare factors.

Methods: We performed a systematic review and meta-analysis by identifying articles in nine databases published between 1980 and 2021, regardless of language, and included articles with coverage on anatomical and visual outcomes. Reported studies were stratified by decade from 1980–2021. Socioeconomic and healthcare factors were extracted from the World Bank and the World Health Organisation data registry. Estimates were pooled by a random-effect model with a fixed-effect model for sensitivity analysis. Associated factors were analysed by multivariable linear regression.

Results: A total of 30,075 patients from 283 studies were included for analysis. Overall anatomical success rate in 1980–1990, 1990–2000, 2000–2010, 2010–2021 was estimated at 0.742 (CI=0.668–0.804), 0.887 (CI=0.847–0.917), 0.9146 (CI=0.877–0.941), and 0.960 (CI=0.922–0.980) respectively. Overall visual success rate was estimated at 0.6667 (CI=0.543–0.771), 0.6510 (CI=0.527–0.757), 0.763 (CI=0.668–0.838), and 0.890 (CI=0.424–0.989) for the above 4 decades. A similar improving trend was observed for advanced-stage cases. Only low-middle income countries showed an increase in overall anatomical success (beta=0.189, CI=0.073–0.305). For advanced cases, high-income countries showed increase in anatomical (beta=0.273, CI=0.064–0.482) and visual (beta=0.345, CI=0.041–0.648) success rate specifically for advanced cases. Prenatal care coverage (beta=0.389, CI=0.369–0.410), physician density (beta=0.813, CI= 0.743–0.884), and social insurance coverage (beta=0.763, CI= 0.738–0.789) were associated with ROP outcomes improvement.

Conclusions: Treatment outcomes have improved globally from 1980 to 2021. Improvements for advanced cases were mainly in high-income locations.

Improving accessibility, financing and technological transfer are important to improve global outcomes further.

Abstract No.: 201522

Gender Based Variability in the Incidence of Retinopathy of Prematurity in Multiple Gestation Premature Infants: A Retrospective Analysis From a Tertiary Care Eye Hospital

First Author: Rabeeah ZAFAR

Purpose: To investigate the incidence of retinopathy of prematurity (ROP) and the association of gender differences in the severity and treatment warranted-ROP in multiple gestation premature infants.

Methods: A 04-year retrospective comparative analysis was conducted on premature infants from multiple gestations who underwent ROP screening from January 2021 to December 2024 in a tertiary care eye hospital in Pakistan. The incidence rates of any ROP, severe ROP, and treatment-warranted ROP were assessed. Gender-based variation in the stage and severity of ROP was also analyzed using SPSS 26.0.

Results: A total of 224 premature infants underwent ROP screening, including 92 sets of twins, 12 triplets, and one set of quadruplets. In this study, the overall incidence of ROP was found to be 33% (n=74), with severe ROP (i.e., stage 4 or 5) occurring in 7.1% of infants (n=16). A significant gender difference was observed, with male infants predominating (p value <0.05). Treatment was required for 28 infants, with greater odds of requiring treatment in male infants (p=0.02, OR=1.4).

Conclusions: A strong association between male gender and retinopathy of prematurity exists in multiple gestation premature infants. Males are more prone to developing ROP and require treatment more often and earlier than their female counterparts. Furthermore, in contrast to the international protocols and International Classification of Retinopathy of Prematurity (ICROP), screening in Pakistan is conducted in infants with a gestational age of ≤ 35 weeks. This screening window, defined as ≥ 31 (in ICROP) and ≤ 35 weeks, yields significant findings and warrants further exploration to guide national-level policy.

Abstract No.: 206427

Gender Differences in Clinical and Demographic Profiles of Community Cataract Surgery: A Study From Garut Regency, West Java, Indonesia

First Author: Ilmah ILMAH

Co-Author(s): Nina RATNANINGSIH, Mayang RINI

Purpose: To describe the characteristics of cataract patients and their visual status prior to community-based cataract surgery, with a focus on gender

differences in Garut Regency during January–December 2024.

Methods: Patients aged over 18 years who underwent cataract extraction in community programs organized by the Community Ophthalmology Unit of a tertiary eye hospital were included. Demographic, clinical, and visual acuity data were collected. Descriptive statistics were applied, and associations between categorical variables were assessed using the Chi-Square test.

Results: A total of 816 patients were included. Most patients were male (50.9%) and 40–65 years old. The majority of subjects with a diagnosis of mature senile cataract were 47.5% male and 50.6% female. The most common comorbid systemic condition among men and women is hypertension (13.7% and 16.2%). As many as 37.6% of men and 43.3% of women have visual acuity in their better eye of less than 3/60. The percentage of visual acuity less than 3/60 in the operated eye was 91.8% in males and 93.8% in females. In this study, statistically significant differences between males and females were found in age ($P < 0.001$) and the diagnosis of the operated eye ($p = 0.002$).

Conclusions: In this study, most patients were aged 40–65 years with hypertension as the most common comorbidity. A high proportion presented with profound visual loss in the operated eye. Gender-related differences were statistically significant in terms of age and cataract diagnosis.

Abstract No.: 207915

Global Cohort Analysis of GUCY2D-Associated Inherited Retinal Dystrophy and Genotype-Phenotype Correlation Study

First Author: Yijing HU

Co-Author(s): Jie CHEN, Xiaoman LI, Yihan ZHENG

Purpose: To systematically review global case data of inherited retinal dystrophy (IRD) associated with GUCY2D gene mutations and analyze the correlation between GUCY2D genotypic features and clinical phenotypes.

Methods: This retrospective study included 419 IRD cases with GUCY2D mutations. Among these cases, 13 were collected from our ophthalmology center, while the remaining 406 cases were compiled from published clinical research reports worldwide. All underwent ophthalmic exams and molecular testing (Sanger or whole-exome sequencing). Using statistical methods, survival analysis, and linear regression, we systematically assessed correlations between GUCY2D mutation features and clinical phenotypes.

Results: This study included 419 IRD patients with GUCY2D mutations, identifying 134 distinct variants, with missense mutations being the most frequent type. The most prevalent pathogenic variants were c.2512C>T (p.Arg838Cys) and c.2513G>A (p.Arg838His), with allele frequencies of 20.11% (107/532) and

14.66% (78/532), respectively. Statistical analysis revealed significant differences in progression of visual acuity to blindness among different mutation types at position 838 ($P < 0.05$). Three novel pathogenic variants (c.1766A>T [p.His589Leu], c.2612T>G [p.Val871Gly], c.2099del [p.Pro700fs]) were first identified in the Chinese cohort, along with the first reported homozygous c.2512C>T carrier in a consanguineous family. Notably, the homozygous carrier showed distinct phenotypes from heterozygous cases, providing new insights into GUCY2D's functional and pathogenic mechanisms.

Conclusions: This study systematically elucidated the core association between GUCY2D mutation characteristics and clinical phenotypes of IRD. Through the identification of novel pathogenic variants and distinctive phenotypes associated with rare homozygous mutations, critical evidence was provided for studies on the functional mechanisms of the GUCY2D gene.

Abstract No.: 205877

Impact of Correcting Refractive Errors on Educational Outcomes: A Community-Based School Screening Study in South India

First Author: Sahithya **BHASKARAN**

Co-Author(s): Vijayalakshmi **PERUMALSAMY**, Jeyachandran S

Purpose: Uncorrected refractive error (URE) is the leading cause of visual impairment in Indian schoolchildren, yet spectacle coverage remains poor. This study assessed whether providing spectacles improves educational outcomes.

Methods: A cluster-randomized controlled trial was conducted across 18 government schools in Tamil Nadu. Of 11,117 screened students (mean age 10.7 ± 3.4 years), 552 (4.9%) had URE and underwent baseline educational assessment using the ELANA tool for reading and arithmetic. Intervention schools received spectacles, while control schools received referral cards. Post-assessment was done after 11 months

Results: A cluster-randomized controlled trial was conducted across 18 government schools in Tamil Nadu. Of 11,117 screened students (mean age 10.7 ± 3.4 years), 552 (4.9%) had URE and underwent baseline educational assessment using the ELANA tool for reading and arithmetic. Intervention schools received spectacles, while control schools received referral cards. Post-assessment was done at

Conclusions: The provision of spectacles significantly enhanced reading performance and overall educational outcomes in formative years. This first India-specific evidence underscores the critical role of school vision programs in improving both eye health and learning outcomes.

Abstract No.: 204045

Impact of Low Vision and Blindness on Characteristics of Developmental Delay in Children Younger Than 6 Years

First Author: Simaporn **SETTHAWONG**

Co-Author(s): Suksri **CHOTIKAVANICH**, Akarawit **ELAMSAMARNG**, Ekipat **EKSUPAPAN**, Piyaphat **JARUNIPHAKUL**, Pridaporn **ONLAMUL**, Amornrat **PENPHATTARAKUL**, Theerajate **PHONGSUPHAN**, Pat **ROJMAHAMONGKOL**, Saranya **SAGAN**, Piangporn **SAKSIRIWUTTO**, Nattapon **SARINAK**, Sureelak **SUTCHRITPONGSA**, Prakasit **WANNAPASCHAIYONG**, Rungtip **YINGYONG**

Purpose: To investigate the developmental impact of low vision and blindness on children under six with common ocular diseases.

Methods: This retrospective study reviewed records of new patients under six with visual impairment at Siriraj Hospital's low vision rehabilitation center (January 2017 to October 2022). Collected data included ocular, systemic, and developmental characteristics. Visual acuity in the better-seeing eye was recorded after refractive correction, and developmental domains with the Denver II. Univariable and multivariable logistic regression analyzed identified factors associated with developmental delay.

Results: Among 161 pediatric patients (mean age 24.9 ± 18.9 months), all had visual acuity worse than 1.07 ± 0.58 LogMAR. 83.2% were diagnosed with global developmental delay (GDD). The most common ocular causes were cortical visual impairment (CVI), optic neuropathy/atrophy, and optic nerve hypoplasia. Extremely poor visual acuity was significantly associated with GDD [adjusted odds ratio (AOR) 41.0] and delays in all domains: gross motor (AOR 10.0), fine motor (AOR 12.8), language (AOR 5.3), and personal-social skills (AOR 13.4) ($P \leq 0.002$). Multiple disabilities, particularly visual impairment with cerebral palsy, were significantly associated with gross (AOR 7.7) and fine motor delays (AOR 4.0) ($P < 0.05$). CVI was associated with language and personal-social skills (AOR 9.1 each) ($P < 0.05$).

Conclusions: Children with visual impairment, especially those with poorer acuity, CVI, and multiple disabilities, are at high risk for developmental delays across all domains. Early multidisciplinary intervention is strongly recommended.

Abstract No.: 207358**Implementation and Evaluation of a Large-Scale School Screening Program for Detection of Pediatric Keratoconus***First Author: Neelima **BALAKRISHNAN****Co-Author(s): Rashmi **DESHMUKH**, Rohit **KHANNA**, Pravin **VADDAVALLI***

Purpose: A large-scale school screening program was designed to detect the population-based prevalence of allergic eye disease, Vernal Keratoconjunctivitis, and keratoconus in school-going children with an age range from 5 to 15 years. This study aimed to screen, diagnose, and refer school-going children with early symptoms and signs of these disorders, thereby enabling timely detection and appropriate treatment.

Methods: Students with ages ranging from 5 to 15 years were screened at various public and private schools in both rural and urban areas of 3 representative states. All children were administered an initial triaging questionnaire which aimed to identify symptoms of allergy, subnormal vision or habitual eye rubbing, followed by vision evaluation. All children aged 10 to 15 years were subjected to topography evaluation by a Scheimpflug-based topographer or a hand-held Placido-based portable topographer. Those aged 5 to 10 years were subjected to topography, and if there were any signs of allergic eye disease or subnormal vision noted on initial screening. Children with suspicious features on topography or on questionnaire-based evaluation were referred to tertiary centers for subsequent management. Measured outcomes included demographic data, ocular diagnosis, and treatment provided.

Results: Of the total population screened, consisting of 50000 children, 13.5% were referred to tertiary centers. 2% of the screened children were diagnosed with abnormal topography, and 5.9% of the children were diagnosed with features consistent with ocular allergy.

Conclusions: This program provides a framework to perform large-scale school screening to detect keratoconus and allergic eye diseases.

Abstract No.: 205114**Improving Cataract Surgery Outcomes Through Quality Management and Benchmarking: A Five-Year Analysis From Vietnam***First Author: Minh Ha **TRAN****Co-Author(s): Van Quy **DAM**, Thi Phuong **NGUYEN***

Purpose: To evaluate five-year trends (2020–2024) in cataract surgery outcomes and complications at a district-level hospital in Vietnam, and to assess how structured quality management and internal benchmarking supported improved outcomes and safe surgical training.

Methods: All cataract surgeries performed between 2020 and 2024 were retrospectively analyzed. Data included demographics, surgical technique, surgeon seniority, pre- and postoperative uncorrected visual acuity (UCVA), and complications. Surgeons were categorized as senior (having performed ≥ 500 prior phacoemulsification cases, $n = 2$) or junior (in training, $n = 4$). Describe quality assurance and internal benchmarking processes that were implemented.

Results: A total of 6,996 surgeries were performed (610 in 2020, 1,008 in 2021, 1,523 in 2022, 1,880 in 2023, 1,775 in 2024). The mean patient age was 71 ± 6.3 years, and 61% were female. Phacoemulsification comprised 98% of procedures. Senior surgeons performed 62–96% annually. The proportion of patients with severe preoperative impairment (UCVA $<20/200$) decreased from 50.2% to 36.4%. Postoperative UCVA $>20/60$ improved steadily from 61.5% (2020) to 87.9% (2024). Borderline outcomes (UCVA $<20/60$ – $20/200$) declined from 36.2% to 10.2%, while poor outcomes (UCVA $<20/200$) remained $\leq 3.6\%$. Intraoperative complications (Oxford Cataract Treatment and Evaluation Team grade 2–3) decreased from 5.9% in 2020 to 0.3% in 2024. Reoperation rates were 0.66% in 2020, 0.20% in 2021, 0% in 2022, 0.42% in 2023, and 0.06% in 2024. Three cases of postoperative endophthalmitis occurred (0.043%). Quality control included systematic recording of all surgical data, monthly team review, and auditing of every complication case to guide corrective action and maintain safety during training.

Conclusions: Cataract surgery outcomes improved consistently over the five years, with the proportion of eyes achieving UCVA $>20/60$ increasing to nearly 88% by 2024. Rates of intraoperative complications, reoperations, and endophthalmitis remained very low and within international benchmarks. The structured application of quality management, systematic data review, and internal benchmarking was instrumental in driving these improvements, ensuring patient safety, and supporting safe surgical training for junior surgeons.

Abstract No.: 205356**Incidence of Visual Impairment in a Multiethnic Asian Population Over a 12-Year Period: The Singapore Epidemiology of Eye Disease Study***First Author: Gabriel Dawei **YANG****Co-Author(s): Miao Li **CHEE**, Ching-yu **CHENG**, Charumathi **SABANAYAGAM**, Yih Chung **THAM***

Purpose: To evaluate the 12-year incidence of visual impairment (i.e., low vision and blindness) and its causes in a multiethnic Asian population.

Methods: The Singapore Epidemiology of Eye Diseases (SEED) Study recruited 10,033 adults at baseline (2004–2011). At the 12-year follow-up (2017–2023),

4,523 participants (1,327 Malays, 1,558 Indians, 1,638 Chinese) were re-examined. Low vision was defined as best-corrected visual acuity (BCVA) $<20/40$ but $>20/200$ and blindness as BCVA $<20/200$ in the better-seeing eye, based on the United States criteria. Incident low vision and blindness were identified at follow-up, and their causes were ascertained through standardized clinical examinations, retinal photography grading, and review of medical records. Poisson regression model with robust variance was applied to examine risk factors' association with visual impairment.

Results: Over 12 years, the age-standardized incidence of low vision was highest among Malays at 5.4% (95% CI: 4.0 -- 7.2), compared with 2.8% (1.8 -- 4.4) in Indians and 1.7% (0.9 -- 3.0) in Chinese. For blindness, the corresponding incidences were 0.0% (0.0--0.0) in Malays, 0.1% (0.0--0.9) in Indians, and 0.6% (0.2--1.5) in Chinese. Cataract was the leading cause of incident visual impairment (59.3%), followed by diabetic retinopathy (7.7%) and age-related macular degeneration (6.4%). Incident visual impairment was significantly associated with older age, Chinese ethnicity, diabetes, chronic kidney disease, lower household income ($< SGD 2,000/month$), and lack of formal education (all $P \leq 0.02$).

Conclusions: In this multiethnic Asian cohort, the 12-year incidence of visual impairment varied across ethnic groups, with Malays showing the highest rates. Leading causes of visual impairment are mostly treatable, with cataract remaining the predominant cause.

Abstract No.: 207766

Large-Scale Study in Chengdu, China: The Prevalence of Myopia Full-Correction Decreased With Increasing Myopia in Adolescents

First Author: Jing WEI

Purpose: This study investigated the situation related to myopia among students in Chengdu, a city in western China, and analyzed the prevalence of myopia spectacle wear and myopia full-correction and their influencing factors to understand the current status of myopia prevention.

Methods: A total of 1,582 schools in seven districts of Chengdu City, China, enrolling a total of 417,337 students aged 6-18 years (elementary, middle, and high school) from 2020 through 2022. Examination items included uncorrected visual acuity (UCVA), slit lamp examination, and non-cycloplegic autorefraction. Myopia was defined as non-cycloplegic SE $\leq -0.50 D + UCVA > 0 \log MAR$ (age ≥ 6). The prevalence of myopia spectacle wear is defined as the number of people wearing glasses for myopia/the number of people with myopia (%) within the study population, and myopia

full-correction is defined as normal vision after wearing glasses for myopia ($\leq 0 \log MAR$ for 6 years and above).

Results: The average age of the entire survey population was (10.96 ± 3.5) years, and the overall prevalence of myopia was 48.7%, myopia spectacle wear was 65.7% and myopia full-correction was 50.5%. With increasing age and educational levels, the prevalence of moderate to high myopia, the prevalence of myopia spectacle wear, and the prevalence of myopia full-correction all rise. The prevalence of mild myopia full-correction (46.5%) was higher than that for moderate myopia (47.1%) and even higher than that for high myopia (39.6%). The correct utilisation rate of myopic spectacles was 33.17%, increasing with age and education levels, with the highest correct utilisation rate of 40.7% among those with moderate myopia.

Conclusions: The prevalence of myopia among children and adolescents in Chengdu is relatively low, and the prevalence of myopia spectacle wear and myopia full-correction need to be improved, and it was found that with the increase of myopia, the prevalence of myopia full-correction among adolescents decreased instead.

Abstract No.: 204518

Longitudinal Analysis of the Impact of Bilateral Visual Acuity on Sleep Quality and Depression Among Patients With Diabetes Mellitus

First Author: Wei LIN

Co-Author(s): Zhong LIN

Purpose: To investigate the impact of bilateral visual acuity (VA) on sleep quality and depression in patients with diabetic mellitus using longitudinal data of the Fushun Diabetic Retinopathy Cohort Study.

Methods: All participants completed the Pittsburgh Sleep Quality Index (PSQI) and Center for Epidemiologic Studies Depression (CES-D) scales. Participants were reexamined at least 1 year later. Patients were categorized into three groups: high bilateral VA, moderate bilateral VA, and low bilateral VA. The parameters of PSQI and CES-D were analyzed between three groups.

Results: We enrolled 1408 patients with gradable fundus photography. Multivariate logistic regression analysis showed no association between the presence of DR or vision-threatening DR and global PSQI score and CES-D scale score. Patients with better bilateral visual acuity (VA) had lower global PSQI scores (β coefficient, 95% confidence interval [CI]: $-1.45, -2.07$ to -0.83) and lower CES-D scale scores (β coefficient, 95% CI: $-2.15, -3.30$ to -1.00). Sleep latency, sleep disturbance, daytime dysfunction, global PSQI score, proportion of poor sleep, CES-D scale score, and proportion of depression were all higher in the group with lower bilateral VA. During follow-up, incidence

or progression of DR were not significantly associated with global PSQI scores and CES-D scale scores.

Conclusions: Using longitudinal data, our study found a positive association between sleep quality or depressed mood and bilateral VA, while no significant association was found with DR incidence or progression.

Abstract No.: 204487

Longitudinal Changes in Astigmatism and the Association With Myopia: Findings From a 6-Year Cohort of School Children in Guangzhou, China

First Author: Xianghua **TANG**

Co-Author(s): Yin **HU**, Pingxiao **YANG**, Xiao **YANG**

Purpose: To characterize the longitudinal changes in astigmatism among school-age children, specifically across different refractive development states, and to explore its association with myopia progression and axial elongation.

Methods: A six-year prospective cohort study was conducted among 2,942 primary school children (1,381 girls) from Guangzhou, China, with a mean baseline age of 7.43 years. From 2018 to 2024, annual follow-up visits were performed, including cycloplegic autorefraction and axial length (AL) measurements. Children were stratified based on their refractive development trajectories.

Results: The Persistent Myopia group exhibited the most significant astigmatism progression, increasing from -1.166 ± 1.258 D to -1.846 ± 1.429 D ($P = 0.0048$). Astigmatism changes primarily manifested as with-the-rule (WTR) or against-the-rule (ATR) shifts (J0), while oblique astigmatism (J45) remained stable across all groups. Multivariate regression suggested higher baseline myopia, more axial elongation, and a persistent myopic trajectory as key risk factors. Linear mixed-effects modeling revealed two opposing trends based on refractive development status. During emmetropization, astigmatism decreased ($+0.074$ D per -1 D spherical change), whereas it increased in cases of persistent myopia (-0.026 D per -1 D spherical change).

Conclusions: This study demonstrates that the natural progression of astigmatism in school-age children is closely associated with their refractive development state. Astigmatism increases with myopic progression but may decrease during emmetropization. The association between astigmatism progression, myopia, and axial elongation provides crucial insights for predicting astigmatism changes and for informing clinical strategies.

Abstract No.: 206364

Natural History and Outcomes of Childhood Anisometropia in a Large Real-World Cohort

First Author: Xiaodong **CHEN**

Co-Author(s): Zhe **PAN**, Yaxing **WANG**, Tien Yin **WONG**

Purpose: To investigate the natural history and clinical outcomes of childhood anisometropia in a large real-world cohort.

Methods: This study included a cross-sectional analysis of 203,314 children aged 3–17 years and a longitudinal cohort of 97,693 children aged 3–15 years, with a mean of 3.6 visits over 5.2 years. Anisometropia was defined as an interocular spherical equivalent (SE) difference ≥ 1.0 D. Outcomes included age-specific prevalence, annual SE and axial length (AL) changes, and incident high myopia ($SE \leq -6.0$ D). Mixed-effects models estimated annual SE and AL progression, and interval-censored Cox models assessed prognostic implications.

Results: Cross-sectionally, anisometropia prevalence showed a biphasic pattern, decreasing from ages 3–7 and increasing from 8–17 years. Longitudinally, children without anisometropia at baseline progressed faster in SE (-0.36 vs -0.04 D/year) and AL (0.33 vs 0.29 mm/year), with higher high-myopia incidence. The greatest risk occurred in children who newly developed anisometropia (HR, 1.61; 95% CI, 1.41–1.84). In contrast, children who remained anisometropic (HR, 0.67; 95% CI, 0.56–0.81) or whose anisometropia resolved (HR, 0.22; 95% CI, 0.16–0.30) had the lowest risks. Baseline anisometropia versus none was protective (HR, 0.39; 95% CI, 0.31–0.48). Findings were robust across multiple sensitivity analyses, including alternative thresholds of anisometropia and high myopia, age-, SE-, AL- specific subgroups, and propensity score-matched analysis.

Conclusions: Childhood anisometropia follows an age-dependent biphasic course and provides prognostic information. Absence of anisometropia predicted faster progression and greater high-myopia risk, while persistence or resolution appeared protective. Monitoring interocular asymmetry may aid early identification and risk stratification.

Abstract No.: 201534

Oculomics-Driven Stratification of High Genetic Risk Individuals: A Pilot Study

First Author: Xiayin **ZHANG**

Co-Author(s): Ching-yu **CHENG**, Yangqin **FENG**, Meng **WANG**

Purpose: The retina provides a unique window for non-invasive in vivo assessment of systemic diseases. Most age-related systemic conditions are polygenic and involve complex genetic backgrounds. However, conventional methods for identifying genetic risk are often costly and laboratory-intensive, hindering timely detection and stratification. This study aimed

to evaluate whether, and to what extent, the retina photographs can estimate polygenic risk scores (PRS) and risk-stratify common complex diseases and traits.

Methods: A total of 55,938 high-quality fundus images from European-ancestry UK Biobank participants were divided into training, validation, and test sets. We assessed 36 standardized polygenic risk scores (PRS) for 28 diseases and 8 quantitative traits, sourced from external GWAS. Image features were extracted using our state-of-the-art foundation model (GlobeReady) to minimize domain shifts. These features trained a linear regression model for continuous PRS prediction and a binary classifier for extreme PRS stratification (top 3%). Fundus-specific uncertainty calibration improved clinical interpretability. Age-stratified analyses were also performed.

Results: The model performed poorly in predicting continuous PRS, with the highest for POAG (MAE = 0.80, $R^2 = 0.02$) and height (MAE = 0.58, $R^2 = 0.004$). In contrast, extreme PRS classification was effective for PRS of POAG (AUC = 0.74, F1 = 0.64) and height (AUC = 0.72, F1 = 0.73). Age-related macular degeneration (AMD) showed moderate performance (AUC = 0.59; F1 = 0.61). Age stratification revealed optimal prediction of POAG in the 40–50 group, AMD and Alzheimer's in those over 60, and consistent height prediction across ages.

Conclusions: Retinal imaging noninvasively detects extreme genetic risk, particularly for ocular conditions and highly heritable traits like height.

Abstract No.: 203374

Prevalence and Risk Factors of Undiagnosed Diabetic Retinopathy: The Tianjin Diabetic Retinopathy Screening Cohort Study

First Author: Juping LIU

Co-Author(s): Han BO, Chen CHEN, Fei GAO, Liying HU, Xiaorong LI, Emmanuel Eric PAZO, Yu SHI, Xiuqing ZHU

Purpose: To determine the prevalence and risk factors of undiagnosed diabetic retinopathy (DR) in patients with type 2 diabetes in a northern Chinese population.

Methods: A total of 4,090 participants from the Tianjin Diabetic Retinopathy Screening Cohort Study were enrolled. All participants underwent a questionnaire survey, physical examination, and non-mydriatic fundus examination. Logistic regression was used to identify clinical and sociodemographic factors associated with undiagnosed DR. Subgroup analyses were performed based on the best-corrected visual acuity of the worse-seeing eye and the presence of vision-threatening DR.

Results: Up to 94.1% of participants with DR were previously undiagnosed. Adjusted multivariable logistic regression analysis demonstrated that a higher number of comorbid ocular diseases (odds ratio [OR], 0.33, 95% confidence intervals [CI], 0.27–0.40), a longer duration of diabetes (OR, 0.96, 95% CI, 0.94–0.98), advanced

stages of severe non-proliferative diabetic retinopathy (NPDR) (OR, 0.33, 95% CI, 0.22–0.50) or proliferative diabetic retinopathy (PDR) (OR, 0.22, 95% CI, 0.10–0.48) were significantly associated with an decreased risk of undiagnosed DR. Denying a history of hyperlipidemia (OR, 2.03, 95% CI, 1.47–2.81), denying a history of renal disease (OR, 1.89, 95% CI, 1.24–2.87), or being unaware of whether they had renal disease (OR, 2.96, 95% CI, 1.46–6.01) were associated with an elevated risk of undiagnosed DR. However, this association disappeared in the blindness subgroup.

Conclusions: A substantial proportion of DR patients remain undiagnosed. It is crucial to identify the risk factors associated with undiagnosed DR in order to achieve earlier disease detection and prevent avoidable vision loss.

Abstract No.: 200828

Projecting the Future Burden of Blindness and Vision Loss: A Global Epidemiological Study Integrating 30-Year Trends and Bayesian Forecasts to 2050

First Author: Quanyong YI

Co-Author(s): Wai Kit CHU, Xueli SHAO, Tianyu WANG, Hongfei WENG

Purpose: To assess global blindness and vision loss (BVL) burden, including cataract, glaucoma, age-related macular degeneration (AMD), refraction disorders, near vision loss, and other vision loss, from 1990 to 2021 through prevalence and disability-adjusted life years (DALYs).

Methods: Data from the Global Burden of Disease study were analyzed. Health inequalities and system efficiency were evaluated using Slope/Concentration Indices of Inequality (SII/CII) and frontier analysis.

Results: Near vision loss dominated BVL burden (2021: 40% of global DALYs), with cases rising 170% and age-standardized rates increasing significantly. Cataract prevalence cases doubled (42.33 to 100.57 million), but age-standardized rates showed minor fluctuations (1145.05 to 1181.01 per 100,000); its DALY rate declined (91.06 to 76.97). Refraction disorders prevalence increased (95.98 to 159.77 million), yet age-standardized prevalence/DALY rates decreased (prevalence: 2053.56 to 1919.66; DALY: 88.04 to 79.11 per 100,000). Glaucoma, AMD, and other vision loss saw rising raw cases but declining age-standardized rates globally. Middle SDI regions experienced the greatest burden growth. South Asia and Sub-Saharan Africa had the highest burdens. Lower sociodemographic index (SDI)/socioeconomic status correlated strongly with higher BVL burden, though absolute inequalities slightly narrowed.

Conclusions: Sustained BVL reduction requires strengthened eye health systems, expanded early detection and treatment of preventable conditions

(especially presbyopia), and prioritized care for aging populations.

Abstract No.: 201505

Proteomic Profiling of Lens Capsule in Cataract Patients From High- and Moderate-UV Regions (Tibet Versus Beijing)

First Author: Shumei TAN

Co-Author(s): Xiaodan JIANG, Xuemin LI, Ziyuan LIU, Yuchen WANG

Purpose: Ultraviolet (UV) radiation is a major risk factor for age-related cataract (ARC). This study compared proteomic alterations in ARC patients from high-UV (Tibet) and moderate-UV (Beijing) regions.

Methods: This observational study adhered to the ethical principles of the Declaration of Helsinki for medical research involving human subjects. Anterior lens capsules were collected from 5 Beijing and 6 Tibet ARC patients matched for age, sex, and clinical parameters. Proteomic analysis was performed using SP3-based LC-MS/MS and DIA-NN. Bioinformatics analysis included GO and KEGG enrichment in R.

Results: We identified 313 differentially expressed proteins (DEPs) ($p < 0.05$ and $|FC| \geq 1.5$). Key antioxidant proteins (GPX1, GPX3, and GPX4) were downregulated in the Tibet group, whereas MGST2 was upregulated. The lens structural protein CRYBB3 (β -crystallin) and the mitochondrial functional protein CYCS were also significantly downregulated in the Tibet group. GO analysis revealed significant differences in molecular functions—including oxidoreductase activity, antioxidant activity, structural molecule activity, phospholipid-hydroperoxide glutathione peroxidase activity, selenium binding, glutathione peroxidase activity, and peroxidase activity—between the two groups. KEGG analysis indicated upregulation of peroxisome and arachidonic acid metabolism, and downregulation of ribosome, glutathione metabolism, and phenylalanine metabolism in the Tibet group.

Conclusions: Chronic high-altitude UV exposure may promote ARC pathogenesis through impaired antioxidant capacity, dysregulated lipid metabolism, and suppression of glutathione pathways. These findings provide novel insights into the molecular mechanisms of UV-induced cataract and suggest potential therapeutic targets.

Abstract No.: 206242

SIGHT: Advancing Super-Specialty Eye Care to Grassroots Populations in Rural Uttar Pradesh

First Author: Diva MISRA

Purpose: To evaluate the effectiveness of the SwarnJyoti Initiative for Grassroots Healthcare Transformation (SIGHT) in reducing preventable

blindness by expanding retinal and glaucoma care in underserved rural communities.

Methods: Specialty outreach camps were organized in rural Lucknow and adjoining regions. Screening was conducted using handheld fundus cameras and rebound tonometers, supported by local health workers. Patients with abnormal findings were referred to the base hospital for subsidized or Ayushman Bharat-covered treatments, including intravitreal injections, retinal and glaucoma surgeries, and long-term medication support.

Results: From 2022–2023, SIGHT screened 6,000 patients, diagnosing 300 with retinal diseases and 121 with glaucoma. In 2024, screenings expanded to another 7,050 patients, with 450 retinal cases and 130 glaucoma cases identified. Among these, 57% received definitive interventions (surgeries/injections/medications) at reduced cost. Outcomes included improved visual prognosis, increased treatment compliance, and reduced disease burden compared with baseline community data.

Conclusions: SIGHT demonstrates that super-specialty eye care delivery is both feasible and impactful at the grassroots level. The program has successfully scaled up screening and treatment for retinal and glaucoma diseases in rural Uttar Pradesh, improving patient outcomes through affordable, technology-enabled, and government-supported interventions. Expansion into pediatric, oculoplasty, and corneal subspecialties is planned.

Abstract No.: 206369

Ten-Year Changes in Diabetic Retinopathy Prevalence in Indonesia From 2014 to 2024: A Multiple Cross-Sectional Survey

First Author: Herdifitriane YANUARISTI

Co-Author(s): Anggraeni PUSPITA, Muhammad SASONGKO, Firman WARDHANA, Rifa WIDYANINGRUM, Felicia WIDYAPUTRI

Purpose: Diabetic retinopathy (DR) remains a leading cause of preventable blindness, reflecting both diabetes control and access to screening. The Jogjakarta Eye Diabetic Study in the Community (JOGED.COM) was an ongoing, community-based survey to map the prevalence of DR in the Indonesian population initiated in 2014. In the same year, 2014, Indonesia began significant health reforms, including the implementation of national health insurance and the integration of eyecare into the national health system. Therefore, we aimed to compare DR prevalence over the past decade to reflect the impact of this health system reform.

Methods: This was a community-based, multiple cross-sectional study of individuals with type 2 diabetes in Yogyakarta. The first cohort was recruited between 2014 and 2016 ($n=1184$), and the second cohort was

between 2021 and 2024 (n=2785). We used multistage, clustered random sampling. Two fields of retinal photographs were graded using the modified Airlie House classification into mild, moderate, and vision-threatening DR (VTDR).

Results: DR and VTDR prevalence declined from 43.1% and 26.3% to 34.4% and 17.3%. Mild and moderate NPDR increased slightly, while severe NPDR and PDR decreased. Declines were more pronounced in urban areas. Urban residence (OR 1.45, 95%CI 1.20–1.75), oral medication (OR 2.67, 95%CI 1.04–6.85), insulin use (OR 5.23, 95%CI 1.95–14.02), and combination therapy (OR 4.57, 95%CI 1.73–12.02) were significantly associated with DR.

Conclusions: DR and VTDR prevalence have decreased over the past decade, reflecting the positive impacts of health system reform on improved screening and diabetes management. However, the burden of VTDR remained substantial, highlighting the continued need for systematic interventions in Indonesia.

Abstract No.: 204965

The Association Between Socio-Behavioral Variables and Visual Impairment Among the Chinese Elderly: A Population-Based Cross-Sectional Study

First Author: Augusta Avril **TANG**
Co-Author(s): Kendrick Co **SHIH**

Purpose: Our objectives were to examine for associations between socio-behavioral variables and visual impairment in Chinese subjects 50 years and older, and also estimate the age- and gender-adjusted rate of visual impairment in this population.

Methods: This was a population-based cross-sectional survey. We included subjects who were local Chinese residents aged ≥ 50 , and scoring ≥ 7 in the Abbreviated Mental Test score. The fieldwork included a comprehensive eye examination, body measurements, and questionnaires on marital status, housing condition, overnight work, and smoking status, and was carried out from 20th May 2019 to 24th January 2020.

Results: Of the 2,665 included subjects, those aged ≥ 80 (vs 50-59: AOR 1.040, 95% CI 1.025-1.054), being widowed (vs unmarried: AOR 1.011, 95% CI 1.001-1.022), living in rental estate (vs private housing: AOR 1.089, 95% CI 1.050-1.129), with VFL ≥ 13 (vs ≤ 12 : AOR 1.006, 95% CI 1.000-1.012), attributed to the 3rd quartile of working overnight (vs never worked overnight: AOR 1.013, 95% CI 1.002-1.024), and the 4th quartile of cigarettes-smoking (vs never smoked: AOR 1.044, 95% CI 1.017-1.073) had significantly worse visual acuity (BCVA). Comparing pinhole VA with best corrected VA, there was a significant decrease in the age-and-sex adjusted rate from 7.99% (6.42-9.95) to 0.83% (0.30-1.91).

Conclusions: Worse visual acuity was highest among cigarette-smokers, followed by night-shift workers in the Chinese elderly, with increased AORs in the high-risk groups of age ≥ 70 , BMI ≥ 25 , hypertension, and VFL ≥ 13 . We propose investigating the adequacy of access to eye-care services in low socioeconomic areas of Hong Kong, and conducting longitudinal studies for follow-up.

Abstract No.: 205409

The Changing Landscape of Barriers to Cataract Surgery Among Adults Aged 50 Years and Older in Sarawak Zone of Malaysia: Comparative Analysis From the National Eye Survey II and III

First Author: Siti Nurhuda **SHARUDIN**
Co-Author(s): Fei Yee **LEE**, Norasyikin **MUSTAFA**, Mohamad Aziz **SALOWI**, Wan Radziah **WAN NAWANG**

Purpose: This study examined barriers to cataract surgery among adults aged 50 years and above in Sarawak, Malaysia, comparing findings from the National Eye Survey II (2014) and III (2023).

Methods: A population-based cross-sectional survey was conducted in 2023 using the RAAB methodology with multistage cluster sampling. Eligible participants underwent standardized visual assessments and structured interviews on barriers to cataract surgery.

Results: Of 4,933 eligible individuals, 4,748 were examined (96.2%). Operable cataract prevalence decreased from 27.1% in 2014 to 20.1% in 2023. In 2014, the main barriers were “need not felt,” unawareness, and fear of surgery. By 2023, “need not felt” dominated (48.1%), followed by unawareness (14.8%) and fear (10.7%), while financial and access barriers declined. Logistic regression in 2014 showed cost, provider denial, no access, and local reasons were significant predictors of poor vision. In 2023, “need not felt” (AOR: 0.480, 95% CI 0.278, 0.843, $p=0.010$), inability to afford (AOR: 4.537, 95% CI 1.810, 11.373, $p=0.001$), provider denial (AOR: 5.482, 95% CI 1.006, 29.879, $p=0.049$), and local reasons (AOR: 1.99, 95% CI 1.116, 3.549, $p=0.020$) remained significant.

Conclusions: Barriers in Sarawak have shifted from financial and access-related issues to perceptual and attitudinal factors. However, both traditional and emerging barriers continue to predict poor visual outcomes. Strengthened health education, financial support, and community engagement are essential to promote timely surgery.

Abstract No.: 203462**Thirteen-Year Risk of Myopic Complications by 3D-MRI-Defined Eye Shape in the Zhongshan High Myopia Cohort***First Author: Wei WANG*

Purpose: The long-term prognostic value of three-dimensional magnetic resonance imaging (3D-MRI)-defined eye shape in high myopia is not well established. This study aims to evaluate the association between baseline eye shape and 13-year risk of myopic complications.

Methods: This longitudinal cohort study, the Zhongshan High Myopia Cohort (ZHMC), included 190 highly myopic eyes (axial length ≥ 26.0 mm) from 126 patients who underwent 3D-MRI imaging at baseline and were followed for 13 years at Zhongshan Ophthalmic Center, Guangzhou, China. The mean (SD) baseline age was 32.0 (13.9) years, and 48.4% were female. Baseline global and detailed eye shapes were classified on 3D-MRI as non-deformed vs deformed, and into spheroidal, ellipsoidal, conical, nasally distorted, temporally distorted, or barrel-shaped morphotypes. Primary outcomes were axial length (AL) elongation trajectories and cumulative 13-year incidence of pathologic myopia-related complications, including myopic macular degeneration (MMD) progression, posterior staphyloma, subfoveal choroidal thinning, visual field defects, and visual impairment.

Results: Deformed eyes showed significantly faster AL elongation than non-deformed eyes (0.091 mm/year vs 0.047 mm/year; difference, 0.044 mm/year; $P < .001$). Baseline deformation was associated with higher risks of fast AL elongation (adjusted odds ratio [OR], 3.59; 95% CI, 1.18–10.93), subfoveal choroidal thinning (OR, 9.18; 95% CI, 2.14–39.44), and incident visual field defects (OR, 11.25; 95% CI, 1.99–63.49). In morphotype-specific analysis, nasally distorted eyes had the highest risk of fast AL elongation (OR, 5.56; 95% CI, 1.35–22.91) and MMD progression (OR, 4.64; 95% CI, 1.44–14.88), while conical eyes showed markedly elevated risk of visual field defects (OR, 9.69; 95% CI, 1.50–62.73).

Conclusions: In this 13-year cohort of high myopia, 3D-MRI-defined eye shape was a strong predictor of subsequent axial elongation and vision-threatening complications. Distinct morphotypes conveyed heterogeneous risk profiles, supporting the utility of eye shape phenotyping for individualized risk stratification in high myopia.

Abstract No.: 204397**Validation of Community-Based Vision Screening by Trained Community Health Workers Against Optometrist Standards***First Author: Maneck NICHOLSON**Co-Author(s): Radhika KRISHNAN, Ashwini ROGYE, Anshu SINGH*

Purpose: In low-resource settings like India, access to optometrists is limited & expensive. We trained local women as community health workers (“Sakhi” in Hindi means “friend”) to perform vision screenings and evaluated the accuracy of their assessments to those of optometrists for cost-effective programs.

Methods: Community health workers underwent one month of training in vision assessment and basic eye examinations under the supervision of an optometrist. Screening included distance visual acuity (VA) using the PEEK ACUITY vision app, near VA using the near vision booklet (multiple languages, numbers, and symbols for illiterate people), a basic torchlight examination, and history taking for common eye conditions in individuals aged 5 years and above. Door-to-door screening in urban slums covered 20,000 individuals; a 2% subset ($n = 500$) was randomly re-examined by optometrists, with complete data for 384 individuals analysed. Results were examined qualitatively for referral ($< 6/12$, $< N6$) and quantitatively for each eye (distance and near VA, logMAR). Sensitivity, specificity, PPV, NPV, tests for significance, and Pearson correlations were used to assess agreement.

Results: Referral decisions showed high accuracy: 164 true positives, 216 true negatives, 21 false positives, 17 false negatives; sensitivity 88% (83.3–92.5%), specificity 91% (88.6–95.4%), PPV 88.6% (85.5–94.1%), NPV 92.7% (86.8–94.1%), kappa = 0.81. Distance VA showed good agreement: OD mean 0.1909 vs 0.1872 ($r = 0.732$, $p = 0.75$, ICC = 0.72); OS mean 0.1764 vs 0.1859 ($r = 0.054$, $p = 0.66$, ICC = 0.65). Near VA: OD 0.38 vs 0.36 ($p = 0.42$); OS 0.41 vs 0.34 ($p = 0.03$), likely reflecting testing order, fatigue, or optometrist sensitivity.

Conclusions: Trained community health workers demonstrated high sensitivity and specificity, with strong agreement with optometrists. These findings support the use of community health workers for large-scale, cost-effective vision screening in underserved populations.

Ophthalmic Trauma

A Novel Animal Model of Intraretinal Proliferative Vitreoretinopathy Induced by Intravitreal Injection of 0.5M NaOH in Mice

First Author: Zhao YIMING

Co-Author(s): Lin XIAOFENG

Purpose: To establish a mouse model of retinal proliferation induced by retinal injury, and evaluate the retinal morphology and glial response in this animal model.

Methods: Healthy SPF C57BL/6J mice (6-8 weeks) were used in this study, and they were divided into the control group and the modeling group (intravitreal injection of four concentrations of NaOH solution: 0.3M, 0.5M, 0.75M, and 1.0M). On the 7th, 14th, and 28th day after modeling, eyeballs were enucleated for HE staining and immunofluorescence staining to observe retinal morphology, retinal thickness, and retinal gliosis.

Results: We developed a robust retinal injury model of intraretinal proliferative vitreoretinopathy in mice by intravitreal injection of 0.5M NaOH. At 7 days after modeling, HE staining images represented the retinal was thickening. Immunofluorescence staining showed that GFAP expression increased significantly, and Müller glial fibrous extended to the outer retina into the subretinal space, forming tiny glial scars. At 14 days after remodeling, retinal damage was aggravated with retinal folds, shrinkage of glial fibrous, and extensive glial scars. At 28 days after remodeling, retinal architecture was completely disorganized, and the retinas were thinning and shortening. Immunofluorescence staining with Vimentin and GS showed a large area of glial scars in the retina.

Conclusions: Intravitreal injection of 0.5M NaOH in mice can successfully elicit massive gliosis that will imitate the status of advanced proliferative vitreoretinopathy in patients. GFAP is a well-suited marker for early reactive gliosis. Glial responses and glial scars in the later stage can be evaluated by co-staining of Vimentin and GS in this animal model.

Abstract No.: 205093

Clinical Characteristics and Prognostic Factors of Visual Outcome in Patients With Anterior Chamber Foreign Bodies: A Retrospective Cohort Study

First Author: Shaolei HAN

Co-Author(s): Tingting WANG

Purpose: This study aimed to evaluate the clinical characteristics, management strategies, and prognostic factors affecting final best-corrected visual acuity

(BCVA) in patients with anterior chamber foreign bodies (ACFBs).

Methods: In this retrospective cohort study, 82 patients (82 eyes) with ACFBs who underwent intraocular foreign body removal between January 2012 and January 2022 were analyzed. Demographic characteristics, injury mechanisms, clinical manifestations, and surgical outcomes were systematically reviewed. Both univariate and multivariate logistic regression analyses were performed to identify factors associated with postoperative BCVA.

Results: Of 912 patients with intraocular foreign body (IOFB) injuries, 82 (9.0%) were diagnosed with ACFBs. The cohort exhibited a male predominance (85.36%) with a mean age of 39.18 years (range: 4–65). Time from injury to surgery ranged from immediate to 12 days (median: 1 day). Primary injury mechanisms included hammering metal (39.0%) and chiseling (12.2%). Foreign bodies comprised metallic fragments (63.4%), eyelashes (12.2%), and plant debris (8.5%). Common complications included traumatic cataract (26.8%) and secondary glaucoma (13.4%). Univariate analysis revealed significant correlations between final BCVA and baseline BCVA ($P < 0.001$), traumatic cataract ($P = 0.011$), secondary glaucoma ($P < 0.001$), and time to surgery >48 hours ($P = 0.025$). Multivariate analysis identified better baseline BCVA (OR = 11.24, 95% CI [6.38–19.82]) and absence of traumatic cataract (OR = 2.15, 95% CI [1.25–3.73]) as independent predictors of a favorable visual outcome.

Conclusions: Better baseline BCVA and the absence of traumatic cataract are critical determinants of good visual prognosis in ACFB patients. Our results support the clinical imperative of early surgical intervention (within 48 hours post-injury) and timely management of secondary complications for optimizing visual recovery.

Abstract No.: 203903

Clinical Features and Prognosis of Intraocular Foreign Body With Endophthalmitis

First Author: Hao CHEN

Co-Author(s): Yifan JIN, Wenlong WEI, Yong WEI, Zhenquan ZHAO

Purpose: To evaluate the clinical features and treatment outcomes of patients with IOFB with endophthalmitis, and analyze the prognostic factors affecting the anatomic and functional outcomes of patients.

Methods: Retrospective clinical study. A total of 1704 patients (1704 eyes) with IOFB were included. Endophthalmitis was diagnosed in 263 eyes. UCVA, BCVA, demographic and trauma characteristics, anatomical injury, clinical treatment, and outcome were recorded. GLMM was used to analyze the

correlation between the timing of treatment, nature of foreign body, nature of infection, number of operations, location of injury, and the anatomic and functional outcomes of patients.

Results: Mean age was 45.7±12.9 years. Magnetic, non-magnetic, unidentified metal and vegetable, mineral, animal and unidentified foreign bodies were 65.8%, 1.3%, 18.1%, 0.6%, 7.7%, 4.5%, 1.9%. The time between injury and removal of foreign body was (98.1±359.5) h. Microbiological examination showed 80 cases were positive for bacterial culture and 73 cases were negative. The mean preoperative UCVA was 1.67±0.79 logMAR. Preoperative visual acuity was strongly correlated with functional outcomes. Preoperative visual acuity and surgical method were closely related to the anatomical outcome. During 2015 to 2024, the incidence of intraocular foreign body-related endophthalmitis was 12.5%-22.7% with a fluctuating upward trend.

Conclusions: The incidence of intraocular foreign body-related endophthalmitis was 15.4%. In patients with intraocular foreign bodies with endophthalmitis, *Staphylococcus epidermidis* and *Bacillus cereus* are the first and second pathogenic bacteria. The incidence of endophthalmitis is not significantly reduced with intravitreal injection of cefazolin sodium. Preoperative UCVA and surgical method were closely related to the anatomic outcome of patients.

Abstract No.: 205840

Epidemiology and Surgical Outcomes of Mechanical Ocular Trauma in the United Kingdom: A Single-Centre Retrospective Study

First Author: Tsz Chun Jason WONG

Co-Author(s): Ankur BARUA, Hoi Ying Alicia LIU, Arijit MITRA

Purpose: Ocular trauma may cause significant visual impairment and numerous retinal complications without timely treatment, yet the epidemiology and surgical outcomes of ocular trauma in the Midlands, UK, remain outdated. This study aims to evaluate the characteristics of eye trauma patients and review their surgical outcomes.

Methods: A single-centre retrospective study was conducted on patients admitted with mechanical ocular trauma during 2022-2024 with surgical intervention. The Birmingham Eye Trauma Terminology (BETT) classification system and Ocular Trauma Score (OTS) were adapted to describe traumatic characteristics. Surgical outcomes were evaluated at presentation, immediately post-operation (post-op), and 3-month post-op using best-corrected visual acuity (BCVA) and intraocular pressure (IOP) adjusted score, which was calculated by absolute value difference between the reference range of 10-21 mmHg and the recorded IOP.

A smaller adjusted score indicates a better surgical outcome.

Results: Seventy-five patients (White 40%; Asian 29.3%) (mean age 43.3±22.0 years) were recruited. Males (80%) dominated ($p<0.0001$). The majority (86%) had graded OTS of 1-3. 73.3% had open wounds, 20% had intra-ocular foreign bodies, and 65.3% involved globe rupture. Notably, 25.3% presented with retinal detachment. Mean BCVA was improved at post-op and 3 months by 0.114 and 0.432 logMAR, respectively (both $p<0.0001$). Post-op, the mean IOP adjusted score improved by 1.861 mmHg ($p=0.005$) and stabilized without significant change at 3 months ($p=0.736$).

Conclusions: This study presented the updated epidemiology and surgical outcomes of traumatic eye injuries in the Midlands, using classification systems dedicated to ocular trauma on first-hand data. Our results show that timely operation may preserve and even enhance mean BCVA & IOP and avoid further structural or functional deterioration despite globe rupture and retinal detachment.

Abstract No.: 205843

Epidemiology and Surgical Outcomes of Traumatic Corneal Perforation: A Retrospective Study in a UK Tertiary Eye Emergency Centre

First Author: Tsz Chun Jason WONG

Co-Author(s): Ankur BARUA, Hoi Ying Alicia LIU, Arijit MITRA

Purpose: Corneal perforation is a frequent complication of ocular trauma and can cause significant visual impairment without timely treatment. However, there is a lack of up-to-date statistics that systematically summarise the epidemiology and clinical outcomes of traumatic corneal perforation in the United Kingdom (UK), especially in the Midlands.

Methods: A single-centre retrospective study was conducted on patients diagnosed with traumatic full-thickness corneal perforation between January 2022 and July 2024. The Birmingham Eye Trauma Terminology (BETT) Classification System and Ocular Trauma Score (OTS) were adapted to describe trauma characteristics. Surgical outcomes were evaluated with best-corrected visual acuity (BCVA) and intra-ocular pressure (IOP) at presentation, immediately post-operation, and three-month post-operation.

Results: Twenty-four cases (White, 41.7%; Asian, 33.3%; not specified, 25%) were recorded. Mean age was 42.2 years (SD=18.6), with no differences in eye laterality (left, 54.2%). The vast majority (87.5%) had graded OTS of 1-3. Males (85.7%) predominated the incidence. The majority, 58.3% had globe rupture, 95.8% open wounds, and 20.8% involved an intraocular foreign body. At presentation, the mean BCVA was 2.24 logMAR, with no significant changes at post-op (2.10)

and 3-month (1.91). The average IOP at presentation was 5.71, and improved and stabilized at 13.4 and 14 at post-operation and 3 months, respectively.

Conclusions: This study presented the updated epidemiology and clinical outcomes of traumatic corneal perforation cases in the UK Midlands. The ability to improve IOP to within the normal range highlights the importance of timely operation to effectively manage post-trauma hypotony and avoid further structural or functional deterioration despite globe rupture.

Abstract No.: 204853

Long-Term Outcomes After Pars Plana Vitrectomy for Branch Retinal Vein Occlusion With Vitreous Hemorrhage: A Retrospective Cohort Study From 2013 to 2022

First Author: Wei LIN

Co-Author(s): Mingxue REN, Yanlin ZENG

Purpose: To describe long-term outcomes after pars plana vitrectomy (PPV) for branch retinal vein occlusion (BRVO) with vitreous hemorrhage (VH) and identify factors that influence final vision and complications.

Methods: This was a single-centre, consecutive, retrospective cohort enrolling 341 eyes of 341 patients of BRVO with VH who underwent PPV between January 2013 and December 2022. Inclusion criteria were: BRVO with the presence of VH and a minimum follow-up of 3 months. Exclusion criteria were previous vitrectomy, concurrent retinal vascular disease, and other ocular diseases that influenced final outcomes.

Results: Mean age was 60.7 ± 9.8 years; 56.0% were female. Single-quadrant superotemporal BRVO predominated (58.6%). Intraoperatively, epiretinal membrane was present in 24.3%, macular oedema in 9.1%, retinal detachment in 24.0%, and neovascularisation elsewhere in 11.4%. Endolaser was applied in 96.5%, adjunct anti-VEGF in 7.0%, and silicone oil tamponade in 17.9%. Mean baseline BCVA was 1.38 ± 0.58 logMAR (Snellen $\approx 20/480$). At 3 months, BCVA improved to 0.56 ± 0.65 ($\approx 20/72$) and remained stable at 0.54 ± 0.75 ($\approx 20/69$) at a mean final follow-up of 21.4 ± 24.6 months (range 3–127). Multivariable regression identified baseline VA ($\beta = 0.094$, $P = 0.041$), postoperative neovascular glaucoma (NVG, $\beta = 2.195$, $P < 0.001$), and postoperative retinal detachment ($\beta = 1.661$, $P < 0.001$) as independent predictors of worse final VA, whereas pre-existing posterior vitreous detachment predicted better outcome ($\beta = -0.097$, $P = 0.034$). Complications occurred in 33.7% of patients. Recurrent VH (9.6%) and new-onset ME (8.8%) were most common; 4.4% developed recurrent retinal detachment requiring re-operation, and 0.6% developed NVG. Silicone oil tamponade and intraoperative retinal laser photocoagulation reduced the risk of recurrent VH (OR 0.129 and 0.193, respectively). Transient IOP

elevation >24 mmHg was noted in 7.0%, with only 1.5% progressing to secondary glaucoma.

Conclusions: PPV achieves rapid and sustained visual improvement in the majority of BRVO with VH. Final vision is principally determined by baseline acuity and avoidance of retinal re-detachment and neovascular glaucoma. Intraoperative retinal laser photocoagulation and appropriate tamponade selection minimise recurrent VH.

Abstract No.: 201699

Multi-Omics Profiling of Retinal Pigment Epithelium Reveals Enhancer-Driven Activation of RANK-NFATc1 Signaling in Traumatic Proliferative Vitreoretinopathy

First Author: Mengyu LIAO

Co-Author(s): Xiaohong WANG, Hua YAN

Purpose: To elucidate the epigenomic and transcriptomic reprogramming that underlies proliferative vitreoretinopathy (PVR) and to identify druggable signaling nodes in retinal pigment epithelium (RPE).

Methods: We subjected male mice to a standardized traumatic PVR model and performed ATAC-seq and ChIP-seq (H3K27ac, H3K4me1, H3K9ac) to capture chromatin accessibility and enhancer activation in freshly isolated RPE. Multi-omics sequencing was integrated to correlate enhancer states with gene-expression programs. Transcription-factor regulatory networks were constructed to identify master regulators, followed by intraocular delivery of (1) enhancer-blocking nanomedicines, (2) AAV-mediated NFATc1 shRNA, and (3) neutralizing anti-RANK antibody. Structural and functional outcomes were assessed by optical coherence tomography, electroretinography, and histopathology.

Results: Progressive PVR was accompanied by enhancer activation, with enhancers converging on the RANK-NFATc1 locus. Transcriptomic integration revealed a strong enhancer–promoter correlation driving fibroblast-associated gene signatures. Treatment with enhancer-blocking eNano-JQ1 reduced chromatin accessibility and PVR progression, AAV-shNFATc1 decreased NFATc1 and fibrosis, anti-RANK antibody attenuated membrane proliferation, collectively preserving retinal architecture and function.

Conclusions: Our findings elucidate the epigenetic basis underlying the activation of PVR-associated genes during RPE cell fate transitions and offer promising therapeutic avenues targeting epigenetic modulation and the RANK-NFATc1 axis for PVR management.

Abstract No.: 205132**Nine-Year Clinical Characteristics and Visual Outcomes of Post-Traumatic Endophthalmitis at a Tertiary Referral Centre in Thailand**

First Author: Dhanach **DHIRACHAIKULPANICH**
Co-Author(s): Thipsukon **AMNARTPANICH**, Pitipol **CHOOPONG**, Sathiya **KENGUNPANICH**

Purpose: To describe clinical characteristics, microbiological profiles, visual outcomes, and prognostic factors of post-traumatic endophthalmitis at a tertiary referral centre in Thailand.

Methods: A retrospective review was conducted of patients diagnosed with post-traumatic endophthalmitis between January 2014 and December 2022. Demographic data, clinical presentation, microbiological profiles, treatment, and outcomes were analyzed. Prognostic factors for poor final visual outcome (final visual acuity worse than 6/60) were assessed using logistic regression.

Results: Forty-eight eyes of 48 post-traumatic endophthalmitis patients were identified: 34 (70.8%) had penetrating injuries, 8 (16.7%) abrasions, and 6 (12.5%) ruptured globes. Causative organisms were identified in 25 patients (58.1%). Gram-positive bacteria predominated (29.1%), with *Staphylococcus* spp. (12.5%) and *Bacillus* spp. (10.5%) being the most common isolates. All patients (100%) received antimicrobial therapy, while 31 (64.6%) received topical corticosteroids. For surgical intervention, pars plana vitrectomy was performed in 28 patients (58.3%), while 5 patients (10.4%) required enucleation or evisceration. At final follow-up (median 7.7 months), 23 patients (47.9%) achieved visual acuity equal to or better than 6/60, whereas 15 (31.3%) remained with no light perception or required enucleation/evisceration. Univariable and multivariable logistic regression were performed for prognostic factors of poor visual outcome (visual acuity < 6/60). The analysis identified positive pathogen isolation (adjusted OR 6.57, 95% CI 1.67–25.88, $p=0.007$) as a predictor of poor outcome, while topical steroid treatment (adjusted OR 0.17, 95% CI 0.04–0.76, $p=0.020$) was associated with better prognosis.

Conclusions: Our findings highlighted the devastating visual consequences of post-traumatic endophthalmitis and suggested that identified positive pathogen isolation and topical steroid use might be potential prognostic factors for visual outcomes of post-traumatic endophthalmitis treatment.

Abstract No.: 205814**Open Globe Injuries and Their Visual Outcome Using Ocular Trauma Score in a Tertiary Care Centre of Central India**

First Author: Nidhi **MUNDADA**
Co-Author(s): Shobhita **KAVURU**, Rekha **KHANDELWAL**

Purpose: To assess visual outcome in Open globe injuries using the Ocular Trauma Score (OTS) at a tertiary care centre.

Methods: After ethical approval, a prospective study was conducted on all patients with open globe injury for a period of 24 months. Demographic data, injury details, initial visual acuity, time from injury to treatment, etc, were noted. The Ocular Trauma Score was calculated, and the final visual outcome at the end of three months after surgical intervention was compared with the OTS.

Results: The study included 55 open globe injury cases where M:F ratio was approximately 7:1. The average time from injury to presentation was 71.93 hours. 87.3% of injuries were penetrating, with farms and industries as the most common sites. The most common causes of OGIs were metallic objects (29.4%), glass (15.4%), and fireworks (9.4%). At presentation, 79% of patients had UCVA < 20/400. Post-treatment, 52% showed improvement in BCVA by two or more lines, while 45% remained unchanged, and 1.5% experienced deterioration. The visual prognosis was significantly influenced by the initial severity of injury, nature of the causative agent, and timely intervention ($p < 0.001$). Corneal injuries were the most frequent, followed by lens involvement and vitreous haemorrhage; the most common causes of poor vision were corneal scarring (34.5%) and traumatic cataract (30.9%).

Conclusions: Unilateral blindness is still largely caused by OGIs, particularly when they appear later. Even while frequent treatment improves outcomes, a significant portion of individuals do not regain functional eyesight. Early intervention and strict occupational safety measures could reduce the burden of OGIs.

Abstract No.: 205318**Overview of Ophthalmic Trauma in 2024**

First Author: Syeed Mehabub Ul **KADIR**
Co-Author(s): Md.Golam **HAIDER**, Ashfaque **KHAN**, Riffat **RASHID**

Purpose: to characterize the demographic profiles, patterns of injuries, management strategies, and clinical outcomes of individuals with ophthalmic injuries.

Methods: A Longitudinal study was conducted on ocular and adnexal injured patients at a tertiary eye hospital in Bangladesh from January to December 2024, including the injured patients of the mass

uprising movement in 2024. The study focused on gunshot-injured patients from July to December 2024. We analysed 1489 consecutive cases of ophthalmic injuries in 2024. Data collection included documenting the mechanisms of injury, imaging findings (X-ray, CT, B-scan), surgical interventions, and visual outcomes.

Results: A total of 1,489 ophthalmic trauma patients received treatment at NIOH. Among them, 700 cases were injured by gunshot in the July Revolution in Bangladesh. During the July Revolution, 699 out of 1,087 patients were treated at the National Institute of Ophthalmology. Radiological evaluations revealed metallic foreign bodies in 95.8% cases, while intraocular foreign bodies were found in 57.4% cases. Surgical interventions were required in 97.6% cases of ocular and adnexal injuries, primarily involving vitreoretinal surgery (63.9%), which was performed after a few weeks of primary repair for all patients. Severe vision loss was observed in 73.6% patients. Sixty-nine cases of bilateral ocular injuries exhibited worse outcomes.

Conclusions: Earlier management is an important tool for getting better outcomes for ophthalmic trauma patients. The ophthalmic trauma score may help assess the final visual outcome.

Abstract No.: 204365

Pediatric Traumatic Canalicular Lacerations: Epidemiology, Characteristics and Prognostic Factors

First Author: Shaolei HAN

Co-Author(s): Tingting WANG

Purpose: To investigate the epidemiological and clinical characteristics of pediatric traumatic canalicular lacerations and to analyze the prognostic factors influencing functional outcomes.

Methods: A retrospective study was conducted involving pediatric patients with primary canalicular lacerations treated at Hebei Eye Hospital between January 1, 2013, and December 31, 2022. Data on demographics, injury mechanisms, and surgical outcomes were collected through detailed medical record review. Univariate analysis using Fisher's exact test and multivariate logistic regression was performed to identify prognostic factors.

Results: A total of 89 pediatric patients (66 males and 23 females) with a mean age of 7.26 years were included. There were 65 patients with lower canalicular lacerations, 19 patients with upper lacerations, and 5 patients with concurrent lacerations. The most common cause of injury was trauma with sharp objects (52.8%), followed by electric bicycle accidents (18.0%), falls (18.0%), and dog bites (7.9%). Univariate analysis showed that the location of the laceration ($P=0.009$), mode of injury ($P=0.045$), and the time interval from injury to surgical repair ($P=0.032$) were significantly associated with functional outcomes.

However, age, gender, affected side, stent type, and removal timing did not significantly impact outcomes ($P>0.05$). Multivariate logistic regression analysis revealed that the time interval from injury to surgical repair was an independent prognostic factor for functional repair after surgery ($OR=16.43, 95\%CI 1.17-230.47, P<0.05$), while the location of the laceration and the mode of injury did not have a significant impact on the prognosis ($P>0.05$).

Conclusions: Time to surgical repair is an independent prognostic factor for functional recovery in pediatric canalicular lacerations. Improving public and caregiver awareness of injury risks and implementing preventive measures are essential to reduce incidence and improve outcomes.

Abstract No.: 204678

Posterior Segment Findings of Carotid-Cavernous Fistula Patients in a Tertiary Hospital

First Author: Oscar Jr ACOPIADO

Co-Author(s): Jose Carlo ARTIAGA, Felice Katrina RANCHE

Purpose: This study aims to describe the posterior segment findings in patients with carotid-cavernous fistulas (CCF), and to correlate these findings with treatment outcomes.

Methods: This is a single-center retrospective cross-sectional study employing a medical chart review of angiographically-confirmed CCF patients from January 2011 to December 2023. Demographic data, clinical findings, treatment, and posterior segment diagnoses were recorded for the initial visit and after at least 6 months of follow-up.

Results: A total of 141 patients, or 161 eyes, diagnosed with CCF using cerebral angiography were included. Direct CCF (DCCF) patients (63.8%) were of a younger population (mean age 35.2 years, $p<0.0001$), had male predominance (72.2%, $p<0.0001$), and generally had a history of trauma (95.6%, $p<0.0001$). Indirect CCF (ICCF) patients (36.2%) were more of an older population (mean age 50.6 years, $p<0.0001$), had female predominance (70.6%, $p<0.0001$), and were associated with vascular comorbidities such as hypertension (58.8%, $p<0.0001$) and diabetes (19.6%, $p<0.0001$). Mild to moderate visual impairment (VI) was more common in the indirect type (94.6%, $p=0.008$), while blindness VI was notably high in the direct type (14.6%). The most common posterior segment findings were retinal vessel tortuosity (35.2% in DCCF, 21.4% ICCF) and disc cupping (29.5% in DCCF, 23.2% in ICCF). The most common posterior segment diagnoses were secondary glaucoma (27.6% in DCCF, 25.0% in ICCF) followed by venous stasis retinopathy (21.9% in ICCF, 12.5% in DCCF). DCCF is associated with a high incidence of traumatic optic neuropathy, contributing to severe VI. No significant differences were observed by type

of CCF and type of treatment in terms of changes in posterior segment findings and diagnoses ($p>0.05$).

Conclusions: Approximately one-third of CCF patients will have posterior segment findings related to venous congestion, such as stasis retinopathy and secondary glaucoma, regardless of the type of CCF and treatment strategy. Blindness is more associated with DCCF.

Abstract No.: 203756

Revised Ocular Trauma Score (rOTS): To Develop and Internally Validate a Predictive Model for Visual Outcomes After Open Globe Injury

First Author: Thansit **SRISOMBUT**

Co-Author(s): Somporn **CHANTRA**, Dolchanok **DOLMAN**, Parinee **KEMCHOKNATEE**, Rinrada **KREESANG**, Pennung **THONGTONG**, Nattaporn **VONGSA**

Purpose: We aimed to develop and validate a prognostic scoring model for predicting poor visual outcomes in patients with open globe injury (OGI).

Methods: A retrospective cohort study of patients with OGI from two teaching hospitals in Thailand. 311 patients diagnosed with OGI between 2016 and 2023 were used to develop a multivariable logistic regression model predicting final visual acuity aimed at 6 months post-OGI. Visual outcomes were categorised into two groups using 20/200 as the cut-off for legal blindness. The model's performance was evaluated using receiver operating characteristic curve analysis. Internal validation was conducted with bootstrapping for 500 replications.

Results: Among the patients, 133 (42.77%) had visual acuity worse than 20/200 at the 6-month follow-up. The median follow-up time was 4.14 months, with an IQR of 3.00–11.74 months. Initial visual acuity (VA), relative afferent pupillary defect, rupture, and eyelid injury were among the strongest predictors of visual outcome. Discrimination and calibration of the scoring model were satisfactory, with a C-statistic of 0.8671, a slope of 1 and a calibration-in-the-large of 0. Risk groups were created, categorised as mild, moderate, and severe, with a C-statistic of 0.8094. The ORs for poor final VA ($\leq 20/200$) at 6 months were 1.51 (95% CI, 0.93–2.48) and 45.06 (95% CI, 11.20–387.94) in the moderate and severe risk groups, respectively.

Conclusions: Revised Ocular Trauma Score can be seamlessly used in emergency settings to predict visual outcomes in patients with OGI. Presenting visual acuity (VA) is the strongest predictor. External validation of our model is needed.

Abstract No.: 206226

Risk Factors of Refractory Hypotony After Vitrectomy in Open Globe Eye Injuries

First Author: Yuntao **HU**

Co-Author(s): Kang **FENG**, Wan **LU**, Zhizhong **MA**

Purpose: To explore the risk factors contributing to refractory hypotony in open globe injuries after vitrectomy.

Methods: A total of 211 eyes of open globe injuries were retrospectively studied from the Eye Injury Vitrectomy Study, EIVS. Among them, rupture 121 eyes; penetrating 52 eyes; perforating 15 eyes; intraocular foreign body 23 eyes. All injured eyes underwent vitrectomy. That refractory hypotony was supposed to be sustained IOP with silicon oil filled less than 10mmHg, and IOP without silicon oil less than 8mmHg. The mean time of follow-up was 20 months.

Results: Among the cases, 98 eyes (46.45%) met the criteria of refractory hypotony. rupture 64 eyes (65.31%); penetrating 19 eyes (19.39%); perforating 6 eyes (6.12%); intraocular foreign body 9 eyes (9.18%). Multivariate analysis revealed that refractory hypotony was significantly related to involvement of injuries with the ciliary body ($P=0.036$) or the choroid ($P=0.004$), and the scope of retinal coloboma ($P=0.003$), but there was no significant relation to the size of the eye wound.

Conclusions: In this study, we determined the risk factors of refractory hypotony after vitrectomy in open globe eye injuries. They included ciliary body or choroidal damage, and the scope of retinal coloboma and retinectomy. It may be helpful for saving injured eyes to take aim measures according to risk factors in the treatment of open globe injuries.

Abstract No.: 200688

Surgical Features of Traumatic Cataract: Lessons From 4 Years of War

First Author: Ilya **KOLOMIETS**

Purpose: To share clinical insights and refined surgical strategies for managing traumatic cataracts in wartime conditions, emphasizing visualization techniques, capsular management, and intraoperative decision-making in complex anterior segment trauma.

Methods: This retrospective clinical analysis summarizes the experience of traumatic cataract surgery over four years of active military conflict. The cases included eyes with anterior capsule rupture, zonular dialysis, vitreous prolapse, and intralenticular foreign bodies. Surgical workflow emphasized ocular stabilization, meticulous wound revision, and control of intraocular pressure prior to cataract removal. Intraoperative visualization was optimized via corneal epithelial debridement, vital dye-assisted capsulorhexis, and use of oblique illumination. Mechanical pupil dilation and synechiolysis were

employed for miotic pupils. Capsulorhexis technique was adapted to the state of zonular support, utilizing forceps, cystotome, or scissors. Anterior vitrectomy was performed in cases with vitreous loss. Hydroprocedures were cautiously used or replaced by viscodissection in the presence of suspected posterior capsule rupture. IOL fixation techniques were chosen based on intraoperative findings, including sulcus implantation, Yamane or Canabrava scleral fixation methods.

Results: Surgical outcomes were optimized through tailored intraoperative tactics addressing structural instability, poor visualization, and capsular compromise. Adaptability in instrumentation and IOL fixation allowed successful visual rehabilitation even in severely traumatized eyes.

Conclusions: Wartime conditions impose unique challenges in cataract trauma surgery, demanding flexible, experience-driven approaches. Mastery of visualization enhancement, individualized capsule management, and IOL fixation strategies is essential for safe and effective outcomes in high-stress surgical environments.

Abstract No.: 200475

Visual Outcome Following Firecracker Ocular Injuries – Multicentric Prospective Study

First Author: Deepika R
Co-Author(s): Sabarinath A

Purpose: To study the demographics, type of ocular injuries, management, and visual outcome of the patients with firecracker-related ocular injuries.

Methods: This is a multicentric prospective study conducted among 254 patients who presented to the emergency and outpatient departments during Diwali 2023 across various centers of the Aravind Eye Care System. Data collected include age, sex, laterality, best-corrected visual acuity (BCVA) at the time of presentation, presenting symptoms, type of firecracker, active participation or passive observation, type of ocular injury, management, and visual outcome.

Results: Out of 254 patients, 198 were males, and 56 were females. The Mean age of presentation was 19.76 ± 15.34 . 211 patients (83.3%). 1/3rd of our patients were observers. 14 % presented with blindness. 4 % had open globe injuries. 90 % had normal visual recovery with prompt measures, either conservative or surgical management based on injuries.

Conclusions: Patient with severe visual Impairment at presentation and those with Open Globe injuries had poorer outcome. The Lack of Knowledge about safety measures or failure to adhere to them contributed to the incidents.

Orbital and Oculoplastic Surgery

Abstract No.: 202444

A Case of Atypical Waardenburg Syndrome Caused by Chromosomal Microdeletion

First Author: Xianzhi ZHAO
Co-Author(s): Zeyi LI

Purpose: This study aims to report a case of atypical Waardenburg syndrome (WS) with ocular manifestations as the main feature, caused by a 22q12.3-q13.1 microdeletion (including the SOX10 gene).

Methods: A child with WS, admitted to the Joint Shantou International Eye Center of Shantou University and The Chinese University of Hong Kong on April 14, 2024, was selected as the research subject.

Results: A 7-year-old boy presented with a history of inability to fully open the left eye since infancy. No hearing impairment was noted. Physical examination findings included: depigmentation on the back skin; VOD: 0.1, corrected to 0.3 with -1.00DS/-5.00DC $\times$ 170°; VOS: 0.1, corrected to 0.3 with -2.50DS/-4.00DC $\times$ 25°; left palpebral fissure was 4mm shorter than the right; 45° exotropia of the left eye; complete gray-white iris of the left eye; and retinal depigmentation in both eyes. Chromosomal microarray analysis confirmed deletion of the SOX10 gene. The patient was diagnosed with Waardenburg syndrome upon admission. He first underwent left frontal muscle flap suspension surgery in our hospital. Subsequent left eye strabismus surgery was recommended.

Conclusions: Chromosomal microdeletions in Waardenburg syndrome (WS) are rarely reported, with only 6 relevant cases identified so far. We conclude that comprehensive molecular analysis of all WS-associated genes is essential. This analysis should encompass not only point mutations but also chromosomal microdeletions, to facilitate more accurate diagnosis and reduce the risk of missed or misdiagnoses of WS.

Abstract No.: 202788

A Case of Chronic Dacryocystitis Secondary to Nasolacrimal Duct Injury From an Orbital Fracture Repair Plate

First Author: Yasushi FUJITA
Co-Author(s): Miwa AIKAWA, Tomoyuki KASHIMA, Yohei SATO

Purpose: We report a case of chronic dacryocystitis resulting from iatrogenic nasolacrimal duct injury caused by an orbital fracture repair plate placed at another institution.

Methods: A 35-year-old woman sustained fractures of the left orbital floor and medial wall following a fall. She underwent orbital fracture repair at another hospital, after which she developed persistent left-sided epiphora and purulent discharge, leading to a diagnosis of chronic dacryocystitis. As symptoms persisted, she was referred to our institution. On presentation, examination revealed an elevated tear meniscus, complete obstruction on lacrimal irrigation from both upper and lower puncta, and purulent reflux. Orbital CT demonstrated that the implant traversed the nasolacrimal duct. Dacryoendoscopy directly confirmed the interruption of the duct by the implant.

Results: Through a transconjunctival inferomedial approach, partial removal of the orbital implant (Super Fixorb®) was performed at the site of ductal transection. Under dacryoendoscopic guidance, the residual nasolacrimal duct was visualized, and a lacrimal intubation tube was successfully placed. Postoperatively, lacrimal irrigation was patent, and the patient's symptoms resolved.

Conclusions: We encountered a rare case of nasolacrimal duct transection secondary to orbital fracture repair. This case highlights the importance of carefully considering the anatomical relationship between orbital implants, the lacrimal sac, and the nasolacrimal duct during fracture reconstruction to prevent iatrogenic injury.

Abstract No.: 203483

A Case of Lacrimal Sac Diverticula: Endoscopic Management and Literature Review

First Author: Wang CHENGMEI

Purpose: We would like to submit an original research article entitled "A Case of Lacrimal Sac Diverticula: Endoscopic Management and Literature Review". In the article, we aim to present a case of lacrimal sac diverticula. To improve the understanding and management of lacrimal diverticula and reduce the misdiagnosis rate. Early detection and surgical intervention for the disease can prevent complications like infection or fistula formation.

Methods: A 52-year-old female presented with a 4-year history of left eye epiphora. Clinical evaluation and imaging confirmed left lacrimal sac diverticulum and nasolacrimal duct obstruction. The patient underwent left endoscopic dacryocystorhinostomy (DCR) with lacrimal stent placement under general anesthesia. Intraoperatively, The diverticulum was integrated with the lacrimal sac cavity by resecting the interposing septum. Postoperatively, epiphora resolved completely, and the DCR ostium demonstrated optimal patency and epithelialization, at 1- and 3-month follow-ups.

Results: Under general anesthesia, endoscopic DCR with stent placement was performed. A cystic

mass severely compressed and displaced the native lacrimal sac inferonasally. The diverticular septum was excised, creating a unified sac cavity. At 1-month follow-up, epiphora resolved completely. Endoscopy confirmed a patent DCR ostium with sac-diverticulum communication. The stent was removed at 3 months, revealing a well-epithelialized, appropriately sized ostium.

Conclusions: Surgical intervention is recommended for symptomatic diverticula to prevent complications like infection or fistula formation. Options include dacryocystorhinostomy (DCR) and diverticulectomy.

Abstract No.: 202191

A Novel Nomogram Based on Orbital MRI Parameters for Early Prediction of Dysthyroid Optic Neuropathy in Thyroid-Associated Ophthalmopathy

First Author: Xianzhi ZHAO

Co-Author(s): Yongran LI, Zeyi LI

Purpose: This study aimed to assess orbital magnetic resonance imaging (MRI) differences across various severity levels of thyroid-associated ophthalmopathy (TAO) and compare them to healthy controls. Additionally, it investigated the correlation and diagnostic potential of multiple MRI parameters for dysthyroid optic neuropathy (DON).

Methods: Patients with TAO were classified into mild TAO (66 orbits), moderate-to-severe TAO (59 orbits), and DON (21 orbits). A control group of 25 healthy orbits was also included. Comprehensive ophthalmic exams were done. Generalized estimating equation (GEE) was used to analyze the clinical and MRI data. Univariate and multivariate binary logistic regression identified independent risk factors for DON. The predictive value of MRI parameters for DON was further evaluated using a nomogram, receiver operating characteristic curve, and decision curve analysis.

Results: Significant variations in angle between the medial rectus and optic nerve (AMR-ON) and angle between the lateral rectus and optic nerve (ALR-ON) were observed across the control, mild TAO, and moderate-to-severe TAO groups compared to the DON group ($P < 0.05$). Regression analysis revealed superior rectus muscle area (SRA) and AMR-ON as independent predictors of DON ($P < 0.05$). The SRA + AMR-ON nomogram demonstrated high predictive performance for DON, with an AUC of 0.906 ($P < 0.001$). DCA further confirmed that the SRA + AMR-ON model outperformed Muscle Index and Crowding Index in predictive efficacy for DON.

Conclusions: SRA and AMR-ON serve as independent predictors for DON, and the predictive model combining these parameters is highly effective in forecasting DON onset.

Abstract No.: 206274

Advancing Orbital Blowout Fracture Repair With AI-Assisted Surgical Planning

First Author: Yining WEI

Co-Author(s): Yuan DENG, Yinwei LI, Wodong SHI, Huifang ZHOU

Purpose: Precise reconstruction of orbital blowout fractures remains challenging, especially for large complex defects. Conventional approaches often result in suboptimal restoration of orbital anatomy and complications.

Methods: We applied a novel AI-assisted surgical planning method incorporating patient-specific 3D printed models in 20 patients with orbital blowout fractures. The main outcome was the efficacy of the surgical repair assessed at 6 months after the surgery. Visual acuity, enophthalmos, ocular movement, double vision condition, designing time of reconstructed orbital model, operative time, and complications were also evaluated.

Results: The method was effectively applied for all patients. Postoperative follow-up revealed no significant enophthalmos. CT scans confirmed adequate orbital reconstruction with no soft tissue incarceration. Four of 5 patients with preoperative visual impairment showed improved visual acuity. Ocular movement restriction was largely relieved, with only 2 patients exhibiting slight residual limitation. Diplopia improved in 10 of 11 affected patients, though 1 patient reported intermittent worsening. The mean time for designing the orbital model was 92.95 ± 7.36 seconds, and the average operation time was 44.65 ± 16.58 minutes. No severe complications were observed.

Conclusions: This AI-assisted method is safe and effective for orbital blowout fracture repair. By enabling precise anatomical reconstruction, it can enhance the patients' functional and cosmetic outcomes, offering a promising approach for individualized orbital reconstruction.

Abstract No.: 203103

Analysis of Eye-Related Factors Affecting the Formation of Amblyopia in Patients With Congenital Ptosis

First Author: Weiwei ZHANG

Co-Author(s): Xiaoxia REN, Jingjing WANG

Purpose: To observe the refractive characteristics and incidence of amblyopia in patients with congenital blepharoptosis, and analyze the eye related factors influencing the formation of amblyopia in patients with congenital ptosis.

Methods: Retrospective case analysis study. The clinical data of 696 cases (1,007 eyes) with congenital blepharoptosis in Shanxi Ophthalmic Hospital from January 2016 to December 2019 were retrospectively

analyzed, including uncorrected visual acuity, best corrected visual acuity, levator function, ptosis degree, spherical equivalent, astigmatism, astigmatism type, strabismus, and amblyopia. According to the degree of ptosis, the patients were divided into mild, moderate, and severe groups. The uncorrected visual acuity, best corrected visual acuity, spherical equivalent, spherical diopter, astigmatism, incidence of amblyopia, and astigmatism were compared among the three groups. Binary logistic regression was used to analyze the related factors of amblyopia in patients with congenital ptosis.

Results: 1. Patients with monocular amblyopia were more likely to have anisometropic, and patients with binocular amblyopia were more likely to have ametropic amblyopia (all $P < 0.05$). The incidence of amblyopia and astigmatism in patients with severe congenital ptosis was higher than that in mild and moderate patients (all $P < 0.05$). The astigmatism in severe patients was higher than that in mild to moderate patients ($P < 0.05$). 2. The incidence of amblyopia in OBL was higher than that in WTR and ATR ($P < 0.05$). 3. SE, amblyopic anisometropia, amblyopic ametropia, strabismus, and OBL were the risk factors of amblyopia with congenital ptosis.

Conclusions: 1. Patients with amblyopia in severe congenital ptosis are often accompanied by refractive abnormalities and/or strabismus. Compared with patients with mild to moderate congenital ptosis, the incidence of amblyopia and astigmatism in severe congenital ptosis patients was higher. 2. SE, amblyopic anisometropia, amblyopic ametropia, strabismus, and OBL were the risk factors of amblyopia with congenital ptosis.

Abstract No.: 203614

Analysis of Recurrence Reasons After Lacrimal Punctoplasty

First Author: Pang ZUOXIANG

Purpose: To analyze the possible reasons for recurrence after lacrimal punctoplasty.

Methods: During January 2022 to June 2024, 94 patients (178 eyes, 84 bilateral, 10 unilateral) with narrow or occluded lacrimal punctums received lacrimal punctoplasty by the same ophthalmologist. Among these, 15 cases (2 males, 13 females) showed no improvement in postoperative epiphora. Physical examination revealed edema and/or congestion of the lacrimal punctums, indicating stenosis or occlusion. We conducted further testings for common autoantibodies associated with ocular surface diseases (ESR, RF, SSA, SSB, HLA-B27, HLA-B51, HLA-DRw53-DNA). Fourteen patients underwent testing, while one male patient refused the examination and was subsequently lost to follow-up.

Results: Among 14 patients with postoperative recurrence, 11 (78.6%) tested positive for HLA-DRw53-DNA, with 4 cases additionally positive for HLA-B51. One female patient tested positive for HLA-B51, while another showed positivity for HLA-B27 with an ESR of 25 mm/h. The latter had a three-year history of iritis and ankylosing spondylitis. Only one patient tested negative for all markers. All patients demonstrated negative results in SSA/SSB/RF testing.

Conclusions: In cases of recurrence after lacrimal punctoplasty, the possibility of autoimmune disease should be considered. Further testing of relevant biomarkers is recommended, with HLA-DRw53-DNA, HLA-B27 and HLA-B51 being suggested as routine screening. Caution should be exercised before performing this procedure if there is or may be a history of autoimmune disease, or if there is congestion or edema of the lacrimal punctum.

Abstract No.: 202676

Anterior Segment Optical Coherence Tomography in Punctal Stenosis: A Clinical Correlation and Proposed Grading Scale

First Author: Tabitha GHEEVARGHESE

Co-Author(s): Shruthi TARA

Purpose: To correlate anterior segment optical coherence tomography (ASOCT) parameters with patient-reported symptoms and slit-lamp based punctal anatomy in punctal stenosis.

Methods: We conducted an observational, cross-sectional study of patients aged 50-80 years with idiopathic inferior punctal stenosis. A detailed history and clinical evaluation were done to exclude factors that could alter natural disease progression, iatrogenic interventions, and other causes of epiphora. Epiphora severity was assessed using the Munk scale, and external punctal anatomy was graded on slit lamp biomicroscopy using the Kashkouli scale. Swept-source ASOCT was used to measure parameters such as Outer Punctal Diameter (OPD), outer and inner Internal Punctal Diameters (oIPD, iIPD), Mean Internal Punctal Diameter (mIPD), and Vertical Punctal Depth (VPD).

Results: OPD showed the strongest correlation with Munk scale. A new metric introduced in our study, mIPD, demonstrated the most consistent and progressive correlation with Kashkouli scale. An OPD cut-off value was proposed to diagnose punctal stenosis in this age group. We also developed a grading scale based on mIPD to assess disease severity, monitor progression, and compare treatment outcomes. These results align with previously published studies on ASOCT in punctal stenosis.

Conclusions: The OPD cutoff had high sensitivity and positive predictive value and may be used as a screening tool. A grading system based on mIPD could accommodate inherent flaws in measurement using

ASOCT. This enables an objective approach to using ASOCT for diagnosis, providing research criteria and comparing treatment outcomes in punctal stenosis.

Abstract No.: 203285

Artificial Intelligence in Thyroid Eye Disease Imaging: A Systematic Review

First Author: Haiyang ZHANG

Co-Author(s): Hoi Chi CHAN, Xianqun FAN, Ziyuan LI, Huifang ZHOU

Purpose: This systematic review aims to characterize the current research landscape of artificial intelligence applications in thyroid eye disease, identifying key challenges and future directions.

Methods: Following PRISMA guidelines, a comprehensive literature search was conducted up to January 2025 across multiple databases. Studies utilizing AI with CT, MRI, nuclear, facial, or retinal imaging in TED patients were included. The quality of each study was critically assessed using the APPRAISE AI tool.

Results: A total of 41 studies were included, with sample sizes ranging from 33 to 2,288 participants, predominantly of East Asian ethnicity. Computed tomography and facial imaging were the most common modalities. The research addressed both clinical tasks (diagnosis, activity assessment, severity classification, and treatment prediction) and technical tasks, with image classification being the most frequent. Deep learning models, particularly ResNet and VGG, were predominantly employed. The overall quality of the included studies was moderate.

Conclusions: In conclusion, image-based AI demonstrates significant potential for enhancing diagnostic precision and guiding personalized treatment in TED. However, future work should focus on more robust study designs, developing public datasets, integrating multimodal imaging, and fostering interdisciplinary collaboration to accelerate clinical adoption.

Abstract No.: 201980

Bilateral Superior Ophthalmic Veins Infiltration by IgG4-related Ophthalmic Disease with concomitant Thyroid-Associated Orbitopathy: a Case Report

First Author: Elaine WONG

Co-Author(s): Karen Kar-wun CHAN, Kam Lung Kelvin CHONG, Alvin Lerrmann YOUNG

Purpose: Presentation of a rare case of definite IgG4-related ophthalmic disease with bilateral infiltration of superior ophthalmic veins (SOVs) and lacrimal glands.

Methods: Retrospective case report.

Results: A 69-year-old man with a history of thyrotoxicosis presented with a 6-year history of increasing prominence, eye redness, and lid swelling. He was clinically compatible with active Thyroid Associated Orbitopathy (TAO) with a clinical activity score of 4 out of 7. His Orbital Computed Tomography confirmed TAO; however, it incidentally found bilateral engorged SOVs. Cerebral angiogram ruled out carotid-cavernous fistula. The patient showed a partial response to two cycles of intravenous pulsed methylprednisolone but rebounded shortly. Orbital Magnetic Resonance Imaging was performed, which revealed marked dilatation of bilateral SOV filled with soft tissue, with adjacent infiltrative soft tissue densities and associated enlargement of bilateral superior ophthalmic nerves and lacrimal glands. Left anterior SOV and lacrimal gland incisional biopsies were performed. Pathology revealed a dense lymphoplasmacytic lesion with storiform fibrosis that stained more than 100 IgG4-positive cells per high-power field in the superior ophthalmic vein and lacrimal gland. Diagnosis of definite IgG4-related ophthalmic disease (IgG4-ROD) infiltrating bilateral SOV and lacrimal glands is reached. The patient was started on a Rituximab-biosimilar, with disease stabilization and improvement.

Conclusions: This case represents the first definite IgG4-ROD of SOV, presenting as gross bilateral SOV enlargement and coexisting with TAO. Good response was only achieved with anti-CD20 monoclonal antibodies. This important differential should be considered in bilateral, grossly enlarged, tumefactive SOVs.

Abstract No.: 201163

Biopsy First and Early Immunomodulation Protocol for Orbital Inflammatory Disease

First Author: Raghuraj HEGDE

Co-Author(s): Shruthi KRISHNA, Abhishek PATIL, Prithvi VISHWANATH

Purpose: To analyze the outcomes of early biopsy and immunomodulation as the first-line management of orbital inflammatory disease.

Methods: A prospective study of 50 patients with orbital inflammatory disease was conducted between September 2023 and May 2025 in a tertiary care center. Data collected and analyzed included demographic details, initial diagnosis and management before presentation, radiological findings, histopathological reports of the specimen, immunomodulation, case-appropriate systemic investigations, and response to treatment at 1, 3, and 12-month follow-up periods. Institutional Review Board approval was obtained.

Results: All cases had unilateral presentation except 1. 12 patients were treated with multiple trials of corticosteroids before presentation to our center. The majority of the patients were treated by incision

biopsy followed by immunomodulation. Few cases received only immunomodulation. Immunomodulation was initiated and modified at follow-ups by the immunologist. Statistical analysis showed that biopsy on presentation and initiation of early immunomodulation reduced recurrent episodes to a bare minimum and resulted in long-term remission.

Conclusions: The "Biopsy first" and early immunomodulation approach should be considered as the primary management of orbital inflammation instead of the standard practice of corticosteroid trial. Excellent remission rates can be achieved with this protocol.

Abstract No.: 206127

CD34+ Orbital Fibroblasts Contribute to the Pathogenesis of Thyroid Eye Disease via miR-182-5p

First Author: Sijie FANG

Co-Author(s): Yinwei LI, Jing SUN, Baiguang YU, Huifang ZHOU

Purpose: CD34+ orbital fibroblasts (OFs) play a pathogenic role in thyroid eye disease (TED). Several micro (mi)RNAs have been shown to promote TED progression. This study aims to explore the regulatory effects of miRNAs on CD34+ OFs and to find potential therapeutic targets.

Methods: In this case-control study, orbital connective tissues (OCTs) and OFs were obtained from 25 TED patients and 24 healthy donors. MiRNA-seq was performed to examine differential expression of miRNAs in OCTs, and miR-182-5p was selected for subsequent experiments. MiR-182-5p was detected in both CD34+ and CD34- OFs. The upstream regulators of miR-182-5p were studied. Downstream targets of miR-182-5p were analyzed. The functionality of miR-182-5p in CD34+ OFs was evaluated.

Results: MiR-182-5p was highly expressed in TED OCTs and their derived CD34+ OFs. TED OCTs displayed increased expression of interleukin (IL)-6, IL-17A, CD34, and phosphorylated STAT3 at Ser727 and Tyr705. Activation of IL-6/STAT3 signaling promoted the expression of miR-182-5p in CD34+ OFs. MiR-182-5p enhanced wound repair ability, proliferation, and RANTES expression while inhibiting apoptosis in CD34+ OFs. CD34+ OFs transfected with miR-182-5p were susceptible to TGF- β -initiated myofibroblast differentiation. Luciferase reporter and pull-down assays revealed Smad7 as the downstream target of miR-182-5p, which modulated the proliferation, migration, fibrosis, and apoptosis of CD34+ OFs.

Conclusions: The IL-6/STAT3/miR-182-5p pathway led to activation of CD34+ OFs. MiR-182-5p promoted the proliferation, migration, fibrosis, and anti-apoptosis of CD34+ OFs via targeting Smad7. Our findings suggest

that miR-182-5p may potentially serve as a therapeutic target for TED.

Abstract No.: 200145

Cellular and Molecular Mechanisms of Nasolacrimal Duct Obstruction: New Insights Into CD4+ T Cell-MIF-Fibroblast Pathways

First Author: Xinyue YU

Purpose: To describe the single-cell picture of the nasolacrimal duct in patients with nasolacrimal duct obstruction (NLDO) and elucidate the immunoregulatory mechanisms during local fibrosis.

Methods: We obtained the nasolacrimal ducts of 4 menopausal female patients by endoscopic DCR (Dacryocystorhinostomy), divided them into obstructive site and para-blocked site, performed single-cell sequencing of the samples, and analyzed the cell composition and cell-cell interactions. Subsequently, we obtained body fluid and tissue samples from 13 patients and performed tissue and cell experiments to verify the fibrosis mechanism.

Results: Ten major cell types were identified in 67,658 cells of the nasolacrimal duct. Intercellular communication analysis reveals the critical role of macrophage migration inhibitory factor (MIF) in fibroblast-immune cell interaction. Histological and cellular experiments showed that the site of nasolacrimal duct obstruction exhibited marked inflammation and fibrosis, and MIF, mainly derived from CD4+ T cells, could activate fibroblasts and promote their proliferation, which could be used as a therapeutic tool for the treatment of nasolacrimal duct obstruction, and secrete inflammatory cytokines and extracellular matrix, a process that is further amplified by the constant stimulation of CD4+ T cells by activated fibroblasts, creating a positive feedback loop.

Conclusions: This study delineates a comprehensive cellular picture of the nasolacrimal duct in NLDO patients, proposing that MIF-centered immunoregulatory circuits are key factors contributing to the progression of fibrosis. This study is of great significance for the understanding of the NLDO immunoregulatory mechanism and targeted therapy.

Abstract No.: 202931

Clinical Features of Chinese Patients With Thyroid Eye Disease: A Multicenter Retrospective Study

First Author: Chaoyu LEI

Co-Author(s): Huifang ZHOU

Purpose: Thyroid eye disease (TED) is a debilitating autoimmune disorder linked to thyroid dysfunction. There is limited knowledge of TED in Asian populations. This multicenter study characterizes the clinical

features and treatment response of TED in a large Chinese cohort.

Methods: A retrospective cross-sectional study included 4157 patients with TED from nine Chinese hospitals from February 2016 to July 2023. Disease severity and activity were evaluated according to the European Group on Graves' Orbitopathy (EUGOGO) standards. We examined associations of variables, including sex, age, smoking status, I131 treatment, consultation department, and geographical region, with clinical outcomes. Logistic regression and nomogram models were developed to examine associations with sight-threatening TED and, in a subgroup analysis (n=126), patients' responsiveness to intravenous glucocorticoid (IVGC) therapy.

Results: We included 4157 patients with a mean age and standard deviation (SD) of 45.96 ± 16.44 years. Of these, 63.6% (n=2644) were females. Over half (55.6%, n=2310) of participants were in the inactive phase, with a mean clinical activity score of 2.19 ± 1.61 (SD) for all patients. TED severity was categorized as mild (9.3%, n=385), moderate-to-severe (82.5%, n=3428), and sight-threatening (8.2%, n=344). The average degree of exophthalmos was 20.04 ± 5.27 mm, and 48.8% (n=2029) of patients had diplopia. Patients treated with I131 had higher disease activity (47.5%, n=468, vs. 43.5%, n=1379, $p < 0.05$). Coastal region patients exhibited more severe TED (sight-threatening cases: 10.1%, n=195 vs. 7.2%, n=147) and higher diplopia scores (1.00 ± 1.10 vs. 0.86 ± 1.09 , $p < 0.001$) than inland counterparts. TED severity was also greater in patients treated in Ophthalmology departments (mild cases: 6.0%, n=213; moderate-to-severe cases: 85.6%, n=3055) compared to Endocrinology departments (mild cases: 29.3%, n=172; moderate-to-severe cases: 63.5%, n=373). Nomograms had an area under the receiver operating curve of 0.742 (95% CI, 0.716-0.768) for sight-threatening TED and 0.759 (95% CI, 0.674-0.843) for IVGC therapy responsiveness.

Conclusions: We characterized the clinical features and treatment response of TED in a large Chinese cohort. These findings offer valuable insights informing TED risk stratification in Asian patients and forming a foundation for future prospective studies.

Abstract No.: 203844

Clinical, Diagnostic, and Treatment Characteristics of Orbital Liposarcoma

First Author: Xin KANG

Co-Author(s): Wei WU

Purpose: To clarify the clinical, diagnostic, and treatment characteristics of orbital liposarcoma.

Methods: A review was performed of electronic medical records, histopathology, radiological images, and follow-up information for 21 patients with orbital liposarcoma.

Results: The predominant clinical manifestation of this disease was painless exophthalmos. The most frequently encountered pathological types were well-differentiated and myxoid liposarcoma. Preoperative radiological images from 15 patients showed that orbital liposarcoma initially developed in extraocular muscle in 9 patients. Furthermore, all well-differentiated liposarcomas exhibited the radiographic characteristics of irregular and ill-defined adipose tissue, whereas only 12.5% of myxoid liposarcomas had the imaging characteristics. For the patients who exclusively underwent surgery, all of those with subtotal excisions experienced recurrence, 63.6% of marginal excisions recurred, and 50% of wide excisions resulted in recurrence. However, none of the patients who underwent marginal excisions or wide excisions combined with adjuvant radiotherapy exhibited recurrence. The analysis of magnetic resonance imaging findings in 3 patients who underwent neoadjuvant radiotherapy revealed that the tumor size remained stable in a patient with well-differentiated liposarcoma, whereas another patient with the same type of tumor exhibited a gradual increase in size. Conversely, a patient with myxoid liposarcoma experienced a significant reduction in tumor size following neoadjuvant radiotherapy.

Conclusions: Orbital liposarcoma demonstrated a propensity for developing in the extraocular muscle. The radiological images of orbital well-differentiated liposarcomas were characterized by irregular and ill-defined adipose tissue. Surgery combined with radiotherapy demonstrated potential in reducing recurrence rates. Notably, orbital myxoid liposarcoma exhibited greater sensitivity to radiotherapy compared to well-differentiated liposarcoma.

Abstract No.: 203327

Contrast-Enhanced Orbital MRI for Activity Assessment and Treatment Response Prediction in Thyroid Eye Disease

First Author: Duojin XIA

Co-Author(s): Sien Ping CHEW, Runchuan LI, Yinwei LI, Jing SUN, Zhangsheng YU, Huifang ZHOU, Haiyang ZHANG

Purpose: To investigate the performance of contrast-enhanced orbital MRI (T1-weighted contrast-enhanced [T1CE] and dynamic contrast-enhanced MRI [DCE-MRI]) for activity assessment and prediction of treatment response to intravenous glucocorticoid (IVGC) treatment in thyroid eye disease (TED).

Methods: A retrospective study of 59 active moderate-to-severe TED patients (36 responsive and 23 unresponsive) treated with IVGC, matched with Thirty-one inactive TED patients were included. T1CE and DCE-MRI were collected from each subject. Univariate and multivariate logistic regression analyses, as well as receiver operating characteristic (ROC) curves

(evaluated by area under the curve, AUC) were used to evaluate the diagnostic and predictive models.

Results: Active patients showed a higher signal intensity ratio of lateral rectus (LR-SIR) on T1CE and a higher wash-in rate of inferior rectus (IR-WIR) on DCE-MRI compared to inactive patients ($p < 0.05$). The AUC for T1CE and DCE-MRI-based models were 0.866, and 0.844, respectively. The combined model (LR-SIR and IR-WIR) significantly enhanced model performance (AUC = 0.914, 95% CI: 0.858–0.970). Responsive patients demonstrated a longer time to peak of lateral rectus (LR-TTP) than unresponsive patients ($p < 0.05$). The cutoff value of prediction probability was 0.678, and the AUC based on this model was 0.739 (95% CI: 0.608–0.807).

Conclusions: T1CE and DCE-MRI could effectively assist in TED activity assessment, and DCE-MRI could help predict IVGC treatment response. Specifically, LR-SIR and IR-WIR were indicators of TED activity, and IR-TTP was predictive of IVGC treatment response. Combining both contrast-enhanced sequences could further enhance the efficiency of TED activity assessment.

Abstract No.: 202666

Correlation Between Duration of Docetaxel Administration and Epiphora Severity in Nasopharyngeal Carcinoma Patients

First Author: Riani ERNA

Co-Author(s): Debby HANDAYATI HARAHAP, Alazi ALAZI, Denny SATRIA UTAMA

Purpose: Docetaxel, an effective chemotherapeutic agent for various cancers, including nasopharyngeal carcinoma, is associated with significant epiphora as a side effect. This study aimed to investigate the correlation between the duration of docetaxel administration and the severity of epiphora, as measured by the Munk score.

Methods: A descriptive study with a case series design was undertaken at the Eye Clinic of Dr. Mohammad Hoesin Hospital, Palembang, from January to August 2024. The study sample comprised 25 patients. Epiphora severity was measured using the Munk score. Statistical analysis was performed using Spearman's Rho correlation test.

Results: The majority of patients were male (68.2%) and aged ≤ 50 years (77.3%). The most common dose of docetaxel administered was 80 mg (91%). The most frequent duration of administration was 6 weeks (77.3%). Based on the Munk score, 86.4% of patients had a Munk score of 1, and 13.6% had a Munk score of 2. No significant differences were found in gender ($p = 0.445$), age ($p = 0.578$), or docetaxel dose ($p = 1.000$) based on the Munk score. However, there was a statistically significant difference in the duration of docetaxel administration according to the Munk score ($p = 0.001$). A moderately significant positive

correlation was observed between the duration of docetaxel administration and epiphora severity based on the Munk score ($r = 0.626$; $p = 0.001$).

Conclusions: Patients with a Munk score of 2 received docetaxel for the longest duration. A longer duration of docetaxel administration is associated with a higher Munk score for epiphora in patients with nasopharyngeal carcinoma.

Abstract No.: 203039

Direct Closure With Cantholysis to Simplify and Optimize Eyelid Coloboma Surgery in Treacher Collins Syndrome

First Author: Monica **SUMARWOTO**

Co-Author(s): Halimah **PAGARRA**, Andi **PRATIWI**, Noor **SYAMSU**

Purpose: Treacher Collins Syndrome (TCS) is a rare autosomal dominant congenital disorder. Common features include downslanting palpebral fissures, malar and mandibular hypoplasia, and lower eyelid coloboma. Ocular manifestations may also involve symblepharon and lacrimal system atresia. This case emphasizes the importance of recognizing the complexity of congenital anatomical defects associated with Treacher Collins Syndrome in order to design surgical strategies that can effectively manage these ocular abnormalities.

Methods: A 12-year-old boy presented with bilateral congenital eyelid coloboma, symblepharon, and lacrimal duct atresia, along with a history of labioschisis repair. Clinical findings led to a diagnosis of Treacher Collins Syndrome. Initial surgical management included sequential symblepharon release, punctal probing, and direct closure, with cantholysis performed on both eyes. Final outcomes demonstrated successful restoration of eyelid anatomy, improved ocular surface protection, and acceptable cosmetic appearance.

Results: In this case, the initial surgery using direct closure without cantholysis failed to correct the eyelid coloboma, leading to an unsatisfactory cosmetic result. A secondary procedure was performed with greater emphasis on palpebral tension management, utilizing direct closure combined with cantholysis.

Conclusions: In our case, a bilateral small-sized, full-thickness congenital eyelid coloboma affecting the medial one-third of the lower eyelid was effectively managed using direct closure combined with cantholysis.

Abstract No.: 201176

Early External Dacryocystorhinostomy in Acute on Chronic Dacryocystitis: Outcomes From a Single-Center Experience

First Author: Ritesh **VERMA**

Purpose: To evaluate the functional outcomes of early external dacryocystorhinostomy (DCR) in patients presenting with acute on chronic dacryocystitis.

Methods: A retrospective analysis was conducted of 15 patients who underwent external DCR with silicone intubation for acute on chronic dacryocystitis over 3 years at a single tertiary care institute. Patient demographics, clinical features, timing of surgery, postoperative outcomes, and complications were reviewed.

Results: The mean age of patients was 58 years (range: 44-76 years), with a mean duration of epiphora of 3 years. Six patients presented with an associated lacrimal fistula. There was spontaneous regression of the fistula in all cases. The mean interval between presentation and surgery was 1.5 days. The mean follow-up period was 11 months. Functional success, defined as resolution of epiphora with a patent ostium on syringing, was achieved in 14 of 15 patients (93.3%). One patient required revision DCR. No major intraoperative or postoperative complications were noted.

Conclusions: Endonasal DCR is well established in the management of acute dacryocystitis, whereas the literature on external DCR in such situations is scanty. Early external DCR with intubation is a safe and effective technique for acute on chronic dacryocystitis, including cases with lacrimal fistula, with high functional success and low complication rates.

Abstract No.: 202347

Efficacy and Safety of Oxymetazoline Hydrochloride 0.1% in Japanese Patients With Acquired Blepharoptosis: Results From a Randomized Phase 3 Trial

First Author: Eri **ISHIKAWA**

Co-Author(s): Hitoshi **ISHIKAWA**, Koji **OKA**

Purpose: To evaluate the efficacy and safety of oxymetazoline hydrochloride 0.1% ophthalmic solution (hereafter referred to as oxymetazoline 0.1%) in Japanese patients with acquired blepharoptosis.

Methods: Patients were randomized 1:1:1 to 3 treatment groups (oxymetazoline 0.1%, either once daily [QD] or twice daily [BID], or to placebo BID) for 3 months. Patients who received oxymetazoline 0.1% continued treatment for an additional 3 months. Those who initially received a placebo were re-randomized to either one of the active treatment groups for the remaining 3 months of the study. The primary efficacy endpoint was the superiority of oxymetazoline 0.1% to

placebo in marginal reflex distance (MRD-1) change at Day 14 (hour 2). Adverse drug reactions (ADRs) were recorded.

Results: Baseline MRD-1 (standard deviation) of the 336 patients analyzed (n=112 per group) was 1.31 mm (0.83). The MRD-1 change (LS mean $\pm$ standard error) from baseline to 14 days (hour 2) after treatment was 1.09 (0.07) mm and 0.93 (0.07) mm for QD and BID, with a difference from placebo of 0.59 ± 0.10 mm and 0.43 ± 0.10 mm (both $P < 0.0001$), respectively. At 3 months, ADRs were reported in 4.5%, 0.9% and 4.5% of placebo, oxymetazoline 0.1% QD and BID groups, respectively.

Conclusions: Oxymetazoline 0.1% QD and BID were superior to placebo in MRD-1 change from baseline at Day 14 in patients with acquired blepharoptosis, with no significant safety concerns over the study period.

Abstract No.: 202821

Efficacy of Botulinum Toxin A for Treatment of Benign Essential Blepharospasm and Hemifacial Spasm: A Hospital Based Study

First Author: Jamuna **GURUNG**

Co-Author(s): Prakash **GURUNG**

Purpose: Abnormal, involuntary spasms of the periorcular and/or facial musculature cause a debilitating disorder known as benign essential blepharospasm (BEB) and hemifacial spasm (HFS). We conduct a study to evaluate the efficacy of botulinum toxin A injections (BtA) for benign essential blepharospasm and hemifacial spasm.

Methods: A prospective observational study was conducted between January 2022 and December 2024. Data collected included diagnoses, patient characteristics, injection dates, doses administered, Jankovic spasm grading response scores before and after BtA injections, duration of effect, and adverse events.

Results: A total of 27 cases, which included 15 cases of hemifacial spasm and 8 cases of benign essential blepharospasm. The mean age of the patient was 58.78 ± 2.11 (range 42-88 years). There were more females, 19 (82.6%), than males, 4 (17.4%). The mean amount of Botox given for HFS was 26.8 ± 3.8 units and 55 ± 9.25 units for BEB. The mean Jankovic spasm grading score was 3.9 ± 0.19 (range 3-4) at presentation with the mean improvement in functional score to 0.81 ± 0.83 (range 1-3) at 3 months duration which was statistically significant $P < 0.001$. The mean duration of effect for HFS was 5.2 ± 0.9 months, and BEB was 4.6 ± 1.6 months. The common adverse effects noted were lagophthalmos 2 (7.4%), watering 2 (7.4%), and ectropion 1 (3.7%).

Conclusions: Our study showed that botulinum toxin injection is an effective and safe method for treating benign essential blepharospasm and hemifacial spasm.

However, the temporary effect, the need for repeated injections, and the cost of the treatment are its drawbacks.

Abstract No.: 206822

Efficacy of Triple Therapy in Dysthyroid Optic Neuropathy: Intravenous Methylprednisolone, Orbital Radiotherapy, and Mycophenolate Mofetil

First Author: Kenneth Ka Hei **LAI**

Co-Author(s): Fatema **ALJUFARI**, Marco **BOWSWELL**, Kelvin **CHONG**, Kervin **DELLOSA**, Alan **LEE**, Chiu Ming **NG**, Chi Pui **PANG**, Clement **THAM**, Varan **VONGSILPAVATTANA**, Alvin **YOUNG**, Hunter KI **YUEN**

Purpose: Dysthyroid optic neuropathy (DON) is a vision-threatening complication of thyroid eye disease. High-dose intravenous methylprednisolone (IVMP) is the standard first-line therapy, but many patients ultimately require orbital decompression. We evaluated the outcomes of an upfront triple therapy regimen consisting of high-dose IVMP, orbital radiotherapy (ORT), and mycophenolate mofetil (MMF) in the management of DON.

Methods: We conducted a retrospective cohort study of 82 patients with DON managed at a tertiary referral center between 2011 and 2025. All patients received upfront IVMP (cumulative dose 8 g), ORT, and MMF. Clinical parameters assessed included Clinical Activity Score (CAS), best-corrected visual acuity (BCVA), color vision, automated visual field, pupil responses, optic disc and fundus appearance, and extraocular motility. Surgical decompression was performed if signs of optic neuropathy persisted or worsened despite medical therapy.

Results: Eighty-two patients (54 female; mean age 60 ± 10 years; 7 euthyroid; 17 smokers) were included. DON reversed with medical therapy alone in 64 patients (78%), who maintained stable vision without the need for orbital decompression at a mean follow-up of 24 months. Significant improvements in CAS, BCVA, color vision, and visual fields were observed at 6 months post-therapy (all $p < 0.05$). Eighteen patients (22%) required orbital decompression; these patients were more likely to demonstrate higher differential intraocular pressure and severe apical crowding on imaging ($p < 0.05$). No severe adverse events were observed.

Conclusions: Upfront triple therapy with IVMP, ORT, and MMF was effective in improving visual outcomes in DON. Vision was preserved without surgical decompression in 78% of patients, suggesting that this combined medical approach may reduce surgical burden while providing meaningful and durable visual recovery.

Abstract No.: 203536**Efficacy of a Novel Three-Dimensionally Designed Customized Entropion Correction Device: A Prospective Randomized Trial***First Author: Lei XIONG**Co-Author(s): Zhang YI, Wang LIJUN*

Purpose: To evaluate the clinical efficacy of a patented, non-surgical entropion correction device based on three-dimensional design and facial scanning.

Methods: In this prospective trial, patients with mild-to-moderate entropion were randomized to an experimental group (n=12) receiving a personalized device manufactured (Granted utility model patent, Patent No:202422114533.4, Patent Grant Date: 2025/07/15) using three-dimensional design and facial scanning technology (1-2 hours/day wear) or a control group (n=12) receiving conventional care. The treatment period was 4 weeks, with outcome assessments conducted immediately after wearing, and on days 3, 7, 14, and 30. Outcome measures included pain (VAS), foreign body sensation, Schirmer's test, lid margin position, eyelash-cornea contact, and safety.

Results: The experimental group demonstrated significantly greater improvement in VAS scores than the control group at all post-wearing assessments (days 3, 7, 14, and 30; $P < 0.05$). Foreign body sensation improved significantly by day 3 ($P < 0.05$). Schirmer's test results showed significant improvement in the experimental group by day 7 ($P < 0.05$). Both the lid-globe angle and eyelash-cornea contact significantly improved at all observed time points compared to the control ($P < 0.05$). Only minor transient skin redness was observed with the device.

Conclusions: The three-dimensionally designed personalized correction device, requiring only 1-2 hours of daily wear, demonstrated rapid and superior efficacy within a 4-week treatment period compared to conventional methods, offering a safe and efficient non-surgical alternative for entropion management.

Abstract No.: 202758**Eyelid Defect Reconstruction Following Malignant Tumor Excision Using Auricular Cartilage as a Substitute of Tarsal Plate***First Author: Zeyi LI**Co-Author(s): Jianhao CAI, Cangeng XU*

Purpose: To evaluate the efficacy of auricular cartilage instead of tarsal plate combined with conjunctiva graft on eyelid reconstruction following eyelid malignant tumor resection for repairing eyelid defect.

Methods: This is a retrospective study including 18 patients with eyelid defects after excision of eyelid malignant tumors, 7 of whom had an entire eyelid defect, and the others had defects of more than half of the eyelid. All of the patients had undergone eyelid

reconstruction with auricular cartilage as a substitute for the tarsal plate. Postoperative follow-up varied from 6 months to 4 years.

Results: Of the 18 subjects who underwent eyelid reconstruction using auricular cartilage, all of which had excellent postoperative outcomes functionally and aesthetically, including repair of defected eyelid and coalesced auricular cartilage without symblepharon. However, in 1 case (5.6%), the auricular cartilage was exposed in postoperative week 1 that was healed after 2 months, and 2 cases (11.1%) had mild eyelid ectropion.

Conclusions: Auricular cartilage was adopted as a substitute for the tarsal plate to repair eyelid defects after eyelid malignant tumor resection. It has a similar histological structure to that of the tarsal plate, as it is convenient to extract and easy to survive. Conjunctival transplantation to reconstruct the palpebral conjunctiva is a key technique affecting the surgery effect.

Abstract No.: 200450**Eyelid Reconstruction Following Mohs Micrographic Surgery: Outcomes, Comparison of Techniques and Complications, an Asian Perspective***First Author: Daniel CHIN**Co-Author(s): Llewellyn LEE*

Purpose: To evaluate the surgical outcomes, complications, and recurrence rates in patients undergoing eyelid reconstruction following Mohs micrographic surgery.

Methods: This single-institution retrospective study included 25 patients who underwent eyelid reconstruction after Mohs surgery between January 1, 2014, and December 31, 2022. Data on demographics, lesion characteristics, surgical techniques, and outcomes were analysed.

Results: The mean patient age was 67.2 years (range: 49–89); 72% were male, and 28% were female. The majority were Chinese (68%), and the rest comprised other races (32%). Lesion sizes were classified as small (<20 mm, 36%), medium (20–30 mm, 40%), or large (>30 mm, 24%). The majority (88%) were basal cell carcinomas, with the lower eyelid most commonly affected (96%), particularly the medial canthus (50%). Reconstruction was successful in all 25 cases, with no evidence of tumour recurrence over a median follow-up period of 36 months. Reconstruction techniques included full-thickness skin grafts (upper inner arm: 64%; upper eyelid: 12%), upper eyelid tarsoconjunctival grafts with lower eyelid myocutaneous flaps (16%), the modified Hughes procedure (4%), and direct closure (4%). Complications requiring repeat surgical intervention occurred in 3 (12%) of cases, while minor complications managed conservatively occurred in 2

(8%). Post-operative issues included lagophthalmos (4%), medial ectropion (8%), and graft dehiscence (8%).

Conclusions: Eyelid reconstruction post-Mohs surgery can be successfully performed through various techniques tailored to defect size, location, and lamella involvement. Asian eyelids with prominent medial epicanthal folds, may benefit from full-thickness skin grafts.

Abstract No.: 201892

From Clinic to Single Cells: Largest Multicenter Lacrimal Gland Adenoid Cystic Carcinoma Cohort and a Therapy-Resolved Atlas Map Immune Ecosystems and Schwann Cell Programs

First Author: Mingshen MA

Co-Author(s): Xin KANG, Jing LI, Jianmin MA, Yong TAO, Liangyuan XU, Xinji YANG

Purpose: To investigate the clinical features, treatment strategies, and prognostic factors of lacrimal gland adenoid cystic carcinoma (LGACC), and to provide the first singlecell map of the tumor immune microenvironment (TIME) across clinical stages and therapeutic contexts, elucidating the role of Schwann cells in perineural invasion (PNI).

Methods: A multicenter retrospective cohort of 127 pathology-confirmed LGACC cases (2003–2024) was analyzed using Kaplan–Meier, Cox, and logistic models to identify independent prognostic factors. In a translational subset, fresh LGACC specimens spanning distinct clinical states underwent singlecell RNA sequencing with unsupervised clustering, lineage annotation, trajectory analysis, and ligand–receptor inference to characterize TIME remodeling across stage and therapy.

Results: LGACC presented predominantly in middle age with female predominance; imaging commonly showed solid masses with frequent orbital bone involvement. Combined surgery+radiotherapy associated with improved outcomes, while metastasis, high-grade bone infiltration, and Ki67 $\geq 20\%$ independently predicted worse prognosis. Singlecell profiling resolved malignant epithelial cells alongside diverse immune and stromal compartments, revealing stage and therapy-specific shifts in Tcell states, myeloid polarization, and CAF activation. Notably, Schwann cells were enriched at invasive and perineural niches, engaged in bidirectional ligand–receptor crosstalk with tumor cells consistent with neurotropic growth; Schwann cell burden and signatures correlated with PNI and metastatic dissemination.

Conclusions: LGACC presents with aggressive behavior; improved surgical outcomes are associated with radiotherapy, whereas metastasis, advanced bone infiltration, and elevated Ki67 predict worse survival. Singlecell RNA sequencing across stage and therapy

reveals corresponding shifts in immune–stromal ecosystems and implicates Schwann cells as mediators of PNI and metastasis, linking cellular circuitry to the observed clinical course.

Abstract No.: 206254

Improved ELDR Outcomes for TS-1–Related Canalicular Obstruction with a New Dacryoendoscope

First Author: Akemi IWASAKI

Co-Author(s): Yoichi MANABE

Purpose: To evaluate the clinical outcomes of endoluminal lacrimal duct recanalization (ELDR) for TS-1–related canalicular obstruction before and after the introduction of a new dacryoendoscope (EZ-Tb.). The new device enables smoother sheath manipulation and superior visualization, particularly in the canalicular segments.

Methods: A retrospective review was conducted of 12 patients who underwent ELDR for TS-1–induced canalicular obstruction. Patients treated before October 2023 were categorized as the old endoscope group (n=5), and those treated in October 2023 or later as the new endoscope group (n=7). The median age was 76 years (range, 62–82); 7 men and 5 women. Primary malignancies included gastric, pancreatic, breast, colorectal, and unknown cancers. The median duration of TS-1 administration prior to surgery was 11 months (range, 3–36 months). Outcomes assessed were: (1) obstruction site [mid-canalicular vs proximal canalicular], (2) tube placement [LACRIFAST CL when both canaliculi were recanalized; Masterka when only one canaliculus was recanalized; failure], and (3) postoperative irrigation patency.

Results: Obstruction sites were mid: 3/proximal: 2 in the old group and mid: 3/proximal: 4 in the new group. Tube placement was LACRIFAST CL: 3 and failure: 2 in the old group, versus LACRIFAST CL: 6 and Masterka: 1 in the new group. All patients who underwent successful tube placement maintained patent irrigation throughout the follow-up period.

Conclusions: The introduction of EZ-Tb. facilitated easier canalicular observation and eliminated insertion failures, allowing more consistent LACRIFAST CL placement. Although the sample size is limited, these findings suggest improved procedural success with the new dacryoendoscope.

Abstract No.: 206280**Interdisciplinary Surgery of Thyroid Eye Disease With Thyroid Disease: A One-Stage Approach***First Author: Yining WEI**Co-Author(s): Yinwei LI, Jing SUN, Huifang ZHOU*

Purpose: Thyroid eye disease patients with thyroid diseases requiring surgery need an appropriate treatment paradigm, and there lacks investigation on the surgical outcomes of one-stage approach of orbital decompression and thyroidectomy.

Methods: Fifteen patients who received one-stage surgery of orbital decompression and thyroidectomy from 2019 to 2023. Surgery was identified as successful if the expected exophthalmometry reduction was attained, thyroid function remained under control, and no cancer recurrence or metastasis was observed. Ophthalmic parameters, thyroid function, tumor recurrence or metastasis, surgical details, and patient satisfaction score were analyzed.

Results: One-stage surgery was successful in all patients. Exophthalmometry was reduced with thyroid eye disease activity controlled or improved. Thyroid function was under control after surgery with a significant decrease in autoantibodies. No cancer recurrence, metastasis, or severe complications were observed.

Conclusions: The one-stage approach of surgical management can achieve satisfactory surgical outcomes for thyroid eye disease patients with thyroid diseases requiring surgery.

Abstract No.: 206154**Intralesional Injection With Systemic Rituximab for Refractory Orbital MALT Lymphoma***First Author: Honglei LIU**Co-Author(s): Cuihong LIU, Jinhua LIU, Yujie WU*

Purpose: To evaluate the clinical efficacy and safety of intralesional (IL) and systemic rituximab in the treatment of refractory orbital MALT lymphoma.

Methods: Patients with a confirmed diagnosis of orbital MALT lymphoma via excisional biopsy were enrolled. All patients received a combination therapy of intralesional and systemic intravenous rituximab. The injection strategy was tailored based on the anatomical location of the lesion, primarily utilizing one of three approaches: subconjunctival, lacrimal gland, or periocular injection. The intralesional dose, ranging from 10 to 40 mg per lesion, was determined by the lesion volume. The intravenous dose was 150-200 mg per administration. Treatments were administered monthly and continued until the orbital lesion was no longer detectable on MRI.

Results: A total of 180 patients diagnosed with orbital MALT lymphoma underwent the combined intralesional and systemic rituximab therapy. Orbital lesions regressed in all but two patients, who were subsequently referred to the hematology department due to systemic symptoms. The mean number of treatment cycles per patient was 8. Five patients experienced mild to moderate allergic reactions during treatment, which were managed with symptomatic treatment (e.g., antihistamines or steroids). All patients completed the treatment regimen.

Conclusions: While the mechanism of action of local rituximab injection warrants further investigation, the combination of intralesional and systemic rituximab represents a safe and effective therapeutic option for refractory orbital MALT lymphoma.

Abstract No.: 203337**Investigating Factors Influencing Quality of Life in Thyroid Eye Disease: Insight From Machine Learning Approaches***First Author: Haiyang ZHANG**Co-Author(s): Xianqun FAN, Shuo WU, Lehan YANG, Huifang ZHOU*

Purpose: Thyroid eye disease (TED) is an autoimmune orbital disorder that diminishes the quality of life (QOL) in affected individuals. Graves' ophthalmopathy (GO)-QOL questionnaire effectively assesses TED's effect on patients. This study aims to investigate the factors influencing visual functioning (QOL-VF) and physical appearance (QOL-AP) scores in Chinese TED patients using innovative data analysis methods.

Methods: This cross-sectional study included 211 TED patients whose initial visit to our clinic was from July 2022 to March 2023. Patients with previous ophthalmic surgery or concurrent severe diseases were excluded. GO-QOL questionnaires, detailed medical histories, and clinical examinations were collected. The distribution of GO-QOL scores was analyzed, and linear regression and machine learning algorithms were utilized.

Results: The median QOL-VF and QOL-AP scores were 64.29 and 62.5, respectively. Multivariate linear regression analysis revealed age ($P = 0.013$), ocular motility pain ($P = 0.012$), vertical strabismus ($P < 0.001$), and diplopia scores as significant predictors for QOL-VF. For QOL-AP, gender ($P = 0.013$) and clinical activity ($P = 0.086$) were significant. The XGBoost model demonstrated superior performance, with an R^2 of 0.872 and a root mean square error of 11.083. Shapley additive explanations (SHAP) analysis highlighted the importance of vertical strabismus, diplopia score, and age in influencing QOL-VF and age, clinical activity, and sex in QOL-AP.

Conclusions: TED significantly affects patient QOL. The study highlights the efficacy of XGBoost and SHAP analyses in identifying key factors influencing the QOL

in TED patients. Identifying effective interventions and considering specific demographic characteristics are essential to improving the QOL of patients with TED.

Abstract No.: 201178

Lacrimal Gland Adenoid Cystic Carcinoma (LACC): Our Experience Over 30 Years at a Tertiary Care Centre

First Author: Sonam NISAR

Co-Author(s): Shahid ALAM, Avriel GUDKAR, Bipasha MUKHERJEE

Purpose: To evaluate the management outcomes and prognostic factors amongst patients with lacrimal gland adenoid cystic carcinoma (ACC).

Methods: This was a retrospective interventional study including 40 patients diagnosed with lacrimal gland ACC from 1990 to 2020. Information analysed included demographic profile, radiological features, histopathological sub-types, risk factors, and management outcomes. Outcome was evaluated based on the recurrence of the disease, metastasis, or death.

Results: A male (62.5%) preponderance with a mean age of 37.18 ± 14.9 years was seen. Excision was done in 27 patients, of which 20 received adjuvant radiotherapy, and Neo-adjuvant chemotherapy followed by excision was done in 1 patient. Exenteration was performed in 10 patients with adjuvant radiotherapy in 5 of them. No surgical intervention was done in 3 patients. Recurrence was seen in 20 (50%), metastasis in 13 (32.5%). Median follow-up 28.5 ± 34.84 months. The 5-year survival rate was 44.4%.

Conclusions: Female sex, age > 40 years, bony erosion on imaging, both tubular and basaloid subtypes, and only administration of adjuvant radiotherapy emerged as poor prognostic factors. Adjuvant radiotherapy may not be able to prevent micro-metastasis, and hence chemotherapy is warranted. Multimodal treatment may help in improving overall survival and reducing the incidence of local recurrence.

Abstract No.: 202446

Lateral Orbital Rim Advancement Plus Balanced Orbital Decompression: A Novel Surgery for Exorbitism Regression in Crouzon Syndrome

First Author: Weijin QIAN

Co-Author(s): Lianfei FANG, Yinwei LI, Huifang ZHOU

Purpose: As a type of syndromic craniosynostosis, Crouzon syndrome (CS) often presents with exorbitism, one of the most disfiguring features that patients urgently seek to correct. Current treatments are not ideal for those preferring less invasive solutions. Herein, we propose an innovative surgery called lateral orbital rim advancement combined with

balanced orbital decompression (LORA-BOD), targeting exorbitism regression in CS patients.

Methods: Three CS patients undergoing LORA-BOD surgery between August 2022 and September 2023 in our center were included. Demographic data, ophthalmological examination and imaging tests were collected. Exorbitism was evaluated using Hertel exophthalmometry and orbital computed tomography (CT), which is defined as the distance from corneal apex to interzygomatic line (CA-LO) or orbitale (CA-IO). Preoperative and postoperative outcomes were compared.

Results: Three patients (two females and one male) aged from 15 to 25 sought consultation for exorbitism regression and received LORA-BOD. All patients showed a decrease in postoperative exorbitism degrees, with an average regression of 7.25 ± 1.97 mm measured by Hertel exophthalmometry, 3.62 ± 1.65 mm by CA-LO and 4.29 ± 2.41 mm by CA-IO. Apart from exorbitism regression, exotropia improved as well, both contributing to a more harmonious aesthetic eye appearance. Overall, patients were satisfied with the treatment outcomes. No complications occurred during follow-up.

Conclusions: LORA-BOD surgery has shown outstanding efficacy as well as promising prospects in exorbitism regression of CS patients, which can be widely applied to treat patients with relevant demands.

Abstract No.: 203377

Long-Term Outcomes of Polycaprolactone (PCL) Implant Used for Orbital Fracture Repair in a Tertiary Hospital in South India

First Author: Samhitha H R

Co-Author(s): Annirudh GUPTA, Neeraja VARMA

Purpose: To evaluate long-term changes and integration of the PCL implant and look at the sequence of changes over time in patients at different timelines after surgery.

Methods: The study includes 8 patients, 6 males and 2 females, from an age range of 19-58 years, the oldest patient operated 2 years back, and the most recent patient operated 5 months back. Post op CT was done at 1-2 weeks for each patient, and Orbital MRI and CT were done at the present time to look for changes.

Results: All patients had BCVA 6/6 after surgery with no hyperglobus, implant extrusion, infection, or granuloma formation. Intraoperatively, there was ease in using the implant for small to large fractures. Post op edema and chemosis were minimal. Patients were comfortable post op with no pain or feeling of heaviness and were back to routine work as early as 1 week.

Conclusions: PCL is a bioresorbable implant that is easy to use with good results for floor and medial

orbital fractures, integrates with bone around 18-24 months, does not need to be removed at a later date and a better natural fit for the patient. It can be shaped intraoperatively for a precise fit.

Abstract No.: 202405

Medial Levator Suture and Eyelid Shortening: A New Technique for Durable Ptosis Repair in Floppy Eyelid Surgery

First Author: Alejandra VALENZUELA

Co-Author(s): Joseph ARNOLD, Chelsea YATES

Purpose: To provide a long-lasting outcome for patients with medial upper eyelid laxity in the context of floppy eyelid syndrome (FES) undergoing upper eyelid ptosis repair, by combining medial upper eyelid shortening with medial placement of the levator advancement suture.

Methods: A non-comparative study was conducted on patients with significant upper eyelid laxity and ptosis (MRD-1 of +2 mm or less with good levator function). Each patient underwent medial full-thickness horizontal upper eyelid shortening, combined with the medial placement of a single polyglactin-910 suture, positioned 2 mm lateral to the wound, through the tarsus to elevate the levator muscle.

Results: Twenty patients were included, all presenting with gross laxity of the medial upper eyelid and near-complete absence of the medial tarsus. Patient ages ranged from 17 to 86 years (mean: 53.1), with a marked male predominance (80%). Common symptoms included ocular discomfort, conjunctival irritation/papillary conjunctivitis with mucous discharge, epiphora, and spontaneous upper eyelid eversion. All patients experienced resolution of their ocular symptoms and maintained a stable, cosmetically pleasing outcome over a 12-month follow-up period.

Conclusions: Patients with FES tend to exhibit greater medial than lateral eyelid laxity and often present with associated upper eyelid ptosis due to chronic stretching of the levator aponeurosis. This new surgical approach offers a single, effective technique to address medial horizontal laxity—where maximal stretching occurs—while simultaneously correcting levator dehiscence through more medially positioned suturing, preserving the natural contour of the upper eyelid.

Abstract No.: 202452

Medial Levator Suture for Upper Lid Ptosis Repair in Floppy Eyelid Syndrome

First Author: Alejandra VALENZUELA

Co-Author(s): Chelsea YATES

Purpose: To provide a long-lasting outcome for patients with mild medial upper eyelid laxity in the context of floppy eyelid syndrome (FES) undergoing upper eyelid

ptosis repair, by one single medial placement of the levator advancement suture.

Methods: A non-comparative study was conducted on patients with mild upper eyelid laxity and ptosis (MRD-1 of +2 mm or less with good levator function). Each patient underwent a single placement of a double-armed polyglactin-910 suture, positioned 2 mm lateral to the most medial aspect of the tarsal plate to advance the levator muscle.

Results: Twenty patients were included, all presenting with mild laxity of the medial upper eyelid and presence of the medial tarsus, with a clear male predominance. All patients experienced an adequate and stable upper lid height and contour over a 6-month follow-up period.

Conclusions: Patients with FES tend to exhibit greater medial than lateral eyelid laxity and often present with associated upper eyelid ptosis due to chronic stretching of the levator aponeurosis. This new surgical approach offers a single, effective technique to address the challenging anatomical contour when the medial upper lid stretches, while simultaneously correcting levator dehiscence through more medially positioned suturing.

Abstract No.: 202441

Microbiological Profile of Bacterial Orbital Cellulitis in a Tertiary Center in Thailand: A Retrospective Study

First Author: Kanokrat PORNANICH

Co-Author(s): Angkoon LUANGARAM, Chutikan PREECHABORISUTHKUL

Purpose: To determine microbiological profile and risk factors for poor visual outcome and complications in bacterial orbital cellulitis at a tertiary referral center in Thailand.

Methods: A retrospective review was conducted of patients admitted with orbital cellulitis at Siriraj Hospital from 2009–2024. Clinical data, microbiological results, antibiotic use, and treatment outcomes were analyzed. Multivariable logistic regression was applied to identify predictors of poor visual outcome and complications.

Results: Of 220 patients with orbital cellulitis, 160(72.7%) were clinical diagnosed with bacterial infection. Mean age was 41.7 ± 25.5 years; 55% were male. At presentation, 42.7% had no visual impairment, while 43.4% had moderate-to-severe impairment. Cultures were positive in 53.7%. Gram-positive aerobes predominated(46.6%), followed by gram-negative aerobes(22.6%), anaerobes(18.5%) and facultative anaerobe(11.6%). The most common isolates were *Staphylococcus aureus*(21.2%), *Streptococcus* spp.(12.3%), and coagulase-negative *Staphylococcus*(8.9%); among gram-negatives, *Pseudomonas aeruginosa*(6.8%) and *Klebsiella* spp.(6.2%) predominated. Common empirical antibiotics

included clindamycin(28.8%), ceftriaxone(26.6%), and amoxicillin-clavulanate(10.6%). After treatment, 70.6% achieved no or mild impairment, while 20.6% had moderate-to-severe loss or required enucleation. Initial poor visual acuity(VA) and older age were significant predictors of poor final vision(VA<6/18). Poor initial VA and abnormal leukocyte counts(neutropenia or leukocytosis) were associated with complications, including subperiosteal/orbital abscess, intracranial extension, central retinal artery occlusion, optic neuropathy, and enucleation.

Conclusions: Bacterial infection is the predominant etiology in orbital cellulitis, with Staphylococcus aureus and Streptococcus species being the most common gram-positive organisms, followed by Pseudomonas aeruginosa and Klebsiella species as the most frequent gram-negative pathogens. Factors associated with poor visual outcomes include poor initial visual acuity and advanced age. Additionally, poor initial visual acuity and abnormalities in leukocyte count are significant factors contributing to complications in orbital cellulitis.

Abstract No.: 202896

Modified Frontalis Muscle Flap Advancement in Patients With Severe Ptosis

First Author: Que Anh VU

Co-Author(s): Thi Thu Hien NGUYEN

Purpose: To assess the effect of a modified frontalis muscle advancement technique for the treatment of severe congenital ptosis. The purpose of this technique is to achieve a more physiologic direction with the frontalis muscle flap and to avoid malpositions of the upper eyelid or ptosis of the eyelashes.

Methods: This is a retrospective, nonrandomized interventional case series of 21 eyes from 18 patients who exhibited severe ptosis and poor levator function. All patients under 12 years of age underwent surgical correction with frontalis muscle flap advancement and a pulley creation through the aponeurosis of the levator muscle. The minimum follow-up time was 12 months. Surgical outcomes were measured by using clinical photographs taken before and after surgery.

Results: The mean age of patients is 6.33 ± 2.3 years of age. The preoperative mean visual acuity of the ptosis eye did not change significantly. The mean MRD1 of ptosis eyes increased from 0.34 ± 0.43 preoperatively to 3.03 ± 0.53 postoperatively ($p < 0.001$). Lapgothalmos decreased from 1.79 ± 1.04 one week after surgery to 0.54 ± 0.59 at 12 months after surgery. There were no cases of upper eyelid entropion or eyelash ptosis after 6 months. However, two corneal complications were noted in two cases, requiring prolonged lubrication treatment after the initial surgery. Complications were observed in a case with monocular elevation deficiency syndrome and in one case of bilateral ptosis with skin laxity and poor frontalis muscle function.

Conclusions: The modified frontalis muscle flap is a safe and effective technique for severe ptosis correction, yielding satisfactory results with minor complications. A careful examination before surgery is highly recommended to ensure good outcomes and avoid complications after surgery.

Abstract No.: 201754

Modified Frontalis Muscle Flap Advancement in Patients With Severe Ptosis

First Author: Que Anh VU

Purpose: To assess the effect of modified frontalis muscle advancement techniques for the treatment of severe congenital ptosis. The purpose of this technique is to achieve a more physiologic direction with the frontalis muscle flap and to avoid malpositions of the upper eyelid or ptosis of the eyelashes.

Methods: This is a retrospective, nonrandomized interventional case series of 21 eyes from 18 patients who exhibited severe ptosis and poor levator function. All patients under 12 years of age underwent surgical correction with frontalis muscle flap advancement and a pulley creation through the orbital septum. The minimum follow-up time was 12 months. Surgical outcomes were measured by using clinical photographs taken before and after surgery.

Results: The mean age of patients is 6.33 ± 2.3 years of age. The preoperative mean visual acuity of the ptosis eye did not change significantly. The mean MRD1 of ptosis eyes increased from 0.34 ± 0.43 preoperatively to 3.03 ± 0.53 postoperatively ($p < 0.001$). Lapgothalmos decrease from 1.79 ± 1.04 one week after surgery to 0.54 ± 0.59 at 12 months after surgery. There were no cases of upper eyelid entropion or eyelash ptosis after 6 months. However, two corneal complications were noted in two cases, requiring prolonged lubrication treatment after the initial surgery. Complications were observed in a case with monocular elevation deficiency syndrome and in one case of bilateral ptosis with skin laxity and poor frontalis muscle function.

Conclusions: The modified frontalis muscle flap is a safe and effective technique for severe ptosis correction, yielding satisfactory results with minor complications.

Abstract No.: 204735

Modified Müller's Muscle Conjunctival Resection Combined With Levator Plication in Moderate to Severe Congenital Ptosis

First Author: Amirhossein AGHAJANI

Co-Author(s): Hanieh FAKHREDIN, Seyed Mohsen RAFIZADEH, Mohammad Taher RAJABI, Amin ZAND

Purpose: To present a modified surgical technique for the correction of moderate to severe congenital ptosis with poor levator function.

Methods: This prospective case series included 34 eyes from 34 patients with unilateral moderate to severe congenital ptosis, defined as marginal reflex distance-1 (MRD-1) ≤ 2 mm and levator function (LF) ≤ 5 mm. The surgical approach was combined Müller's muscle conjunctival resection with an extended range (12–17 mm) and levator plication. An «ideal» response was defined as a postoperative inter-eyelid MRD-1 difference of ≤ 0.5 mm, while an inter-eyelid MRD-1 difference of 0.5–1 mm was considered an «acceptable» response. Secondary outcomes included achieving an open visual axis. Eyelid contour was objectively graded as excellent, good, fair, or poor based on curvature and symmetry with the contralateral eyelid.

Results: At the 6-month follow-up, the overall success rate was 76.5%, with 26.5% achieving an ideal response and 50.0% achieving an acceptable response. Among the 25 cases with visual axis obstruction due to ptosis, only 1 case (4%) failed to achieve an unobstructed visual axis at 6 months. Excellent eyelid contour was achieved in 73.5% of cases at the 6-month follow-up.

Conclusions: This modified surgical technique demonstrates favorable functional and aesthetic outcomes for treating moderate to severe congenital ptosis in young adults with poor levator function. Further studies with larger cohorts and longer follow-up are needed to confirm its long-term efficacy and safety.

Abstract No.: 203513

Multi-Dimensional Tear Proteomic Signatures in Thyroid Eye Disease: Ophthalmopathy, Autoimmunity, and Hyperthyroidism

First Author: Runchuan LI

Co-Author(s): Yi PAN, Jing SUN, Yining WEI, Li YANG, Haiyang ZHANG, Huifang ZHOU

Purpose: Thyroid eye disease (TED) is the most common extrathyroidal manifestation of Graves' disease (GD). Despite its clinical significance, the pathogenic mechanisms and reliable diagnostic biomarkers for TED remain incompletely defined. Tear fluid offers a noninvasive window into disease-related molecular changes.

Methods: Tear samples were collected using Schirmer strips from 20 TED patients, 20 GD patients without ocular involvement, and 14 healthy controls. Proteomic profiling was performed using a pressure cycling technology-pulse data-independent acquisition mass spectrometry (PCT-PulseDIA-MS) workflow.

Results: A total of 5,966 tear proteins were quantified, representing the most comprehensive tear proteome to date. Differentially expressed proteins (DEPs) were identified through pairwise group comparisons. TED patients showed the most extensive tear proteomic alterations among the studied groups.

174 DEPs were associated with ophthalmopathy, 14 with autoimmunity, and 13 with hyperthyroidism. The ophthalmopathy-related DEPs were enriched in immune regulation, lipid metabolism, vascular function, and extracellular matrix remodeling. Several key DEPs showed significant correlations with clinical, laboratory, and imaging variables. A three-protein panel comprising CANT1, IGFBP7, and CASP14 showed high diagnostic accuracy in distinguishing TED from GD (AUC=0.971).

Conclusions: Tear proteomics reveals distinct molecular signatures shaped by the combined influences of ophthalmopathy, autoimmunity, and hyperthyroidism throughout the pathogenesis of TED, underscoring tear proteins as promising noninvasive diagnostic biomarkers.

Abstract No.: 202932

Multimodal Large Language Models for Orbital Disease Detection: A Sequential Sensitivity Analysis in Multinational, Multiracial Populations

First Author: Chaoyu LEI

Co-Author(s): Sunisa SINTUWONG, Chee Chew YIP, Huifang ZHOU

Purpose: Delayed diagnosis of orbital diseases is frequently attributed to limited clinical awareness and experience. This study aims to evaluate whether integrating diverse clinical data modalities can enhance the diagnostic accuracy of MLLMs for orbital diseases.

Methods: This multinational, multiracial, retrospective study focused on three orbital conditions: orbital inflammation, orbital tumors, and thyroid eye disease. The first dataset included 6,786 single-eye photographs in China, and was used to fine-tune a Contrastive Language–Image Pretraining (CLIP) model for initial triage. The second dataset, comprising 170 participants from China, Singapore, and Thailand, was used to evaluate a state-of-the-art MLLM (GPT-4o-Latest). We performed a sequential sensitivity analysis to progressively incorporate external eye photographs, chief complaints, racial information, and diagnostic reasoning prompts. We also assessed the MLLM's capability to autonomously generate medical reports and examination recommendations.

Results: When relying solely on external eye images, the top-1, top-3, and top-5 detection accuracies were $13.72 \pm 2.38\%$, $21.37 \pm 3.02\%$, and $25.68 \pm 2.96\%$, respectively. The fine-tuned CLIP model reached an overall three-class classification accuracy of 90.21%, with accuracies of 90.61% for healthy eyes, 88.18% for orbital diseases, and 92.69% for non-orbital diseases. Integration of all inputs and the formation of an AI agent boosted the top-5 accuracy to $85.29 \pm 0.59\%$. In addition, the model-generated medical reports scored 3.00 ± 0.03 in readability, 2.85 ± 0.25 in comprehensiveness, and 2.78 ± 0.27 in accuracy.

Conclusions: Integrating diverse multimodal data significantly enhances the diagnostic performance of MLLMs for orbital diseases. Our study demonstrated the potential of multimodal AI approaches in improving diagnostic accuracy and supporting clinical decision-making for rare and complex orbital diseases.

Abstract No.: 202903

Novel Tear Drop Rotation Surgery for the Treatment of Moderate to Severe Congenital Epiblepharon

*First Author: John **BLADEN***

*Co-Author(s): Tejaswi **BOMMIREDDY***

Purpose: Mild epiblepharon is successfully treated with 'scarless' techniques and stab incisions; however, recurrence occurs in moderate/severe epiblepharon. We describe a novel minimally invasive surgical technique for moderate to severe epiblepharon that hides the scar within the eyelid fold, and maintains the natural eyelid shape: specifically, a medially based tear drop blepharoplasty, tiny ellipse orbicectomy, combined with retractor everting sutures to avoid overcorrection or loss of the natural eyelid shape

Methods: Retrospective review between 2022-24 and greater than 1 year follow-up. Epiblepharon severity was categorised using class and keratopathy (K) grade pre- and post-operatively: classes 3 and 4 were included.

Results: Sixteen eyelids, from 8 East-Asian patients aged between 5 and 19 years, showed improvement in epiblepharon class (from a mean of 3.5 pre-operatively to a mean of 1.6 post-operatively) and keratopathy grade (from a mean of 2.4 pre-operatively to a mean of 0.4 post-operatively). Three eyelids who were class 4 at the outset had a class recurrence (no keratopathy recurrence) with symptoms from eyelash-conjunctival touch: two at 10 months and one at 17 months; re-do surgery with tear drop rotation technique was successful with no further recurrence.

Conclusions: The tear drop rotation surgery is an effective treatment for moderate to severe epiblepharon with minimal cosmetic effect on the East-Asian eyelid. Keratopathy improved in all cases, and remained better than pre-operatively. In addition, this technique can also be used for recurrent epiblepharon in a step-wise approach. As it is a minimally invasive procedure, recurrence of class can occur although resolution of keratopathy tends to persist.

Abstract No.: 204024

Objective 3D Analysis of Lateral Tarsal Strip: Quantifying Eyelid Fissure and Canthal Tilt Changes

*First Author: Adam **KOPECKY***

*Co-Author(s): Ludwig M **HEINDL**, Jan **NEMCANSKY**, Alexander C. **ROKOH***

Purpose: To objectively evaluate whether lateral tarsal strip (LTS) surgery for involutional lower eyelid malposition (ectropion and entropion) induces upper eyelid ptosis or alters periorcular dimensions at six-month follow-up, using 3D stereophotogrammetry.

Methods: Twenty patients with involutional lower eyelid malposition (12 ectropion, 8 entropion) underwent unilateral LTS. Standardized 3D facial scans (Vectra 3D) were obtained preoperatively and at six months. Primary outcomes were palpebral fissure height (PFH), palpebral fissure width (PFW), upper lid fold distance (FPD), canthal tilt (CT), lateral canthal angle (LCA), lower lid margin position (Pi), medial canthal angle (MCA; control), and interpupillary distance (PD; control). Exploratory outcomes included eyebrow-palpebral distance (EPD_M) and eyebrow length.

Results: LTS significantly increased PFH ($p < 0.001$) and PFW ($p = 0.016$) in operated eyes. FPD remained unchanged ($p > 0.1$), indicating absence of induced upper eyelid ptosis. Significant postoperative changes were detected in upper and lower palpebral margin lengths (UPMLm $p = 0.015$, LPMLm $p = 0.003$). MCA decreased significantly ($p < 0.001$), whereas LCA ($p = 0.145$) and CT ($p = 0.097$) remained stable. Parameters of the non-operated eye were stable throughout follow-up. Exploratory eyebrow parameters (EPD_M, EL_M, EL_S) demonstrated no consistent or clinically relevant changes.

Conclusions: LTS surgery effectively restores lower eyelid position by enlarging palpebral fissure height and width, without inducing upper eyelid ptosis, as objectively confirmed by 3D stereophotogrammetry. Eyebrow metrics remained stable. These findings highlight LTS as a reliable functional and aesthetic procedure for involutional lower eyelid malposition.

Abstract No.: 203846

Ocular and Orbital Manifestations of Encephalocraniocutaneous Lipomatosis (ECCL) in a Neonate: A Case Report From a Level III Hospital in Manila, Philippines

*First Author: Justine Mariz **LIMQUECO***

*Co-Author(s): Jan Eric **BALETE**, Nickey Angelo **CAYETANO**, Manuel **PALMERO***

Purpose: Encephalocraniocutaneous Lipomatosis (ECCL) is a rare neurocutaneous disorder that occurs sporadically. It mainly involves neurologic, cutaneous, and ocular anomalies. This case report presents

a 3-day-old Filipino patient who manifested with nevus psiloliparus, epibulbar dermoid choristoma, and multiple neurologic manifestations such as intracranial atrophy, multiple intracranial lipomas, and calcifications, all of which clinically fit the diagnostic criteria of ECCL.

Methods: The patient's ocular and cutaneous lesions were initially treated conservatively. Early diagnosis and prompt surgical management of the ocular lesions were eventually performed by excision of the epibulbar mass for cosmesis and to prevent further visual complications. A skin punch biopsy of the cutaneous lesions was also done, which confirmed the diagnosis of nevus psiloliparus.

Results: There is possible guarded visual and developmental prognosis given the ocular and neurological findings. However, the parents were heavily counseled for close monitoring and follow-up.

Conclusions: A multidisciplinary approach for management is warranted for this condition, given its numerous manifestations.

Abstract No.: 202529

Optimizing Surgical Management of Craniofacial and Orbital Fibrous Dysplasia: A Multi-Center Retrospective Cross-Sectional Study

First Author: Yinwei **LI**

Co-Author(s): Lianfei **FANG**, Yue **HE**, Zhifeng **SHI**, Huifang **ZHOU**

Purpose: Fibrous dysplasia (FD) is a rare osseous disorder with limited understanding. This study aimed to evaluate clinical characteristics of craniofacial FD (CFD) and orbital FD (OFD), explore vision impairment mechanisms, and identify recurrence risk factors.

Methods: A retrospective analysis was conducted on 54 CFD patients across three centers, including 30 patients with orbit involvement.

Results: OFD patients exhibited higher prevalences of polyostotic FD and McCune-Albright syndrome, and more often underwent debulking rather than radical surgery. Vision impairment was primarily attributed to compressive and stretched optic neuropathy. Polyostotic involvement ($p = 0.034$) was a risk factor for subjective recurrence. Surgery age <16 years ($p = 0.046$) and abnormal body mass index ($p = 0.002$) were associated with greater postoperative lesion regrowth volume.

Conclusions: OFD patients exhibit distinct clinical features. Optic canal decompression is not required for all OFD-related vision loss patients. Recurrence risk should be thoroughly assessed before surgery.

Abstract No.: 202990

Orbital Myoepithelial Carcinoma: Clinical Profile and Treatment Outcomes From a Single-Center Study

First Author: Wang **NAN**

Co-Author(s): Jing **LI**, Jianmin **MA**

Purpose: Orbital myoepithelial carcinoma (OMC) is an exceptionally rare malignancy with limited published data regarding its clinical behavior and management. This study aims to characterize the clinical, radiological, and histopathological features of OMC, and evaluate prognostic factors based on a single-institution case series.

Methods: A retrospective review was conducted of 12 patients with histopathologically confirmed OMC treated at Beijing Tongren Hospital between January 2000 and December 2024. Data collected included demographics, clinical presentation, imaging characteristics, treatment modalities, recurrence, and survival outcomes. Progression-free survival (PFS) and overall survival (OS) were analyzed.

Results: The cohort comprised 7 males and 5 females, with a mean age of 55.1 years. Common initial symptoms included abnormal globe position (41.7%). Tumors were frequently large (median diameter: 25.5 mm) and invasive, with sinonasal or intracranial extension in 41.7% of cases. Bone destruction was observed in 66.7% of imaging studies. A notable history of pleomorphic adenoma was present in 50% of patients. Over a mean follow-up of 6.6 years, the overall survival rate was 77.8%, with a recurrence rate of 55.6%. All patients with prior pleomorphic adenoma developed recurrence. The median progression-free survival was 3 years.

Conclusions: OMC is an aggressive orbital malignancy often associated with large tumor size, local invasion, and high recurrence rates, particularly in cases arising from pleomorphic adenoma. Long-term postoperative surveillance and multidisciplinary management are critical given the substantial risk of recurrence and progression.

Abstract No.: 201789

Outcomes of Intracanalicular Antibiotic Instillation and Surgical Management of Canaliculitis

First Author: Meghana **TANWAR**

Co-Author(s): Sabyasachi **CHAKRABARTY**, Usha **KIM**

Purpose: A retrospective review of treatment outcomes of canaliculitis -intracanalicular ointment instillation (IOI) or punctal snip and marsupialization (Sx) in achieving resolution of infection and patency.

Methods: The treatment modalities and outcomes of canaliculitis cases between January 2022 and February 2025 were studied. $p < 0.05$ was considered significant.

Results: Eighty-four cases with a median follow-up of 3 months with IOR(1-10) were eligible. The mean age was 59.67 ± 12.54 years. 72.6%(n=61) showed a lower canalicular involvement. The causative microbe could be identified in 65 cases, and 8 showed polymicrobial involvement. The most common isolate was *Staphylococcus* spp(n=21; 32.3%). 41.7%(n=35) patients received IOI alone, 50%(n=42) patients received a primary Sx and 8.3%(n=8) patients underwent IOI followed by Sx. The median IOIs per recipient was 5 (IQR 3-6). IOI was more successful than Sx in attaining canalicular patency(p=0.003).

Conclusions: IOI is more effective than Sx in treating canaliculitis. Intracanalicular antibiotic instillation requires multiple sittings but is more successful at attaining canalicular patency in canaliculitis. Surgery may be planned for a patient unwilling for further repeated follow-ups, but watering may persist post-surgery due to persistent canalicular blockage.

Abstract No.: 206155

Outcomes of Post-Teprotumumab Orbital Decompression in Residual or Reactivated Thyroid Eye Disease

First Author: Rolika **BANSAL**

Co-Author(s): Eman **AL-SHARIF**, Don **KIKKAWA**, Bobby **KORN**, Catherine **LIU**

Purpose: To assess the clinical outcomes of orbital decompression in patients previously treated with teprotumumab for thyroid eye disease (TED).

Methods: Retrospective analysis of TED patients post-teprotumumab who underwent orbital decompression for residual exophthalmos. Outcomes measures assessed were change in exophthalmos (primary outcome), diplopia, and CAS (secondary outcomes).

Results: We identified 139 TED patients who were treated with a full course of teprotumumab. A total of 38 orbits or 18% (25/139) patients underwent orbital decompression. Indications for surgery were residual disease (persistent exophthalmos and/or large angle diplopia) in 89% (34/38) or reactivated disease (increase in exophthalmos >2mm and/or CAS >4) in 11% (4/38). The mean interval prior to surgery was 8.6 ± 4.8 (range 1.0 - 26.0) months from the last infusion. The mean pre-decompression exophthalmos was 21.0 ± 2.0 (range 19.0 - 26.5) and the mean post-decompression exophthalmos was 19.2 ± 1.9 (range 16.0 - 24.0), corresponding to a reduction of 10% at a mean follow-up of 27.3 ± 11.8 (range 3.0 - 52.0) months. There were no cases of induced diplopia following decompression. Decompression led to resolution of diplopia in 23% (5/22) of cases without additional strabismus procedures. Prior to any treatment, the median CAS score was 4, which reduced to 2 post-teprotumumab and <1 post-orbital decompression.

Conclusions: Prior studies have shown that the rate of orbital decompression has declined significantly with the advent of teprotumumab. Our study shows that patients with residual or reactivated disease post-teprotumumab therapy, in the form of exophthalmos, diplopia, and elevated CAS score, can be further improved with surgical orbital decompression, providing disease control and excellent outcomes.

Abstract No.: 201641

Outcomes of Surgical Management in Moderate to Severe Contracted Anophthalmic Sockets: A 10-Year Retrospective Review

First Author: Alene, Ker Hsin **NG**

Co-Author(s): Pimkwan **JARU-AMPORN PAN**, Kanograt **PORN PANICH**

Purpose: To evaluate surgical outcomes in moderate to severe contracted anophthalmic sockets at a tertiary hospital, addressing a critical gap in the literature, particularly within Asian populations.

Methods: A retrospective review of 63 patients with Grade 3 and 4 socket contractures, classified by Tawfik's grading, was conducted at a tertiary hospital (January 2015–December 2024). Clinical data, surgical techniques, prosthetic rehabilitation, satisfaction, and complications were analyzed. Outcomes were defined as complete success (restoration of a deep fornix with stable customized prosthesis retention), partial success (persistence of focal scarring or symblepharon with prosthesis still retainable, often requiring adjustments), and failure (inability to retain prosthesis).

Results: Grade 4 sockets comprised 54.0%. Trauma (47.6%) and congenital anomalies (17.5%) were the leading etiologies. Following reconstruction, all patients retained a customized prosthesis: 71.4% achieved complete success and 28.6% partial success, with 85.7% reporting satisfaction. Oral mucous membrane grafts (OMMG) were most frequently employed (69.8%) and strongly predicted successful outcomes (OR = 11.3, p = 0.007). Dermis fat graft (31.7%) yielded 50% complete and 50% partial success, while hard palate grafts (19.0%) achieved 75% complete and 25% partial success. Persistent contracture was the predominant complication, significantly requiring multiple surgeries. Grade 4 sockets demonstrated higher complication rates and surgical burden, reflecting greater baseline scarring and tissue loss.

Conclusions: This 10-year review provides the most comprehensive dataset on contracted socket reconstruction in Asia. Stable prosthetic rehabilitation was achievable in all patients, though outcomes depended on severity and technique. OMMG proved pivotal for sustained success, while advanced contractures demanded more complex management, underscoring the importance of individualized strategies.

Abstract No.: 203506**Preliminary Clinical Application of Three Lacrimal Duct Reconstruction Techniques***First Author: Pang ZUOXIANG*

Purpose: To report the clinical application of three different methods of lacrimal duct reconstruction surgery in our hospital.

Methods: Since November 2022, 11 cases of lacrimal duct reconstruction have been carried out. Among them, 9 cases of lacrimal duct reconstruction using nasal mucosa (nasal mucosa group), 1 case of lacrimal duct reconstruction using nasolacrimal duct and lacrimal sac (nasolacrimal duct group), and 1 case of conjunctival dacryocystic anastomosis surgery. Postoperative care included antibiotic and corticosteroid eye drops, with triamcinolone acetonide nasal spray used in the first two groups. Regular follow-ups were scheduled within 3 months postoperatively, with subsequent visits as needed.

Results: In the nasal mucosa group, 6 cases have been followed up for over one year postoperatively (13-28 months postoperative), and 3 cases have been followed up for 5-8 months postoperative. Among them, 8 cases maintained intubation status without any epiphora symptoms. The fluorescein dye disappearance test (FDDT) showed negative results, and the lacrimal stent is properly positioned at the medial canthus, and the surgical stoma in the nasal cavity is well-formed. Patients in the nasolacrimal duct group had 6-month follow-ups showing no epiphora, good anastomotic and nasal mucosal healing, and the stent in a satisfactory position. The patients in the conjunctivodacryocystostomy group had 3-month follow-ups demonstrating no epiphora or discharge, a patent anastomosis, and the stent in a satisfactory position.

Conclusions: For refractory upper lacrimal duct obstruction, lacrimal duct reconstruction can effectively alleviate symptoms. The long-term outcomes of lacrimal duct reconstruction still require a large sample and long-term observation.

Abstract No.: 204328**Preoperative Intralesional Triamcinolone Acetonide and 5-Fluorouracil Injections: Enhancing Outcomes in Post-Traumatic Eyelid Cicatrix Reconstruction***First Author: Hisar DANIEL**Co-Author(s): Ferdy ISKANDAR*

Purpose: To evaluate the role of combined preoperative intralesional triamcinolone acetonide (TA) and 5-fluorouracil (5-FU) injections in improving surgical outcomes for post-traumatic eyelid cicatrix.

Methods: We describe two young adults with severe eyelid cicatrix after primary repair following motorcycle

trauma. Case 1 involved a 22-year-old female with a full-thickness lower eyelid rupture (>50% vertical loss). Case 2 was a 23-year-old male with a full-thickness upper eyelid rupture causing complete lagophthalmos and corneal exposure. Both developed significant eyelid contracture one month post-injury. A combined regimen of intralesional TA (4 mg/0.1 mL) and 5-FU (45 mg/0.9 mL) was administered weekly for three sessions, followed by eyelid re-reconstruction one week after the final injection.

Results: Marked improvement in eyelid mobility and reduction of cicatrix were observed in both cases prior to re-reconstruction. Postoperatively, eyelid contour and function were restored, lagophthalmos resolved, and corneal protection was achieved. Importantly, no adverse events related to the injections occurred.

Conclusions: Preoperative intralesional TA and 5-FU injections appear to favorably modulate scar remodeling and facilitate optimal conditions for eyelid re-reconstruction. This protocol demonstrates potential as a safe and effective adjunct for managing complex cicatricial eyelid deformities, particularly in high-risk post-trauma cases where functional and aesthetic outcomes are critical.

Abstract No.: 204127**Primary Results of the Phase-3 SatraGO-1 and SatraGO 2 Trials: Efficacy and Safety of Satralizumab in Thyroid Eye Disease***First Author: Dongmei LI**Co-Author(s): César A. BRICEÑO, Alexander BURDESKA, Oluwatobi IDOWU, Thomas KUENZEL, Santiago ORTIZ-PEREZ*

Purpose: Satralizumab is a humanized monoclonal antibody targeting IL-6R (interleukin-6 receptor) with a longer duration of circulation and subcutaneous dosing Q4W (every-4-weeks). SatraGO-1/SatraGO-2 trials are investigating satralizumab's efficacy and safety in moderate-to-severe, active and chronic-inactive TED (thyroid eye disease) participants.

Methods: SatraGO-1 (NCT05987423; n=131, 12 countries)/SatraGO-2 (NCT06106828; n=127, 10 countries) are ongoing, identical, global, phase 3, double-masked, two-stage randomized, placebo-controlled, 72-week multicenter studies. Participants aged ≥18 years with moderate-to-severe, active TED (symptom onset ≤12 months before baseline) or stable, chronic-inactive TED (diagnosed 1–10 years before screening) were eligible if systemic disease was controlled. Participants were randomized 1:1 to subcutaneous satralizumab or placebo at Weeks 0, 2, 4 (loading doses), then Q4W through Week 20 (maintenance). Week-24 primary efficacy endpoint was the proportion of active TED participants with proptosis response (≥2mm improvement from baseline in study eye). Secondary endpoints included proptosis response in all TED participants, overall response (≥2-point

reduction in clinical activity score from baseline and proptosis response in the study eye) in active TED, and proportion of patients achieving ≥ 1 grade improvement in diplopia. Safety included incidence, seriousness, and severity of adverse events.

Results: During abstract submission, trials are ongoing. By the proposed APAO presentation, the primary endpoint at Week-24, with key safety and secondary endpoints, will be available and presented.

Conclusions: SatraGO-1/SatraGO-2 are investigating IL-6R inhibition via satralizumab in TED participants. Primary efficacy and safety data are expected to provide insights into satralizumab's potential as a disease-modifying therapy for TED.

Abstract No.: 203023

Prolonged Subperiosteal Orbital Hemorrhage – a Case-Based Literature Review

First Author: Brigitha **RAHMADDINI NAVIRA PAPUTUNGAN**

Co-Author(s): Suliati P. **AMIR**, Halimah **PAGARRA**, Andi **PRATIWI**, Syukriyah **SOFYAN**

Purpose: Subperiosteal orbital hemorrhage (SOH) is an uncommon and potentially vision-threatening ailment. Traumatic subperiosteal hemorrhage mostly happens due to traumatic events to the craniomaxillofacial structure. This case report aims to present a case of subperiosteal orbital hemorrhage and to provide a review of similar cases from the existing literature.

Methods: The patient was a 15-year-old boy with a protruding left eye for two weeks, right after blunt trauma, along with a watery left eye and dizziness. Best corrected visual acuity (BCVA) was 20/30 PH 20/25, and the IOP was 30 mmHg on the left eye. Proptosis and 1 mm lagophthalmos were present on the left eye. There was no RAPD detected on both eyes, and the pupillary reflex on both eyes showed a normal response. There was restricted ocular movement in all directions of the affected eye. CT-Scan of the orbit showed left retrobulbar hemorrhage. He was diagnosed with proptosis of the left eye caused by retrobulbar hemorrhage of the left eye.

Results: In this case, anterior orbitotomy with cantholysis and hemorrhage evacuation was done on his left eye, and it was revealed that the hemorrhage was located in the subperiosteal rather than in the retrobulbar area. After one month of follow-up, the BCVA of the affected eye was 20/20 without any complications. The final CT Scan one month after hemorrhage aspiration revealed no hemorrhage in the subperiosteal space.

Conclusions: Traumatic subperiosteal orbital hemorrhage is rare in children, with surgical drainage offering good visual outcomes. Without adequate resolution, it may progress to a chronic hematic cyst.

Abstract No.: 200362

Prospective Clinical Study of Tocilizumab for the Treatment of Pediatric Patients With Thyroid Eye Disease

First Author: Pengsen **WU**

Co-Author(s): Guiqin **LIU**

Purpose: To evaluate the clinical efficacy and safety of tocilizumab in the treatment of pediatric patients with thyroid eye disease (TED).

Methods: This prospective clinical study included Pediatric patients with TED at Shenzhen Eye Hospital from September 2023 to December 2024. Inclusion criteria consisted of progressive worsening of ocular symptoms, including increased proptosis and/or eyelid retraction. The treatment protocol involved intravenous administration of tocilizumab (8 mg/kg) once every four weeks for a total of 3 to 6 doses. Outcome measures included: clinical activity score (CAS), proptosis, palpebral fissure height, and routine ophthalmic examinations. Patients were followed up for 6 months post-treatment.

Results: This study enrolled 11 pediatric TED patients (mean age 13.1 ± 2.3 years; range 9-17 years) with a female predominance ($n=10$, 90.9%). All patients received an average of (3.09 ± 2.34) doses of the medication. Treatment results showed that 10 patients responded well to the medication. Significant improvements were observed following treatment. Proptosis decreased from 18.45 ± 3.26 mm to 17.32 ± 2.98 mm ($P < 0.0001$). Palpebral fissure height reduced from 11.14 ± 1.81 mm to 10.05 ± 1.36 mm ($P = 0.0002$). CAS showed marked reduction from 1.73 ± 1.39 to 0.27 ± 0.46 ($P < 0.0001$). Regarding safety, 1 patient (9.09%) experienced mild neutropenia during tocilizumab treatment, which did not require special intervention and resolved spontaneously after discontinuation; no other adverse reactions were observed.

Conclusions: This study demonstrates that tocilizumab effectively treats pediatric thyroid eye disease with a low incidence of mild adverse effects, showing promising clinical application prospects.

Abstract No.: 201882

Prospective Study on the Epidemiology of Demodex in Pediatric Chalazion and the Possibility of Maternal Transmission

First Author: Ryo **KIKUCHI**

Co-Author(s): Tomoyuki **KASHIMA**

Purpose: Pediatric chalazion is a common eyelid disorder, but its underlying etiologies remain incompletely understood. Demodex infestation has been implicated in blepharitis and chalazion in adults, while its role in children and the possibility of maternal transmission are less clear. This study aimed to determine the prevalence of Demodex in pediatric

chalazion and to evaluate the potential maternal association.

Methods: From August 2024 to August 2025, a prospective interventional study was conducted in 31 children (mean age 6.97 ± 4.06 years) undergoing chalazion surgery under general anesthesia. During the procedure, eyelashes were epilated and examined microscopically for Demodex mites. Clinical features, including recurrence, anterior/posterior blepharitis, and maternal history of chalazion, were recorded. Additionally, maternal eyelashes were examined for Demodex to explore the possibility of vertical transmission.

Results: Among the 31 patients, 24 presented with primary chalazion and 7 with recurrent disease. Demodex was detected in 4 children (12.9%), and all isolates were identified as Demodex folliculorum. Anterior blepharitis was observed in 6 cases and posterior blepharitis in 4 cases. A maternal history of chalazion was noted in 3 of 31 cases, while Demodex was identified in only 1 mother.

Conclusions: Demodex can be detected in pediatric chalazion, particularly in recurrent cases with blepharitis. All positive cases involved D. folliculorum, suggesting this species may predominate in children. The low maternal positivity indicates that mother-to-child transmission is not a major factor. Larger studies are warranted to confirm species-specific roles and to guide preventive strategies.

Abstract No.: 201302

Quantification of Apical Crowding Using Computed Tomography and Its Relationship With Visual Function in Dysthyroid Optic Neuropathy

First Author: Shengnan CHENG

Purpose: To assess the performance of computed tomography-based extraocular muscle area (EOMA) measurement, as a marker of apical crowding, for early detection of dysthyroid optic neuropathy (DON) in patients with Graves' ophthalmopathy (GO).

Methods: Medical records and CT scans of 60 patients were reviewed: 36 with GO and DON, and 24 with GO without DON. On coronal CT slices 18 mm posterior to the inter-zygomatic line, the EOMA to orbital bone area ratio (EOMA/OA) was calculated. Apical crowding was also subjectively graded (Nugent score). Visual function parameters, including best-corrected visual acuity (BCVA, logMAR), visual field mean deviation (MD), pattern standard deviation (PSD), and pattern-reversal VEP P100 latency and amplitude, were evaluated. Correlation between EOMA/OA and visual function was analyzed. ROC analysis evaluated the sensitivity and specificity of EOMA/OA for DON detection.

Results: All visual function parameters except P100 amplitude ($P = 0.261$) differed significantly between

groups (all $P < 0.05$). The EOMA/OA ratio was significantly higher in DON orbits (0.72 ± 0.14 vs. 0.44 ± 0.16 , $P < 0.0001$), as was the Nugent score (2.19 ± 0.78 vs. 1.00 ± 0.91 , $P < 0.0001$). ROC analysis showed EOMA/OA predicted DON with 92% sensitivity and 71% specificity at a cutoff of 0.53, outperforming the Nugent score. EOMA/OA significantly correlated with BCVA, MD, PSD, and P100 latency.

Conclusions: The quantitative EOMA/OA ratio demonstrates high sensitivity and specificity for identifying DON in GO patients and correlates significantly with visual functional impairment, supporting its use for early detection.

Abstract No.: 205848

Risks and Benefits of Local Anesthesia Versus General Anesthesia in Endoscopic Dacryocystorhinostomy

First Author: Shelley CHANG

Co-Author(s): Yi-lin liao, Yen-chang CHU

Purpose: Endoscopic dacryocystorhinostomy (DCR) is a common procedure, typically performed for nasolacrimal duct obstruction (NLDO) under general anesthesia (GA), while performing it under local anesthesia (LA) may offer benefits to patients and surgeons. This study analyzes the outcomes and assesses the risks and benefits of performing endoscopic DCR under GA versus LA.

Methods: A retrospective chart review was conducted in patients aged 18 years or older with acquired NLDO who underwent endoscopic DCR at a tertiary center between January 2019 and December 2024. The primary outcome was the surgical failure, while secondary outcomes included operative time, intraoperative bleeding, complications, predictors of failure, and the need for revision surgery between the 2 groups. Surgical failure was evaluated using multivariable Cox proportional hazards models, adjusted for age and sex, with propensity score-matched analyses serving as sensitivity analyses. Potential predictors were initially screened through univariable analyses, and variables with a P -value < 0.15 were then entered into multivariable models. All statistical tests were two-tailed with a significance threshold of $P < 0.05$.

Results: The study enrolled 211 eyes of 163 patients, with 118 patients (160 eyes) in the GA group, and 45 patients (51 eyes) in the LA group. The mean age was 61.8 ± 12.2 years in the GA group, and 72.3 ± 12.7 years in the LA group. The duration of surgery was significantly shorter in the LA group ($P < 0.001$). Surgical success was comparable between groups, with the LA group exhibiting a shorter operative time ($P < 0.001$). No major adverse events were reported. Small lacrimal sac size was identified as an independent associated factor of surgical failure ($P < 0.001$).

Conclusions: LA offers a safe and effective alternative to GA for endoscopic DCR, particularly in older patients. Potential drawbacks include patient discomfort and an uncontrollable surgical field, which can be mitigated with appropriate patient selection. Both methods demonstrated similarly high success rates.

Abstract No.: 206311

Role of Conjunctival Map Biopsy in Determining Outcome in Sebaceous Gland Carcinoma

First Author: Kirthi KOKA

Co-Author(s): Md Shahid ALAM

Purpose: To evaluate the role of conjunctival map biopsy (MB) in nodular and diffuse variants of eyelid sebaceous gland carcinoma (SGC).

Methods: All patients with histopathologically proven SGC who underwent MB over the last twelve years were retrospectively analyzed.

Results: Twenty-eight patients with a mean age of 66.86 ± 11.68 were analyzed. There was no sex predilection. Nodular lesion was seen in ten patients (35.7%), whereas a diffuse presentation was seen in 18 patients (64.3%). Initial management consisted of an excision biopsy with lid reconstruction in 19 (67.8%) and incisional biopsy in 4 patients (14.3%). A total of 368 conjunctival MB sites were analyzed of which 162 (44.02%) sites were positive for pagetoid spread of SGC. The positivity of map biopsy was 14.6 % and 58.7% in nodular and diffuse variants, respectively ($p=0.001$). The mean follow-up period was 15.67 ± 19.79 months. Recurrence was seen in 7 patients at a mean duration of 11 ± 7.05 months, of which six patients had an initial diffuse eyelid involvement. A total of nine patients underwent exenteration, all of whom had a diffuse presentation on clinical examination and on map biopsy.

Conclusions: Diffuse SGC showed a statistically high positivity rate on MB compared to the nodular variant. Diffuse SGC had a higher recurrence rate and a higher probability of undergoing exenteration. Nodular SGC can also show pagetoid spread. Early recognition and treatment with topical chemotherapy can prevent recurrence. Hence map biopsy is recommended in all cases of SGC.

Abstract No.: 203475

Scarless Eyelid Augmentation and Lift (SEAL): Simultaneous Ptosis and Double Lid Technique

First Author: Stacey LAM

Co-Author(s): Alice GOH

Purpose: To introduce and evaluate the SEAL (Scarless Eyelid Augmentation and Lift) technique, a novel

posterior approach for simultaneous ptosis correction and double eyelid creation without external scars.

Methods: The SEAL technique utilizes a posterior white-line advancement combined with precise internal fixation to achieve functional elevation of the upper eyelid and aesthetic supratarsal crease formation. Patients undergoing SEAL were assessed for eyelid height, symmetry, crease definition, and complications. Follow-up included both functional and aesthetic outcomes, as well as patient satisfaction.

Results: Early experience demonstrates consistent improvement in margin reflex distance (MRD1), stable and natural-appearing double eyelid crease formation, and high patient satisfaction. No visible external scars or significant complications were observed.

Conclusions: The SEAL technique offers a reliable, minimally invasive approach for patients seeking both functional correction of ptosis and aesthetic enhancement through double eyelid creation, advancing the paradigm of scarless oculoplastic surgery.

Abstract No.: 203951

Suture-Assisted Three Snip Punctoplasty for Stenosed Punctum: A Novel Technique

First Author: Mohammad IDRIS

Purpose: To compare the usefulness of forceps versus 6/0 vicryl suture in opening the stenosed punctum surgically and excision during three snip punctoplasty.

Methods: Punctum was dilated with an appropriately sized dilator, followed by a lacrimal probe and syringing to check the patency of the nasolacrimal drainage system. Posterior wall of the inferior punctum is grasped with forceps compared with the same, where instead of forceps, a 6-0 vicryl suture is used for traction and holding. In both techniques, a triangular tissue with 60-degree angles to each other was removed with the base parallel to the inferior fornix. A video demonstration will be presented to explain both methods.

Results: Both forceps and suture were helpful in achieving a desired goal, but suture proved to be superior in completing three snip punctoplasty in terms of easy access and accurate triangle of tissue removal. Ten patients in group 1 (forceps group) and 10 patients in group 2 (suture group) were included. Age ranges from 41-78 years. Males were 09, females were 11. Two patients in group one showed restenosis. None of the patients in group 2 showed recurrence of stenosis.

Conclusions: Compared to the forceps technique, the suture technique was superior to surgically opening the stenosed punctum. Suture was found to facilitate the easy entry of scissors to get a desired size of tissue excision during three snip punctoplasty with no recurrence.

Abstract No.: 209071**TSHR-Targeting Nucleic Acid Aptamer Treats Graves' Ophthalmopathy via Novel Allosteric Inhibition***First Author: Yanchen ZHANG**Co-Author(s): Wencan WU*

Purpose: Dysregulated thyrotropin receptor (TSHR) signaling drives a spectrum of diseases, including the vision-threatening Graves' orbitopathy (GO). Despite its prominence as a therapeutic target, TSHR has remained pharmacologically intractable, with no clinically approved inhibitors. This study aims to bridge this critical gap by developing a novel TSHR-targeted therapy for GO, addressing the urgent unmet need for effective and precise treatments to halt its debilitating ocular complications.

Methods: A tandem approach combining protein-targeted cell-SELEX with specific functional selection was utilized to develop the aptamer YC3. Specifically, HEK293T cells engineered to highly express the TSHR protein were used as positive controls for cell-SELEX, while HEK293T cells that do not express TSHR served as negative controls. The levels of cAMP in the cells and the expression of phospho-ERK were measured as bio-functional indicators to assess the activity of the aptamers. The specificity and affinity of YC3 were evaluated using recombinant proteins, cell lines with varying TSHR expression levels, human and mouse tissues, and in vivo models. The binding site of YC3 on TSHR was investigated through competitive analyses, followed by molecular docking and dynamic simulations to predict the interaction details. These predictions were validated through site-directed mutagenesis. In vitro, the bio-function of YC3 in modulating TSHR signaling and its impact on the phenotypes of primary human orbital fibroblasts were assessed. In vivo, the effect of YC3 on orbital pathological remodeling was evaluated in GO mouse models using imaging, serological, and histopathological assessments.

Results: YC3 exhibited nanomolar affinity with robust pharmacodynamic efficacy. In vitro studies, YC3 potently reversed thyroid-stimulating antibodies (TSABs)-driven hyperactivation in primary human orbital fibroblasts, markedly suppressing pathogenic hallmarks of GO. In vivo studies, therapeutic administration of YC3 in a GO mouse model alleviated pathological remodeling of orbital tissues and improved ocular symptoms. Mechanistically, YC3 bound to a previously unidentified allosteric site within the leucine-rich repeat domain of TSHR, thereby inhibiting receptor activation.

Conclusions: This study identifies YC3 as a promising TSHR-targeted therapeutic candidate for GO and unveils a novel allosteric site for next-generation inhibitors. These findings underscore the translational potential of aptamers to dissect receptor mechanisms and uncover cryptic druggable sites, forging a critical

link between structural biology and precision-driven drug discovery.

Abstract No.: 201731**Targeted Delivery of Simvastatin via Neutrophil-Derived Exosomes Promotes Orbital Bone Defect Repair: A Translational Study***First Author: Yun SU**Co-Author(s): Xianqun FAN, Wanzhuo HE, Miao WANG*

Purpose: Orbital bone defects often lead to functional and aesthetic impairments. Current implants face challenges like inflammation and poor integration. This study developed a neutrophil exosome-based system (Exo-pep-Sim) for targeted delivery of simvastatin to enhance bone regeneration by modulating inflammation and promoting vascularized osteogenesis.

Methods: Exosomes derived from neutrophils were loaded with simvastatin via peptide modification. The system was characterized by TEM, nanoparticle tracking, and Western blot. In vitro assays included macrophage polarization (flow cytometry), osteogenic differentiation (ALP staining), and angiogenesis (tube formation). A rat orbital defect model was established, and repair was evaluated using Micro-CT and immunohistochemistry (CD31). Proteomics and pathway analysis were performed to explore mechanisms.

Results: Exo-pep-Sim showed sustained release ($82.3 \pm 5.6\%$ at 24 h) under high MMP-2 conditions. It significantly promoted M2 macrophage polarization ($38.7 \pm 3.5\%$ vs $15.2 \pm 2.1\%$, $p < 0.01$) and reduced IL-1 β . Micro-CT showed higher bone volume (BV/TV $45.3 \pm 4.7\%$ vs $19.8 \pm 3.2\%$, $p < 0.001$) and increased CD31+ vessel density (1.8-fold, $p < 0.01$). Key proteins (NRP1, VEGFR2, p-AKT) were upregulated, and PI3K-AKT/VEGF pathways were significantly activated.

Conclusions: The Exo-pep-Sim system effectively targets inflammatory sites, enhances M2 polarization, and improves vascularized bone repair, offering a promising clinically applicable strategy for orbital reconstruction.

Abstract No.: 200927**Tear miRNA Expression Profiles in Patients With Thyroid Eye Disease***First Author: Min Joung LEE**Co-Author(s): Hokyung CHOUNG, Bo Sook HAN, Namju KIM, Sang Earn WOO*

Purpose: To characterize tear microRNA (miRNA) expression profiles in patients with thyroid eye disease (TED) and identify candidate miRNA biomarkers associated with disease activity.

Methods: Total RNA was extracted from the tears of patients with TED (n=30) and healthy controls (HCs,

n=6). miRNA expression profiling was performed using the Nanostring assay, and differentially expressed miRNAs were identified based on TED activity. Selected miRNAs were validated using quantitative real-time polymerase chain reaction (qRT-PCR).

Results: Compared to HCs, 132 miRNAs were differentially expressed in TED patients. Bioinformatic analysis revealed enrichment in the MAPK signaling pathway, longevity regulation, and adherens junctions. Eleven miRNAs were significantly different between active and inactive TED: miR-193b-3p, miR-206, let-7i-5p, miR-146b-3p, miR-28-5p, miR-30a-3p, miR-485-3p, miR-499a-3p, miR-571, miR-579-3p, miR-874-5p. Among these, miR-571 and miR-579-3p were found to be significantly differentially expressed in the validation cohort by qRT-PCR.

Conclusions: We successfully profiled tear miRNA expressions in TED patients and identified several candidate miRNAs associated with disease activity. Notably, miR-571 and miR-579-3p showed significant differences in expression and may serve as tear biomarkers for TED activity. Further studies with larger cohorts are needed to confirm their roles in TED pathogenesis.

Abstract No.: 203135

Temporal Sequence Between Onset of Hyperthyroidism and Thyroid Eye Disease: A Multicenter Retrospective Study

First Author: Yujie **REN**

Co-Author(s): Chaoyu **LEI**, Huifang **ZHOU**

Purpose: Thyroid eye disease (TED) often coexists with hyperthyroidism, yet the clinical implications of their onset sequence remain unclear. This multicenter study aims to characterize the epidemiological patterns, clinical features, and serological indicators across different onset patterns.

Methods: A total of 3,834 TED patients were recruited from nine Chinese hospitals from February 2016 to July 2023 and stratified into three groups: simultaneous onset (SO), TED onset first (EF), and hyperthyroidism onset first (HF). Demographic data, clinical features, and serological indicators were analyzed.

Results: Among EF patients, 80.5% developed hyperthyroidism within 24 months of TED onset, while HF patients faced a prolonged risk of TED, with 80.3% developing it by 53 months post-hyperthyroidism onset. SO patients had the highest proportion of active (56.2%) and moderate-to-severe cases (85.0%). EF patients exhibited the highest sight-threatening cases (9.8%), smoking rates (22.3%), and longest disease duration. HF showed the highest proportion of elevated TPOAb (44.8%) and TRAb (71.4%). Logistic regression indicated HF and EF groups were less likely to be active than SO (OR: 0.442 and 0.626, respectively). In XGB, the onset sequence ranked as the third most influential

predictor of activity and severity. Among patients ≥ 60 years, HF cases were likely to have higher severity (OR: 2.60).

Conclusions: These results of the granular time-stratified analysis highlight the critical role of considering onset sequence in managing TED: EF patients require early endocrine evaluation, HF patients need prolonged ophthalmic monitoring, while SO patients may benefit from aggressive immunomodulation. Distinct serological indicators and progression patterns suggest underlying pathophysiological differences.

Abstract No.: 202830

The Scar That Kept Coming Back: Recurrent Unilateral Corneal Filament Formation Post Ptosis Surgery

First Author: Piyush **BAJAJ**

Co-Author(s): Ishita **KAK**

Purpose: To report a rare case of recurrent corneal filament formation secondary to localized tear pooling over a conjunctival scar following ptosis surgery.

Methods: A 67-year-old female presented to the ophthalmology outpatient department with complaints of bilateral redness, watering, and foreign body sensation. Slit-lamp examination revealed normal conjunctiva, lids, anterior segment, and posterior segment findings in both eyes, except for a single corneal filament located at the 1 o'clock position in the right eye. The filament was debrided, and the patient was initially managed conservatively as a case of dry eye with lubricants. However, the filament recurred at the same location over subsequent follow-ups.

Results: On detailed examination with eyelid eversion, a subtle conjunctival scar was noted on the upper tarsal conjunctiva directly opposing the site of filament formation. Upon re-evaluating the history, the patient recalled undergoing surgical correction for ptosis several years ago. It was hypothesized that the localized scar acted as a microreservoir for tear pooling, leading to focal desiccation of the corneal epithelium and recurrent filament formation.

Conclusions: This case highlights an uncommon but important sequela of ptosis surgery—localized conjunctival scarring leading to recurrent filamentary keratitis due to tear film disruption. It reinforces the importance of careful lid eversion in recurrent unilateral filament cases and thorough history-taking. Targeted management addressing the underlying cause is essential to prevent recurrence and patient discomfort.

Abstract No.: 205632

To Evaluate the Real-World Efficacy, Safety, and Outcomes of Cemiplimab for Advanced Periocular Conjunctival and Cutaneous Squamous Cell Carcinoma (SCC)

First Author: Nirodha **JAYAWICKREMA**

Purpose: Retrospective case series of adults treated with cemiplimab for periocular conjunctival or cutaneous SCC at Moorfields Eye Hospital (2021–2025).

Methods: Retrospective consecutive case review of all adult patients (≥ 18 years) with biopsy-proven periocular conjunctival or cutaneous SCC treated with cemiplimab between February 2021 and February 2025 at Moorfields Eye Hospital in London, UK. We included patients referred to our unit from other sites.

Results: We included 9 patients (mean age 66, range 43–79; 56% female; 78% Caucasian). Prior treatments included surgery (44%), radiotherapy (22%), and one exenteration. Tumour origin was conjunctival (56%), cutaneous (33%), or unknown (11%). 8 (89%) showed orbital invasion, including 2 with intracranial spread. Cemiplimab was indicated when surgery was refused or as palliative treatment in cases not amenable to localised treatment. Mean cemiplimab duration was 12.3 months (range 2.1–36.4). Immune-related adverse events included grade 2 hypothyroidism ($n=2$, continued therapy) and grade 2 hepatitis ($n=1$, discontinued). Complete and partial responses were seen in 22% and 33%, respectively; 44% progressed. No significant difference in response was observed between conjunctival and cutaneous SCC ($p=1.00$). 2 patients (22%) underwent exenteration after starting treatment. Average total follow-up was 50.8 months (range 17.4–130.6). One recurrence occurred 12 months after treatment cessation; no new metastases were reported during follow-up. Two patients died from unrelated causes.

Conclusions: The results underscore the potential of cemiplimab as globe-sparing and vision-preserving treatment in advanced periocular conjunctival and cutaneous SCC, including more aggressive and complex cases with intracranial involvement or perineural spread, both as primary and secondary treatment.

Abstract No.: 202457

Transcriptomic and Cellular Decoding of Brain Functional Alterations in Thyroid Eye Disease

First Author: Haiyang **ZHANG**

Co-Author(s): Xianqun **FAN**, Zilin **FANG**, Shufan **JIANG**, Yuting **LIU**, Huifang **ZHOU**

Purpose: This study aims to integrate resting-state functional MRI (rs-fMRI) and transcriptomics to reveal the brain alterations in thyroid eye disease (TED), and elucidate its molecular and cellular basis.

Methods: We combined rs-fMRI data from a retrospective cohort of 116 TED patients with transcriptomic data from the Allen Human Brain Atlas to reveal disease-associated brain regions. To validate the observed changes, we prospectively collected rs-fMRI and peripheral blood transcriptomic data from 39 TED patients and 42 healthy controls (HC). The integrative analysis of brain functional activities and peripheral blood transcriptomics was conducted to uncover the imaging-associated genes and validate key brain regions. Moreover, immune cell infiltration patterns were assessed to explore the immune mechanism underlying the transcriptomic and neural changes.

Results: The frontal, parietal, subcortical and brainstem were identified as potential disease-related brain regions in the TED retrospective cohort. Brain functional alterations were intimately related to synaptic signaling, neurovascular regulation and immune activation. Tissue and cellular level enrichment further showed its close association with cortex and neuron. The integration of rs-fMRI and peripheral blood data revealed alterations consistent with imaging-associated genes in TED. Furthermore, the relationship between immune cell infiltration and brain functional alterations was observed.

Conclusions: This study elucidates the brain functional alterations at the molecular and cellular level in TED, providing deeper insight into its brain-immune crosstalk.

Abstract No.: 200269

Treatment Outcomes of Early Versus Late Surgical Timing of Primary Orbital Blowout Fracture Repair in a Tertiary Hospital in Seoul, South Korea

First Author: Kervin Luke **DELLOSA**

Co-Author(s): Ho-seok **SA**, Min Kyu **YANG**

Purpose: Comparison of Treatment Outcomes Between Early and Delayed Repair of Orbital Blowout Fractures: A Single-Centre Study

Methods: This retrospective cohort study included 172 adult patients who underwent primary BOF repair between 2014 and 2024 in a tertiary center in Seoul, South Korea. Patients were categorized into early ($n=123$) and late ($n=49$) repair groups. Demographic data, fracture characteristics, and clinical outcomes were analyzed. Primary outcomes included changes in EOM motility and enophthalmos. Secondary outcomes included diplopia and infraorbital hypesthesia rates and resolution times, operative time, and complications.

Results: Preoperatively, early repair patients had poorer EOM motility (-0.93 vs -0.49 , $p=0.01$) while late repair patients had greater enophthalmos (1.77 vs 1.33 , $p=0.01$). Both groups showed significant postoperative improvement, with no differences in final motility

(-0.12 vs -0.04, $p=0.16$) and enophthalmos (0.23 vs 0.23, $p=1.00$). Residual diplopia rates were similar, with all cases resolving within one year (67.7 vs 87.1 days, $p=0.83$). Residual infraorbital hypesthesia rates (4.4% vs 6.3%, $p=0.76$) and recovery times (109.4 vs 122.8 days, $p=0.85$) were also comparable. Operative time and complication rates did not differ significantly.

Conclusions: BOF repair beyond 4 weeks yields favorable outcomes comparable to early repair in ocular motility, enophthalmos correction, and neurosensory recovery without increasing complications. Observation may be appropriate in select patients with low enophthalmos risk or improving symptoms. Delayed repair remains effective for patients with persistent diplopia or late-presenting enophthalmos.

Abstract No.: 203847

Unveiling ROBO1: A Candidate Target in Fibrosis Through Integrated Single-Cell Transcriptomics and Proteomics of the Lacrimal Gland in IgG4-Related Ophthalmic Disease

First Author: Zhiyan **XU**

Co-Author(s): Linyang **GAN**, Xiaowei **LIU**

Purpose: IgG4-related ophthalmic disease (IgG4-ROD) is a chronic orbital inflammatory condition causing tissue dysfunction and fibrosis; the lacrimal gland (LG) is a frequently involved site. The mechanisms driving LG fibrosis remain unclear. This study aims to define cellular heterogeneity and fibrosis-related mechanisms in LG from IgG4-ROD patients versus healthy controls.

Methods: Fourteen fresh LG samples (7 IgG4-ROD, 7 controls) were collected during surgery and dissociated within 4 hours for optimal viability. Six samples underwent single-cell RNA sequencing; analyses were performed in R (v5.3.0). Proteins were extracted and analyzed from the remaining eight samples. Immunofluorescence staining verified protein expression and subcellular localization.

Results: Single-cell RNA sequencing analyses identified 13 major LG cell types. "TNF signaling via NF- κ B" and "epithelial_mesenchymal_transition" pathways were enriched in LG mesenchymal cells in IgG4-ROD. Sex-specific differentiation patterns were noted in acinar cells. A significant loss of mature secretory acinar cells was observed in IgG4-ROD. Joint gene-protein expression analysis showed 93.41% concordance. Roundabout Guidance Receptor 1 (ROBO1) was markedly upregulated and co-localized with SLIT3 in fibroblasts in IgG4-ROD versus controls.

Conclusions: We present a comprehensive single-cell atlas of LG in IgG4-ROD, revealing resident cell dysplasia and identifying ROBO1-SLIT3-associated fibroblast activation as a potential therapeutic target for LG fibrosis.

Abstract No.: 204393

White Matter Alterations of the Visual Pathway in Thyroid Eye Disease

First Author: Yinwei **LI**

Co-Author(s): Mengda **JIANG**, Haiyang **ZHANG**, Huifang **ZHOU**

Purpose: Thyroid eye disease (TED), particularly its sight-threatening complication, dysthyroid optic neuropathy (DON), profoundly impacts patients' visual health. The pathological changes in the white matter (WM) fibers within the intracranial visual pathway in TED have been infrequently studied. Understanding these changes holds crucial importance for exploring the pathogenesis and prognosis of TED. This paper is to utilize fixel-based analysis (FBA) to clarify the type of microstructural damage occurring in the visual pathway in TED.

Methods: Twenty-eight TED with DON patients, 28 TED without DON patients, and 28 healthy controls (HCs) were enrolled in this study. All the subjects underwent multishell diffusion MRI using echo planar imaging. Fiber density (FD) and fiber-bundle cross-section (FC) were calculated to characterize WM microstructural alteration in TED visual pathway. The correlations between FBA metrics and visual field index and mean deviation were examined.

Results: Both DON and non-DON groups showed significant FD loss in the right optic tract compared with HCs, with DON patients experiencing more severe FD loss. Only DON patients had FD loss in the right optic radiation (OR) compared with the non-DON patients and HCs, with no FC difference across groups. FD in DON patients' ORs significantly correlated with visual field index ($r = 0.857$) and mean deviation ($r = 0.751$).

Conclusions: Both DON and non-DON affect the WM microstructure of the visual pathway to varying extents. Visual field metrics can reflect the severity of FD damage to the OR in the visual pathway of DON patients.

Pediatric Ophthalmology and Strabismus

Abstract No.: 200204

0.01% Atropine Eyedrops in Children With Myopia and Intermittent Exotropia (AMIXT): A 2-Year Randomized Clinical Trial

First Author: Hu **LIU**

Co-Author(s): Tianxi **LI**, Zijin **WANG**

Purpose: To evaluate the efficacy and safety of 0.01% atropine eyedrops on myopia progression, exotropia conditions, and binocular vision in children with

myopia and intermittent exotropia (IXT) over a 2-year treatment period.

Methods: This randomized, double-masked, placebo-controlled trial enrolled 300 children aged 6–12 years with myopia and IXT at the First Affiliated Hospital of Nanjing Medical University, China, between December 2020 and September 2022. Participants were randomly assigned in a 2:1 ratio to receive either 0.01% atropine or a placebo.

Results: At 2 years, the atropine group exhibited significantly slower spherical equivalent progression (-1.09 D vs. -1.53 D; $P < .001$) and axial length elongation (0.57 mm vs. 0.78 mm; $P < .001$) than the placebo group. The two groups were similar in changes in distant magnitude of exodeviation (0.25 PD vs. 0.88 PD; $P = .31$), near magnitude of exodeviation (-2.22 PD vs. -0.51 PD; $P = .09$), distant exotropia control (-0.06 vs. 0.01 ; $P = .66$), and near exotropia control (0.01 vs. 0.07 ; $P = .69$). Accommodative amplitude decreased significantly in the atropine group (-3.33 D vs. -0.05 D; $P < .001$). Binocular vision and adverse effects showed no significant difference across groups ($P > .05$).

Conclusions: The findings suggest that 0.01% atropine eyedrops, though compromising accommodative amplitude to some extent, can be used effectively and safely in slowing myopia progression, yet without interfering with exotropia conditions or binocular vision in children with myopia and IXT.

Abstract No.: 208578

A Hybrid Surgical Approach: LR Recesson With Augmented, Compartmentalized MR Plication for Small-Angle Exotropia and Convergence Insufficiency

First Author: Juan **DING**

Co-Author(s): Yueping **LI**, Wei **ZHANG**

Purpose: Convergence-insufficiency intermittent exotropia (CI-IXT) with a near–distance difference (NDD) ≥ 10 prism diopters (PD) is difficult to correct when the angle is small (< 25 PD). We evaluated the efficacy and safety of combining lateral rectus recession (LRc) with compartmentalized inferior medial rectus plication (CIMRP), guided by neuromuscular compartment anatomy, in achieving stable ocular alignment and functional improvement in children.

Methods: A retrospective analysis was conducted on 69 pediatric CI-IXT patients (mean age: 8.13 ± 2.46 years) who underwent LRc + CIMRP between September 2022 and January 2024. Outcomes included near/distance deviations, NDD, control scores, stereopsis, and complications, assessed preoperatively and postoperatively at 1 day, 2 months, 6 months, and final follow-up (≥ 12 months).

Results: Significant reductions were observed in near deviation (median: -30 (-32 , -28) PD to -12 (-16 , -6) PD), distance deviation (-20 (-20 , -18) PD to -6

(-10 , -1) PD), and near-distance difference (NDD) (10 (10 , 10) PD to 4 (4 , 6) PD; all $P < 0.001$). The surgical success rate was 88.41% at both 2 and 6 months, decreasing slightly to 81.16% at the final follow-up (≥ 12 months). The overcorrection rate peaked at 8.7% at 2 months and subsequently stabilized at 2.9%, whereas the undercorrection rate gradually increased to 15.9%. Control scores and near stereoacuity demonstrated significant improvement ($P < 0.001$ and $P < 0.05$, respectively). No complications such as scleral perforation, muscle slippage, or anterior-segment ischemia were observed.

Conclusions: LRc combined with CIMRP is a safe and effective surgical approach for small-angle CI-IXT, providing significant and stable correction of NDD and ocular alignment with minimal complications. This technique leverages compartmentalized innervation principles to selectively enhance convergence, offering a refined alternative to conventional methods. Further prospective studies are warranted to validate long-term outcomes.

Abstract No.: 201706

A Rare Intronic ABCA4 Variant Causing Stargardt Disease in a Filipino Adolescent: A Case Report

First Author: Raphael **GUMAFELIX**

Co-Author(s): Michelle **LINGAO**

Purpose: To report a case of Stargardt disease (STGD1) associated with an intronic mutation in the ABCA4 gene.

Methods: The patient underwent a comprehensive ophthalmic evaluation, multimodal imaging, sequence analysis, and deletion/duplication testing of the ABCA4 gene.

Results: A 14-year-old Filipino female presented with a five-year history of progressive, painless bilateral decrease in central vision and color vision deficits, without associated night blindness. Best-corrected visual acuity was 20/400 in both eyes, with refractive errors of -3.00 sph -1.50 cyl $\times 166^\circ$ OD and -3.00 sph -2.25 cyl $\times 174^\circ$ OS. Anterior segment examination was unremarkable. Fundus evaluation revealed macular atrophy with a beaten-bronze appearance. Fundus autofluorescence showed central hypoautofluorescence and patchy subretinal flecks throughout the posterior pole. Optical coherence tomography of the macula demonstrated retinal thinning, loss of retinal pigment epithelium integrity, and photoreceptor degeneration. Analysis of the nerve fiber layer and ganglion cell complex revealed thinning of the macular ganglion cell complex. Automated perimetry revealed bilateral central scotomas with generalized field depression. Sequence analysis of the ABCA4 gene revealed compound heterozygosity for two pathogenic variants, c.302+4A>C (intronic) and c.878T>G (p.Met293Arg, missense). Notably, targeted

parental testing revealed that the mother carries the missense variant and the father the intronic variant, confirming autosomal recessive inheritance and illustrating the clinical relevance of familial genotyping.

Conclusions: This case underscores the presence of a pathogenic intronic ABCA4 variant in a Filipino patient, broadening the known mutation spectrum of Stargardt disease and highlighting the value of genetic screening and family-based testing in the Philippines.

Abstract No.: 201214

A Study on the Accuracy of the Gaze-Tilt Test in Predicting the Postoperative Head Posture Improvement in Patients With Congenital Superior Oblique Palsy

First Author: Siyuan HE

Co-Author(s): Xiaotong LI, Wei ZHANG

Purpose: To investigate the accuracy of the gazetilt test in predicting the postoperative head posture improvement in patients with congenital superior oblique palsy (CSOP).

Methods: A diagnostic test was conducted, enrolling children aged 3 to 6 years diagnosed with unilateral CSOP and scheduled for unilateral inferior oblique weakening surgery between May 2023 and January 2024. Preoperatively, the single eye cover test and the gazetilt test were used to assess the patients' compensatory head posture improvement. The overall predictive accuracy, predictive accuracy for different head position improvement outcomes, and error rates (false positive rate and false negative rate) of the two methods were compared by evaluating the predicted outcomes against the actual head postures at postoperative day 1 and month 1. The paired ttest, paired Wilcoxon signedrank test, and paired chisquare test were used for statistical analysis.

Results: Thirty-two children (17 males, 15 females) were analyzed. Preoperative head tilt was 77.5° (75.0°–80.75°); postoperative day 1 and month 1 angles were 88.0° (82.64°–89.99°) and 88.9° (87.35°–90.0°). The gazetilt test predicted 87.0° (86.0°–89.07°), closer than the single eye cover test (83.0°; 80.27°–87.3°). Gazetilt had higher accuracy (86.36%/81.48%) and lower false negatives (15.63%/18.75%) than the single eye cover test (50.0%/44.44%; 43.75%/56.25%), with smaller prediction errors, all statistically significant ($P < 0.05$).

Conclusions: Compared to the single eye cover test, the gazetilt test demonstrated higher accuracy and smaller predictive errors in predicting the postoperative head posture improvement in patients with CSOP.

Abstract No.: 203333

AI-Assisted Abnormal Eye Movement Detection System: A Nationwide, Multicenter Study

First Author: Xiaotong LI

Co-Author(s): Wei ZHANG

Purpose: Strabismus has diverse etiologies, leading to heterogeneous clinical manifestations and complex diagnosis and treatment. To develop an AI-assisted abnormal eye movement detection system to enhance the diagnostic and treatment potential of primary medical institutions.

Methods: The study was conducted in three stages. Stage 1: model development and internal validation using 27,974 images, including three framework structures: 1) strabismus type recognition model, 2) abnormal extraocular muscle recognition model, and 3) fundus photography-based torsion judgment model. Stage 2: prospective external validation using 3,948 images from four hospitals. Stage 3: evaluation of AI's effect on clinicians' diagnostic ability using 75 patients from 15 hospitals.

Results: Framework 1 achieved accuracies of 0.857–0.921 for different strabismus types. Framework 2 achieved functional judgment accuracies of 0.71–0.98 for extraocular muscles. Framework 3 achieved an overall judgment accuracy of 0.935 and an FDA torsion angle deviation of $-0.40 \pm 1.53^\circ$. With AI assistance, doctors' diagnostic accuracy improved by 12%, the missed diagnosis rate decreased by 17.3%, and the surgical design rationality increased by 22.67%.

Conclusions: The abnormal eye movement detection system has the potential to significantly improve the strabismus diagnosis and treatment capabilities of young doctors.

Abstract No.: 204183

Accuracy of a System Combining Virtual Reality and Artificial Intelligence for Screening Pediatric Strabismus

First Author: Yumeng WANG

Co-Author(s): Jing FU

Purpose: To explore the accuracy of a system combining virtual reality (VR) and artificial intelligence (AI) for screening pediatric strabismus.

Methods: A total of 131 subjects aged 3–18 years were included in this study, out of which 110 were included in the final data analysis. Among them, 28 were normal, 60 patients had external strabismus, 18 patients had internal strabismus, and 4 patients had vertical strabismus. After the patients were independently diagnosed and evaluated by two strabismus and pediatric ophthalmologists, the mean value was used as the gold standard. All patients completed the AI system within 2 minutes. The

agreement between the two methods for diagnosis and classification of strabismus was compared by the Kappa consistency test. The agreement between the two methods for measuring ocular strabismus results was assessed by Bland-Altman plots, and interclass correlation efficiency (ICC), and linear regression plots were used to analyze the two methods' correlations.

Results: The system screened for strabismus with a sensitivity of 83.0%, a specificity of 79%, and moderate agreement with manual results (Kappa=0.562, $p<0.001$). The system performed well in the diagnosis and classification of strabismus (Kappa=0.749 for external strabismus, Kappa=0.898 for internal strabismus, and Kappa=1 for vertical strabismus, $p<0.001$). In terms of measuring the angle of ocular deviation, the two methods were strongly correlated ($R=0.7595$) and highly consistent ($p>0.05$) in the near mode of esotropia, and although the correlation was high ($R=0.7652$) in the far mode and the ICC results showed high consistency (ICC=0.689), the BA charts showed poorer consistency. The two methods showed strong correlation ($R=0.731$ and 0.561) in the near and far looking modes in the exotropia group, but the agreement was low (ICC<0.4, $p<0.05$).

Conclusions: The system combines VR and AI can be used clinically to screen pediatric strabismus with high sensitivity and specificity.

Abstract No.: 200442

Additive Effect of Highly Aspherical Lenslet Target (HALT) Spectacles to Children Inadequately Controlled by Atropine Monotherapy

First Author: Bryan **SIM**

Purpose: To assess the efficacy of combination myopia control spectacle lens (HALT) with atropine in children still progressing whilst on low-dose atropine (LDA).

Methods: Children aged 6-11 years old still progressing on atropine (by $>-0.5D$ in at least 1 eye in the past 6 months) were started on HALT (Essilor® Stellest®) glasses. Change in spherical equivalent (SE), cycloplegic autorefraction (cAR) and axial length (AL), were calculated prior and after treatment.

Results: Fifty children (age 8.9 ± 1.1 years) were recruited and divided into: Group A: on atropine 0.01% (A0.01) daily ($n=20$); and Group B: on A0.01 twice daily ($n=5$); or A0.025 daily ($n=25$). The majority (86%) of the children were ethnic Chinese (Table 1). No significant difference in baseline SE, cAR, AL, or pupil size was noted between groups. Prior to study, myopia progression was estimated at $-0.60D/0.24mm$ over 6 months. After the addition of HALT glasses, the change in SE/AL decreased to $-0.06D/0.06mm$ over the first 6 months. At 12 months, the overall change in SE/AL was $-0.15D/0.14mm$. Benefit appeared to be present in all age groups. A hyperopic shift in AL was seen in 11

children (24%) at 12 months. However, progression of $>0.5D$ was noted in 20%, with 18% and 40% progressing by $>0.3mm$ and $>0.15mm$, respectively.

Conclusions: These findings showed that children still progressing on low-dose atropine benefited from the addition of HAL glasses. Significant reductions in SE and AL was noted in children as young as 7YO.

Abstract No.: 201604

Anterior Segment Clues to Posterior Segment Disease in Infants With Congenital Corneal Opacities: A Clinical and Genetic Perspective

First Author: Sonam **YANGZES**

Co-Author(s): Amit **GUPTA**, Savleen **KAUR**, Simar **SINGH**

Purpose: To describe an anterior-posterior segment phenotype in infants presenting with bilateral congenital corneal opacity, thick corneas, and shallow anterior chambers, and to explore its association with retinal pathology and genetic mutations.

Methods: An observational case series was conducted on four infants (eight eyes) at a tertiary pediatric ophthalmology center. All were presented at birth with bilateral corneal opacities along with various retinal changes. Multimodal imaging included anterior segment OCT, ultrasound biomicroscopy (UBM), and B-scan ultrasonography. Whole exome sequencing (WES) was performed to identify pathogenic variants. Fundus examination and fluorescein angiography were conducted for family screening.

Results: All infants had thickened corneas (>850 microns), flat or shallow anterior chambers accompanied by posterior segment findings suggestive of vitreoretinopathy, including vitreous hemorrhage, falciform folds, and retinal detachment. AS-OCT and UBM revealed retrocorneal hyperreflective membranes and vitreous stalks suggestive of fibrovascular proliferation. WES identified homozygous or heterozygous mutations in LRP5 and BMP4, implicating Wnt/TGF- β pathway dysregulation. Family screening revealed peripheral vascular anomalies in two of the four families (50%).

Conclusions: Infants with congenital corneal opacity, thick corneas, and shallow anterior chambers may harbor underlying vitreoretinal pathology due to posterior fibrotic contracture. Mutations in LRP5 and BMP4 suggest a genetic and developmental etiology, resembling a "pseudo-Peters" phenotype. This underscores the importance of posterior segment imaging and genetic evaluation in such presentations.

Abstract No.: 205924

Artificial Intelligence-Quantified Fundus Tessellated Density and Its Association With Myopia Severity in Chinese Children: A Cross-Sectional Study

First Author: Nan LIU

Co-Author(s): Li LI, Jifeng YU

Purpose: This study aimed to quantitatively assess the whole fundus tessellated density (FTD) using artificial intelligence(AI) and evaluate its association with myopia severity in Chinese children with myopia.

Methods: A cross-sectional analysis was conducted on participants with myopia from Beijing Children's Hospital, Capital Medical University, from October 2023 to June 2024. AI technology was used to quantitatively measure FTD based on fundus photographs. Participants were classified into mild, moderate, and high myopia(HM) groups based on cycloplegic spherical equivalent (SE) values. To explore the relationship between FTD and SE, Spearman correlation coefficients along with linear regression analysis were utilized. The ability of FTD to discriminate HM was assessed using a receiver operating characteristic (ROC) curve.

Results: The study included 263 children aged 6-12 years. Median FTD values were 0.01 (IQR: 0.00–0.02), 0.01 (IQR: 0.00–0.03), and 0.04 (IQR: 0.01–0.12) for the three groups respectively. Significant difference was found when comparing the HM group with the mild and moderate myopia groups ($P < 0.001$). A negative correlation between FTD and SE was observed (Spearman coefficient: -0.41 , $P < 0.001$). The modified linear regression analysis additionally supported the significant correlation between FTD and SE ($P < 0.001$), and indicated that an increase of one unit in FTD resulted in a reduction of SE by 7.17D. The area under the curve (AUC) of FTD for identifying HM was 0.75 (95% CI: 0.68–0.81). Combining FTD with axial length-to-corneal radius ratio (AL/CR) improved the discriminative performance, achieving an AUC of 0.94 (95% CI: 0.91–0.97), significantly higher than AL, AL/CR, FTD, or FTD combined with AL ($P < 0.05$). The cutoff values were $FTD \geq 0.03$ and $AL/CR \geq 3.27$.

Conclusions: AI-quantified FTD demonstrates a significant correlation with the severity of myopia.

Abstract No.: 205482

Atropine and Spectacle Lens Combination Treatment (ASPECT): 24-Month Interim Results of a Randomised Controlled Trial for Myopia Control

First Author: Rosario GOMEZ-DE-LIANO

Co-Author(s): Rafael BELLA-GALA, Julian GARCIA-FEIJOO, Noemi GUEMES-VILLAHOS, Elena HERNANDEZ-GARCIA, Paloma PORRAS-ANGEL, Paula TALAVERO-GONZALEZ

Purpose: This randomized controlled trial (RCT) aims to evaluate the long-term efficacy of combination treatment using 0.025% atropine and Defocus Incorporated Multiple Segments (DIMS) spectacle lenses compared to 0.025% atropine and single vision (SV) lenses in slowing myopia progression over 24 months.

Methods: RCT conducted on myopic children aged 4-16 years, randomised into two treatment groups: 0.025% atropine and SV lenses (group A) or 0.025% atropine and DIMS lenses (group B). Cycloplegic spherical equivalent refraction (SER) and axial length (AL) were measured at baseline, 6, 12, 18, and 24 months (M).

Results: Seventy-one patients completed the 24M follow-up: $n=34$ in group A, mean age 8.97 ± 2.8 years; $n=37$ in group B, mean age 9.78 ± 2.75 years. At 12M and 24M, mean $AL \pm SD$ change was 0.18 ± 0.13 mm and 0.36 ± 0.24 mm in group A ($p=0.01$), and 0.09 ± 0.17 mm and 0.22 ± 0.25 mm in group B ($p=0.02$), respectively. Mean $SER \pm SD$ progression at 12M and 24M visit was -0.16 ± 0.31 D and -0.37 ± 0.60 D in group A ($p=0.90$), and -0.17 ± 0.35 D and -0.19 ± 0.62 D in group B ($p=0.23$), respectively. Younger subjects ($\beta = -0.066$, $p < 0.001$), greater baseline AL ($\beta = 1.041$, $p < 0.001$) and group A ($\beta = -0.132$, $p=0.02$) were associated with an increase in AL over 24M.

Conclusions: Combination treatment with 0.025% atropine and DIMS spectacle lenses is more effective in controlling axial elongation than 0.025% atropine with SV lenses in myopic children over a 24-month period, though SER differences were not significant. While full sample analysis is pending, current findings suggest an additive effect of the two treatments, with a stronger impact in the first year.

Abstract No.: 203982

Augmented Medial Rectus Recession vs BTXA Therapy in AACE and Predictors for Recurrence: A Prospective, Nonrandomized Clinical Trial

First Author: Yueping LI

Purpose: To compare the motor and sensory outcomes and quality of life (QOL) of augmented medial rectus recession (aMRc) and Botulinum Toxin A (BTXA) therapy

in acute acquired comitant esotropia (AACE) treatment, and to investigate the predictors of recurrence.

Methods: We conducted a prospective, non-randomized clinical trial that enrolled 63 AACE patients with a disease course of 6 months to 2 years and deviation angles of 15 to 60 PD. The patients were assigned to BTXA (n=31) and aMRc group (n=32). We compared and analyzed the deviation angles, fusion amplitudes (FA) of convergence and divergence, stereopsis, and scores of quality of life (QOL) and diplopia between the two groups before treatment and at 2, 4, 6, and 12 months post-treatment.

Results: Both groups exhibited significant improvements in motor and sensory outcomes. The aMRc group showed more stable and satisfactory deviation than the BTXA group at 6 and 12 months post-treatment, with a significant increase in divergent FA. The aMRc group achieved a higher success rate (93.75%) than the BTXA group (64.52%) one year post-treatment. QOL improved significantly in both groups after treatment, except for reading function in the BTXA group. Compared with the BTXA group, the aMRc group showed greater improvements in self-perception, general function, and diplopia scores ($P < 0.05$). Survival analysis revealed a significant difference between the two groups ($P = 0.0046$). Treatment method and convergent FA at near before treatment were identified as recurrence predictors ($P = 0.023$ and 0.025).

Conclusions: Augmented MRc treatment was superior to BTXA injection in AACE patients with courses > 6 months during 1-year observation, particularly in maintaining alignment, eliminating diplopia, and improving divergent fusion amplitude and QOL.

Abstract No.: 202105

Axial Length Dynamics and Safety of Occlusion Therapy in Pediatric Amblyopia: A Longitudinal Analysis

First Author: Wentong YU

Co-Author(s): Yunsu HE, Jinrong LI, Xuan QIU, Yun WEN, Junpeng YUAN

Purpose: To evaluate the impact of occlusion therapy on the elongation of axial length (AL) in children with amblyopia using real-world big data.

Methods: A cohort of 2,932 children aged 3-15 years undergoing occlusion therapy with varying patching durations was analyzed using longitudinal data from the Zhongshan Ophthalmic Center (May 1, 2019–September 30, 2023). Retrospective analyses utilized multivariable linear regression to assess associations between patching duration and AL elongation. Generalized estimating equations (GEE) were used to evaluate interocular AL differences. The analyses were adjusted for factors including revisit interval, age, sex, baseline best-corrected visual acuity (BCVA), initial AL,

spherical equivalent, amblyopia type, and concurrent treatments.

Results: The mean annual AL increase was 0.23 ± 0.22 mm. Patching had no significant overall effect on AL elongation ($\beta = -0.02$; $p = 0.12$), even for long daily patching (≥ 5 hours/day). Subgroup analyses revealed reduced AL elongation in patched eyes of school-age children (6–12 years) with shorter baseline ALs, suggesting age- and baseline-specific effects. GEE analysis showed no significant interocular differences except among preschool children (3–5 years), where observed eyes exhibited slightly less AL elongation compared to fellow eyes.

Conclusions: Occlusion therapy is safe for amblyopia management. Tailored regimens based on age and baseline ocular characteristics are recommended to optimize therapeutic outcomes.

Abstract No.: 206640

Binocular Visual Dysfunction: A Novel Biomarker for Rapid Myopia Progression in Adolescents

First Author: Zhongfei CHEN

Purpose: This study aims to investigate the association between binocular visual dysfunction and the progression of myopia in adolescents. Moving beyond traditional biological ocular parameters, we innovatively explore this relationship from a cerebral visual perspective, analyzing the impact of visual perceptual deficits on myopia development.

Methods: In this one-year prospective study, 104 myopic adolescents (aged 8–14) were categorized into two groups based on annual changes in spherical equivalent refraction and axial length: Group A (slow progression, $n=51$; SER: -0.50 to -0.75 D, $AL < 0.3$ mm/year) and Group B (rapid progression, $n=53$; SER ≤ -1.00 D, $AL \geq 0.3$ mm/year). Visual perceptual functions, including perceptual eye position and dynamic random dot stereopsis, were assessed using a standardized system.

Results: Significant intergroup differences were observed in visual perceptual functions. The mean near perceptual eye position deviation was greater in Group B (100.52 pixels) than in Group A (57.62 pixels, $P=0.043$). The prevalence of dynamic stereopsis impairment was also significantly higher in Group B (67.9% vs. 23.5%, $P < 0.05$). No significant differences were found in other stereopsis tests.

Conclusions: This study demonstrates a strong correlation between rapid myopic progression and deficits in binocular visual function, particularly perceptual eye position deviation and dynamic stereopsis impairment. These findings suggest that visual perceptual assessment may serve as a biomarker for identifying adolescents at risk of rapid myopia progression.

Abstract No.: 208798

Brainwashing Excyclotorsion

First Author: Vincent PARIS

Purpose: Classical approaches to excyclodeviation, such as double Maddox testing, Knapp's classification, and inferior oblique (IO) recession have remained unchanged for years. This prospective study challenges those paradigms, emphasizing the role of the superior rectus (SR) in torsional analysis and proposing a more dynamic clinical framework.

Methods: We studied 117 consecutive patients with unilateral excyclotorsion over seven years, all operated on by the same surgeon. Torsion was assessed subjectively via the Hess-Weiss method and objectively via fundus examination. Vertical deviation was evaluated in head tilt and downgaze, introducing a "fourth step test" to assess SR contracture. Surgery focused on the superior oblique (SO), with anterior transposition of the resected tendon. In cases of complete palsy or recurrent excyclotorsion, IO anterior nasal transposition was performed. Procedures were guided by intraoperative elongation testing.

Results: Success, defined as resolution of head tilt, vertical deviation, torsion, and asthenopia, was achieved in all cases using one to five surgical steps. Combined oblique muscle surgery was required in 55%, IO nasal transposition in 7%, and single IO recession in 37%. SR recession was needed only in two elderly patients. The fourth step test was positive in 76%. Reintervention was rare and mostly related to acquired Brown syndrome.

Conclusions: This study demonstrates that we can rethink our clinical mindset, examination methods, classification, and surgical strategies in this frequent pathology. Patient-centered outcomes are best achieved through tailored oblique muscle surgery, minimizing the need for SR or inferior rectus recession.

Abstract No.: 206592

Breaking the Pattern: Addressing Large Angle A-Pattern Exotropia With Superior Oblique Overaction in Helveston Syndrome

First Author: Nur Aisyah RAHMAWATI

Co-Author(s): Anna Puspitasari BANI

Purpose: To report a case of successfully managed Helveston syndrome presenting with large-angle A-pattern exotropia and vertical deviation.

Methods: A 29-year-old female presented with outward and downward deviation of the left eye (LE) since childhood, without abnormal head posture or diplopia. Best-corrected visual acuity was 6/6 in both eyes, with normal anterior and posterior segments, except for 10 degrees of right incyclotorsion on fundus examination. Primary position showed a 55 prism diopters (PD) of exotropia with a large left hypertropia

of 50 PD, asymmetrical superior oblique overaction (SOOA, LE>RE), and asymmetrical dissociated vertical deviation (DVD, LE>RE), consistent with Helveston syndrome. Sensory testing exhibited LE suppression. She underwent bilateral rectus recession (9 mm) with half-width infraplacement, combined with right SO lengthening of 8 mm chicken suture. Due to residual hypertropia, a second surgery of left inferior rectus recession (5 mm) and right superior rectus recession (5 mm) was performed 6 months later.

Results: Six months after the second surgery, the A-pattern had completely collapsed, with 4 PD esophoria in the primary position and diminished DVD. The downshoot on the LE improved from +3 to +1, with the residual movement likely due to end-to-end tendon suturing without a spacer. No complications such as SO underaction, ptosis, or diplopia occurred, but unmasking of right SOOA was observed. However, she has not consented to further procedure.

Conclusions: Management of Helveston syndrome requires individualized surgical planning according to the degree of A-pattern, SOOA, DVD, and fundus torsion. A tailored, and possibly multiple-staged surgical approach can achieve satisfactory functional and cosmetic outcomes.

Abstract No.: 202892

Changes in Choriocapillaris Blood Flow Density and Associated Factors Affecting Axial Elongation in Chinese Children and Adolescents With Mild to Moderate Myopia: A Cross-Sectional Study

First Author: Cui XIN

Co-Author(s): Liping CHEN, Xuefeng SHI

Purpose: To investigate changes in choriocapillaris blood flow density (CFD) and identify factors influencing axial elongation in Chinese children and adolescents with mild to moderate myopia.

Methods: A hospital-based cross-sectional study was conducted. A total of 288 participants aged 8 to 15 years were recruited from Tianjin Eye Hospital, including 186 children and adolescents with myopia and 102 age-matched participants without refractive error who served as the control group. Based on cycloplegic spherical equivalent (SE), the myopic participants were further categorized into moderate and mild myopia groups. Refractive power was determined through refraction tests, while various parameters—including axial length (AL) and choriocapillaris flow density (CFD)—were obtained through ophthalmic examinations. Statistical analyses were performed to examine changes in CFD and to identify factors associated with axial length.

Results: AL and SE differed significantly among all three groups (all $P < 0.001$). SFCT was significantly lower in the moderate myopia group compared to

the mild myopia and control groups ($P < 0.05$ for both comparisons), while no significant differences in SFCT or FRT were found between the mild myopia and control groups (all $P > 0.05$). CFD peri was significantly lower in the moderate myopia group compared to both the mild myopia and control groups ($P = 0.006$ and $P < 0.001$, respectively), while no significant differences were found in CFD-fovea or CFD-para among the three groups ($P > 0.05$). Spearman correlation analysis revealed significant negative correlations between AL and SE ($r = -0.770$), SFCT ($r = -0.170$), CFD-fovea ($r = -0.347$), CFD-para ($r = -0.368$), and CFD-peri ($r = -0.359$) (all $P < 0.01$). Hierarchical regression analysis identified SE ($\beta = -0.751$, $P < 0.001$) and CFD-peri ($\beta = -0.118$, $P = 0.005$) as independent predictors of axial length, with the final model explaining 71.5% of its variance ($R^2 = 0.715$).

Conclusions: Choriocapillaris blood flow density in the macular region changes in the early stages of myopia, showing decreases in the perifoveal region. Both SE and CFD-peri may serve as potential biomarkers for predicting axial length elongation in the early stage of myopia.

Abstract No.: 204139

Changes of Accommodation and Convergence After Strabismus-Corrected Surgery for Basic Type Intermittent Exotropia

First Author: Zhao **YIYANG**

Co-Author(s): Fu **JING**

Purpose: To explore the difference in binocular accommodation and convergence before and after strabismus-corrected surgery for basic type intermittent exotropia during a 24-month follow-up.

Methods: Observational study. A total of 138 children aged 3-14 years who have strabismus-corrected surgery for their basic-type intermittent exotropia were recruited in this study. All patients underwent assessments of spherical equivalent (SE), axial length (AL), exodeviation, visual and perceptual function, stereopsis, control ability scores, and binocular function relating to accommodation and convergence. Examinations were conducted at baseline and 6-, 12-, 18-, and 24 months after surgery. Self-comparison before and after surgery was adopted. Paired t-tests were used to investigate the parameter changes.

Results: The SE, AL, exodeviation, visual and perceptual function, stereopsis, and control ability scores showed prominent differences before and after surgery till 24-month follow-up. The changes of horizontal phoria showed significant difference at 6-, 18- and 24 months ($t = -2.593$, $p = 0.018$; $t = -2.714$, $p = 0.016$; $t = -2.926$, $p = 0.009$). Accommodative convergence/accommodation ratio (AC/A) showed differences and tend to decrease at 12-, 18- and 24 months ($t = -2.493$, $p = 0.020$; $t = 2.636$, $p = 0.013$; $t = -2.410$, $p = 0.022$). At 18 months, the binocular positive relative

accommodation (PRA) ($t = 2.804$, $p = 0.009$), accommodative amplitude (AMP) ($t = -3.408$, $p = 0.002$), and accommodative response ($t = -2.444$, $p = 0.020$) showed changes and a tendency toward the normal range. At 24 months, the accommodative facility (AMF) began to change ($t = 2.061$, $p = 0.046$).

Conclusions: The strabismus-corrected surgery not only altered the exodeviation, visual and perceptual function, stereopsis, and control ability for a long time, but also changed the parameters of the accommodation and convergence, especially the horizontal phoria and AC/A ratio, which also have a long-term change.

Abstract No.: 202011

Characteristic Thinning of Temporal Parafoveal Retinal Thickness in Patients With Intermittent Exotropia

First Author: Tao **SHEN**

Co-Author(s): Mengya **HAN**, Jianhua **YAN**

Purpose: To quantitatively compare the temporal parafoveal retinal thickness between intermittent exotropia (IXT) and healthy controls using optical coherence tomography, exploring the relationship between retinal structural changes and retinal correspondence.

Methods: Twenty basic type IXT with an exodeviation angle of 35 prism diopters (PD) were compared with 20 age-matched healthy controls. All enrolled participants underwent a comprehensive ophthalmic evaluation, including optical coherence tomography, axial length, prism alternate cover test, retinal correspondence, and stereoacuity. The retinal thickness at the parafoveal position corresponding to the exodeviation angles of 25 PD, 30 PD, 35 PD, 40 PD, and 45 PD was measured. Interocular symmetries of the retinal thickness were analyzed according to ocular laterality or dominance in the IXT group. Comparative analysis of temporal parafoveal retinal thickness was conducted between the IXT group and the normal control group. According to the retinal correspondence, IXT patients were divided into the anomalous retinal correspondence (ARC) group and the non-ARC group, and further comparative analysis was conducted on retinal thickness between the two groups.

Results: The temporal parafoveal retinal thickness was symmetrical between the eyes in IXT patients without significant interocular difference ($P > .05$). However, the retinal thickness at the corresponding parafoveal position of the exodeviation angle (35 PD) was significantly reduced in IXT patients ($P < .0001$), which was thinner in the nondominant eyes of the ARC group ($P = .007$).

Conclusions: Patients with IXT showed characteristic thinning of the retinal thickness in the temporal parafoveal region corresponding to the exodeviation

angle, presenting a structure similar to a shallow “pseudo-fovea.”

Abstract No.: 204221

Clinical Pattern of Duane Retraction Syndrome

First Author: Tariq ALDOAIS

Purpose: To evaluate the clinical pattern of Duane retraction syndrome.

Methods: A cross-sectional observational study was conducted from June 2022 to December 2024 at Rowad Alnour Eye Hospital, Sanaa region, Yemen. Participants gave verbal consent prior to data collection. Data was collected using a sheet containing eighteen simple items, which include demographic data, family history, surgical history, and the clinical characteristics of the disease. Forty-three patients were included in this study.

Results: Out of 43 duane patients, there was female predominance with a percentage of 65.1% compared with male patients 34.9%. The mean age of the subjects was 6.7 years old. Oldest 26y.o. and youngest one year at time of diagnosis. There was female predominance with a percentage of 65.1% compared with male patients 34.9%. The mean age of the subjects was 6.7 years old. Oldest 26y.o. and youngest one year at time of diagnosis. Refraction of the affected eye ranged from emmetropia to different degrees of astigmatism. Emmetropes were most commonly observed with a percentage of 26.8% followed by hypermetropia and hypermetropic astigmatism of affected eyes with percentages of (27.9% and 4.7%) respectively. The least types of refractive errors were myopia, astigmatism, and the myopic astigmatism with percentages of (0%, 2.3% and 2.3%) respectively. Left eye was more commonly affected than right eye (60.5% and 34.9%) respectively.

Conclusions: DRS consists of a complex set of involvement, including an abnormal head position, globe retraction, pseudoptosis in adduction, or abnormal eye movements. Though DRS is present at birth, in the early stages, it may appear only as an abduction deficit.

Abstract No.: 204515

Clinical and Histopathological Correlation of Peters' Anomaly in King Khaled Eye Specialist Hospital (KKESH)

First Author: Ghadah ALQAHTANI

Co-Author(s): Aljawhara ALDAMRI, Abdulrahman ALFARHAN, Hind ALKATAN, Rawan ALSHABEEB, Ahmed MOUSA

Purpose: Peters' Anomaly (PA), the commonest form of anterior segment dysgenesis, is a congenital condition characterized by corneal opacity together with

iridocorneal adhesions or lenticulocorneal adhesions. This study aims to describe and correlate the clinical and histopathological findings of PA patients in a tertiary eye care hospital in Saudi Arabia.

Methods: This study is a retrospective descriptive study. Data of all patients who were clinically diagnosed with PA or anterior segment dysgenesis and underwent Keratoplasty between January 2004 and December 2020 in King Khaled Eye Specialist Hospital were included. Medical records were reviewed to extract clinical and histopathological data of their corneal buttons.

Results: Fifty-seven eyes of 38 patients were included; 26 (68.4%) of whom were females. The inheritance was sporadic in the majority of eyes, 45 (78.9%). Clinically, 35 (61.4%) eyes presented with central corneal opacity, and 17 (29.8%) with diffuse corneal opacity. Fifty-four (94.7%) had associated glaucoma upon presentation. Type I PA was present in 41 (71.9%), while type II was found in 15 (26.3%). Histopathologically, absent Bowman's layer was observed in 35 (61.4%) of the included eyes, diffuse scarring of stroma in 46 (80.7%), centrally absent Descemet membrane in 42 (73.7%), absent endothelium in 17 (29.8%), and uveal tissue adhesion to the posterior cornea in 33 (57.9%). Corneal graft was clear in 22 (38.6%) eyes.

Conclusions: Peter anomaly shows diverse clinical and histopathological features, and various severities of corneal opacities. Further studies on the role of histopathological features in predicting the visual outcome and graft survival are suggested.

Abstract No.: 200621

Common Diagnostic and Therapeutic Misunderstandings in Congenital Fibrosis of Extraocular Muscles: A Case Series Approach

First Author: Nguyet MINH DUONG

Co-Author(s): Hanh NGUYEN, Truyen NGUYEN

Purpose: Congenital Fibrosis of Extraocular Muscles (CFEOM) is a rare condition that presents significant diagnostic and therapeutic challenges. This study aims to highlight five common misunderstandings in the diagnosis and treatment of CFEOM, using clinical case examples to demonstrate the importance of accurate clinical judgment and selective use of diagnostic tools.

Methods: A retrospective review of clinical cases diagnosed with CFEOM at our institution was conducted. We analyzed cases that exemplify common misunderstandings, focusing on diagnostic errors, improper imaging, and inappropriate treatment approaches. The cases were reviewed to identify key issues and propose corrective strategies.

Results: The following misunderstandings were identified: (1) Routine magnetic resonance imaging (MRI) is unnecessarily ordered for all CFEOM cases. (2) MRI slices are not properly selected; quasi-coronal

(perpendicular to the orbital axis) and quasi-sagittal (parallel to the orbital axis) slices are crucial. (3) Genetic testing is frequently ordered for every case, though it is only needed for prenatal counseling or when specific genetic syndromes are suspected. (4) CFEOM is sometimes mistaken for an isolated ocular condition, though it may be associated with systemic disorders like developmental delays. (5) Ptosis surgery is performed before strabismus correction, leading to exposure keratopathy; strabismus should be addressed first.

Conclusions: This case series emphasizes the importance of clinical diagnosis in CFEOM, highlighting the need for selective use of genetic and imaging tests. Proper understanding of these common misunderstandings can improve patient outcomes by ensuring appropriate treatment strategies and minimizing complications.

Abstract No.: 206699

Comparing Lateral Rectus Recession and Bupivacaine Injection of Medial Rectus With Conventional Recession–Resection in Moderate-Angle Intermittent Exotropia

First Author: Arash **MIRMOHAMMADSADEGHI**
Co-Author(s): Mohammad Reza **AKBARI**, Hassan **ASADIGANDOMANI**, Babak **MASOOMIAN**, Motahhareh **SADEGHI**

Purpose: To compare the clinical outcomes of lateral rectus (LR) recession and bupivacaine injection of medial rectus (MR) with conventional recession–resection (R&R) surgery in patients with moderate-angle intermittent exotropia.

Methods: This prospective study included 105 patients with intermittent exotropia between 25–30 prism diopters (PD), treated at a single tertiary center. Patients were assigned to either bupivacaine injection of MR combined with LR recession (n=53) or standard R&R surgery (n=52). Follow-up evaluations were conducted at 1, 6, 12, 18, and 24 months postoperatively. The primary outcome was surgical success, defined as exotropia ≤ 10 PD or esotropia ≤ 5 PD in the primary position. Secondary outcomes included postoperative angle changes, need for prism, and complication rates.

Results: The bupivacaine group demonstrated statistically significantly higher success rates than the R&R group across all follow-up intervals (P-value < 0.05). The R&R group had significantly higher overcorrection rates (P-value < 0.001), while none of the bupivacaine patients were overcorrected. The bupivacaine group consistently showed an undercorrection rate of 20.75%, which was significantly higher than the 7.69% rate in the R&R group at all follow-up time points (P-value < 0.001). No serious complications were reported in either group at all follow-up time points.

Conclusions: Adding bupivacaine injection of MR to LR recession appears to be a safe, effective, and minimally invasive alternative to traditional R&R surgery for moderate-angle intermittent exotropia. It is associated with favorable outcomes, low complication rates, and no overcorrection. Further randomized, controlled trials with extended follow-up are necessary to confirm these findings.

Abstract No.: 204059

Comparing the Efficacy of Defocus Incorporated Multiple Segments (DIMS) Spectacle Lenses and 0.01% Low-Dose Atropine in Slowing Myopia Progression in Indian Children

First Author: Shruti **NISHANTH**
Co-Author(s): Ameena **JENNIFER**, Arockia Agila

Purpose: To compare the one-year efficacy of DIMS spectacles and 0.01% low-dose atropine in slowing myopia progression.

Methods: A total of 162 myopic patients aged 7–12 years were assigned to either a DIMS group (n=80) or an atropine group (n=82) based on parental choice. Cycloplegic spherical equivalent refraction (SER) and axial length (AL) were measured at baseline, 6, and 12 months.

Results: After one year, the DIMS group showed a significantly lower mean SER progression (−0.258D) compared to the atropine group (−0.486D) (p=0.007). The mean AL elongation was also lower in the DIMS group (0.109 mm) compared to the atropine group (0.153 mm), though this difference was not statistically significant (p=0.17). A significantly higher proportion of patients in the DIMS group showed no or low SER progression at one year (88.7%) compared to the atropine group (63.3%) (p=0.0001). The DIMS spectacles were particularly effective in children aged 10 years and above, with a significantly slower SER progression (−0.21D vs −0.49D; p=0.0006) and AL elongation (0.06 mm vs 0.15 mm; p=0.001) compared to the atropine group.

Conclusions: DIMS spectacles were more effective than 0.01% atropine in slowing myopia progression in Indian children over one-year period, with the most significant effect in the older age group (10 years and above). The high proportion of DIMS users with no or low progression highlights its strong efficacy as a primary intervention for myopia control.

Abstract No.: 206893

Comparison of 3-Photograph Versus 5-Photograph Grading for Retinopathy of Prematurity Screening

First Author: Sudarshan SESHASAI

Co-Author(s): Tsai SHIH HSIANG ANDREW, Tay SU ANN

Purpose: To compare the diagnostic performance of 3-photograph versus 5-photograph grading protocols against clinical examination for detecting retinopathy of prematurity (ROP) and treatment-requiring ROP.

Methods: This prospective study evaluated 64 premature infants (31 males, 33 females) who underwent retinal imaging for ROP screening, yielding 138 eye evaluations. The mean gestational age of infants was 26.4±2.3 weeks, the mean birth weight was 912±380 grams, and the mean corrected gestational age at imaging was 39.1±5.0 weeks. Each eye was independently graded using both 3-photograph (posterior pole, nasal, temporal) and 5-photograph (adding superior and inferior images) protocols by masked graders. Clinical examination served as the reference standard, classifying cases into Type 1 ROP (treatment-requiring), Type 2 ROP (pre-threshold), other ROP (ROP not meeting Type 1 or 2 ROP), or no ROP. Sensitivity and specificity were calculated.

Results: Of 138 evaluations, 110 (79.7%) had ROP, including 8 (5.8%) with Type 1 ROP and 42 (30.4%) with Type 2 ROP. Both protocols achieved identical 96.4% sensitivity for detecting any ROP, while 3-photograph grading demonstrated superior specificity (92.9% versus 89.3%). Critically, both protocols achieved 100% sensitivity for Type 1 ROP (8/8) and Type 1 or Type 2 ROP combined (50/50), with no treatment-requiring cases missed.

Conclusions: Three-photograph grading demonstrated equivalent sensitivity with superior specificity compared to 5-photograph grading, detecting all treatment-requiring and pre-threshold ROP. The streamlined 3-photograph protocol may be sufficient for ROP screening, potentially improving efficiency and infant tolerability without compromising detection of clinically significant disease.

Abstract No.: 201976

Comparison of Two Different Extraocular Muscle Suturing Techniques for Strabismus Surgery

First Author: Tiantian ZHOU

Co-Author(s): Hu LIU, Hui ZHU

Purpose: To compare the surgical outcomes after bilateral medial rectus recession (BMR) or bilateral lateral rectus recession (BLR) performed with the 3-point fixation (3PF) vs 2-point fixation (2PF) suturing techniques.

Methods: Patients diagnosed with concomitant esotropia or concomitant exotropia and undergoing BMR or BLR with the 3PF or 2PF techniques between January 2022 and January 2025 were included. Postoperative deviation angles were recorded at regular follow-up visits. A Cox proportional hazards model was used to estimate the association between suturing techniques and surgical outcomes. The primary outcome was overcorrection, defined as distant eso/exodeviation >10 prism diopters (PD) after BLR or BMR. The secondary outcome was undercorrection/recurrence, defined as distant exo/esodeviation >10 PD after BLR or BMR.

Results: A total of 248 patients were included. Of these, 113 underwent surgery with 2PF, and 135 with 3PF. The cumulative incidence of overcorrection was higher in the 2PF group (33.72%; 95% CI, 30.39% to 37.22%) compared with the 3PF group (13.09%; 95% CI, 11.71% to 14.43%) across the follow-up period (difference: 20.64%, 95% CI, 16.96% to 24.28%). Patients in the 3PF group had a 62% decreased risk of overcorrection compared with those in the 2PF group (hazard ratio [HR] =0.38; 95% CI, 0.16 to 0.91). The suturing technique was not associated with undercorrection/recurrence (HR =1.07; 95% CI, 0.42 to 2.76).

Conclusions: These findings support that the 3PF suturing technique is a superior alternative to the 2PF technique for reducing overcorrection in bilateral horizontal rectus muscle recession surgery.

Abstract No.: 205864

Correlation Analysis of Fundus Tessellation Density and Refractive Parameters in Preschool Children

First Author: Jiawen WANG

Co-Author(s): Yunwei FAN, Li LI

Purpose: To investigate the age-related changes in fundus tessellated density (FTD) in preschool children aged 3–5 years and analyze its correlation with spherical equivalent (SE), axial length (AL), and corneal curvature radius (CR).

Methods: This retrospective study included 183 children aged 3–5 years from a kindergarten in Beijing between April 2023 and April 2025. Data collected included SE, AL, corneal curvature (K), and color fundus photographs. Artificial intelligence (AI) algorithms were used to quantitatively assess the choroidal exposure area and FTD. Participants were divided cross-sectionally into three age groups: 3-year-old (n=45), 4-year-old (n=55), and 5-year-old (n=83). The correlations between FTD and SE, AL, and height were analyzed. Dynamic developmental curves were plotted. Longitudinal follow-up was performed in 25 children to track dynamic changes in ocular parameters during eye development.

Results: The overall incidence of tessellated fundus in normal children aged 3–5 years was 79.78%. Cross-sectional analysis showed that AL and AL/CR increased significantly with age, while no statistically significant differences were observed in FTD, SE, or CR among age groups ($P < 0.05$). FTD was significantly positively correlated with AL and CR ($P < 0.05$) but not with SE or height ($P > 0.05$). Longitudinal analysis revealed that for every 1 cm increase in height, SE decreased by 0.029 D ($P = 0.043$) and AL increased by 0.033 mm ($P = 0.002$). For every 1 mm increase in AL, SE decreased by 0.301 D ($P = 0.007$).

Conclusions: Fundus tessellated density may serve as a sensitive biomarker for ocular wall extensibility in children, and its developmental trajectory provides a new indicator for early warning of myopia.

Abstract No.: 206367

Depth-Resolved Axial Analysis of Retinal Vasculature Development in Very Premature Infants

First Author: Ye HE

Co-Author(s): Christian ALTENBACH, Xiaorong LI, Juping LIU, Srinivas SADDA, Irena TSUI

Purpose: To investigate region-specific effects of anti-VEGF treatment on retinal vascular development in very premature infants using depth-resolved OCTA axial profiles, focusing on differences between parafoveal and perifoveal capillary layer formation.

Methods: This retrospective study included 17 premature infants (30 eyes), including 10 treated with intravitreal anti-VEGF for retinopathy of prematurity (ROP) and 7 untreated. OCTA scans ($10^\circ \times 10^\circ$, 512 B-scans) were acquired using the Spectralis Flex platform. A custom algorithm generated depth-resolved OCTA axial profiles by averaging flow signal intensity at each of 100 depth levels from the inner limiting membrane to the outer plexiform layer using LabView. Two retinal zones were analyzed: the parafoveal region ($1.68\text{--}2.5^\circ$, $86\text{--}128$ pixels) and the perifoveal region ($3.34\text{--}4.16^\circ$, $171\text{--}213$ pixels), across four quadrants. Subjects were stratified by postmenstrual age (PMA <50 vs. ≥ 50 weeks) and treatment status.

Results: In the parafovea, anti-VEGF-treated infants <52 weeks PMA predominantly exhibited a single SCP peak, with minimal ICP or DCP signal, while untreated infants of the same age already demonstrated a visible ICP and occasional weak DCP peak. By ≥ 52 weeks, both groups developed clearer ICP and DCP peaks, but these were sharper and more distinct in untreated infants. In the perifovea, treated infants <52 weeks occasionally showed three vascular peaks, though ICP and DCP remained shallow with little progression over time. Conversely, untreated infants demonstrated progressive strengthening of both ICP and DCP peaks, with markedly sharper profiles by ≥ 52 weeks.

Conclusions: Anti-VEGF-treated infants showed delayed maturation of deeper capillary plexuses, though it's unclear if this reflects treatment effects or greater prematurity. Depth-resolved OCTA revealed regional and temporal differences in vascular development.

Abstract No.: 206897

Diplopia Quantifying as an Indicator for Botulinum Toxin Type A Injection to Acute Acquired Concomitant Esotropia With Micro-Deviation

First Author: Jie HAO

Co-Author(s): Jing FU

Purpose: To determine whether diplopia quantifying can serve as an indicator for botulinum toxin type A (BTX-A) injection in acute acquired concomitant esotropia (AACE) patients with micro-deviation.

Methods: The patients were divided into three groups. The diplopia quantifying score was evaluated based on reports of near reading and straight-ahead distance gaze diplopia severity. The success rate of diplopia elimination was calculated as the proportion of patients with diplopia score eliminated to never or rarely at follow-up to the total number of patients. A non-inferiority analysis with a margin of 10% as a priori was performed. Logistic regression and the Receiver Operating Characteristic curve were used for analysis.

Results: Seventy AACE patients were enrolled, with 92.9% completing the diplopia questionnaire at the final follow-up. After BTX-A injection, high success rates of diplopia elimination were observed across all groups during follow-up, although these rates slightly decreased over time. The non-inferiority analysis demonstrated that the success rates of diplopia elimination in patients with micro-deviation were comparable to those with small or moderate deviations at 1 month, 3 months, and 6 months. In the regression analysis, the interval from disease onset to treatment initiation was positively associated with diplopia scores and was an independent risk factor for the success rate of diplopia elimination, with a critical cut-off value of 30 months.

Conclusions: This study innovatively highlighted that diplopia quantifying can serve as an indicator for the intervention in AACE patients with micro-deviation that can eliminate diplopia symptoms without inferiority to small to moderate deviations.

Abstract No.: 201165

Discovery of Tear Protein Markers for Non-Invasive ROP Screening: Potential Association Between Omics Dysregulation in Tear Fluid and Blood Serum Samples

First Author: Alicia Hoi Ying LIU

Co-Author(s): Chung Yin CHU, Connie LAI, Thomas Chuen LAM, Wai Ching LAM, Ying Hon SZE

Purpose: Retinopathy of prematurity (ROP) is a leading cause of preventable childhood blindness. Current screening via indirect ophthalmoscopy is stressful and skill-dependent.

Methods: A case-control, cross-sectional study identifying novel tear protein markers of ROP. Tear fluid from ROP (n = 13) and non-ROP preterm infants (n = 21) was collected with Schirmer strips. Tear proteins were quantified with label-free SWATH-MS, followed by functional and pathway enrichment analyses.

Results: A total of 2,279 tear proteins were quantified; 50 were consistently dysregulated in both Spectronaut and DIA-NN software. Protein-protein interactions show enhanced lipid metabolism and transport driven by the reduced apolipoprotein A1 (APOA1, Log2FC = -1.4), APOA4 (Log2FC = -1.4), and APOD (Log2FC = -1.2). Pathway enrichment analysis showed reduced LXR/RXR (liver X receptor/retinoid X receptor) signalling (p < 0.01). Concurrently, the serum showed upregulated aspartate transaminase (AST) and alanine transaminase (ALT), which is consistent with the reduced LXR/RXR signalling. Reduced LXR signalling lowers cholesterol efflux and anti-inflammatory signalling, leading to altered lipid metabolites and lipid raft formation, which may increase oxidative stress and upregulate VEGF and angiogenesis, resulting in ROP neovascularisation.

Conclusions: This is one of the first comprehensive, untargeted tear proteome analyses in ROP. Our study revealed a potential association of dysregulated apolipoproteins, lipid metabolism, and LXR/RXR signalling in ROP angiogenesis. These changes in ROP tear samples mirror the blood serum alterations within the same patient cohort, supporting tear fluid as a feasible and promising non-invasive screening tool for ROP.

Abstract No.: 208269

Effect of Secondhand Smoke on Children's Ocular Microbiome

First Author: Qihang SUN

Co-Author(s): Xiangtian LING, Jason YAM, Yuzhou ZHANG

Purpose: To investigate whether secondhand smoke (SHS) exposure alters the ocular surface microbiome (OSM) in children and to explore potential functional consequences.

Methods: A total of 491 children aged 3-18 years were enrolled, including 142 SHS-exposed and 349 unexposed controls. Conjunctival swabs were collected and analyzed by 16S rRNA gene sequencing targeting the V3-V4 region. Sequencing data were processed with Qiime2 and DADA2, and taxonomic classification was based on the SILVA 138 database. Alpha diversity and beta diversity were compared using t-tests and PERMANOVA. Differentially abundant taxa were identified using LEfSe, and predicted functional pathways were analyzed using PICRUST2 with MetaCyc and KEGG annotation.

Results: No significant differences in alpha or beta diversity were detected between SHS-exposed and control groups. Both groups were dominated by Firmicutes, Proteobacteria, and Actinobacteriota. However, SHS exposure enriched opportunistic genera, including Massilia and Serratia, while reducing commensal taxa such as Anaerococcus and Dietzia. Functional prediction showed enrichment of metabolism pathways such as L-methionine salvage, biphenyl, heparin, and toluene degradation and immune-related pathways, including complement activation, T and B cell receptor signaling, MAPK, and TGF-beta pathways.

Conclusions: SHS exposure did not affect overall microbial diversity but induced compositional and functional shifts favoring opportunistic pathogens and immune modulation. These changes may increase susceptibility to ocular infections or inflammation, highlighting the importance of minimizing SHS exposure in children.

Abstract No.: 200433

Efficacy and Safety Analysis of 0.05% Atropine Combined With Orthokeratology With Progressive Myopia

First Author: Yunyun WANG

Purpose: To study the additive effect and safety of 0.05% and 0.01% atropine in progressive myopia patients wearing OK lenses.

Methods: A total of 125 patients with progressive myopia after wearing OK lenses for 1 year. They were randomly divided into 3 groups. In group A, 42 eyes were treated with OK lens combined with 0.01% atropine; 45 eyes in group B were combined with 0.05% atropine, and 38 eyes in the control group continued to wear the same type of OK lens.

Results: Compared with before treatment, the AL in groups A, B, and control increased 1 year after treatment, respectively: 0.23±0.08mm, 0.12±0.05mm, 0.31±0.03mm, the increase in group B was significantly lower than that in group A and control group (P<0.001). After 1year treatment, the SE of the three groups increased by -0.35±0.68D, -0.12±0.35D and -56±0.43D, respectively, and the increase of group B

was significantly lower than that of group A and control group ($P < 0.001$). One year after treatment, the relative position relationship between the defocus ring and pupil under photopic pupil the difference in A was statistically significant ($P = 0.001$). During treatment, the occurrence of adverse reactions among the three groups was no statistical significance between the three groups ($P > 0.05$).

Conclusions: Orthokeratology combined with 0.01% and 0.05% atropine can effectively slow down the rapid growth of AL and myopia, 0.05% atropine combined with orthokeratology has a better control effect on progressive myopia.

Abstract No.: 202933

Efficacy and Vascular Redevelopment of Anti-Vascular Endothelial Growth Factor Therapy for Stage 2 Early-Diagnosed Familial Exudative Vitreoretinopathy

First Author: Haonan MA

Co-Author(s): Jie PENG, Peiquan ZHAO

Purpose: To report the efficacy of anti-vascular endothelial growth factor (VEGF) therapy in stage 2 familial exudative vitreoretinopathy (FEVR) diagnosed under 3 months of age, and to present the first evidence of continued peripheral vascular growth and its influencing factors.

Methods: This retrospective, consecutive study included 24 eyes (14 patients) between January 1, 2017, and December 1, 2024. Outcome measures were the response to anti-VEGF treatment and the vascular growth assessed by disc-vascularized border/disc-fovea (DB/DF).

Results: The median age of patients at treatment was 10.5 days, with a median follow-up duration of 22 months. Nineteen (79%) eyes showed "Regression," and 3 (13%) demonstrated "Persistence". Among them, six eyes received additional laser photocoagulation. The remaining two (8%) eyes showed "Progression" and underwent lens-sparing vitrectomy. The generalized estimating equations model revealed that retinal vessels continued to grow progressively after treatment ($\beta = 0.0010$; 95% CI, 0.0005–0.0014; $P < 0.001$). The segmented mixed model demonstrated that the relative DB/DF ratio increased at a rate of 0.004 per week (95% CI, 0.0023–0.0056) until 35.4 weeks post-treatment.

Conclusions: Anti-VEGF therapy may effectively regress the high vascular activity of stage 2 early-diagnosed FEVR and promote continued vascular growth toward the periphery.

Abstract No.: 202111

FGF10 / IGSF3 Variants in Bony Congenital Nasolacrimal Duct Obstruction: A Genotype-Phenotype Study of Syndromic Versus Isolated Disease

First Author: Yuchen LI

Co-Author(s): Chengyue ZHANG

Purpose: To identify pathogenic variants associated with congenital bony nasolacrimal duct obstruction (bony CNLDO) and to clarify genotype-phenotype correlations.

Methods: In this single-center retrospective case study, children with clinically confirmed bony CNLDO and their relatives underwent detailed ophthalmic, systemic examinations, orbital computed tomography (CT), and maxillofacial magnetic resonance imaging (MRI). Whole-exome sequencing (WES) was performed on peripheral blood samples. Bioinformatics tools were utilized to predict variant pathogenicity, and classifications were performed according to the American College of Medical Genetics and Genomics (ACMG) guidelines.

Results: Thirty-two participants were included in this study, comprising six families and seven sporadic cases. WES identified eight novel FGF10 variants, including six missense mutations (c.598C>G, c.316T>G, c.395T>C, c.316T>C, c.327C>G, c.332T>G), one intronic splicing mutation (c.429+2T>A), and one heterozygous deletion at chromosome 5p12 encompassing the FGF10 gene. Two sporadic cases had no identifiable pathogenic variants. All patients with FGF10 variants exhibited a syndromic aplasia of lacrimal and salivary glands (ALSG) phenotype characterized by bony CNLDO, punctal anomalies, and hypoplasia of lacrimal, parotid, and submandibular glands. Three novel IGSF3 variants were also identified, including two missense mutations (c.2872G>C, c.2531G>A) and one nonsense mutation (c.2416G>T). In contrast, individuals carrying IGSF3 variants showed isolated bony CNLDO with normal glandular morphology.

Conclusions: Bony CNLDO is predominantly a monogenic disorder involving FGF10 or IGSF3. FGF10 mutations are associated with syndromic, gland hypoplasia, whereas IGSF3 mutations result in isolated bony CNLDO. These findings enhance understanding of the genetic heterogeneity and genotype-phenotype correlations underlying bony CNLDO, with implications for genetic diagnosis and counseling.

Abstract No.: 202130

Factual Evidence on Digital Therapeutics in Pediatric Amblyopia — Insights Into Rapid Axial Elongation Risk

First Author: Yunsi HE

Co-Author(s): Lei FENG, Jinrong LI, Xuan QIU, Yun WEN, Ying YAO, Wentong YU

Purpose: To evaluate the impact of daily digital therapeutics (DTx) on the risk of rapid axial elongation (RAE) in children with amblyopia using data from clinical settings.

Methods: This retrospective cohort study included 1394 children 3-to-12 years of age with amblyopia, 477 of whom received DTx. Children in the DTx group underwent 30 minutes of daily vision therapy, with axial length (AL) measured at baseline and during follow-up. Cox proportional hazards models were used to assess the risk of RAE, defined as an annual axial elongation exceeding safety thresholds based on age and myopia status. The primary outcome was the hazard ratio (HR) for RAE associated with DTx, adjusted for age, sex, best-corrected visual acuity, cycloplegic spherical equivalent refraction, amblyopic eye, type of amblyopia, and baseline AL.

Results: Six hundred forty-one children (45.98%) experienced RAE. Use of DTx increased the risk of RAE by 65% (HR, 1.65; 95% confidence interval, 1.40- 1.96; $P < 0.001$), with consistent findings across all subgroups ($P > 0.05$ for interaction). The increased risk was noted particularly in children with hyperopia, suggesting the potential for DTx to influence axial growth in this population.

Conclusions: Digital therapeutics are associated with an increased risk of RAE in children with amblyopia, highlighting the need for careful monitoring of AL during therapy. Although DTx offers visual acuity improvements, its potential impact on ocular growth should be balanced, particularly in children with hyperopia and prematurity.

Abstract No.: 205867

Feasibility of an App-Based Assessment Tool for Cerebral Visual Impairment Screening

First Author: Sahithya BHASKARAN

Co-Author(s): Harini KANNAN, Vijayalakshmi PERUMALSAMY

Purpose: Cerebral visual impairment (CVI) is a leading cause of pediatric blindness, but often goes undiagnosed in part due to access barriers. Visual perceptual (VP) skills are critical for understanding cognitive vision, yet traditional evaluation methods rely on numerous expensive physical tools. We evaluated whether an app-based assessment could serve as a feasible alternative to standard physical tools.

Methods: Children with suspected CVI who were referred for assessment were included. Subjects completed the physical kit assessment and the app-based assessment. We compared the child's ability to complete each of the ten visual perceptual skills tests in both modalities, the time to complete each modality and each specific skill test, and the difficulty of the task based on how much prompting or help the child needed

Results: Of 51 children, 34 completed the physical kit, and 37 completed the app-based assessments. The app showed 85% agreement with the physical kit. Task difficulty was rated higher in the app 25% of the time, lower 14%, and the same 60%. Completion time was only 11 seconds longer in the app (SD=18 s). In 5 out of 7 tasks with levels, at least 60% of children who successfully completed the task got to the highest level. 63% of children were able to successfully complete more tasks in the app than in the physical kit.

Conclusions: App-based visual perceptual tests are a promising, low-cost, scalable tool for CVI screening, providing comparable results with added accessibility and efficiency. This app could improve early detection and intervention for children with CVI.

Abstract No.: 205852

Feeding the Retina: Can DHA Drop the Risk of ROP?

First Author: Nadhira Rahma AUGUSTRIA

Co-Author(s): Julie Dewi BARLIANA, Angieta Putri SUPRAPTO

Purpose: Retinopathy of prematurity (ROP) is a major cause of preventable childhood blindness worldwide, particularly affecting high-risk infants. Access to advanced treatment remains limited in developing countries such as Indonesia. Docosahexaenoic acid (DHA) supplementation has been proposed to reduce the risk of severe ROP.

Methods: We conducted a systematic review through PubMed and Scopus using relevant keywords to identify studies reporting the effect of enteral DHA supplementation and ROP. Eligible studies were screened based on predefined inclusion criteria. Meta-analysis was performed using RevMan 5.4 software.

Results: All six studies (n=890 infants) included were eligible for meta-analysis. Analysis indicated enteral DHA supplementation has no significant effect on the incidence of any stage ROP (OR 0.98; 95% CI 0.72–1.34; $p=0.90$; $I^2=3\%$). Subgroup analysis comparing high-dose versus low-dose DHA likewise demonstrated no difference in ROP risk (OR 0.95; 95% CI 0.12–7.32; $p=0.96$; $I^2=0\%$). However, pooled analysis of four RCTs reporting ROP type 1 showed that DHA supplementation was associated with a significant reduction in incidence (OR 0.51; 95% CI 0.30–0.89; $p=0.02$; $I^2=20\%$). Small earlier studies (n=58 infants)

reported no significant difference in ROP-needed treatment. In contrast, the latest larger trials (n=316 infants) showed reduced risk of severe ROP in the DHA supplementation group.

Conclusions: Enteral DHA supplementation does not reduce the overall incidence of any stage ROP but significantly lowers the risk of ROP type 1. DHA has emerged as a promising strategy to prevent severe ROP in high-risk infants.

Abstract No.: 206241

Global and Regional Trends in Retinopathy of Prematurity: Global Disparities in Visual Impairment, Projected to 2050

First Author: Wai Chak **CHOY**

Co-Author(s): Emily Suhan **WONG**, Jason Cheuk Sing **YAM**, Yuzhou **ZHANG**

Purpose: To analyze trends in ROP-related visual impairment from 1990 to 2021 and identify risk factors for increased prevalence of visual loss with disease burden projection to 2050.

Methods: Utilizing the Global Burden of Disease 2021 dataset to identify ROP-related visual outcomes across 204 countries from 1990 to 2021, we incorporated socioeconomic risk factors and healthcare indicators from the dataset and employed machine-learning models for forecasting until 2050.

Results: The total number of patients globally with visual loss due to retinopathy of prematurity remained stable from 1990-2021. Low SDI and low-middle SDI countries accounted for the majority of ROP related visual loss cases in 2021. The largest disparity lies in the prevalence of ROP-related blindness, which remains disproportionately high in low and low middle SDI countries, but a sharp decline has been seen since 2000s. The prevalence pattern shows a shifting burden of ROP-related visual impairment, with high-middle SDI countries in particular experiencing an increasing prevalence rate in all grade visual loss related to ROP. Multivariable regression analysis identified lower primary completion rate (estimate=-2.33[95%CI=-3.11--1.55]), higher out-of-pocket healthcare expense (estimate=2.61[95%CI=1.86-3.35]), lower social insurance coverage (estimate=-2.79[95%CI=-3.76--1.82]), lower prenatal screening coverage (estimate=-3.91[95%CI=-4.63--3.19]) and nursing staff density (estimate=-2.07[95%CI=-3.03--1.11]) were associated with higher visual loss prevalence. Projections indicate that without targeted interventions, the burden of ROP-related visual impairment will continue to escalate, particularly in high-middle and middle SDI regions

Conclusions: Significant disparities remain between SDI groups, especially for ROP-related blindness. The global burden of ROP-related visual loss may further increase,

particularly for middle to high-middle SDI countries without timely intervention.

Abstract No.: 203837

Impact of Surgery on Reading Ability in Children With Infantile Esotropia

First Author: Bibigul **BEGEEVA**

Co-Author(s): Ivan **STEPANETS**

Purpose: Infantile esotropia disrupts binocular vision early and may impair reading. As reading is a key academic skill, this study was designed to evaluate functional outcomes beyond visual acuity by assessing changes in reading performance before and after surgical correction in children aged 8–10 years.

Methods: A prospective study was conducted on 18 children (aged 8–10 years) with infantile esotropia who underwent surgical alignment. Reading ability was assessed with standardized, age-appropriate charts. Three parameters were measured: maximum reading speed (MRS, words/min), critical print size (CPS, smallest fluent print size), and reading acuity (RA, minimum legible print size with errors). Evaluations were performed preoperatively and at 3 months postoperatively.

Results: All parameters improved significantly after surgery. - MRS increased from 100 ± 13 to 132 ± 14 words/min ($p < 0.005$). - CPS improved from 0.36 ± 0.06 to 0.27 ± 0.05 logMAR ($p < 0.005$). - RA improved from 0.29 ± 0.07 to 0.21 ± 0.05 logMAR ($p < 0.005$). These findings demonstrate better reading fluency and fine visual function after alignment.

Conclusions: Surgical correction of infantile esotropia in children aged 8–10 years restores ocular alignment and significantly enhances reading performance. Improvements in MRS, CPS, and RA emphasize the value of including reading assessment in postoperative follow-up. Early surgery may provide substantial visual and educational benefits.

Abstract No.: 200905

Is Amblyopia of Any Severity Fully Treatable at Any Age?

First Author: Sameera **IRFAN**

Purpose: To determine whether visual recovery in amblyopia is influenced by a patient's age at presentation.

Methods: In a prospective interventional study, 1701 consecutive cases with poor vision were included irrespective of the patient's age. After wearing refractive correction for 8-12 weeks and experiencing no further improvement in the BCVA, amblyopia therapy was initiated, comprising full-time patching of the good eye, along with active use of the amblyopic eye through reading and writing for at least 6 hours daily. Regular two-weekly follow-ups were conducted.

The endpoint of therapy was achieving a BCVA equal to that of the good eye. A regular post-patching follow-up was conducted for 1-3 years. Statistical analysis comparing visual acuity at the start and end of therapy was performed using a paired t-test for each group.

Results: There were 896 male and 805 female cases. 1383 cases (81.3%) had previously failed amblyopia therapy. Forty-nine cases (2.9%) dropped out of the study. For a simplified analysis of the results, the 1701 cases were divided into three age groups: Group A, aged 4-7 years (473 cases), Group B, aged 8-12 years (618 cases), and Group C, aged 13-46 years (610 cases). The overall success rates after therapy for 2-4 months were 97.6%.

Conclusions: Full visual recovery is possible in amblyopia of any severity and age. The age of a patient at presentation should not preclude the initiation of therapy. Compliance with therapy is the only limiting/deciding factor.

Abstract No.: 206108

Longitudinal Alterations in Cerebral Large-Scale Functional Network Connectivity Associated With Exodrift Following Surgery in Children With Intermittent Exotropia

First Author: Ying WANG

Co-Author(s): Jianlin GUO, Jingjing JIANG, Li LI, Yun PENG

Purpose: To investigate alterations in children with intermittent exotropia (IXT) by comparing the large-scale brain network functional connectivity (FC) preoperatively and postoperatively using functional magnetic resonance imaging (fMRI), and analyzing the relationship between changes in FC and postoperative exodrift in IXT patients.

Methods: A prospective cohort study. 20 children diagnosed with IXT who underwent extraocular muscle surgery by a single surgeon were enrolled. Assessments included the evaluation of angle of deviation, binocular fusion, distance and near stereopsis, and cerebral network FC both preoperatively and 1 month postoperatively. The amount of exodrift was also recorded at 1 month postoperatively. Utilized a longitudinal analysis to compare the dynamic changes in large-scale brain network FC following surgical intervention, and investigated the association between FC alterations and postoperative exodrift.

Results: Resting state fMRI at 1 month postoperative revealed a significant increase in FC between the sensorimotor network (SMN) and the bilateral superior occipital gyrus (SOG), a component of the visual network (VN), compared to preoperative baseline ($\Delta\text{FC}_{\text{SMN-SOG.R}} = 0.082 \pm 0.110$, $T = 4.158$; $\Delta\text{FC}_{\text{SMN-SOG.L}} = 0.085 \pm 0.106$, $T = 3.959$). The mean postoperative exodrift was -3.90 ± 7.49 PD, showing significant negative correlations with pre- and post-

operative FC alterations between the SMN and SOG.R ($r = -0.457$, $P = 0.043$) / SOG.L ($r = -0.575$, $P = 0.008$).

Conclusions: A significant increase in the FC between SMN and SOG (VN) was observed in patients with IXT postoperatively, with FC alterations exhibiting a negative correlation with the exodrift following surgery, suggesting that the plasticity of the central nervous system plays a crucial role in maintaining alignment stability after surgery.

Abstract No.: 200940

MRI Evaluation of Cranial Nerve Abnormalities and Extraocular Muscle Fibrosis in Duane Retraction Syndrome and Congenital Extraocular Muscle Fibrosis

First Author: Shiqi LIU

Co-Author(s): Xiaotong LI, Wei ZHANG

Purpose: To investigate the alterations in extraocular muscles (EOMs) by magnetic resonance imaging (MRI) among patients diagnosed with Duane retraction syndrome (DRS) and congenital fibrosis of the extraocular muscles (CFEOM), who present with various cranial nerve anomalies.

Methods: A case-control study was conducted to evaluate 27 patients with DRS and 14 patients with CFEOM. All patients underwent MRI scans of the brainstem and orbital examination. Neurodevelopmental assessments were conducted through MRI, and the maximum cross-sectional area and volumes of EOMs were obtained. Three types of models were constructed using machine learning decision tree algorithms based on EOMs to predict disease diagnosis, cranial nerve abnormalities, and clinical subtypes.

Results: Patients with bilateral CN VI abnormalities had smaller volumes of LR, MR, and IR muscles compared to those with unilateral involvement ($P < 0.05$). Similarly, patients with CFEOM and unilateral third cranial nerve abnormalities had a smaller maximum cross-section of SR compared to the contralateral eye ($P < 0.05$). In patients with both CN III and CN VI abnormalities, the volume of SR was smaller than in patients with CN III abnormalities alone ($P < 0.05$). The prediction model using EOMs volume showed a diagnostic precision of 82.5% for clinical cases and 60.1% for predicting cranial nerve abnormalities. Nonetheless, the precision for identifying clinical subtypes was only 41.7%.

Conclusions: The distinctive volumetric alterations in EOMs among individuals exhibiting distinct cranial nerve anomalies associated with DRS or CFEOM provide valuable diagnostic insights into Congenital Cranial Neurodevelopmental Disorders (CCDDs). MRI analysis of EOMs should be emphasized.

Abstract No.: 204906**Machine Learning Model Tool Development for Prediction of Neonatal Retinal Hemorrhage Using Birth Parameters***First Author: Juahn OH**Co-Author(s): So Young KIM, Juahn OH, Minah PARK*

Purpose: Neonatal retinal hemorrhage (NRH) affects newborns, with macular involvement risking visual impairment. Early detection is critical, yet systematic screening is limited by a pediatric ophthalmologist shortage and equipment needs. This study developed a machine learning model to predict NRH severity using routine delivery data and created a web-based clinical tool implementing this trained model.

Methods: We retrospectively analyzed a 10-year cohort dataset of 123,855 neonates, including 96,596 without NRH and 27,259 with NRH. NRH severity was classified using the standardized retinal hemorrhage (RH) scoring system (0-12 scale). Clinical predictors included sex, delivery mode, gestational age, birth weight, and Apgar scores at 1 and 5 minutes. Additional engineered features were the Apgar score difference and the weight-to-gestational-age ratio. Four ML models—Extreme Gradient Boosting (XGBoost), Random Forest, Light Gradient Boosting Machine (LightGBM), and K-Nearest Neighbors (KNN)—were trained with 5-fold cross-validation. Performance was evaluated using multi-class area under the curve (ROC-AUC) and F1-weighted score.

Results: For 13-class severity prediction (RH scores 0-12), XGBoost performed the best (ROC-AUC 0.784, F1 0.684), surpassing Random Forest (AUC 0.762, F1 0.653), LightGBM (AUC 0.734, F1 0.609), and KNN (AUC 0.623, F1 0.695). When applied to binary NRH detection, the model demonstrated strong screening performance with 87% sensitivity and 78% specificity.

Conclusions: This represents the largest ML study on NRH and first clinical application for multi-class severity prediction at birth. The tool transforms routine delivery data into triage signals, enabling clinicians to prioritize high-risk neonates for referral. This scalable solution addresses gaps in neonatal eye care, particularly in resource-limited settings.

Abstract No.: 202479**Macular Thickness & Vascular Density Changes Following Treatment in Unilateral Amblyopia: An OCTA-Based Prospective Study***First Author: Mariam SAAD**Co-Author(s): Siddharth AGRAWAL, Rajat SRIVASTAVA*

Purpose: To evaluate structural & vascular changes in amblyopic eyes pre- & post-treatment using optical coherence tomography (OCT) and OCT angiography (OCTA), and to correlate these changes with visual outcomes.

Methods: This prospective observational study included 60 children (5–12 years) with unilateral amblyopia (strabismic, anisometropic, or deprivation). All subjects underwent baseline and post-treatment assessment after 3 months of occlusion and dichoptic therapy. Functional parameters included best-corrected visual acuity (BCVA) and contrast sensitivity (CS). OCT and OCTA were used to measure central macular thickness (CMT), ganglion cell–inner plexiform layer (GCL–IPL) thickness, macular volume, and superficial vascular density. Statistical analyses compared amblyopic versus fellow eyes, and pre- versus post-treatment changes.

Results: At baseline, amblyopic eyes showed significantly worse BCVA (0.94 ± 0.43 vs 0.05 ± 0.06 logMAR, $P < 0.001$), reduced CS (0.52 ± 0.33 vs 1.50 ± 0.00 , $P < 0.001$), increased CMT (251.2 ± 32.7 vs 241.0 ± 17.5 μm , $P < 0.001$), thicker GCL–IPL (83.9 ± 6.9 vs 78.5 ± 6.1 μm , $P < 0.001$), and reduced vascular density ($44.5 \pm 3.4\%$ vs $53.5 \pm 3.0\%$, $P < 0.001$). Post treatment, amblyopic eyes demonstrated significant improvement in BCVA (to 0.72 ± 0.42 , $P < 0.001$) and contrast sensitivity (to 0.72 ± 0.32 , $P < 0.001$), along with a reduction in CMT and GCL–IPL thickness, and an increase in superficial vascular density (to $45.6 \pm 3.1\%$, $P < 0.001$). Non-amblyopic eyes showed no significant change.

Conclusions: Amblyopic eyes demonstrated increased macular thickness and reduced vascular density, both improved after therapy. These structural and vascular changes paralleled functional recovery, highlighting OCTA's role in monitoring retinal plasticity during treatment.

Abstract No.: 208434**Modeling a Multi-Disciplinary Clinic for Complex Pediatric Uveitis Management***First Author: Mary HO**Co-Author(s): Assunta HO, Sophia LI, Andrew MAK, Regina YIU, Alvin YOUNG*

Purpose: To evaluate the model for a multi-disciplinary combined pediatric rheumatology and ophthalmology clinic.

Methods: This retrospective study was conducted from June 2024 to September 2025, involving a total of 25 cases co-managed in the combined clinic. The clinic is equipped with a slit lamp, indirect biomicroscopy, and clinical photography modalities.

Results: Of the cases, 68% required combined immunomodulatory therapy (IMT) and systemic bridging steroids for control, while the remaining cases required biologics combined with IMT. The biologic agents utilized included anti-TNF alpha (adalimumab) and IL-6 inhibitors (tocilizumab). The ages of the children ranged from 2 to 16 years. The most common etiologies were: idiopathic panuveitis (36%), idiopathic

chronic anterior uveitis (32%), JIA-associated anterior uveitis (8%), Behçet's-associated uveitis (12%), B27-associated uveitis (8%), and sarcoidosis (4%). The model demonstrated over a 60% reduction in clinic visits, shortened consultation durations, and a decrease in the total period of systemic steroid use.

Conclusions: The combined pediatric rheumatology and ophthalmology clinic provides an effective approach for managing complex cases, facilitating discussions on cases requiring surgical intervention for glaucoma, perioperative management of steroids, and minimizing the family burden, along with potential risks and side effects from systemic medications.

Abstract No.: 206643

Multidimensional Assessment of Stereopsis Deficits in Children With Congenital Ptosis

First Author: Jinxin SONG

Purpose: To investigate the patterns of stereopsis deficits in children with congenital ptosis by comparing static and dynamic stereopsis, and to characterize impairments related to distinct visual pathways.

Methods: In this prospective observational study, 80 postoperative children with congenital ptosis (46 boys, 34 girls; mean age 5.79 ± 2.03 years) underwent standardized binocular vision testing. Static random-dot stereopsis and dynamic disparity stereopsis were assessed, and discordant results were analyzed using paired comparisons.

Results: Static stereopsis deficits were present in 41.2% (33/80) of patients, whereas dynamic stereopsis deficits occurred in 57.5% (46/80). Among them, 13 patients showed deficits only on static testing, 26 only on dynamic testing, 20 on both, and 21 on neither. McNemar's test indicated that dynamic stereopsis deficits were more prevalent than static deficits ($\chi^2 = 3.69$, exact $P = 0.035$).

Conclusions: Children with congenital ptosis demonstrate multidimensional stereopsis impairment, with dynamic stereopsis being more frequently affected. This pattern may reflect pathway-specific vulnerability to motion disparity processing. Incorporating both static and dynamic assessments provides a more comprehensive profile of stereopsis deficits and may guide individualized visual rehabilitation strategies.

Abstract No.: 205858

Muscle Transplantation in the Management of Large-Angle Exotropia: A Single-Eye Surgical Approach

First Author: Pankhudi VERMA

Co-Author(s): Amit KUMAR, Amit RAJ

Purpose: To evaluate the outcomes of muscle transplantation in patients with large-angle

exotropia, focusing on its efficacy as a single-eye surgical intervention that avoids manipulation of the contralateral healthy eye.

Methods: We present a case series of eight patients with large-angle exotropia (>50 prism diopters), each managed with unilateral lateral rectus recession combined with medial rectus muscle transplantation. Surgical planning was tailored according to individual deviation magnitude and duction patterns. Postoperative outcomes were assessed based on alignment in primary gaze, binocular function, and ocular motility.

Results: All eight patients achieved satisfactory postoperative alignment within 8 PD in primary gaze, with preservation of full ductions and no significant complications.

Conclusions: Muscle transplantation represents a safe and effective option in the surgical management of large-angle exotropia. Notably, this method facilitates significant alignment through unilateral surgery, obviating the need to operate on the contralateral, non-deviating eye.

Nasal Insertion of the Superior Oblique Tendon Presenting As Brown Syndrome

First Author: Ahmed AWADEIN

Co-Author(s): Ahmed ALI

Purpose: Anomalous ocular muscle insertions are a rare cause of ocular motility disturbances.

Methods: We report the clinical presentation and the intraoperative findings of two cases with abnormally nasally inserted superior oblique tendons presenting with a Brown syndrome-like clinical picture.

Results: Case no 1 was a 5-year-old girl presenting with a chin-up position. There was bilateral limitation of elevation in adduction, -4 on the right side and -3 on the left side, with $+1$ downshoot on adduction on either side. Patient was orthotropic in down-gaze with a small V-pattern exotropia. Case no 2 was a 4-year-old boy presenting with an esotropia of 35Δ that was partially corrected with his spectacles to 20Δ . Ductions showed -4 defective elevation in the adduction of the right eye. Surgical exploration in both cases revealed abnormal nasal insertion of the superior oblique tendons. The line of insertion had a convexity facing superonasally. The posterior fibers were inserted 7-8 mm posterior and just nasal to the nasal border of the superior rectus insertion, while the anterior fibers were shorter and inserted 5 mm nasal and 4 mm posterior to the nasal edge of the superior rectus insertion. In both cases, there was improvement in the elevation on adduction after superior oblique lengthening.

Conclusions: Abnormal nasal insertion of the superior oblique muscle enhances the depressor effect of the muscle and can create a Brown-like picture.

Abstract No.: 201849

Neural Basis of Impaired Binocular Vision in Strabismus

First Author: Shuai **CHANG**

Co-Author(s): Ming **MENG**, Yan **YANG**, Xinping **YU**

Purpose: To investigate neural activation and representational patterns in early visual areas across the transition from the presence to the disappearance of diplopia in strabismus, by comparing monocular and binocular viewing between strabismic and control individuals.

Methods: We recruited 26 strabismic patients (16 with diplopia, 10 without) and 20 controls. Functional MRI was performed while participants viewed oriented Gabor stimuli under dominant-eye, non-dominant-eye, and binocular viewing. Analyses focused on early visual ROIs, including BOLD activation and multivoxel pattern analysis (MVPA) for orientation decoding.

Results: In V1, controls showed stronger BOLD responses under binocular than monocular viewing, whereas strabismic patients—especially those without diplopia—exhibited weaker binocular than monocular activation. Binocular and dominant-eye responses in controls were significantly higher than in strabismic groups. MVPA revealed above-chance decoding across all conditions, but binocular decoding accuracy was significantly higher in controls, with similar effects in V2. Cross-eye decoding showed that, in both strabismic groups, non-dominant eye input could not be reliably decoded when classifiers were trained on binocular or dominant-eye data.

Conclusions: Strabismus disrupts the normal binocular enhancement of the early visual cortex. Although orientation information was decodable across conditions, decoding accuracy was reduced in strabismic individuals, particularly under binocular viewing. Cross-eye decoding further indicated ineffective integration of non-dominant eye input, suggesting abnormal binocular information integration as a neural basis for the disappearance of diplopia and impaired binocular function in strabismus.

Abstract No.: 202531

New Onset Esotropia Following Hyperopic Orthokeratology

First Author: Jayvee **RIVERA**

Co-Author(s): Kevin **DY**, Sonal **FARZAVANDI**

Purpose: To report a child with partially accommodative esotropia (PAET) with a high AC/A ratio after initiating hyperopic orthokeratology.

Methods: Case report.

Results: An eight-year-old Chinese girl, hyperopic since age four and previously asymptomatic with spectacles, presented with a new onset intermittent esotropia. At age seven, she began hyperopic orthokeratology lens wear, which she continued for six months. During this period, she developed horizontal diplopia and inward deviation of the right eye. The family subsequently discontinued orthokeratology lens use. The visual acuity was right eye 6/6 (+6.0 D sph / -2.00 cyl x170) and left eye 6/6 (+4.25D sph / -1.75 cyl x50). Cover test with glasses showed a residual esotropia of 35 PD for far and 45 PD for near. The AC/A ratio was 11.67:1D (gradient method). The child was given executive bifocals and prism adapted with 15 PD base-out for the right eye and 15 PD base-out for the left eye to achieve orthophoria, and is pending surgery.

Conclusions: To our knowledge, this is the first documented case of new onset PAET with high AC/A ratio after initiating hyperopic orthokeratology. This case emphasizes the prudence required when prescribing orthokeratology in hyperopic children. The resultant decompensation into a constant strabismus with symptomatic diplopia is an extremely unnerving consequence for the family.

Abstract No.: 206179

Objective Associations Between Postural Asymmetry and Refractive Error in a Student Population

First Author: Bolin **DENG**

Co-Author(s): Zhengzheng **WU**

Purpose: To evaluate the associations between objectively measured postural misalignments and refractive errors, as well as ocular biometric parameters, among students in Ziyang, China.

Methods: A cross-sectional study was conducted involving 567 students aged 12–18 years. All participants underwent comprehensive ocular examinations, including cycloplegic autorefraction and axial length (AL) measurements. Postural parameters (head tilt, shoulder imbalance, forward head posture) were quantified using a photogrammetric analysis system based on standardized photographs.

Results: The study cohort (mean age: 14.96 ± 1.60 years; 43.39% male) had a myopia prevalence of 82.54% and an anisometropia prevalence of 34.74%. Multivariate analysis indicated that older age, female sex, and shoulder imbalance were significant independent predictors of a more myopic spherical equivalent (SE). Specifically, shoulder imbalance was significantly associated with a more negative SE ($\beta = -0.48$, $P = 0.030$) and longer AL ($\beta = 0.24$, $P = 0.025$). Head tilt was a significant risk factor for anisometropia ($OR = 1.71$, $P = 0.013$) and was correlated with greater interocular differences in SE ($\beta = 0.22$, $P = 0.026$) and AL ($\beta = 0.11$, $P = 0.007$). No significant associations

were observed between forward head posture and any refractive parameters.

Conclusions: Asymmetrical postural misalignments are significantly associated with refractive errors in adolescents, with distinct patterns: head tilt is linked to anisometropia, while shoulder imbalance correlates with higher myopic severity and axial elongation. Postural assessment may hold potential value in refractive error management.

Abstract No.: 204887

Ocular Comorbidities and Trace Element Dysregulation in Childhood Excessive Blinking: A Real-World Cohort Study

First Author: Huihui CHU

Co-Author(s): Jifeng YU

Purpose: Childhood excessive blinking lacks a comprehensive characterization of ocular comorbidities and potential neurological associations. This real-world cohort study investigates ocular comorbidities and analyzes trace element profiles in the subgroup with tic disorders.

Methods: A total of 533 children with excessive blinking (January 2020–April 2025) were enrolled. Demographic/clinical data were extracted from electronic records. A subgroup of tic disorder patients (n=64) and controls (n=21) underwent blood analysis for seven trace elements (Cu, Zn, Ca, Mg, Fe, Mn, Pb) using ICP-MS.

Results: • Ocular Comorbidities: 91.6% (488/533) had ≥ 1 eye disease. Most prevalent were dry eyes (67.0%), conjunctivitis (27.8%; allergic: 11.4%, bacterial: 7.3%), and ametropia (25.1%). • Age/Gender Differences: Allergic conjunctivitis was higher in boys (13.3% vs. 7.3%, $P < 0.05$) and school-age children (≥ 7 years); bacterial conjunctivitis predominated in preschoolers (< 7 years). Myopia was significantly higher in school-age children (25.7% vs. 6.9%, $P = 1.69 \times 10^{-8}$). • Tic Disorder Subgroup (12.0%, 64/533): Higher prevalence in school-age children (15.7% vs. 9.1%, $P = 0.020$). Blood analysis revealed significant dysregulation: $\downarrow$ Cu, Zn, Mg, Fe, Mn, Pb ($P < 0.001$), and $\uparrow$ Ca ($P = 1.44 \times 10^{-13}$) versus controls.

Conclusions: Childhood excessive blinking is strongly associated with ocular comorbidities (primarily dry eyes). A distinct subgroup with tic disorders exhibits trace element dysregulation, suggesting potential neurophysiological mechanisms. Screening for ocular disease and targeted neurological evaluation are recommended.

Abstract No.: 206850

Outcomes of Additional Posterior Barrage Laser in Early Stage 4A Retinopathy of Prematurity

First Author: Devesh KUMAWAT

Co-Author(s): Shoryavardhan AZAD, Ritweez SAHU

Purpose: To evaluate the outcomes of posterior barrage laser (PBL) in addition to standard peripheral laser (SPL) of avascular retina in eyes with stage 4A retinopathy of prematurity (ROP).

Methods: This ambispective observational study included preterm infants with zone II early stage 4A ROP managed with PBL at a tertiary referral center in North India between January 2024 and June 2025, with a minimum follow-up of 12 weeks. All eyes underwent additional PBL along the posterior edge of the junction, in conjunction with SPL. Anatomical outcomes were assessed in terms of regression or progression of tractional retinal detachment (TRD), requirement for lens-sparing vitrectomy (LSV), and final macular status. Adverse events, including vitreous hemorrhage, retinal breaks, or rhegmatogenous retinal detachment, were noted.

Results: Twenty-five eyes of 14 infants were included. Mean gestational age was 30.6 ± 1.6 weeks, and mean birth weight was 1408 ± 235 grams. Barrage was performed as primary treatment in 22 eyes (planned in 17; unplanned in 5, where infants were unfit for LSV) and as rescue in 3 eyes. TRD involved zone II anterior in 18 eyes (72%) and zone II posterior in 7 eyes (28%), with a mean extent of 3.96 ± 1.03 clock hours, and plus disease in 21 eyes (84%). Median follow-up was 54 weeks (range 12–80 weeks). Regression occurred in 23/25 eyes (92%), with residual traction in 2 eyes. TRD progressed in 2 eyes, requiring LSV. No adverse events were observed.

Conclusions: Posterior barrage laser, combined with standard peripheral laser, is effective in early stage 4A zone II ROP with low height and < 6 clock hour extent, promoting regression and reducing the need for vitrectomy.

Abstract No.: 204203

Outcomes of Four-Point Scleral Fixated Intraocular Lens in Paediatric Eyes

First Author: Li Yen CHAN

Co-Author(s): Shuan DAI, Ye LI

Purpose: To report the visual and refractive outcomes of scleral-fixated intraocular lens (SFIOL) for the management of paediatric ectopia lentis.

Methods: A retrospective chart review of children who underwent SFIOL, using the Akreos AO60 or Luxgood IOL from June 2019 to March 2025, was undertaken.

Results: Forty-seven eyes of 28 children were included for review. The mean age at surgery was 7.69 ± 3.44

years, with a median follow-up time of 24 months (IQR 37, range 1-77). The main indication was ectopia lentis secondary to Marfan Syndrome (39 eyes, 83%). Best corrected visual acuity (BCVA) was maintained or improved from the preoperative BCVA in 93.5% of eyes. Median postoperative BCVA improved to 0.2 (IQR 0.18) at 1-year follow-up ($p < 0.01$). There was a myopic shift at 12 months postoperatively (median -0.31, IQR 1.63), but this was not statistically significant. In 31 eyes that had more than 1 year of follow-up, residual refractive error was within 1.00D for 19 eyes, within 2.00D for 7 eyes, within 3.00D for 5 eyes, and greater than 3.00D for 5 eyes. Retinal detachment occurred in 2 eyes (4.3%), and asymptomatic IOL tilt/decentration was noted in 1 eye (3.03%).

Conclusions: SFIOL was a safe and effective method for the correction of aphakia in children with insufficient zonular or capsular support. There was a significant improvement in visual acuity for all patients, no new cases of amblyopia, and minimal postoperative complications.

Abstract No.: 202306

Pamrevlumab Targeting CTGF: A Translational Approach to Prevent Pediatric Posterior Capsular Opacification

First Author: Lely Retno **WULANDARI**

Co-Author(s): Happy Kurnia **PERMATASARI**, Hidayat **SUJUTI**, Sri **WINARSIH**

Purpose: Posterior capsular opacification (PCO) is a frequent complication after pediatric cataract surgery, and no effective pharmacologic prevention exists. This study investigated whether pamrevlumab, an anti-connective tissue growth factor (CTGF) antibody, reduces TGF- β 2-induced activation of pediatric lens epithelial cells (LECs).

Methods: Pediatric LECs (capsulorhexis specimens; ethical approval obtained) were pretreated with Pamrevlumab (50–150 μ g/mL) one hour before TGF- β 2 (10 ng/mL). Proliferation (CCK-8) at 24, 48, and 72 h and migration (wound-healing; 0–72 h, larger area = less migration) were analyzed by ANOVA with Tukey post hoc. Primary endpoint: proliferation at 72 h; secondary: wound-area at 72 h.

Results: At 72 h, proliferation was 2.44 ± 0.04 (Pamrevlumab 50 μ g) versus 2.69 ± 0.09 (TGF- β 2), a 9.3% reduction ($p < 0.001$; Cohen's $d = 0.72$, moderate-large effect). Pamrevlumab 100 μ g yielded 2.54 ± 0.02 (5.6% reduction; $d = 0.60$), while 150 μ g showed no effect. A greater wound area was retained by the 50 μ g group (34.5% vs. 24.1% of baseline), indicating less migration (between-group $p = 0.122$; within-group $p = 0.002$; $d = 0.56$). These results demonstrate consistent dose-response trends, and clinically meaningful endpoints. A plausible mechanism is CTGF blockade, limiting extracellular matrix deposition and myofibroblastic transition.

Conclusions: Pamrevlumab attenuates TGF- β 2-driven LEC proliferation and preserves wound area, addressing a therapeutic gap in pediatric PCO prevention. This strategy could preserve vision, lower retreatment rates, and lessen the incidence of PCO. Ocular delivery/safety assessment and molecular validation are the next steps.

Abstract No.: 206624

Pediatric Endophthalmitis: Clinical Profile and Visual Outcome Following Vitrectomy in a South Indian Patient Cohort

First Author: Prema **SUBRAMANIAM**

Co-Author(s): Abhishek **DAS**, Ninan **JACOB**, Parag **SHAH**, Narendran **VENKATAPATHY**, Vivek Kumar **JHA**, Chandravathan **KAPARTHI**

Purpose: To investigate the etiology, microbiological spectrum, and visual outcomes following vitrectomy for pediatric endophthalmitis.

Methods: Retrospective analysis was conducted on all patients under 16 years of age diagnosed with infectious endophthalmitis from a single institution from January 1, 2020, to June 30, 2025. The clinical characteristics, aetiology, microbiological spectrum, management, and visual outcomes were analysed. Subgroup analysis included patients who underwent Two-staged vitrectomy (Vitreous biopsy with blind core vitrectomy with empirical antibiotics at day 1, followed by repeat core vitrectomy at day 5–7).

Results: A total of 89 eyes were included, with a mean age of 8.1 ± 4.5 years. Trauma was the most common etiology (75.3%), followed by endogenous endophthalmitis (21.3%). Overall, 35 (39.3%) cases had positive cultures: gram-positive (16.8%), gram-negative (15.7%), and fungal (6.7%). The final visual outcomes were 20/200 or better in 37 (41.5%) eyes. The difference between the mean baseline (2.16 ± 0.67) and final visual acuity (1.50 ± 1.16) was statistically significant. Subgroup analysis of 15 patients who underwent staged vitrectomy showed a 60% culture positivity rate and final visual acuity of 20/200 or better in 46.6% of cases.

Conclusions: Trauma is the most common aetiology in pediatric endophthalmitis. Two-staged vitrectomy can be considered for severe vitritis with poor media clarity over single-stage vitrectomy for better visual outcomes and a minimal complication rate.

Abstract No.: 205870

Percepto: A Digital Screening Tool for Cerebral Visual Impairment

First Author: Sahithya BHASKARAN

Co-Author(s): Raj AGRAWAL, Harini KANNAN, Krishna MADHAV

Purpose: Cerebral Visual Impairment (CVI) affects 25% of children under 3 in Tamil Nadu, diminishing their learning, mobility, and daily activities if left unaddressed. Current CVI assessment tools are expensive and require expertise to administer, leaving many children struggling without support. We aimed to develop a digital screening tool to screen for CVI.

Methods: Percepto is an innovative, game-based screening app that transforms complex assessments into engaging activities. Designed for use by pediatricians, educators, and field workers, Percepto collects key response metrics to provide insight into a child's visual perceptual abilities, identifying children at risk for CVI.

Results: Our prototype has shown promising results in clinical settings, and with continued data collection, we aim to integrate machine learning for precise risk prediction.

Conclusions: By making CVI screening affordable and accessible, we can intervene early, helping children get the support they need to thrive. This tool ensures no child's potential is limited by undiagnosed CVI.

Abstract No.: 201567

Perceptual Learning for Refractive Amblyopia With Limited Response to Conventional Therapy: Real-World Outcomes and a Decision Tree Approach

First Author: Mengya HAN

Co-Author(s): Weiyin CHEN, Yin HU, Jinyun JIANG, Zhipeng LAI, Runtong MA, Ruozhen RUAN, Qihao SUN, Xianghua TANG, Mengyi WANG, Xiao WANG, Xiao YANG, Feng ZHAO

Purpose: This study evaluated the effectiveness of perceptual learning (PL) using a decision tree approach applied to real-world data in refractive amblyopic patients with limited response to conventional therapy.

Methods: Real-world clinical data were derived from 108 patients with refractive amblyopia who had previously received standard treatment for at least 6 months but showed minimal improvement, defined as a change in best-corrected visual acuity (BCVA) of less than 0.1 logarithm of the minimum angle of resolution (logMAR). All patients subsequently underwent a structured PL program targeting contrast sensitivity. Visual outcomes were assessed before and after the PL intervention.

Results: Overall, 35.2% of patients (n=38) achieved clinically meaningful BCVA improvement, including

14.8% (n=16) with significant gains. Multivariate linear regression identified baseline BCVA ($\beta = -0.192$, $P < 0.001$), and age ($\beta = 0.005$, $P = 0.007$) as significant predictors of BCVA improvement ($R^2 = 0.673$). A bagging-based machine learning model highlighted younger age (<8.2 years) and poorer baseline BCVA (≥ 0.12 logMAR) as key factors associated with benefit. Subgroup analysis further revealed that younger children and those with poorer baseline visual acuity showed greater post-training improvement in BCVA ($P < 0.001$). Across age and baseline acuity subgroups, improvements in contrast sensitivity were consistently observed.

Conclusions: Perceptual learning is a promising adjunctive approach for improving visual acuity in refractive amblyopic patients with limited response to conventional therapy. Using real-world evidence, we developed an interpretable decision tree model to identify patients most likely to benefit, offering practical support for individualized treatment planning.

Abstract No.: 201950

Persistent Diplopia Despite Intraocular Lens Exchange in a Patient With Latent Strabismus

First Author: Ralene SIM

Co-Author(s): Sonal FARZAVANDI

Purpose: To describe a case of decompensated long-standing diplopia after sequential cataract surgery with toric intraocular lens (IOL) implantation and subsequent IOL exchange.

Methods: Case report of clinical presentation, surgical interventions, and postoperative course.

Results: A 64-year-old Chinese male hairdresser and motorcyclist with a 6-year history of prism-corrected diplopia presented in February 2023 with bilateral visual blurring. Visual acuity was 6/60 (pinhole 6/30) in the right eye and 6/19 (pinhole 6/12) in the left eye. Nuclear sclerotic cataracts (RE NS2+ C4+, LE NS2+ C2+) and myopic astigmatism (RE -3.50/-0.75x85; LE -3.25/-0.25x80) were noted. The left eye was dominant. Monovision was planned (RE -2.00 D, LE plano). Right eye cataract surgery with toric IOL implantation was performed (3 April 2023). Postoperatively, BCVA improved to 6/12 but diplopia developed despite well-positioned IOL. He proceeded with left eye surgery (12 May 2023), achieving BCVA 6/9.5, but remained symptomatic. Orthoptic assessment revealed comitant exotropia (2 PD) and right hypotropia (6 PD), consistent with decompensated squint worsened by monovision. Prisms were prescribed, but he remained intolerant. Given persistent diplopia, right IOL exchange to a monofocal non-toric IOL (aim plano) was performed (9 June 2025). Postoperatively, BCVA was 6/7.5+1 RE and 6/6-2 LE, but residual diplopia persisted (XT 4 PD, R hypotropia 4 PD).

Conclusions: This case highlights the risk of decompensating latent strabismus after monovision and toric IOL implantation. Even with an IOL exchange, fusion may not recover. Thorough preoperative orthoptic assessment and careful counselling are crucial for patients with pre-existing prism use or long-standing diplopia before refractive cataract surgery.

Abstract No.: 204967

Plus Is Not the Sole Indicator: Imaging Predictors of Retinopathy of Prematurity Progression – Analysis of 42,000 Babies in South-Indian Cohort

First Author: Prema SUBRAMANIAM

Co-Author(s): Abhishek DAS, Ninan JACOB, Parag K SHAH, Narendran VENKATAPATHY, Vivek KUMAR JHA

Purpose: To analyze the risk of development of Treatment Requiring ROP (TROP) in fundus imaging showing Peripheral Vascular Shunting (PVS) and Islands of Ischemic Retina (IIR) without plus

Methods: A retrospective analysis of tele-screening images captured using wide-field fundus imaging from January 2020 to July 2025, based out of a tertiary eye care centre, was included. Fundus images showing PVS and IIR were included. Demographic and clinical data such as gestational age (GA), birth weight (BW), post-conceptual age (PCA) at PVS, zone, number of quadrants of PVS, presence of IIR, and PCA at TROP were collected.

Results: A total of 42,000 babies screened. 795 babies (1.8%) had PVS, of which 103 babies (12.9%) developed TROP. The Mean GA and BW were 30.4 weeks and 1365 g, respectively. The Mean PCA at shunting was 33 weeks. The average number of Quadrants of PVS was 3.4, TROP in Zone 1 was seen in 37% and in Zone 2, it was seen in 63%. Average duration from shunting to TROP was 3.2 weeks, and IIR was noted in 46%. Subgroup analysis showed shunting in all 4 quadrants, and treatment duration was 2 weeks in zone 1 TROP.

Conclusions: ROP evolves in phases, from vasoconstriction to vasoproliferation, hampering the development of plus in some zone 1 disease. The presence of PVS and IIR should be considered as predictors of ROP progression, and follow-up should be scheduled closely.

Abstract No.: 204296

Posterior Scleral Reinforcement Combined Exotropia Surgery in High Myopia Children: An Observational Study

First Author: Haiyun YE

Purpose: To assess outcomes of combined posterior scleral reinforcement (PSR) and exotropia surgery in children with high myopia, evaluating axial length (AL)

control, best-corrected visual acuity (BCVA), retinal vascular changes, and strabismus correction.

Methods: This retrospective study analyzed 62 children (124 eyes; mean age 9.19 years) treated at Shanghai Children's Hospital (2021-2024) with ≥ 6 -month follow-up. AL, spherical equivalent (SE), BCVA, exotropia angle, and ETDRS-grid-based angio-OCT analysis of nine retinal zones were examined by standard ophthalmic assessments.

Results: Postoperatively, BCVA improved slightly, and AL showed a non-significant reduction. All grafts remained stable without complications. Exotropia angle decreased significantly ($p < 0.05$). Contrast sensitivity (CST) improved at high spatial frequencies (12/18 cpd bilaterally; 6 cpd right eye). Foveal and superior parafoveal vessel density increased significantly in both superficial (SCP) and deep capillary plexuses (DCP) ($p < 0.05$). FAZ area decreased significantly in SCP/DCP (right SCP most pronounced). Perifoveal vessel density (300 μ m) improved significantly except in the left DCP. No significant correlation existed between AL reduction and vascular improvements.

Conclusions: Our findings demonstrate that combined PSR and exotropia surgery effectively controls AL in pediatric high myopia while significantly improving retinal microcirculation. The angio-OCT detected vascular improvements appear more pronounced and immediate than AL changes, suggesting this modality may serve as a sensitive biomarker for monitoring myopia progression. Additionally, this combined approach successfully corrects ocular misalignment and enhances binocular visual function.

Abstract No.: 204351

Prediction and Research on Risk Factors for Premature Retinopathy in Low Birth Weight Fetuses Less Than 32 Weeks

First Author: Yi Yuan LIANG

Co-Author(s): Qiong WU

Purpose: To investigate the current situation of retinopathy of prematurity (ROP) in our hospital and analyze the influencing factors, so as to provide a scientific basis for the formulation of clinical treatment and preventive strategies.

Methods: A retrospective study of 322 cases of premature infants with a gestational age of < 32 weeks who underwent fundus examination at Northwest Women's and Children's Hospital from January 1, 2024, to January 1, 2025. The incidence of the ROP group was according to the screening results, and all premature infants were divided into an ROP group (160 cases, 160 eyes) and a non-ROP group (162 cases, 162 eyes). The general clinical data and perinatal-related data of the two groups of premature infants were compared, and the influencing factors of premature

infants with ROP were analyzed by multivariate logistic regression.

Results: A total of 322 preterm infants were included in this study, and the results of the fundus screening showed that 160 cases of ROP patients were detected, 162 cases of non-ROP, and the total incidence of ROP was 49.7% (60/322), of which 17.1% (55/322) required treatment; According to the international classification standard of ROP determine the severity (ROP is divided into 5 stages, stage I is the lightest, stage V is the most serious), in 160 eyes of ROP, 76 eyes (47.50%) were stage I, 48 eyes (30%) were stage II, 36 eyes (22.%) were stage III, combined with PLUS 42 eyes (26.3%), and no cases of stage IV and V were found. By comparing the clinical relevant data the two groups of preterm infants, it was concluded that there was no difference in gender, respiratory system diseases, cardiovascular system, digestive system, infection, hydrocephalus intestinal and extraintestinal nutrition methods, and whether breast-feeding was compared between the two groups of preterm infants (all $P > 0.05$), birth weight, gestational age, and 20-day weight gain value of the ROP group were all lower than those of the non-ROP group (all $P < 0.05$), and the number of days of oxygen inhalation and mechanical ventilation were higher than those of the non-ROP group, and the proportion of history asphyxia after birth, combined nervous system diseases, anemia, blood transfusion therapy, and neonatal sepsis were higher than those of the non-ROP group (all $P < 0.05$). Multivariate Logistic regression analysis showed that combined anemia (OR = 2.497, 95% CI 1.258-4.957, $P < 0.05$); combined blood transfusion therapy (OR = 2.316, 95% CI: 1.245-4.309, $P < 0.05$), more than 21 days of oxygen inhal (OR = 1.974, 95% CI: 1.022-3.814, $P < 0.05$, 20-day weight gain (OR = 0.997, 95% CI: 0.995-1.000, $P < 0.05$) was associated with an increased risk of ROP in preterm infants, and the larger gestational age of preterm infants was a protective factor for occurrence of ROP.

Conclusions: low gestational age at birth, oxygen ination, neonatal anemia and blood transfusion therapy are high risk factors

Abstract No.: 202921

Preliminary Efficacy of Intravitreal Faricimab for Type 1 Retinopathy of Prematurity: A Prospective Pilot Study

First Author: Haonan MA

Co-Author(s): Jie PENG, Peiquan ZHAO

Purpose: This study aimed to present the first report on the preliminary efficacy, reactivation rate, and safety of intravitreal faricimab (IVF), a novel bispecific antibody, in patients with type 1 retinopathy of prematurity (ROP).

Methods: This prospective, non-randomized, interventional pilot case series evaluated IVF (3 mg/0.025 mL) monotherapy in patients with type 1

ROP. The primary outcomes were treatment response, the reactivation rate, and the interval to reactivation. Secondary outcomes included the absence of ocular complications and significant systemic adverse events.

Results: A total of 10 eyes from 5 patients with type 1 ROP were enrolled, all of whom completed at least 16 weeks of follow-up. The mean gestational age at birth was 27.17 ± 0.60 weeks (range, 26.29–28.00 weeks), and the mean birth weight was 1132 ± 344 g (range, 910–1760 g). All eyes (100%) demonstrated complete regression of ROP with continued retinal vascularization. Two eyes (20%) experienced reactivation at 15 weeks after treatment and underwent repeat IVF injection. At the last follow-up, all eyes achieved complete vascularization or zone III, with no unfavorable anatomical outcomes, ocular complications, or systemic adverse events.

Conclusions: IVF monotherapy demonstrated good efficacy and safety in type 1 ROP and may provide lower reactivation rates and greater durability than ranibizumab. Larger prospective randomized controlled studies with longer follow-up are needed to confirm these findings.

Abstract No.: 206391

Preliminary Observation on the Effect of Hyperopic Defocus Lens on the Growth of Eye Axis in Children With Hyperopia

First Author: Jing ZHANG

Purpose: To observe the effect of a hyperopic defocus lens on the growth of the children's eye axis.

Methods: We collected data from children under 5 years old wearing corrective glasses for hyperopia, requiring emmetropic status ≤ 6.00 DS after cycloplegic refraction, astigmatism < 2.00 DC, and no anisometropia. Using multispectral topography, we examined retinal defocus and custom-made hyperopic refractive lenses. The study observed axial length (AL) changes before and after lens fitting.

Results: The study included 74 children (148 eyes), with 37 males (50%) and 37 females (50%). The average age at initial wear of hyperopic lenses was 6.78 years (range 5-11 years). Post-wear observation lasted 291 days (range 108-637 days). Pre-wear AL showed an average annual increase of 0.199 mm, while post-wear increased by 0.279 mm. Among 34 eyes with AL < 21 mm, the pre-wear increase was 0.133mm vs. post-wear 0.225 mm, representing a 69.2% increase. For 100 eyes with 21-23mm AL, pre-wear showed 0.212mm vs. post-wear 0.288 mm, indicating a 35.8% increase. In 14 eyes with AL > 23 mm, pre-wear showed 0.363mm vs. post-wear 0.348 mm, showing no significant effect. Eyes with equivalent spherical power (SER) ≤ 3 D showed pre-wear AL growth of 0.186mm vs. post-wear 0.290 mm, a 55.9% increase. For 70 eyes with 3-6 SER, pre-wear showed 0.198mm vs. post-wear 0.262 mm, a 32.3%

increase. In 54 eyes with SER $\geq 6D$, pre-wear showed 0.204mm vs. post-wear 0.296 mm, representing a 45.1% increase.

Conclusions: Hyperopic defocus lens can promote the growth of the eye axis in hyperopic children, and the effect is better when the eye axis is shorter and the equivalent spherical degree is greater, but it still needs to expand the sample and extend the follow-up time for observation.

Abstract No.: 200535

Prevalence of Pediatric Eye Disease in Peri-Urban Nepal: A Population-Based Study

First Author: Manisha **SHRESTHA**

Purpose: This prospective, population-based study was performed to assess the burden of pediatric eye disease in peri-urban Nepal.

Methods: A door-to-door census was conducted to identify all children aged 3-8 years in 3 geographic wards. Children were screened in the community using the Spot vision screener. Children who failed screening and a 10% random sample of those that passed screening were referred for a comprehensive eye examination by a masked pediatric ophthalmologist. Population-level prevalence data were calculated using probability sampling weights accounting for non-response.

Results: Of the 2,091 eligible children, 1731 (82.8%) were screened, of which 376 were referred: 213 (12.3%) who failed screening and 163 (9.4%) who passed screening (random sample). 317 children (84.30%) attended the referral visit. The most common diagnoses were visually significant refractive error (21.1%), amblyopia (15.1%), and strabismus (12.3%). The prevalence of visually significant childhood eye disease in Nepal was higher than that previously reported in high-income countries.

Conclusions: Rates of preventable pediatric vision loss are higher in low- and middle-income countries, but there is limited data regarding the prevalence of childhood eye disease at the population-level. Determining the prevalence of childhood eye disease in low-resource settings allows for a data-driven approach to create and evaluate screening strategies designed to detect preventable childhood vision loss.

Abstract No.: 207073

Quantification and Comparison of Saccade Dynamics in Subjects With Horizontal Strabismus Pre and Post Strabismus Surgery Using Novel REMOBI Device

First Author: Vinay **GUPTA**

Co-Author(s): Rebika, Zoi **KAPOULA**, Swati **PHULJEHE**, Rohit **SAXENA**

Purpose: The study aims to quantify and compare the saccade parameters (Latency, velocity amplitude, duration, and disconjugacy) using the novel REMOBI device before and after strabismus surgery.

Methods: This was a prospective observational study that enrolled individuals with horizontal strabismus, aged 20–40 years, with visual acuity better than 6/12, who underwent strabismus surgery (Resection & Recession) in one eye. Ethical approval and informed consent were obtained. Horizontal deviation was assessed using the prism-bar cover-test. Participants wore a head-mounted eye tracker that captured wide-angle saccadic eye movements at 200 Hz. Testing was conducted with the REMOBI device, generating a saccadic audiovisual target at a distance of 40cm. Eye movement analysis was carried out using AIDEAL software, evaluating saccadic parameters in both directions. All assessments were performed at baseline(pre-surgery) and 3-month post-surgery follow-up.

Results: Fifty-five subjects with a mean age of 28.2 ± 6.4 years were included with a baseline horizontal deviation of 51 ± 12 prism-dioptres. The deviation significantly reduced to 8 ± 4 prism-dioptres 3-month post-surgery. The saccadic parameters at baseline before surgery [amplitude(Right: $10.2 \pm 2.2^\circ$; Left: $12.2 \pm 2.6^\circ$), latency(Right: 291 ± 54 ; Left: 279 ± 48), duration (Right: 104 ± 26 msec; Left: 88 ± 19 msec), average velocity (Right: $57 \pm 26^\circ/\text{sec}$, Left: $68 \pm 23^\circ/\text{sec}$) and saccade disconjugacy (Right: 2.85 ± 1.3 ; Left: 3.9 ± 2.2)] were significantly different at 3-month post-surgery follow-up [amplitude (Right: $15.4 \pm 2.1^\circ$; Left: $15.8 \pm 2.2^\circ$), latency (Right: 253 ± 46 ; Left: 248 ± 39), duration (Right: 69 ± 14 msec; Left: 63 ± 12 msec), average velocity (Right: $165 \pm 31^\circ/\text{sec}$, Left: $188 \pm 35^\circ/\text{sec}$) and saccade disconjugacy (Right: 2.2 ± 1.1 ; Left: 2.4 ± 1.5)] ($P < 0.05$ for all).

Conclusions: The REMOBI device enables an objective and precise evaluation of saccadic parameters in individuals with horizontal strabismus. At the three-month follow-up, all recorded saccadic parameters demonstrated significant improvement, indicating enhanced binocular coordination and more synchronized eye movements following strabismus surgery.

Abstract No.: 200830

Reading Eye Movement Improvements After Strabismus Surgery in Children With Intermittent Exotropia: A Prospective Cohort Study

First Author: Yan YANG

Co-Author(s): Shuai CHANG, Jinen HOU, Jing LIU, Jiangtao LOU, Xinping YU

Purpose: To compare reading speed and associated eye movement patterns in children with intermittent exotropia (IXT) preoperatively and at six months postoperatively, relative to age-matched controls.

Methods: In this prospective cohort study, children aged 10–14 years with IXT completed the International Reading Speed Texts (IReST) under binocular viewing while eye movements were recorded using an EyeLink 1000 Plus eye tracker (SR Research, Canada) at baseline (preoperatively), 2-month, and 6-month postoperative follow-up. Age-matched visually normal children served as controls and were tested once. Eye movement metrics included mean fixation duration, total fixation count, number of regressions, saccade amplitude, saccade velocity.

Results: A total of 59 children with intermittent exotropia (IXT) (mean age: $11.54 \pm 1.69y$) and 37 healthy controls (mean age: $11.03 \pm 2.12y$) were enrolled. At baseline, fixation parameters did not differ significantly between groups; however, IXT patients exhibited reduced forward saccade velocity and poor vertical amplitude during reading ($p < 0.05$) than healthy controls. In 30 IXT patients reassessed 2 months after surgery, fixation measures remained stable, whereas total and forward saccade velocity and amplitude improved significantly ($p < 0.05$). At 6-month follow-up ($n = 18$), further enhancements in saccadic dynamics were observed, most notably in saccade velocity and vertical amplitude ($p < 0.05$, Cohen's $d > 0.9$).

Conclusions: Children with IXT showed impaired saccadic control despite stable fixation. Strabismus surgery led to significant improvements in saccadic dynamics, particularly at six months, suggesting potential benefits for reading performance and functional visual outcomes in clinical practice.

Abstract No.: 203605

Reading Performance in Children With Decompensated Exophoria: Improvement After Surgical Treatment

First Author: Ivan STEPANETS

Co-Author(s): Bibigul BEGEEVA

Purpose: Decompensated exophoria in children may compromise binocular vision and reduce reading performance. Because reading ability is fundamental for academic development, it is important to assess functional outcomes beyond standard visual acuity.

This study aimed to evaluate changes in maximum reading speed (MRS), critical print size (CPS), and reading acuity (RA) before and after surgical treatment in pediatric patients with decompensated exophoria.

Methods: A prospective study included 25 children (aged 7–10 years) diagnosed with decompensated exophoria who underwent surgical correction. Reading performance was assessed using standardized age-appropriate reading charts. Three parameters were measured: MRS (words per minute), CPS (smallest print size read fluently), and RA (minimum legible print size including errors). Assessments were performed preoperatively and 3 months postoperatively.

Results: All three reading parameters showed statistically significant improvement after surgery. • MRS increased from 112 ± 14 to 148 ± 17 words/min ($p < 0.005$). • CPS improved from 0.30 ± 0.05 to 0.23 ± 0.04 logMAR ($p < 0.005$). • RA improved from 0.22 ± 0.06 to 0.16 ± 0.05 logMAR ($p < 0.005$). These results demonstrate both enhanced fluency and improved fine visual function during reading following surgical alignment.

Conclusions: Surgical correction of decompensated exophoria in children aged 7–10 years not only restores ocular alignment but also significantly enhances functional reading performance. Improvements in MRS, CPS, and RA emphasize the importance of including reading assessments in postoperative evaluation. Early surgical intervention may provide substantial visual and educational benefits in this population.

Abstract No.: 200319

Rebalance Binocular Temporal Vision Improves the Stereopsis in Amblyopia

First Author: Changwu TAN

Co-Author(s): Longqian LIU, Tong LIU, Alexandre REYNAUD, Xi WANG

Purpose: To investigate the effects of binocular temporal balance on stereopsis, and the effect of rebalancing interocular delay (IOD) on stereopsis in patients with amblyopia.

Methods: We recruited sixteen healthy controls and ten adult amblyopes. Stereoscopic acuity (SA) was measured by using a digital stereopsis detection paradigm with two stimulus durations (50 and 200 ms). In controls, Binocular Temporal Imbalance (Con-BTI) was induced by placing neutral density filters (NDF; 1, 1.3, and 2 log units) over one eye, and then Binocular Temporal Rebalance (Con-BTR) was achieved by delaying stimulus onset in the fellow eye. In amblyopes, IOD was quantified with a mouse-tracking paradigm, and SA was assessed under three conditions: imbalanced IOD (Amb-BTI), IOD rebalanced by matched NDF (Amb-BTR-NDF), or by delaying stimulus onset in the faster eye (Amb-BTR-Delay).

Results: In controls, SA was elevated under Con-BTI at 1.3 and 2 NDFs relative to baseline ($P \leq 0.023$). Compared with Con-BTI, Con-BTR improved SA at 2 NDF ($P \leq 0.037$), while at 1.3 NDF the improvement reached significance at 200 ms ($P = 0.021$). In amblyopes, SA under Amb-BTR-Delay was significantly better than under Amb-BTI (50ms: 1609" versus 2295"; 200ms: 1186" versus 1650"; $P \leq 0.038$). No difference was found between Amb-BTR-NDF and Amb-BTI (50ms: 2059" versus 2295"; 200ms: 1680" versus 1650"; $P \geq 0.482$).

Conclusions: Binocular temporal imbalance impairs stereopsis, whereas rebalancing restores it in normal populations. In amblyopia, delaying stimulus onset in the faster eye to rebalance binocular temporal vision improves stereopsis. These findings highlight the potential interventions targeting binocular temporal balance to improve binocular function in amblyopia.

Abstract No.: 204894

Refractive and Corneal Astigmatism: Characteristics, Interrelationship, and Visual Impact in Children

First Author: Nguyen Le Hoang **NGUYEN**

Co-Author(s): Tuan Anh **LE**, Huy Dinh Minh **TRAN**

Purpose: To investigate the characteristics and interrelationship between refractive astigmatism (RA) and corneal astigmatism (CA), and their impact on visual performance in children.

Methods: A cross-sectional study examined 582 children (1164 eyes) aged 6-15 years in Ho Chi Minh City, Vietnam. Comprehensive examinations, including refraction, keratometry, axial length measurement, and optical aberration analysis, were performed. Vector analysis using J0 and J45 components assessed the RA-CA relationship.

Results: Mean refractive astigmatism was -1.26 ± 1.05 D while corneal astigmatism was -1.41 ± 0.91 D, with significantly higher values observed in females than males ($p < 0.01$). Mean keratometry was 43.38 ± 1.37 D (females: 43.67 ± 1.37 D vs males: 43.08 ± 1.30 D, $p < 0.01$). Astigmatism prevalence was 60.4%, predominantly with-the-rule (92.2%). A strong positive correlation was found between RA and CA ($r = 0.76$, $p < 0.001$), with vector analysis revealing a higher correlation for the J0 component compared to the J45 component. Best corrected visual acuity deteriorated with increasing astigmatism severity, from 0.005 LogMAR in non-astigmatic eyes to 0.048 LogMAR in severe astigmatism ($p < 0.001$). Strong negative correlations existed between both RA and CA with astigmatic aberrations ($r = -0.76$ and $r = -0.80$, respectively).

Conclusions: Corneal astigmatism is the primary determinant of refractive astigmatism in children, with

progressively decreasing visual acuity accompanying increasing astigmatism severity.

Abstract No.: 205277

Retinal and Microvasculature Characteristics in Schubert-Bornschein Congenital Stationary Night Blindness: An OCT and OCTA Study

First Author: Wenlong **HAO**

Co-Author(s): Mengya **HAN**, Yin **HU**, Songshan **LI**, Zhenbang **RUAN**, Chuqi **XIANG**, Xiao **YANG**

Purpose: To investigate the characteristics of retinal structure and macular microvasculature in Schubert-Bornschein congenital stationary night blindness (S-B CSNB) and identify their structure-function association.

Methods: Genetically confirmed CSNB patients and age, sex, spherical equivalent, axial length-matched control subjects underwent complete ophthalmic examination, optical coherence tomography (OCT), and optical coherence tomography angiography (OCTA). Retinal sublayer thickness and vessel density at foveal and parafoveal areas, as well as foveal avascular zone (FAZ) parameters, were measured using OCT and OCTA.

Results: A total of 44 eyes of 44 CSNB patients, comprising 21 with complete CSNB and 23 with incomplete CSNB, and 22 eyes of 22 control subjects were examined. The thickness of parafoveal inner retinal layers was thinner in the CSNB groups than in the control group, especially in the iCSNB group. The vessel density of the superficial vascular complex (SVC), as well as the FAZ parameters in the iCSNB group, were significantly lower compared with the cCSNB and control groups. Multivariate analysis revealed that the parafoveal thickness of the inner nuclear layer (INL) and the vessel density of the SVC were significantly correlated with BCVA in all CSNB patients.

Conclusions: This study revealed the retinal structural characteristics in subtypes of S-B CSNB. The structural deterioration of inner retinal cells and superficial retinal vessels best reflects the degenerative changes of S-B CSNB and its considerable relations with visual outcome, which will enhance the understanding of the functional status of this disease.

Abstract No.: 205122

Retinopathy of the Mature Newborn (ROM): A Consensus Statement on Diagnosis and Management

First Author: Daoman **XIANG**

Co-Author(s): Wensi **CHEN**

Purpose: To address the nosological challenge of classifying ROP-like retinal pathology in full-term newborns that does not fit existing definitions (e.g., FEVR), this consensus aimed to establish and standardize the new disease entity «Retinopathy of the Mature Newborn (ROM).»

Methods: The Children's Ophthalmology Committee of the China Medicine Education Association convened a panel of experts to develop a consensus through iterative discussions based on clinical experience and literature review. ROM was defined as retinal vascular dysplasia in infants born at ≥ 37 weeks' gestation, presenting with ROP-like features but not meeting full criteria for ROP or FEVR. Two subtypes were proposed: ROM-FEVR (with genetic background) and idiopathic ROM (iROM). A structured diagnostic pathway incorporating fundus examination, parental screening, and genetic testing was established, along with follow-up and treatment recommendations.

Results: The consensus formally recognizes ROM as a distinct clinical entity. It provides a diagnostic flowchart, 10 key recommendations, and illustrative case examples demonstrating the utility of the ROM classification. The new terminology helps avoid misdiagnosis and reduces the psychosocial burden associated with the "familial" label of FEVR, thereby improving clinician-family communication.

Conclusions: The introduction of ROM represents a significant advance in understanding retinal disorders in full-term newborns, addressing previous nosological confusion. This consensus offers a standardized framework for the diagnosis, subclassification, and management of ROM, facilitating early detection, appropriate intervention, and systematic follow-up, with important clinical and psychosocial implications.

Abstract No.: 203283

Retrolental Fibroplasia as a Biomarker for Stage 5B Familial Exudative Vitreoretinopathy

First Author: Huanyu **LIU**

Co-Author(s): Zupeng **LU**, Haonan **MA**, Jie **PENG**, Wenting **ZHANG**, Peiquan **ZHAO**

Purpose: To report the characteristics of retrolental fibrosis (RLF) for eyes with stage 5B familial exudative vitreoretinopathy (FEVR).

Methods: In this retrospective case series, RLF images at lensectomy from 26 patients (29 eyes) with FEVR were compared to those from 22 patients (28 eyes) with retinopathy of prematurity (ROP). The relative size of the RLF area and diameter to the cornea was determined. The presence or absence of RLF characteristics, including relatively small area (rsA) and diameter (rsD), dense (DE), not adherent to the ciliary processes (NA), and sharp edge (SE), were compared.

Results: The RLF in FEVR eyes had a smaller area (35.0% vs 47.7%, $P < 0.001$) and a smaller diameter (57.4% vs 68.0%, $P = 0.002$) than those in ROP eyes. The rsA was set at $<42.5\%$ of the area of the cornea, and the rsD was set at $<60.2\%$ of the horizontal diameter of the cornea. The rsA or rsD was attributed to the diagnosis of FEVR ($P = 0.008$, $P < 0.001$) rather than the presence of prior treatment, age of lensectomy, or complications

of the anterior segment. The FEVR eyes had more frequent characteristics than ROP eyes for DE (55.2% vs 25.0%, $P = 0.031$), NA (48.3% vs 0.0%, $P < 0.001$), and SE (58.6% vs 28.6%, $P = 0.033$). The combination of NA and rsD had a sensitivity of 65.5% and specificity of 92.9% with the area under the curve of 0.805.

Conclusions: The combination of NA and rsD can be a specific biomarker for patients with stage 5B FEVR.

Abstract No.: 204850

Risk Factors and Prevalence of Retinopathy of Prematurity in Very Low Birth Weight Preterm Infants: A Meta-Analysis

First Author: Wensi **CHEN**

Co-Author(s): Daoman **XIANG**

Purpose: The present study explored the risk factors and prevalence of retinopathy of prematurity in very low birth weight preterm infants by a meta-analysis method.

Methods: PubMed, Embase, Cochrane Library, and Web of Science databases were searched with a cut-off date of 15 March 2024. Stata 15.0 was used to merge and analyze the data, and the quality of the included studies was assessed using the Newcastle-Ottawa Scale.

Results: Fourteen articles (including three case-control studies and 11 cohort studies) involving 12,666 newborns were finally included. The results of the meta-analysis found that blood transfusion [OR=1.83, 95%CI (1.42, 2.35), $P=0.001$], gestational age [OR=1.67, 95%CI (1.27, 2.20), $P=0.001$], gestational weight at birth [OR=1.05, 95%CI (1.02, 1.08), $P=0.02$], sepsis [OR=1.47, 95%CI (1.26, 1.71), $P=0.02$], intraventricular hemorrhage [OR=1.67, 95%CI (1.25, 2.22), $P=0.001$], lung disease [OR=2.08, 95%CI (1.37, 3.17), $P=0.001$], necrotizing small bowel colitis [OR=1.71, 95%CI (1.24, 2.36), $P=0.001$], and congenital arterial ductus arteriosus [OR=1.72, 95%CI (1.31, 2.25), $P=0.003$] were risk factors for retinopathy of prematurity in very low birth weight preterm infants.

Conclusions: Based on the current study, we found that retinopathy of prematurity should be prevented early in very-low-birth-weight preterm infants with a combination of blood transfusions, small gestational weeks, low gestational weight, sepsis, intraventricular hemorrhage, lung disease, necrotizing small bowel colitis, and congenital arterial ductus arteriosus.

Abstract No.: 201475**Risk Factors and Surgical Options for Recurrent Retinal Redetachments in an Australian Paediatric Population***First Author: Thuan NGUYEN**Co-Author(s): Lawrence LEE, Cindy LIU, Shaheen SHAH, Abhishek SHARMA*

Purpose: To determine risk factors for recurrent paediatric retinal detachments (RD) from a tertiary paediatric ophthalmology referral centre.

Methods: Retrospective study of all children ≤ 18 years old who underwent RD repair at the Queensland Children's Hospital, Brisbane, from November 2014 to December 2022. Primary outcome measures were anatomic success and best corrected visual acuity (BCVA).

Results: Sixty-eight patients, for a total of 76 eyes (75% male) were included. Median age was 11 (IQR 8.5-13). 42 eyes (55.3%) had anatomic reattachment after initial surgery, improving to 54 eyes (71.1%) at final follow-up. Multivariate analysis found younger age (OR 1.14, $p=0.047$) and proliferative vitreoretinopathy (OR 2.85, $p=0.037$) predictive of recurrent detachment, while protective factors included scleral buckle (SB) only (OR 0.16, $p=0.036$) and combined vitrectomy and scleral buckle (PPV/SB) (OR 0.33, $p=0.050$). Developmental ocular conditions (OR 5.00, $p=0.035$) were a risk factor for final anatomic detachment. Presence of only one retinal tear (OR 0.05, $p=0.030$), SB only (OR 0.05, $p=0.015$) and combined PPV/SB (OR 0.15, $p=0.020$) were protective against recurrent RD at final follow up. Final BCVA was inferior in the PPV group compared to both SB only ($p<0.001$) and combined PPV/SB groups ($p=0.039$).

Conclusions: We identified multiple protective and risk factors for recurrent retinal detachments in a complex paediatric cohort, guiding prognosis and post-operative follow-up timing.

Abstract No.: 201007**Safety and Efficacy of Low-Dose Atropine in Nepalese Children With Progressive Myopia: Phase – II and III Report***First Author: Namrata GUPTA**Co-Author(s): Srijana ADHIKARI, Manish POUDEL*

Purpose: To evaluate the progression of myopia following cessation of low-dose atropine 0.01% (washout phase) and to determine the efficacy and safety of retreatment in Nepalese children over a 5-year follow-up.

Methods: This retrospective observational study was conducted at Tilganga Institute of Ophthalmology as part of the Nepal Atropine Myopia Study. Children aged 6–16 years with baseline myopia -2.00 D to -6.00 D and annual progression >0.5 D were enrolled.

Phase I involved 2 years of atropine treatment, Phase II was a 1-year washout, and Phase III included 2 years of retreatment for children with progression >0.5 D during Phase II. Main outcome measures are Spherical equivalent (SE) and axial length (AL) progression at years 3 (washout) and 5 (retreatment).

Results: Of 200 children, 105 (52.5%) completed follow-up. During washout, 52 (49.5%) showed >0.5 D progression, while 53 (50.5%) remained stable. Forty-four progressing children restarted atropine. In the progressive group, mean SE changed from -4.4 D (year 2) to -5.3 D (year 3) and -5.8 D (year 5). Mean AL increased from 25.1 mm to 25.3 mm and 25.5 mm, respectively. Progression rates slowed significantly after retreatment. No major ocular or systemic side effects were reported.

Conclusions: Low-dose atropine 0.01% does not completely halt myopia but significantly reduces progression, particularly after retreatment, supporting its safety and efficacy as a long-term myopia control strategy in children.

Abstract No.: 206397**Sandhoff Disease Presenting With Cherry-Red Spots in a Pediatric Patient: A Case Report***First Author: Kaixuan CUI**Co-Author(s): Zhenquan WU, Guoming ZHANG, Xinyu ZHAO*

Purpose: To report a rare case of infantile Sandhoff disease initially detected through fundus abnormalities and confirmed by genetic testing, highlighting the role of ophthalmic examination in the diagnosis of systemic neurodegenerative disorders.

Methods: A 14-month-old boy presented with developmental regression and abnormal fundus findings. Clinical history, systemic evaluation, ophthalmic examination, fundus photography, fundus fluorescein angiography (FFA), optical coherence tomography (OCT), and genetic analysis were performed.

Results: Fundus examination revealed bilateral macular "cherry-red spots." OCT demonstrated subtle inner retinal edema with indistinct retinal layers. Systemic examination showed generalized hypotonia and global developmental delay, without cardiac or pulmonary abnormalities. Genetic testing identified compound heterozygous mutations in the HEXB gene, confirming the diagnosis of infantile Sandhoff disease.

Conclusions: Cherry-red spots are a key ocular hallmark of lysosomal storage diseases. This case emphasizes the importance of detailed ophthalmic evaluation in infants with unexplained neurodevelopmental delay. Early recognition and genetic confirmation of Sandhoff disease facilitate accurate diagnosis, appropriate counseling, and multidisciplinary management.

Abstract No.: 206187

Spatial Distribution and Type Differences of Binocular Suppression in Patients With Concomitant and Intermittent Exotropia: A Multidimensional Clinical Study Based on Dynamic Binocular Visual Function Reconstruction

First Author: Zhengzheng WU

Purpose: To compare the preoperative binocular suppression levels between patients with concomitant exotropia (CXT) and intermittent exotropia (IXT), and to explore the spatial distribution characteristics of suppression in the foveal and extrafoveal regions, aiming to provide a basis for precise preoperative evaluation and personalized treatment strategies.

Methods: A total of 170 patients with exotropia were included, consisting of 106 CXT patients and 64 IXT patients. Preoperatively, binocular suppression was quantitatively assessed using a binocular separation visual system, evaluating suppression in the foveal (0.5°) and extrafoveal (10°) regions. The suppression level was classified into four grades based on perceptual integration: R0 (no suppression), R1 (mild suppression), R2 (moderate suppression), and R3 (unilateral suppression). The Mann-Whitney U test was used to compare the differences in suppression levels between the two groups.

Results: Preoperatively, the suppression levels in both the foveal and extrafoveal regions were significantly higher in CXT patients than in IXT patients (foveal: 2.64 ± 0.62 vs. 2.36 ± 0.84 , $p=0.022$; extrafoveal: 1.84 ± 1.28 vs. 1.23 ± 1.34 , $p=0.005$). This suggests that CXT patients experience more severe and widespread binocular suppression. Moreover, suppression levels in the foveal region were generally higher than in the extrafoveal region for all patients.

Conclusions: Binocular suppression in exotropia patients exhibits significant type-specific and spatial distribution-specific characteristics. CXT patients have more severe suppression than IXT patients, with higher suppression in the foveal region compared to the extrafoveal region. These baseline differences suggest that CXT and IXT may represent different levels of binocular visual system impairment. Therefore, precise preoperative suppression evaluation is crucial before planning surgical and rehabilitation strategies.

Abstract No.: 206249

Spectacles Induced Esotropia in Myopic Patients

First Author: Heba FOUAD

Co-Author(s): Ahmed AWADEIN

Purpose: To introduce an unreported group of myopic children who present with spectacle-induced Esotropia in the absence of a high AC/A ratio, and to report the

results of bilateral medial rectus recession in this group of patients.

Methods: A retrospective study included 12 patients with ET up to 50 PD induced by spectacle correction. Patients were orthotropic without spectacles, and the age range was from 5 to 19 years, with pure horizontal muscle imbalance. The AC/A ratio was normal. MRI imaging for assessment of any extra-ocular muscle pathology was performed, and the results were normal. Patients with a history of extra-ocular surgeries, neurological abnormalities, vertical muscle imbalance >5 pd, oblique muscle dysfunction, and paralytic or restrictive strabismus were excluded. Patients were managed by bilateral medial rectus recession, using Kenneth Wright's surgical dose table. The study was conducted at the Aboryosh Pediatric Hospital, Cairo University. Success was defined as orthotropia or small-angle ET <10 pd.

Results: No intraoperative complications were recorded, spherical equivalent of refractive error ranged from -7.25 D to -14.50 D OD, and from -6.25 D to -16.50 OS. MR recession ranged from 5 to 7.5 mm. Six months post-operatively, 10 patients (83.3%) were orthotropic, and 2 (16.7%) patients showed residual ET with glasses of 25 PD.

Conclusions: Some myopic patients might present with ET induced by spectacle correction, in the absence of high AC/A ratio and normal MRI of extra-ocular muscles. Bilateral medial rectus recession seems to be a good option for the treatment of esotropia induced by spectacle correction in myopic patients.

Abstract No.: 201605

Spectrum of Congenital Corneal Staphyloma: Clinicopathologic Insights and Genetic Associations in a Case Series Undergoing Keratoplasty

First Author: Sonam YANGZES

Co-Author(s): Amit GUPTA, Vipasha SHARMA

Purpose: To describe the clinical and histopathological spectrum of congenital corneal staphyloma (CCS) in a series of rare cases, including genetic correlations and surgical outcomes following keratoplasty.

Methods: This retrospective case series includes six patients presenting with congenital corneal staphyloma managed at a tertiary eye care center. The cohort comprised two cases of corneal dermoid with central staphylomatous extension, one case of corneal keloid, one syndromic case associated with Kabuki syndrome, and two cases harboring BMP4 gene mutations. All patients underwent penetrating keratoplasty or tectonic grafting, and detailed anterior segment imaging, systemic evaluation, and genetic testing were performed where indicated. Excised corneal buttons were subjected to histopathological examination.

Results: All cases presented at birth with dense corneal opacification, protrusion, and associated ocular anomalies. Histopathology revealed dense fibrovascular proliferation in dermoid and keloid cases, disorganized stromal architecture with absent Descemet's membrane and endothelium in BMP4-associated staphylomas, and collagenous thickening in the Kabuki-associated case. Genetic testing confirmed pathogenic or likely pathogenic variants in BMP4 in two cases and Kabuki syndrome in one. Surgical intervention led to globe preservation and improved cosmesis in all cases, though visual prognosis remained guarded due to associated anterior segment dysgenesis and microphthalmia.

Conclusions: Congenital corneal staphyloma represents a phenotypically and genetically heterogeneous entity. Early surgical intervention is essential for anatomical restoration, while histopathology and genetic work-up provide valuable insights into underlying pathomechanisms. A multidisciplinary approach is critical for diagnosis, management, and counseling in these complex pediatric cases.

Abstract No.: 206015

Strabismus Following Endonasal Sinus Surgery (ESS): A 10-Year Retrospective Analysis of Clinical Profile and Outcomes

First Author: Lily **MYINT**

Co-Author(s): Manjushree **BHATE**

Purpose: To evaluate the clinical characteristics, ocular motility deficits, strabismus patterns, and management outcomes in patients developing strabismus following Endonasal Sinus Surgery (ESS).

Methods: This retrospective study was conducted over 10 years (2015–2025) at a tertiary eye care center. Demographic details, type and severity of ocular motility restriction, strabismus pattern, imaging findings, and management (surgical, prisms, or observation) were documented. Outcomes were assessed in terms of ocular alignment and symptomatic improvement.

Results: Fifteen patients were identified, with a male-to-female ratio of 2.7:1 (11:4) and a mean age of 41.5 years (range 24–66 years). Ocular motility limitation was present in (n=13; 87%) patients. Limitation of adduction was most commonly involving the medial rectus (n=8; 53%). Large-angle exotropia was the predominant pattern, with a deviation range of 30–75 prism diopters (PD). Management varied: 6 patients (40%) underwent strabismus surgery, showing improvement but residual deviation in most; 1 patient (7%) was managed with prisms, achieving partial symptomatic relief; and 6 patients (40%) were observed conservatively, some showing spontaneous resolution. 2 patients (13%) were lost to follow up and did not receive further management. Despite

intervention, restrictive cases often showed incomplete recovery.

Conclusions: Strabismus is a rare but significant complication following Endonasal sinus surgery, typically presenting as restrictive large-angle exotropia. Surgical correction and prisms provide functional improvement, though complete resolution is uncommon. Early recognition and multidisciplinary management are crucial to optimize outcomes.

Abstract No.: 200945

Superior Oblique Tucking Combined With the Ipsilateral Inferior Oblique Muscle Botulinum Toxin Injection: A New Strategy for Treatment of Superior Oblique Palsy

First Author: Xinping **YU**

Purpose: This study evaluates intraoperative botulinum toxin injection to the ipsilateral inferior oblique during superior oblique tucking (SOT) to minimize postoperative regression and the risk of iatrogenic Brown syndrome.

Methods: This retrospective study analyzed 15 patients with Knapp II or III SOP undergoing either isolated SOT (n=8) or SOT combined with ipsilateral inferior oblique botulinum toxin injection (n=7). Vertical deviation, abnormal head posture (AHP), and iatrogenic Brown syndrome incidence were assessed at short-term (<2 weeks) and long-term (8–12 months) follow-up.

Results: Seven patients in the combined group aged 19.14 ± 14.92 years, with 4 males (57.14%) and followed 9.43 ± 1.81 months, which similar as the 8 patients in SOT group of 18.25 ± 17.56 years and 5 males (62.50%) with followed 9.86 ± 1.68 months. At the final visit, combined group gained significantly lower distance vertical deviation at primary position (2.14 ± 2.64 PD vs. 7.57 ± 5.19 PD; $P=0.04$), and in down gaze (1.57 ± 2.50 PD vs. 9.71 ± 5.80 PD; $P=0.02$). Greater vertical deviation correction (14.71 ± 6.24 PD vs. 5.57 ± 5.56 PD; $P=0.03$) and superior stability in maintained correction were observed in combined group. Additionally, this group exhibited enhanced long-term AHP improvement (85.71% vs. 14.29%; $P=0.03$) and a lower incidence of iatrogenic Brown syndrome (28.57% vs. 85.71%; $P=0.05$).

Conclusions: Combination of SOT with ipsilateral inferior oblique botulinum toxin injection significantly improved vertical deviation correction (particularly in down gaze), improved abnormal head posture, and mitigated the risk of iatrogenic Brown syndrome.

Abstract No.: 206183

Supra-Maximal Strabismus Surgery in Internuclear Ophthalmoplegia: A Case Series

First Author: Leena PATEL

Co-Author(s): Maria THEODOROU

Purpose: Internuclear Ophthalmoplegia (INO) frequently causes large-angle exotropia with diplopia. Any lesion affecting the medial longitudinal fasciculus, eg, demyelinating diseases and cerebrovascular events, can cause INO. Botulinum toxin or 'standard' strabismus surgery often causes unsatisfactory outcomes, although Adams et al(2009) and Roper-Hall et al (2008) published small successful case series over 15 years ago. We present the outcomes of 4 patients undergoing supra-maximal strabismus surgery.

Methods: Retrospective case notes review of patients who have had supra-maximal surgery for bilateral INO between 2021 and 2024.

Results: All patients had bilateral INO secondary to Multiple Sclerosis. Mean age was 45 years (39-57) with varying degrees of adduction deficit (-2 to -4). Three patients had bilateral squint surgery, and one had unilateral. All had medial rectus resect of 8-10mm, and lateral rectus recessions (>8mm). Mean pre-operative exotropia(XT) for near fixation was 60 prism dioptres(PD) (range 50-85) and for distance 50PD(range 40-60). Postoperatively, this reduced to 5PD XT (range 6ET(esotropia)-14XT), and at distance it was 5PD ET (20ET-4XT). 1 year postoperatively, 3 had a much smaller residual XT, and 1 had a controlled exophoria with proven fusion. 3 did not require further treatment, 1 is undergoing botulinum toxin injection (unilateral lateral rectus rather than bilateral pre-op).

Conclusions: Our case series, though limited by small numbers, supports that supra-maximal surgery can lead to significant improvement in ocular alignment, resolution of diplopia, and restoration of binocular single vision. Supra-maximal surgery should be considered as a treatment option in patients with bilateral INO.

Abstract No.: 201864

Surgical Management and Visual Outcomes in Pediatric Stickler Syndrome: A Retrospective Single-Center Study

First Author: Yaojia HU

Co-Author(s): Jing TIAN

Purpose: Stickler syndrome is a rare hereditary connective tissue disorder characterized by high myopia, vitreous anomalies, and early-onset retinal detachment, frequently resulting in significant visual impairment. This study aimed to characterize the demographic and genetic features of hospitalized children with Stickler syndrome, document their family histories and socioeconomic context, describe surgical treatment pathways and costs, and evaluate

postoperative outcomes. Our goal was to generate evidence to inform early screening strategies and improve the long-term management of this rare but vision-threatening disorder.

Methods: We conducted a retrospective study of 19 children (29 hospital admissions) diagnosed with Stickler syndrome at a tertiary ophthalmic center between 2022 and 2024. Demographic characteristics, family history, genetic testing results, surgical interventions, costs, and visual outcomes were collected. Univariate analyses were performed to compare preoperative and postoperative visual acuity and intraocular pressure.

Results: Most patients were full-term (94.7%), singleton births (89.5%), and resided in rural areas (68.4%). while vitrectomy and other advanced procedures may be performed in patients with retinal detachment or other severe complications. Mean intraocular pressure remained within the normal range perioperatively in both eyes (right eyes: preoperative 17.60 ± 2.52 mmHg and postoperative 20.23 ± 0.84 mmHg; left eyes: preoperative 16.63 ± 2.37 mmHg and postoperative 20.75 ± 2.03 mmHg; $P < 0.01$). The median interval between initial hospitalization and disease progression was 7.57 months.

Conclusions: Pediatric Stickler syndrome requires early recognition and proactive management to prevent severe visual loss. Our findings underscore the importance of family-based screening, timely surgical intervention, and comprehensive follow-up.

Abstract No.: 205866

Surgical Management of Type II Monocular Elevation Deficit Associated With Horizontal Deviation Using Knapp's Procedure Combined With Resection

First Author: Nithya SRIDHARAN

Co-Author(s): Antony Arockiadass BASKARAN

Purpose: This retrospective study shows the outcome of adding resection on one vertically transposed horizontal rectus for correcting horizontal strabismus in type II monocular elevation deficit (MED).

Methods: Ten cases of type II MED with horizontal strabismus who underwent full tendon Knapp's along with resection of the medial rectus for exotropia and the lateral rectus for esotropia were taken. All patients had ptosis with elevation restriction. The resection is done for 3mm in the medial rectus or lateral rectus based on the horizontal deviation. 2 cases had posterior fixation sutures done. The postoperative follow-up was at 4 weeks and 6-12 months.

Results: In the esotropia group, the mean vertical deviation for distance and near were 33.0pd and 27.60pd, which reduced to 4.0 and 4.80pd postoperatively. The mean horizontal deviation correction was 18.20pd /18.0pd, decreased to

10.20pd/11.60 postoperatively for distance and near. Exotropes had vertical deviation corrected preoperatively (distance- 30.20pd / near- 31.80pd) to postoperative values (distance- 14.60pd / near- 10.40pd). Horizontal deviation in exotropia reduced to 8.80pd / 12.4pd from 10.40 / 18.6pd for distance / near, respectively. Overall, the mean vertical correction was 29 PD (distance) and 23 PD (near) in esotropes, and 16 PD and 21 PD in exotropes. Horizontal correction averaged 8 PD for distance in exotropes and ~2 PD for near in both groups.

Conclusions: Knapp's procedure with adjunctive horizontal rectus resection provides effective vertical correction in MED with associated horizontal deviation. Horizontal correction was minimal but clinically useful, with no significant adverse effects noted during follow-up.

Abstract No.: 203822

Surgical Outcome and Saccadic Parameters Following True Muscle Transplantation in Horizontal Comitant Strabismus

First Author: Chavi **HARKAWAT**

Co-Author(s): Rebika **DHIMAN**, Deepak **GUPTA**, Vinay **GUPTA**, Rohit **SAXENA**

Purpose: To investigate the surgical outcome and saccadic parameters following true muscle transplantation in horizontal comitant strabismus.

Methods: Thirty participants (15 with exotropia and 15 with esotropia) with best-corrected visual acuity of $\geq 6/18$ in both eyes and horizontal strabismus of ≥ 60 prism diopters (PD) underwent augmented R&R with muscle transplantation in one eye. Saccadic parameters were assessed using the novel REMOBI device. Eye movement analysis was performed using AIDEAL software to evaluate saccadic dynamics. Vertical palpebral aperture width (PAW) was measured in primary gaze, abduction, and adduction. Comparison of pre- and post-operative primary deviation, vertical PAW, duction limitation, and saccadic parameters was evaluated (baseline and 6-month follow-up).

Results: The mean baseline deviation of 74 ± 9 PD improved significantly to 6 ± 2 PD postoperatively ($p < 0.05$). No significant changes were observed in vertical PAW ($p > 0.05$), and minimal postoperative limitation of extraocular movements was noted. Saccadic parameters of the operated eye showed significant improvement at 6 months compared with baseline ($p < 0.05$). 13 % (2/15) of patients with esotropia developed consecutive exotropia, and 26% (4/ 15) and 13 % (2/15) of patients with exotropia and esotropia had residual deviation of mean 25 ± 6 PD and 25 ± 7 PD, respectively.

Conclusions: Augmented R&R with true muscle transplantation not only achieves satisfactory ocular alignment in large-angle strabismus but also restores

coordinated extraocular movements including saccades.

Abstract No.: 201181

Surgical Outcomes of Slanted Bilateral Lateral Rectus Recession in Children With Intermittent Exotropia With Convergence Insufficiency: A Comparative Analysis Based on Preoperative Deviation Angles

First Author: Bo Young **CHUN**

Co-Author(s): Soolienah **RHIU**

Purpose: This study aimed to investigate the efficacy of slanted bilateral lateral rectus recession (S-BLR) in children with intermittent exotropia with convergence insufficiency (IXT-CI), analyzing outcomes based on preoperative deviation angles.

Methods: This retrospective study included 115 pediatric patients with IXT-CI who underwent S-BLR and were followed up for a minimum of one year postoperatively. Patients were divided into two groups based on preoperative deviation angles: the moderate-angle group (Group 1, $n=62$), having patients with distant deviation angles ≥ 20 prism diopters (PD) and ≤ 30 PD; and the large-angle group (Group 2, $n=53$), having patients with distant deviation angles ≥ 35 PD. The surgical outcome measures included postoperative deviation angles, final success rates, the impact of the slanting procedure, and the effect/dose ratio.

Results: Statistical analysis revealed significant inter-group differences in mean deviation angles at distance throughout the postoperative period ($p < 0.05$). However, final success rates were comparable between the two groups ($p = 0.314$). Group 2 demonstrated significantly higher values for both the impact of slanting procedure (9.7 PD/mm vs. 7.3 PD/mm, $p < 0.0001$) and the effect/dose ratio (2.20 PD/mm vs. 2.06 PD/mm, $p = 0.014$) compared to Group 1.

Conclusions: The enhanced surgical effect observed in the large-angle group, as evidenced by greater impact of slanting procedure and effect/dose ratio, suggests that S-BLR may be particularly efficient in IXT-CI patients with larger preoperative deviations.

Abstract No.: 204921

The First Structured Orthoptic Binocular Vision Training Program in Hong Kong: Bridging Service Gaps in the Management of Intermittent Exotropia and Amblyopia

First Author: Sze Lok Gabriela **CHONG**

Co-Author(s): Kam Chuen **CHAN**, Simon Tc **KO**, Po Lin **LEOW**, Peter **LEUNG**, Tsz Hin **MAK**, Alan **TSANG**, Ho On **WONG**, Patrick Kw **WU**

Purpose: Intermittent exotropia (IXT) and amblyopia are prevalent childhood visual disorders in Hong Kong. Long-standing service gaps, including limited orthoptic

manpower and inadequate progress monitoring, have led to deteriorating alignment, impaired binocular vision development, and suboptimal visual outcomes. To address these challenges, a Structured Orthoptic Binocular Vision Training Program was launched in 2020 across two public hospitals.

Methods: The program integrates individualized training plans including convergence, anti-suppression, and fusional vergence exercises, a standardized grading system for exotropia control, enhanced compliance monitoring, and active parental engagement. Clinical and service outcomes were assessed through retrospective analysis of patient records and parental feedback collected between 2020 and 2024.

Results: A total of 542 patients participated, including 450 with IXT and 92 with amblyopia. Among amblyopic patients, 95% achieved the best corrected visual acuity of 1.0. For IXT cases, 96% showed improved fusional range and squint control. Overall, 2,460 treatment sessions were delivered. Four percent of IXT patients transitioned to surgical intervention, while 12% exited the program with stable alignment. The standardized grading system enabled the appropriate discharge of improved patients from the strabismus surgery waiting list, reducing its burden by 80%. Parental satisfaction exceeded 96%, with reporting observable progress and enhanced functional outcomes. Personalized rehabilitation strategies and consistent encouragement were keys to maintaining treatment adherence.

Conclusions: This structured program effectively bridges service gaps in IXT and amblyopia management. It enhances treatment compliance, improves binocular vision outcomes, and optimizes surgical resource allocation. The model demonstrates scalability and sustainability, offering a promising framework for strengthening orthoptic care standards in Hong Kong.

Abstract No.: 201820

The Outcome and Patient Satisfaction of the Nasal Transposition of the Split Lateral Rectus Muscle for Oculomotor Nerve Palsy

First Author: Miao KONG
Co-Author(s): Junhong LI

Purpose: To evaluate the outcomes and complications associated with nasal transposition of the split lateral rectus muscle (NTSLR) procedure, and assess the satisfaction of the patients and/or patients' parents with respect to the surgery outcome in patients with complete oculomotor nerve palsy.

Methods: This is a retrospective study. All patients with complete oculomotor nerve palsy treated between February 2016 and July 2023 with Y splitting and transposition of the lateral rectus muscle to the medial rectus muscle were included. The patient satisfaction was assessed using a 5 Likert scale.

Results: A total of 7 patients were included. Patients had a preoperative horizontal deviation ranging from -90 to -120PD. Of the 7 patients, one achieved orthotropia, two were slightly overcorrected (+8PD, +15PD), and others were undercorrected (-15PD, -20PD) in the primary position after surgery. Those three patients with orthotropia or overcorrection had satisfactory appearance in the primary position at the last visit, but they were not satisfied with the almost fixed eyeball since they had an obvious restriction in abduction and had little improvement in adduction. However, the other four patients with slightly undercorrection in the primary position after the operation were more satisfied since there was no severe restriction of both abduction and adduction.

Conclusions: Acceptable cosmetic results can be achieved in the treatment of complete oculomotor nerve palsy by transporting the split lateral rectus muscle to the medial rectus muscle. In view of patient satisfaction, slightly undercorrection is better than orthotropia and overcorrection.

Abstract No.: 208425

The Relationship Between the Appearance Features of Children's Eyelids and Astigmatism

First Author: Haihua LIU
Co-Author(s): Rongjun LIU

Purpose: This study aimed to explore the relationship between the appearance features of children's eyelids and astigmatism, and to investigate potential predictive factors for astigmatism based on eyelid appearance.

Methods: This cross-sectional survey included 3- to 6-year-old children from the Department of Ophthalmology Center, Peking University First Hospital. Clinical data, including external eye images and personal information, were collected. Six factors representing the appearance features of children's eyelids were defined and analyzed for their correlation with astigmatism. These factors included palpebral fissure tilt angle (AIP), ratio of the inner canthal distance to the pupillary distance (EFD/PD), angle between the lower eyelid margin's horizontal line and the line connecting the inner canthus (ALEIE), ratio of the area of the upper eyelid covering the cornea to the total corneal area (UCATA), upper eyelid lash tilt angle (AUEI), and ratio of the vertical to horizontal diameter of the cornea (VDHD). The study was conducted in accordance with the Declaration of Helsinki and approved by the Ethics Committee of Peking University First Hospital.

Results: Thirty participants were included in the study. Statistically significant differences were found in UCATA, AUEI, ALEIE, and EFD/PD between different astigmatism groups ($P < 0.001$). Multiple logistic regression analysis indicated correlations between UCATA, AUEI, and EFD/PD factors and astigmatism.

Specifically, UCATA ($\beta=-3.28$, $P<0.001$), AUEI ($\beta=1.46$, $P<0.001$), and EFD/PD ($\beta=0.28$, $P<0.001$) were significantly associated with astigmatism.

Conclusions: The study suggests that UCATA, EFD/PD, and AUEI could be predictive factors for astigmatism. These findings may enhance the understanding of the complex interplay between eyelid morphology, eyelid pressure, and corneal astigmatism.

Abstract No.: 201811

The Safety and Effectiveness of 0.03% Tacrolimus Ointment in Pediatric Patients Presenting With Vernal Keratoconjunctivitis

First Author: Muhammad Ajmal **CHAUDHARY**

Purpose: To evaluate the safety and effectiveness of tacrolimus 0.03% ointment in treating pediatric patients with vernal keratoconjunctivitis (VKC).

Methods: This prospective, interventional study included 60 children with bilateral VKC. Patients in the tacrolimus cohort were treated with 0.03% tacrolimus ointment twice daily for 60 days, followed by once daily application for 60 days, and then once on alternate days for two months. The control group got topical 0.1% fluorometholone drops, thrice a day for two weeks, after which the dose was gradually tapered for the next two weeks. During the follow-up period, both groups received topical 0.1% olopatadine eye drops twice daily. Improvement in symptoms and signs was documented among the groups to measure the success of the therapy, and their severity was rated using a four-point scale.

Results: This study included 60 children with bilateral VKC. The mean age of both groups was similar. Papillary hypertrophy and conjunctival hyperemia were the most common signs, while itching was the most frequent symptom. After treatment, symptoms and signs decreased significantly in both groups. However, at three and six months, the group treated with 0.03% tacrolimus ointment showed a more notable improvement in symptom and sign scores. The tacrolimus group tolerated the treatment well, with only a few complaining of a stinging sensation. The control group experienced one incidence of elevated intraocular pressure.

Conclusions: Tacrolimus 0.03% ointment is an effective treatment for VKC in pediatrics. This treatment may help chronic VKC patients and lower the risk of steroid-related problems in these patients.

Abstract No.: 203339

The Study of Peripheral Refractive Profile in Children With Myopia

First Author: T S **SURENDRAN**

Co-Author(s): Sumita **AGARKAR**, Akshay **BADAKERE**, Neha Nitin **KOTWAL**, Asha **THARSIS**

Purpose: To study the profile of children with myopia and to investigate the distribution and relationship between central and peripheral refractive error.

Methods: This cross-sectional study looked at data from 60 children between the ages of 8 and 14. The data included central Spherical equivalent and peripheral spherical equivalent using an open-field auto-refractometer (WAM-5500, Grand Seiko CO. LTD., Hiroshima, Japan) at two specific locations: nasal and 25 temporal. We calculated descriptive statistics, found the mean and standard deviation of the differences between central and peripheral measurements, and checked the correlation between the central refractive error and these differences.

Results: The average central refractive error was $-3.79D$. The average absolute difference between central and nasal peripheral refraction was $0.96\pm0.74D$, while the average difference on the temporal side was $1.13\pm0.88D$. Most of the central-to-peripheral refractive error differences were less than 2 D. We found a weak positive correlation between the central refractive error and the difference with both nasal ($r=0.21$) and temporal ($r=0.11$) peripheral refraction.

Conclusions: Our findings suggest there's only a weak link between the magnitude of central myopia and the peripheral refractive profile. This means that central refractive error alone may not be a strong predictor of peripheral refractive state, highlighting the need for more research into other factors that influence it. This work helps us better understand the complexity of childhood myopia, especially now that new peripheral defocus-modulating glasses are available to help control its progression.

Abstract No.: 201659

Therapeutic Use of Atropine 1% Eye Drop in Accommodative Excess

First Author: Saima **SHAMS**

Co-Author(s): Mehedi **HASAN**, Mostafa **HOSSAIN**, Sidratulmuntaha **NAZNIN**

Purpose: To evaluate the role of atropine eye drop in the management of accommodative excess.

Methods: An 11-year-old child had complaints of blurred vision for both near and distance, along with a headache. The unaided visual acuity of each eye was 6/60 for distance and N8 for near. Dry retinoscopy showed myopization up to $-4.75D$ with no improvement in visual acuity. On examination, there was 8 prism diopter esophoria for distant and 12 prism

diopter esophoria at near. MEM retinoscopy reveals Lead with poor stereopsis. Near point accommodation was 6 cm, no break of near point of convergence till 6 cm amplitude of accommodation was 16.5 dioptre. Cycloplegic refraction was done, and it was +1.00 dioptre. The patient was prescribed two spectacles with +1.00 Dioptre for distant and +2.50 Dioptre for near vision. With spectacles, the vision was 6/12 and N5. Atropine 1% eye drop was prescribed for 30 days. The patient was advised to follow up after 45 days in the post-cycloplegic state. Visual acuity was improved to 6/9 (unaided). Then, the final visual acuity was 6/6 (partial) for distant and N6 at near with +0.75 diopre. This spectacle was prescribed. Asthenopic symptoms are also relieved. The patient was advised not to continue the atropine eye drops.

Results: In addition to significant improvement of vision, Atropine 1% eye drop relieves the symptoms of asthenopia in accommodative excess.

Conclusions: Not all visual impairment is refractive error. Cycloplegic refraction confirms the diagnosis, and atropine 1% eye drop can also be used therapeutically in accommodative excess.

Abstract No.: 201872

Ultrasound Biomicroscopic Characteristics of the Anterior Segment in Patients With Primary Congenital Glaucoma

First Author: Anh Tm **DAO**

Co-Author(s): Anh Tv **BUI**, Son N **NGUYEN**

Purpose: To evaluate ultrasound biomicroscopic features of the ocular anterior segment in patients with primary congenital glaucoma.

Methods: This is a cross-sectional study; 16 patients diagnosed with primary congenital glaucoma were included in the study, and an anterior segment ultrasound was performed under anesthesia using VuMax Ophthalmic Ultrasound with a 50MHZ frequency probe.

Results: Sixteen cases (9 males and 7 females) with 24 eyes with primary congenital glaucoma (PCG) were confirmed, with a mean age of 5.8 ± 3.1 years. 16 eyes (66.7%) had abnormal angle structure, 41.7% had iris anterior insertion, and ciliary body attachment to the iris was found in 12.5%. PCG eyes have greater corneal diameter, anterior chamber depth, and zonular length than normal eyes (12.7 ± 1.23 mm, 3.9 ± 0.4 mm, 1.5 ± 0.4 mm with $p < 0.001$, $p < 0.001$, and $p < 0.05$, respectively). The mean iris thickness in the study group was 0.27 ± 0.07 mm, smaller than that of the normal group, $p < 0.05$.

Conclusions: Ultrasound biomicroscopy is a useful method to detect structural changes of the anterior segment in patients with PCG. This tool can help confirm diagnosis as well as contribute to understanding pathogenesis.

Abstract No.: 200397

Virtual Reality-Based Vision Therapy for Intermittent Exotropia: A Randomized Clinical Trial

First Author: Hui **ZHU**

Co-Author(s): Hu **LIU**

Purpose: To assess the efficacy and safety of virtual reality-based vision therapy (VRVT) in children with intermittent exotropia (IXT).

Methods: Children aged 6 to 18 years with previously untreated IXT were enrolled between July 1, 2023, and November 17, 2024. Eligibility criteria included an exodeviation magnitude of 10 to 30 prism diopters at distance, an exotropia control score of 1 to 3 at both distance and near, and a cycloplegic spherical equivalent (SE) between -6.00 diopters (D) and +0.50 D in both eyes, with an interocular SE difference less than 2.50 D. Participants were randomly assigned in a 1:1 ratio to receive VRVT or no intervention for 12 weeks. The primary outcome was the change in the distance exotropia control score from baseline to week 12. Participants with at least one post-randomization assessment were analyzed for treatment efficacy.

Results: Among 177 randomized participants, 161 were included in the analysis. At week 12, the median change in distance exotropia control score was -0.33 (interquartile range [IQR], -1.00 to 0.00) in the intervention group versus 0.00 (IQR, -0.33 to 0.33) in the control group ($P < 0.001$, Mann-Whitney U test). Significant between-group differences were also observed in near exotropia control score, magnitude of exodeviation at both distance and near, near stereoacuity, near point of convergence, as well as simultaneous perception and retinal correspondence (all $P < 0.05$). No intervention-related adverse events were reported.

Conclusions: Our findings support the value of VRVT as a safe and effective intervention for children with IXT.

Abstract No.: 207020

Visual Axis Opacification and Complications After Bag-in-the-Lens Intraocular Lens Implantation in Pediatric Cataract Surgery: A Systematic Review

First Author: Brigitta Marcia **BUDIARDJA**

Co-Author(s): Dian Estu **YULIA**

Purpose: Pediatric cataract is a leading cause of childhood blindness, and visual axis opacification (VAO) remains a major challenge in its surgical management. The bag-in-the-lens (BIL) intraocular lens was developed to minimize this risk. This systematic review evaluates the rate of VAO following BIL IOL implantation in pediatric cataract cases, along with associated intraoperative and postoperative complications.

Methods: This review included studies with pediatric patients who received cataract surgery with primary IOL implantation using BIL IOL that evaluated the VAO rate. A comprehensive search was performed across five databases (PubMed, Cochrane Library, EBSCO, Scopus, and ProQuest). Risk of bias was assessed using the NHLBI Quality Assessment Tool.

Results: From 97 studies identified, seven met the inclusion criteria, comprising five case series and two cohort studies. Reported VAO rates ranged from 4.6% to 46%. In most cases where VAO developed, the BIL IOL was not correctly positioned, preventing its intended mechanism of confining lens epithelial cells from functioning effectively. Reported intraoperative complications included vitreous prolapse, iris-related events, capsule-related complications, and IOL luxation. Postoperative complications included glaucoma and IOL dislocation.

Conclusions: Current evidence on BIL IOL outcomes in pediatric cataract is limited. When anterior and posterior capsule edges are properly positioned within the IOL groove, BIL IOL implantation is associated with a relatively low risk of VAO. Further high-quality comparative studies are required to establish its safety, efficacy, and potential advantages over other IOL designs in pediatric cataract surgery.

Refractive Surgery

Abstract No.: 201598

A Ring to Protect Vision: Role of Capsular Tension Rings to Prevent Posterior Capsule Opacification in High Myopia; a Systematic Review and Meta-Analysis

First Author: Cynthia VIRYAWAN

Co-Author(s): Faraby MARTHA

Purpose: To evaluate the effectiveness of capsular tension rings (CTR) in preventing posterior capsule opacification (PCO) in patients with high myopia undergoing cataract surgery

Methods: A systematic search was performed in PubMed, Cochrane, Scopus, and ProQuest databases up to March 2025. Eligible studies included patients with high myopia undergoing cataract surgery using CTR and no CTR, reporting outcomes of PCO or Nd:YAG capsulotomy. Risk of bias was evaluated using the Newcastle–Ottawa scale

Results: CTR use was associated with a significantly smaller PCO area compared to controls. Furthermore, meta-analysis of PCO presence revealed a significant difference ($p=0.05$), indicating that CTR use was associated with lower incidence and severity of PCO compared to the control group. Three studies showed a significant reduction in Nd:YAG capsulotomy rates with

CTR (OR 0.34, $p=0.007$, moderate heterogeneity 49%), indicating a 66% risk reduction. While CTRs did not fully prevent PCO, they reduced its severity. Long-term benefits for intraocular lens stability were inconsistent.

Conclusions: CTRs may reduce PCO severity and decrease the need for Nd:YAG capsulotomy in high myopia patients. However, prophylactic use remains controversial and should be considered primarily in those with zonular instability or retinal pathologies that increase the risk of Nd:YAG capsulotomy. Further randomized controlled trials with long-term follow-up are needed to confirm safety and efficacy.

Abstract No.: 201826

An Innovative Marking Method for Astigmatism Correction of Small Incision Lenticule Extraction

First Author: Jiamei ZHANG

Co-Author(s): Yan WANG, Pinghui WEI, Yanan WU, Lulu XU, Xinheng ZHAO

Purpose: To evaluate the effectiveness of a novel method with cyclotorsion compensation and epithelial marking in improving the accuracy of astigmatic axis correction of small incision lenticule extraction (SMILE) surgery.

Methods: This prospective study adopted a novel epithelial-marking strategy for 103 eyes of 55 subjects undergoing SMILE for myopia and myopic astigmatism correction. Combined with compensation of static cyclotorsion, these accurate and clear markings could quantify the value of cyclotorsion. Two local, symmetric spots were ablated along the same direction of the static cyclotorsion angle. These markers were then aligned to adjust for static cyclotorsion of the SMILE procedure.

Results: A tendency towards external torsion in both eyes was found, with a mean static cyclotorsion of $(0.147 \pm 3.113)^\circ$ in right eyes and $(-2.128 \pm 3.396)^\circ$ in left eyes. At 3-month follow-up, all eyes achieved uncorrected distance visual acuity (UDVA) of 20/25 or better and retained their corrected distance visual acuity (CDVA). None of the eyes had a residual cylinder value exceeding -0.50 D. The absolute value of angle of error (AoE) was only offset by $(1.863 \pm 2.897)^\circ$, with 89% of eyes showing an angular shift of less than $\pm 5^\circ$, indicating minimal misalignment

Conclusions: This novel epithelial-marking approach can provide accurate, safe, and effective outcomes for astigmatism treatment in SMILE surgery. It offers more precise, quantitative intraoperative cyclotorsion compensation during the femtosecond laser scanning, representing a currently accurate and reliable solution for astigmatism correction

Abstract No.: 204562

Analysis of Factors Influencing Postoperative Refractive Outcomes in SMILE Based on XGBoost Model

First Author: Mingdong ZHANG

Co-Author(s): Yan WANG

Purpose: To analyze the influence of individual parameters on the postoperative refractive outcomes of small incision lenticule extraction (SMILE) in myopic eyes using the XGBoost model.

Methods: This study included 477 patients (922 eyes) of SMILE from Tianjin Eye Hospital. We take the postoperative spherical equivalent (SE) as the XGBoost model's label and divided the patients into two groups: the poor refractive outcomes group ($SE \leq -0.50$ D) and the good refractive outcomes group (-0.50 D < $SE < +0.50$ D), to analyze the factors influencing postoperative refractive outcomes. The XGBoost model took 72 clinical parameters, including corneal biomechanical parameters, corneal morphological parameters, surgical-related parameters, and preoperative refractive parameters as features, selected 42 eyes from the good refractive outcomes group randomly, and all eyes (a total of 42 eyes) from the poor refractive outcomes group to conduct 100 times influence factors analysis. Each analysis can obtain the average gain value of each factor that affects the difference in surgical results. The number of occurrences and average gain values of all parameters in 100 analyses are counted, and the number of occurrences is used as a reference standard. Factors that appeared more than 50 times were considered to have a more important influence on the outcomes of refractive surgery. The 10 parameters with the highest occurrence frequency were selected as the most important factors affecting the postoperative refractive outcomes. And we used SPSS to divide these 10 parameters into 10 equal groups, spaced every 10 percentiles, to compare postoperative SE and parameter value range when the SE value was the largest or a significant change was determined.

Results: The 10 most important factors influencing postoperative refractive outcomes included PTA (Percentage thickness ablation), SE, R Per F(Center of zone radius between the anterior corneal 7 and 9mm rings), HC (Highest concavity) Time, Deflection Amp Max (The time of maximum deflection amplitude), RST (Residual stroma thickness), Rs F(Steep radius of curvature in the anterior cornea's center), LTmax (The maximum lenticule thickness), SSI(The corneal stress-strain index) and SD (spherical diopter). When PTA $\geq 25.09\%$, LTmax ≥ 139 μ m, SE ≤ -7.00 D, or SD ≤ -6.75 D, the postoperative SE significantly increased (all $P < 0.05$), with averages of -0.183 D, -0.171 D, -0.188 D, and -0.184 D. After controlling for age, intraocular pressure, and corneal thickness, the postoperative SE significantly increased when HC time was ≥ 17.422 and

Deflection Amp Max (ms) ≥ 16.616 , reaching -0.209 D and -0.202 D.

Conclusions: More corneal thickness ablation, longer HC Time and Deflection Amp Max (ms), lower SSI, and higher preoperative refractive error may result in poor postoperative refractive outcomes. Appropriate nomogram adjustments could improve results. And the refractive outcomes after the SMILE may be influenced by the preoperative biomechanical properties of the cornea.

Application of Refractive Lens Replacement (RLE) in Patients With Short Ocular Axis

First Author: Shunhua ZHANG

Purpose: Patients with short ocular axis usually have hyperopia, impairment of near vision, and risk of anterior chamber angle closure. RLE surgery can simultaneously solve cataracts, the risk of anterior chamber angle closure, hyperopia, and presbyopia. Therefore, short ocular axis patients benefit more from RLE surgery. But there is still controversy because some problems remain unsolved, such as high surgical risk and difficulty in IOL calculation. It is necessary to conduct a comprehensive evaluation of the effectiveness and safety of RLE surgery for short eye axis patients.

Methods: A total of 39 patients with short eye axis (AL < 22.5mm) who underwent bilateral RLE by phacoemulsification combined with ATLAS Atri839MPIOL implantation surgery at Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, from January 2021 to June 2024, were included. Systematic examinations were conducted on the first day, first month, and sixth month after surgery. The evaluations include uncorrected vision of far, medium, and near, apparent refraction, iTrace examination, defocus curve, and VF-14 visual scale. Intraoperative and postoperative complications were recorded.

Results: Visual acuity: The patient's preoperative UDVA, UIVA, and UNVA were 0.30 (0.10,0.54) log MAR, 0.50 (0.30,0.80) log MAR, 0.60 (0.47,0.80) log MAR, and the corresponding numbers of the first day postoperatively were 0.00 (0.00,0.01) log MAR, 0.00 (0.00,0.01) log MAR, and 0.00 (0.00,0.10) log MAR. The proportions of UDVA, UIVA, and UNVA equal to or better than 0.1 log MAR at 6 months after surgery were 93.6%, 87.2%, and 85.9%, respectively. The refractive prediction error at 6 months after surgery was -0.070 ($-0.331, 0.163$) D. The detachment rates of far vision and near vision were 93% and 100%, respectively. There were no intraoperative or postoperative complications.

Conclusions: The combination of RLE and ATLAS Atri839MP IOL implantation can solve cataract, risk of angle closure, hyperopia and presbyopia in

patients with short ocular axis. It demonstrates good safety and effectiveness. Thorough preoperative testing, customized IOL selection, and gentle surgical technique are the keys to successful outcomes.

Abstract No.: 200480

CAMP Protocol With ZOOM Simulator: A New Proprietary Software for Hyperopic Presbyopic LASIK Planning

First Author: Zain KHATIB

Purpose: To evaluate the clinical outcomes of hyperopic presbyopic LASIK using the CAMP protocol, a novel treatment strategy combining conservative Q-value modulation with personalized monovision planning, aided by a real-time ray diagram simulator (ZOOM Simulator).

Methods: A total of 52 eyes from 26 hyperopic presbyopic patients underwent bilateral Custom-Q LASIK using the CAMP protocol on the Alcon Wavelight EX500 platform. Planning incorporated Binocular Inherent Accommodation (BIA), monovision testing, and simulated depth of focus (DOF) profiles via the ZOOM Simulator. The simulator allowed individualized adjustment of Q-value modulation (max -0.36) and monovision offset (up to -1.5 D), ensuring optimal binocular DOF overlap. A standardized surgical technique was followed, and outcomes were evaluated at 6 months. Main outcome measures included uncorrected and corrected distance and near visual acuity, refractive predictability, spectacle independence, and subjective satisfaction.

Results: At 6 months, 88.5% achieved binocular UDVA of 6/6 or better, and 92.3% achieved UNVA of J2 or better. Mean final SEQ was $+0.08 \pm 0.43$ D in distance eyes and -0.76 ± 0.45 D in near eyes. No eye lost more than one line of CDVA. Spectacle independence was achieved in 77% of patients. Patient-reported satisfaction scores were high, and dysphotopsia was minimal.

Conclusions: The CAMP protocol offers a safe, effective, and customizable approach to treating hyperopic presbyopia using individualized planning and Q-modulation. The ZOOM Simulator enables real-time visualization of DOF profiles, improving clinical precision and patient outcomes.

Changing the Paradigm: Laser Vision Correction As Early Intervention for Accommodative Strabismus

First Author: Igor AZNAURYAN

Co-Author(s): Victoria BALASANYAN, Evgenii MORDYUKOV

Purpose: The aim of the work was to assess the parameters of patients before and after laser correction

for their accuracy relative to the expected result, and the stability of the effect.

Methods: A total of 50 patients aged 5 to 15 years (average 6.7 ± 0.3) years with hypermetropia, accommodative, and partially accommodative strabismus were observed. Of these, high hyperopia was observed in 17 patients, moderate hyperopia in 20 patients, and mild hypermetropia in 13 patients; complex hypermetropic astigmatism was observed in 33 patients. In 70% of cases, clinically significant convergent strabismus with an accommodative component of 5 to 30 degrees was observed.

Results: As a result, we observed a change in AL of 0.15 during the follow-up period. The standard deviation of refractive values (SE) is 2.61 before laser correction and 2.13 after laser correction. Mean change in sph of 3.27 diopters after laser correction, cyl of 2.39 diopters, and Ax of 3. Change in visual acuity (VIS): an average improvement of ≈ 0.15 (from 0,83 to 0,98 conventional units). Change in strabismus angle: on average, a decrease of $\approx 8,6$ degrees (from $\approx 16,8^\circ$ to $\approx 8,2^\circ$). Corneal opacities are minimal (mean 0.3/3).

Conclusions: The surgery resulted in a significant reduction in hyperopia (average ≈ 3.27 D). Postoperative refraction approached emmetropia (normal vision). A significant decrease in the angle of strabismus was noted (on average by 8.6°). Slight enlargement of the axis (AL) of the eye after surgery (mean $\approx 0,2$ mm).

Abstract No.: 202908

Clinical Results of SMILE PRO Using Corneal Apex and Cyclotorsion-Guided Lenticule Centration

First Author: Olesia ZIIATDINOVA

Co-Author(s): Chun Chun HE, Lina ZHOU

Purpose: To evaluate visual outcomes following SMILE PRO laser vision correction with adjusted lenticule centration and cyclotorsion for the treatment of myopia and astigmatism.

Methods: Fifty eyes of patients (mean age: 27 years; mean corneal thickness: $525.3 \mu\text{m}$) with myopia ranging from -1.50 to -6.5 diopters (D) and astigmatism from -1.50 to -3.75 D underwent SMILE PRO treatment. Preoperative lenticule centration was determined using Pentacam apex data. Cyclotorsion alignment was managed by placing two corneal surface markers (2–3 mm from the limbus) along the horizontal meridian under slit-lamp guidance. During docking, lenticule centration was adjusted relative to the Pentacam blue fixation dot, and the vacuum interface was rotated according to the corneal markers. Visual acuity and refraction outcomes (UCVA, MCVA, autorefractometry) were assessed at 1 day, 1 week, 1 month, and 3 months postoperatively.

Results: At day 1, 97.5% of eyes achieved UCVA equal to or better than preoperative MCVA. Mean SE was

$\pm 0.42 \pm 0.23$ D with residual astigmatism 0.40 ± 0.17 D. At week 1, 98.3% of eyes achieved UCVA equal to or better than MCVA, with stable refractive error. At 1 month and 3 months, nearly all eyes maintained UCVA equal to or better than preoperative MCVA, with mean SE close to plano and residual astigmatism ≤ 0.40 D.

Conclusions: SMILE PRO with adjusted lenticule centration based on corneal apex alignment and cyclotorsion control provides excellent refractive accuracy and visual outcomes in patients with myopia and astigmatism. At 3 months, nearly all patients achieved their target MCVA with stable refractive results.

Comparative Analysis of Vertical Coma Aberrations in SMILE Surgery: Visumax 800 Versus Visumax 500

First Author: Ankita **SANJAY KULKARNI**

Co-Author(s): Sri **GANESH**, Supriya **SMAKA SRIGANESH**, Savio **SYLVAN PEREIRA**

Purpose: To evaluate and compare the vertical coma aberrations induced by SMILE surgery performed on Visumax 500 and Visumax 800 platforms, shedding light on their impact on visual quality.

Methods: This prospective study included 128 eyes from patients undergoing SMILE for myopia or myopic astigmatism (<10 D spherical equivalent), evenly divided between Visumax 500 and Visumax 800 groups. Comprehensive preoperative and postoperative assessments (UCVA, manifest refraction, slit lamp, Pentacam, MS-39, ATLAS topography, ITrace, HD Analyzer) were conducted at baseline, Day 1, Day 15, and 3 months. Patients with corneal pathology, cataracts, or angle kappa >0.5 mm were excluded. Vertical coma was analyzed and correlated with angle kappa values.

Results: At 3 months, mean vertical coma was significantly lower in the Visumax 800 group (-0.029 ± 0.060) compared to the Visumax 500 group (0.020 ± 0.052). More detailed analysis by angle kappa revealed that the Visumax 800 consistently induced less vertical coma across subgroups (<0.3 and >0.3 mm), with statistically significant differences. Furthermore, the Visumax 800 group showed superior objective scatter index (OSI) values, indicating enhanced optical quality.

Conclusions: Our findings present compelling evidence that SMILE surgery using Visumax 800 induces less vertical coma aberration and offers improved optical quality compared to Visumax 500. This data supports the evolution of refractive laser technology toward optimized visual outcomes and patient satisfaction.

Abstract No.: 203230

Comparative Evaluation of Lenticule Quality in Small Incision Lenticule Extraction (SMILE) Using VisuMax 800 Versus VisuMax 500

First Author: Meiyun **LI**

Purpose: To evaluate the surface characteristics of the lenticule extracted by Small Incision Lenticule Extraction (SMILE) using VisuMax 500 and VisuMax 800.

Methods: In this study, twelve eyes treated with small incision lenticule extraction were included at the Eye and ENT Hospital of Fudan University (Shanghai, China) from November 2024 to January 2025 and divided into two groups: Group VisuMax 500 and Group VisuMax 800. The extracted lenticules were immediately fixed for electron microscopy after removal. Both the anterior and posterior lenticular surfaces were scanned using scanning electron microscopy (SEM), and the quality of the lenticule was assessed using a 16-point scoring system.

Results: The mean surface characteristic scores of the lenticules in Group VisuMax 800 and Group VisuMax 500 were 13.39 ± 1.12 and 13.88 ± 0.65 , respectively, showing no significant difference between the two groups ($P=0.29$). In Group VisuMax 800, no significant difference was observed in the overall surface characteristics between the anterior (13.22 ± 1.24) and posterior surfaces (13.53 ± 2.02) ($p=0.83$). Similarly, the anterior (14.07 ± 0.25) and posterior surfaces (13.86 ± 0.82) showed no significant difference in Group VisuMax 500 ($p=0.64$). Furthermore, intergroup analysis confirmed comparable surface characteristics for both anterior ($p=0.17$) and posterior ($p=0.74$) lenticule surfaces.

Conclusions: The lenticules extracted using the VisuMax 800 demonstrated high quality and were comparable to those obtained with the VisuMax 500.

Abstract No.: 203486

Compare the Clinical Outcome of 5 Different Keratorefractive Lenticule Extraction (KLEx) and Laser-Assisted in Situ Keratomileusis (LASIK)

First Author: I-hung **LIN**

Co-Author(s): Chao-kai **CHANG**, Chen-cheng **CHAO**, Tsung-jen **WANG**

Purpose: To compare clinical outcomes of five keratorefractive lenticule extraction (KLEx) techniques — SMILE (Zeiss Visumax 500), SMILE Pro (Zeiss Visumax 800), CLEAR (Zeimer Z8), SmartSight (Schwind ATOS), SILK (Johnson & Johnson Elita), and LASIK (Alcon EX 500), focusing on uncorrected distance visual acuity (UDVA), residual refractive error, Effective Optical Zone (EOZ), Central Stromal Thickness Reduction (CCSR), contrast sensitivity, and higher-order aberrations (HOAs).

Methods: A prospective study was conducted at Taipei Nobel Eye Clinic (Aug 2024–Jan 2025), involving 72 SMILE (144 eyes), 82 SMILE Pro (164 eyes), 8 CLEAR (16 eyes), 26 SmartSight (52 eyes), 7 SILK (14 eyes), and 5 LASIK (10 eyes) patients. Pre- and post-operative BCVA, UDVA, EOZ, CCSR, contrast sensitivity, and HOAs were analyzed. Baseline characteristics (age, sex, sphere, cylinder, programmed optical zone) were matched across groups.

Results: Patients' average age ranged from 29–33 years. Preoperative spherical errors were -4.63 to -6.15D and cylindrical errors -0.68 to -1.30D. One month post-op, UDVA was similar across all groups (0.016 to 0.055 logMAR), with residual refractive errors near OD. All groups had smaller EOZ compared to POZ, with LASIK showing the largest reduction (1.35mm) and SILK the least (0.59mm). KLEx techniques overestimated CCSR by 12–26µm, while LASIK underestimated by 8µm. Contrast sensitivity and increases in HOAs were comparable among all procedures.

Conclusions: At one month post-op, all five KLEx techniques and LASIK showed comparable results in UDVA, residual errors, contrast sensitivity, and HOAs. However, EOZ reduction was greatest in LASIK and least in SILK, with KLEx overestimating and LASIK underestimating CCSR.

Abstract No.: 203634

Comparing Early Visual Quality: SMILE Pro (VisuMax 800) vs. SMILE (VisuMax 500)

First Author: Chen LI

Co-Author(s): Yuehua ZHOU

Purpose: To compare the early postoperative visual quality after myopia with astigmatism correction using SMILE pro with the VisuMax 800 versus SMILE with the VisuMax 500.

Methods: A prospective randomized case-control study was conducted, including 120 eyes undergoing VISUMAX 800 SMILE pro and 120 eyes undergoing VisuMax 500 SMILE at our hospital. Visual acuity, MRSE, higher-order aberrations (HOAs), including total HOAs, and contrast sensitivity were evaluated preoperatively and at 1 week, 1 month, and 3 months postoperatively.

Results: At 3 months postoperatively, 71.1% of eyes in the SMILE pro group achieved UDVA $\geq 20/16$, which was significantly higher than 55% in the SMILE group ($P = 0.041$). Additionally, 52.2% of eyes in the SMILE pro group gained ≥ 1 line of Snellen CDVA, superior to 36.7% in the SMILE group ($P = 0.043$). No significant difference in postoperative MRSE was observed between the two groups. At 3 months, total HOAs were lower in the SMILE pro group compared with the SMILE group ($0.431 \mu\text{m}$ vs $0.554 \mu\text{m}$, $P = 0.047$). Vertical coma was also significantly lower in the SMILE pro group ($P = 0.036$), whereas no significant differences were found in horizontal coma or spherical aberration ($P > 0.05$).

Furthermore, contrast sensitivity at 6.0 cpd and 12.0 cpd was significantly higher in the SMILE pro group than in the SMILE group ($P = 0.016$ and $P = 0.021$, respectively).

Conclusions: Both SMILE techniques demonstrated efficacy and safety in myopia correction. Compared with conventional SMILE, SMILE pro provided superior outcomes in terms of visual improvement, reduction of higher-order aberrations, and preservation of contrast sensitivity.

Abstract No.: 201686

Comparing the Effect of Mechanical and Tetracaine-Assisted Epithelial Debridement on Central Corneal Endothelial Cells in PRK

First Author: Nader NASSIRI

Co-Author(s): Sara KAVOUSNEZHAD, Kourosh SHEIBANI

Purpose: To compare the effects on central corneal endothelial cells measured by confocal microscopy after photorefractive keratectomy (PRK) with mitomycin C (MMC) using mechanical and tetracaine-assisted epithelial debridement methods.

Methods: In this prospective, randomized, comparative study, 44 patients (88 eyes) with myopia of up to -6.00 diopters were enrolled. Each patient's right eye was randomly assigned to either the tetracaine-assisted or the mechanical debridement group, with the left eye assigned to the other method. Preoperative and 3-month postoperative assessments were conducted using confocal microscopy. These assessments measured epithelial thickness, the number of keratocytes in the anterior, mid, and posterior stroma, and the characteristics of central corneal endothelial cells. These characteristics included cell density, mean cell area, polymegathism, and hexagonality.

Results: No statistically significant differences were observed between the two groups considering the mean epithelial thickness at the 3-month follow-up. Additionally, there was no statistically significant difference in central corneal endothelial cell characteristics, including mean cell density, mean cell area, mean hexagonality, or mean polymegathism. The density of mid and posterior stromal keratocytes remained unchanged compared to baseline in both groups. However, a significant decrease in anterior stromal keratocyte density was observed in both groups three months after surgery, with no significant difference between the two debridement methods.

Conclusions: The effects of PRK with MMC using mechanical or tetracaine-assisted epithelial debridement methods on central corneal endothelial cells are similar. Additionally, both techniques lead to comparable reductions in stromal keratocyte density in the anterior stromal layer.

Abstract No.: 200240
Comparison of 110- and 145- μ m Small-Incision Lenticule Extraction Cap Thickness

First Author: Siamak ZAREI-GHANA VATI

Purpose: To investigate the visual, refractive, and biomechanical outcomes of small incision lenticule extraction (SMILE) with two different cap thicknesses.

Methods: Thirty-four patients were included in this prospective, randomized, contralateral eye study. Subjects were randomized to receive SMILE surgery with a 110- μ m cap thickness in one eye and 145- μ m cap thickness in the fellow eye. Uncorrected and corrected distance visual acuity, contrast sensitivity (CS), total higher order aberrations (THOAs) and corneal biomechanical properties were compared 3 months after surgery.

Results: Postoperative refractive and visual outcomes, CS and THOAs were similar between the two groups ($P > 0.05$ for all parameters). At 3 months postoperatively, there was a significant difference in Corvis ST Biomechanical Index (CBI); stiffness parameter at first applanation (SP A1), and Integrated Radius between the two groups (all $P < 0.05$).

Conclusions: Eyes with thicker SMILE corneal caps showed no advantage regarding visual acuity, CS and THOAs over eyes with thinner caps. However, higher cap thickness may result in better corneal biomechanical properties postoperatively.

Abstract No.: 203697
Comparison of Clinical Outcomes Between Ray-Tracing-Guided and Wavefront Aberration-Guided FS-LASIK for Myopia Correction

*First Author: Mingyan WANG
Co-Author(s): Yuehua ZHOU*

Purpose: This prospective study included patients undergoing either RTG FS-LASIK or WFG FS-LASIK, with a 12-month postoperative follow-up. Assessments using the iDesign™/InnovEyes SightMap™ systems evaluated wavefront, tomographic, and biomechanical parameters. Visual acuity, refraction, higher-order aberrations (including total HOA), MRSE, and contrast sensitivity were measured pre- and postoperatively.

Methods: This prospective study included patients undergoing either RTG FS-LASIK or WFG FS-LASIK, with a 12-month postoperative follow-up. Assessments using the iDesign™/InnovEyes SightMap™ systems evaluated wavefront, tomographic, and biomechanical parameters. Visual acuity, refraction, higher-order aberrations (including total HOA), MRSE, and contrast sensitivity were measured pre- and postoperatively.

Results: This study analyzed 46 patients who underwent RTG FS-LASIK and 46 who received WFG FS-LASIK. At 12 months postoperatively, the spherical

equivalent refraction (MRSE) was significantly better in the RTG FS-LASIK group (0.13 ± 0.28 D) compared to the wavefront-guided group (-0.17 ± 0.28 D; $P < 0.001$). At 3 and 12 months, the RTG FS-LASIK group showed significantly lower values of total higher-order aberrations (HOA), trefoil, and spherical aberration (all $P < 0.05$). Uncorrected visual acuity (UCVA) at 12 months improved to -0.08 ($-0.18, -0.08$) logMAR in the RTG FS-LASIK group and -0.08 ($-0.18, -0.08$) logMAR in the wavefront-guided group, compared to preoperative values of 1.00 (0.70, 1.30) logMAR and 0.82 (0.82, 1.30) logMAR, respectively (all $P < 0.05$). The RTG FS-LASIK group also demonstrated significantly higher contrast sensitivity under 6.0 cpd, 12.0 cpd, 18.0 cpd, and under glare conditions at 12.0 cpd and 18.0 cpd (all $P < 0.05$). Compared to preoperative values, both groups showed significant reductions in total HOA, coma, trefoil, SRI, SAI, and spherical aberration.

Conclusions: Both techniques effectively corrected myopia and astigmatism. However, from the perspective of superior optical quality, RTG FS-LASIK resulted in significantly fewer higher-order aberrations, less trefoil and spherical aberration, and better preservation of contrast sensitivity compared to wavefront-guided FS-LASIK.

Abstract No.: 203688
Comparison of Postoperative Outcomes of SMILE 4.0 Guided by Cycloplegic and Manifest Refraction

*First Author: Mingyan WANG
Co-Author(s): Yuehua ZHOU*

Purpose: To compare the clinical efficacy of SMILE 4.0 surgery guided by cycloplegic refraction versus manifest refraction inputs based on a VISULYZE-generated nomogram in patients with myopia and astigmatism.

Methods: This study included 144 patients (245 eyes) with myopia and astigmatism who underwent SMILE 4.0 from September to December 2024. Based on the preoperative refraction method, patients were categorized into a cycloplegic group (79 patients, 134 eyes) or a manifest refraction group (65 patients, 111 eyes). Visual and refractive outcomes were assessed preoperatively and at 1 week, 1 month, and 3 months postoperatively, with VISULYZE-based nomogram predictions compared at 3 months and all complications recorded.

Results: At 3 months post-op, the cycloplegic refraction group showed significantly better predictability of the spherical equivalent (SE), with 96.27% (129 eyes) achieving a result within ± 0.50 D of the target, compared to 92.79% (103 eyes) in the manifest refraction group ($P=0.048$). Both groups exhibited strong correlations between attempted and achieved SE. The mean error (ME) was significantly lower in the cycloplegic group than in the manifest group ($P=0.012$).

Additionally, the correction of spherical error (S) differed significantly between groups ($P=0.001$). Strong correlations were observed between target-induced astigmatism (TIA) and surgically induced astigmatism (SIA) in both groups ($R^2 = 0.95$ vs. 0.91), with a lower index of success (IS) observed in the cycloplegic group ($P=0.007$).

Conclusions: Both cycloplegic and manifest refraction-guided SMILE 4.0 procedures proved safe and effective. At 3 months, the cycloplegic group demonstrated superior outcomes in spherical equivalent and power, suggesting it may be preferred for optimizing refractive results.

Abstract No.: 202875

Comparison of the Central Corneal Thickness Reduction Outcomes After SMILE and SMILE Pro for Myopia: A Retrospective Matched Case-Control Study

First Author: Xin **ZHANG**

Co-Author(s): Yuxia **GUO**, Chunming **LI**

Purpose: SMILE Pro was performed using the CentraLign aid for vertex centration, making it much easier to accurately measure and study central corneal thickness (CCT) reduction. To evaluate the agreement between the predicted and measured CCT reduction after SMILE and SMILE pro surgery, and explore the clinical application value of CentraLign aid in the real world of China.

Methods: This was a retrospective, matched, and case-control study (1:2) controlled for preoperative CCT and spherical equivalent (SE). One eye for each patient was randomly selected and included for analysis. CCT was measured by corneal tomography captured with Pentacam preoperatively and 1 month postoperatively. The measured CCT reduction was calculated by comparing the preoperative with postoperative CCT. Comparative statistics and linear regression analyses were performed.

Results: A total of 150 patients were enrolled. The mean predicted CCT reduction was $97.63 \pm 21.74 \mu\text{m}$ in SMILE group and $100.93 \pm 24.33 \mu\text{m}$ in SMILE Pro group. The prediction of the laser platform was found to overestimate the measured CCT reduction for both groups (SMILE: $8.2 \pm 5.3 \mu\text{m}$, SMILE Pro: $7.57 \pm 5.17 \mu\text{m}$). No statistically significant difference was observed in the CCT reduction outcome between the two procedures. In the SMILE Pro group, the difference between predicted and measured CCT reduction was found to be significantly related to the predicted CCT reduction ($P < 0.001$), preoperative SE ($P < 0.001$), and optical zone ($p < 0.05$).

Conclusions: SMILE Pro has been introduced in China for more than a month, making corneal thickness research clearer. Our results showed the actual CCT reduction was less than the estimated one, filling the

existing research gap and having significant clinical value. Larger samples, long-term, and more studies concerning different refractive powers are still needed.

Abstract No.: 206911

Corneal Dynamic Radiomics as a Novel Biomarker for Detection of Forme Fruste Keratoconus

First Author: Shenglong **LUO**

Co-Author(s): Xuefei **LI**, Kuangching **LIN**, Fan **LU**, Junjie **WANG**

Purpose: To propose CVS-omics, a radiomics framework integrating dynamic Corvis ST (CVS) imaging with machine learning, and to evaluate corneal dynamic texture features as a novel biomarker for detecting forme fruste keratoconus (FFKC).

Methods: A total of 410 eyes were evaluated, including 265 normal eyes and 145 FFKC eyes. Radiomics texture features were extracted from Corvis ST (CVS) images acquired at three key biomechanical phases: initial state, first applanation, and maximum deformation. Machine learning models, including Random Forest (RF), C5.0, and XGBoost, were trained on 328 eyes and independently validated on a test set of 82 eyes. Diagnostic performance was evaluated using receiver operating characteristic (ROC) analysis and compared with traditional biomechanical parameters.

Results: The CVS-omics RF model achieved superior diagnostic performance (AUC = 0.989, sensitivity = 0.931, specificity = 0.962, accuracy = 0.951), significantly outperforming traditional CVS parameters (best AUC = 0.728). Integration of dynamic texture features from multiple deformation phases improved diagnostic accuracy compared to single-time-point analysis. Machine learning models demonstrated high generalizability of dynamic texture features (XGBoost and C5.0 AUC > 0.83).

Conclusions: CVS-omics effectively detects subtle alterations in FFKC with superior accuracy compared to conventional biomechanical parameters. These radiomics-derived features may serve as novel biomarkers, complementing existing diagnostics and supporting clinical decision-making in keratoconus management.

Abstract No.: 200254

Corneal Epithelial and Stromal Thickness Profile After Photorefractive Keratectomy (PRK) Using Anterior Segment Optical Coherence Tomography (AS-OCT)

First Author: Basitali **LAKHANI**

Purpose: To study the epithelial remodeling after photorefractive keratectomy (PRK) using Anterior Segment Optical Coherence Tomography (AS-OCT).

Methods: This prospective observational study was performed from October 2018 to March 2020. 85 eyes with simple myopia in the age group of 21-38 years, and spherical equivalent range of -2.25 to -6 underwent PRK with Mitomycin-C (MMC). Epithelial and corneal thickness maps were acquired by AS-OCT preoperatively and postoperatively at 1 week, 1 month, 3 months, and 6 months.

Results: The visual acuity of all patients was 0 LogMAR until 6 months. We observed epithelial thickening of the cornea at 1 week, followed by a decrease at 1 month, and a slight increase at 3 months and 6 months. The mean corneal thickness increased from the baseline values in the central 2mm to 5mm and 5 to 7mm zones at 6 months, respectively ($p < 0.001$).

Conclusions: The corneal epithelial thickness increased up to 6 months after PRK-MMC and did not have any significant effect on the visual acuity.

Abstract No.: 203444

Early Objective and Subjective Evaluation of Visual Quality After KLEx With VISUMAX 800

First Author: Ruoyan **WEI**

Co-Author(s): Meiyan **LI**, Xingtao **ZHOU**

Purpose: To evaluate early visual quality after keratorefractive lenticule extraction (KLEx) using VISUMAX 800 femtosecond laser for myopia correction.

Methods: This prospective cohort study included 193 eyes of 97 consecutive myopic patients (mean SE -4.48 ± 1.66 D) who underwent KLEx using the VISUMAX 800 at Fudan University Eye and ENT Hospital. Standardized preoperative and postoperative evaluations included slit lamp, visual acuity, manifest refraction, corneal topography, wavefront aberration, and subjective visual quality questionnaires. All patients completed the 3-month follow-up protocol.

Results: All procedures were successfully completed with high patient satisfaction. The efficacy and safety indices were 1.07 ± 0.11 and 1.10 ± 0.11 , respectively. No eye lost two or more lines of CDVA. Among eyes targeted for plano correction, 99% (184/185) achieved UDVA ≥ 1.0 . All eyes achieved SE within ± 0.50 D of the target. Total higher-order aberration (HOA), coma, and trefoil increased significantly (all $p < 0.05$), while spherical aberration showed no significant changes ($p > 0.05$). Postoperative glare and halo symptoms became less frequent, severe, and bothersome over time, yet scores of glares remained above baseline levels. Multivariate analysis identified coma (OR=1.68, $p=0.02$) and scotopic pupil diameter (OR=1.92, $p=0.01$) as individual factors for postoperative glare and haloes, respectively.

Conclusions: KLEx with VISUMAX 800 demonstrated excellent safety, efficacy, and predictability for myopia correction, with high patient satisfaction. The early postoperative glare and halo gradually diminished.

Abstract No.: 208882

Effect of Different Concentrations of Mitomycin C on Corneal Nerve Regeneration and Ocular Pain Score After SPT-TransPRK for Moderate Myopia

First Author: Taorui **YU**

Co-Author(s): Chunxiao **YAN**, Lijun **ZHANG**

Purpose: To investigate the effects on corneal nerve regeneration and early ocular surface pain index in moderate myopia undergoing transepithelial photorefractive keratectomy with smart pulse technology (SPT-TransPRK) combined with 0.01% and 0.02% mitomycin C (MMC).

Methods: Prospective self-controlled study. Thirty patients (60 eyes) with preoperative spherical equivalent -6.00 to -3.00 D who voluntarily underwent binocular refractive surgery from October 2022 to January 2023 in the ophthalmic laser center of Dalian Third People's Hospital were included. The study used an in vitro pairing design, with one eye randomly using 0.01% MMC for the MMC0.01 group (30 eyes), and the other eye using 0.02% MMC for the MMC0.02 group (30 eyes). Confocal microscopy was used to observe the repair of subepithelial nerves in different areas of the cornea before and 14 days, 1 month, and 3 months after surgery. Image J software was used to analyze the changes in central corneal nerve fiber density (CNFD) and nerve fiber length (CNFL). The visual acuity and the degree of pain scored by visual analogue scale (VAS) were recorded before and 1, 3, 7, 14 days after surgery.

Results: There was no statistically significant difference in CNFD and CNFL in the central corneal region between the MMC0.01 group and the MMC0.02 group before and 14 days, 1 month, and 3 months after surgery ($P > 0.05$). Compared with preoperative values, CNFD and CNFL in both groups decreased at 14th days postoperatively, and gradually increased at 1 and 3 months postoperatively. The differences at each time point were statistically significant compared to preoperative values ($P < 0.001$). The postoperative pain levels in both the MMC0.01 and MMC0.02 groups were within a mild to moderate range, and decreased with recovery time. On the first day after surgery, the VAS of the two groups were 4.15 ± 0.83 and 5.39 ± 1.18 , respectively. And on the third day after surgery, they were 2.31 ± 0.84 and 3.07 ± 0.83 , respectively. The differences were statistically significant ($P < 0.001$; $P = 0.001$). But there was no statistically significant difference in VAS scores between the two groups on the 7th and 14th day after surgery. There were statistically significant differences in UCVA between the two groups on the 1st, 3rd, and 7th day after surgery (all $P < 0.001$), with the MMC0.01 group having a better UCVA. Within 3 months after surgery, two patients showed a grade 0.5 haze (6.67%) in both eyes.

Conclusions: The combination of 0.01% and 0.02% MMC during surgery has a similar promoting effect on

nerve regeneration in the early postoperative period (within 3 months) of SPT-TransPRK. At 3 months after surgery, the central nerve fibers in the ablation area of both groups of corneas did not return to preoperative levels. The use of 0.01% MMC during surgery has better eye pain relief and faster visual recovery in the early postoperative period.

Abstract No.: 203470

Effect of Intraoperative Mitomycin C Application at Different Concentrations on Corneal Densitometry After Transepithelial Photorefractive Keratectomy

First Author: Lijun ZHANG

Co-Author(s): Taorui YU

Purpose: This study aimed to investigate corneal densitometry (CD) and haze after transepithelial photorefractive keratectomy (TPRK) in patients treated with or without mitomycin C (MMC) at concentrations of 0.01% and 0.02%.

Methods: This retrospective study analyzed 138 eyes of 138 patients who underwent surgery and were categorized into three groups based on intraoperative MMC concentration: the MMC0.02 group (0.02% MMC), the MMC0.01 group (0.01% MMC), and the Control group (no MMC), with 46 eyes per group. Corneal haze and Corneal densitometry were assessed preoperatively and at 2 weeks, 1 month, and 3 months postoperatively. Corneal densitometry was performed across different concentric radial zones (0-2, 2-6, and 6-10 mm annulus) and layers (anterior, central, posterior, and total).

Results: The incidence of haze was significantly lower in the MMC0.01 (6.52%) and MMC0.02 (4.35%) groups than in the Control group (15.22%) ($P=0.048$ and $P=0.01$, respectively), the MMC0.01 and MMC0.02 groups showed no significant differences in haze incidence ($P=0.244$) in the third month after surgery. In terms of corneal densitometry, three months after surgery, the central layer CD values in the 0-2 mm zone (MMC0.01: 14.48 ± 1.21 GSU vs MMC0.02: 14.56 ± 1.01 GSU vs Control: 15.23 ± 1.25 GSU) and the posterior layer CD values (MMC0.01: 11.49 ± 0.70 GSU vs MMC0.02: 11.40 ± 0.70 GSU vs Control: 11.96 ± 0.78 GSU) were significantly lower in both MMC groups compared to the Control group (all $P < 0.05$). In the 2-6 mm zone, the posterior layer CD values (MMC0.01: 10.41 ± 0.75 GSU vs MMC0.02: 10.38 ± 0.59 GSU vs Control: 10.88 ± 0.71 GSU) and total layer CD values (MMC0.01: 13.39 ± 0.54 GSU vs MMC0.02: 13.36 ± 0.49 GSU vs Control: 13.65 ± 0.51 GSU) were significantly lower in both MMC groups than in the Control group (all $P < 0.05$). However, no significant differences in CD values were found between the MMC0.01 and MMC0.02 groups across any zone or layer (all $P > 0.05$).

Conclusions: Both 0.01% and 0.02% MMC are similarly effective in preventing haze and enhancing corneal clarity following TPRK surgery.

Abstract No.: 205273

Explainable Artificial Intelligence for Preoperative Prediction of Night Vision Disturbances After SMILE Surgery

First Author: Dan CHENG

Co-Author(s): Kai-ming RUAN, Mei-xiao SHEN, Shi-qi SUN, Yu-feng YE

Purpose: To develop an interpretable artificial intelligence (AI) model for predicting night vision disturbances (NVCs) following Small Incision Lenticule Extraction (SMILE) surgery based on optical zone and pupil-related parameters.

Methods: This prospective study utilized preoperative clinical and biometric data from patients undergoing SMILE. A novel threshold was established to classify postoperative visual quality outcomes. Feature selection was performed using a regularization technique, and multiple machine learning models were trained and evaluated. Model interpretability was enhanced using a game theory-based explanatory method.

Results: A key optical parameter ratio was identified as a highly significant predictor of NVCs. Among the models tested, a tree-based ensemble algorithm demonstrated superior predictive performance on both internal and external validation sets. Explainable AI analysis highlighted several preoperative factors including pupil size, refractive error, and corneal morphology as the most influential contributors to postoperative visual quality outcomes.

Conclusions: This study presents a robust and interpretable AI framework for preoperative prediction of NVCs after SMILE. The model enables personalized risk assessment and surgical planning, contributing to improved patient counseling and postoperative satisfaction, without disclosing critical technical details.

Abstract No.: 202730

Five-Year Outcomes of IC-8 Small-Aperture IOL Implantation: Monocular and Bilateral Results in a Single-Center Study

First Author: James Michael JACOMINA

Co-Author(s): Robert Edward ANG

Purpose: To report outcomes of IC8 small-aperture intraocular lens (IOL) implantation in a single eye center.

Methods: This retrospective review included 54 patients who underwent IC8 implantation: 44 received monocular implantation, and 10 received bilateral implantation. The binocular group was subdivided into patients with a virgin fellow eye, a history of refractive

surgery, and those with prior IC8 inlay. Postoperative visual outcomes were assessed over 5 years. Parameters included uncorrected distance (UDVA), intermediate (UIVA), and near acuity (UNVA), best corrected distance acuity (BDVA), refractive measures (sphere, cylinder, MRSE), and cumulative visual acuity indices.

Results: In the monocular group, all patients achieved UDVA of 20/25 or better, with 78% reaching 20/20. CDVA was 92.9% at 20/25 and 100% at 20/32 or better. Over 5 years, mean UDVA (0.09 ± 0.07) and UIVA (0.11 ± 0.04) showed mild regression, while UNVA remained stable with slight improvement. MRSE improved from +0.47 D in year 1 to -0.05 D by year 5. In the bilateral group, 95% achieved UDVA of 20/25 or better, and 10% achieved 20/20 or better, with refraction stable over time (MRSE -0.35 D at year 1 to -0.13 D at year 5). At the latest follow-up, binocular outcomes were favorable: mean UDVA was 0.03 in IC8 + virgin eyes, 0.15 in IC8 + post-refractive eyes, and 0.05 in IC8 + post-inlay eyes.

Conclusions: IC8 implantation was associated with reliable visual function across near, intermediate, and distance ranges. Monocular eyes demonstrated gradual refractive regression, whereas bilateral implantation maintained stability over 5 years.

Abstract No.: 201263

Five-Year Results of Lenticule Transplantation for Hyperopic Residual Refraction and Presbyopia After Laser In Situ Keratomileusis

First Author: Ceren Ece **SEMİZ**

Co-Author(s): Fetih Furkan **ARSLAN**, Njomza **HIMA-MUSA**, Faruk **SEMİZ**

Purpose: To evaluate the long-term efficacy, safety, and corneal morphological changes of fresh lenticule transplantation for hyperopic residual refraction and presbyopia following LASIK (Laser in Situ Keratomileusis).

Methods: This study included 84 eyes of 42 patients (aged 32.9 ± 7.5 years, range 22–44) with post-LASIK hyperopic residual refraction (+1.00 to +6.00 D) and cylinder (+0.75 to +2.50 D). Donor lenticules, obtained from 20–29-year-old patients who had undergone SMILE (Small Incision Lenticule Extraction) for myopic correction, had a mean thickness of 88.4 ± 28.1 μ m, diopter -4.42 ± 1.40 D, and optical zone 660 ± 15 μ m. In recipient corneas, the LASIK flap was left untouched; instead, a 140- μ m intrastromal pocket was created, and a fresh lenticule was transplanted with a -0.50 D target. Follow-up evaluations included uncorrected and corrected distance visual acuity (UDVA, CDVA), slit-lamp biomicroscopy, corneal topography, pachymetry, and anterior segment optical coherence tomography. All patients completed a 5 years of follow-up.

Results: No cases of rejection, complications, or surgical revision occurred during follow-up. At 5 years, UDVA improved from 0.63 ± 0.21 to 0.03 ± 0.03 logMAR, UNVA from J7 to J2 (40 cm) and J6 to J3 (80 cm). Central corneal thickness increased from 490.0 ± 33.8 to 572.3 ± 27.1 μ m, sphere decreased from $+3.95 \pm 1.40$ to -0.40 ± 0.13 D, K1 from 41.52 to 44.27 D, and K2 from 42.87 to 44.98 D. Q-value shifted from -0.43 to -0.79. All changes were significant ($p < 0.001$).

Conclusions: This procedure safely modifies corneal asphericity while improving both distance and near visual acuity.

Abstract No.: 201760

Flexivue Microlens for Treatment of Presbyopia: Clinical Evidence of Long-Term Safety, Efficacy, and Versatility

First Author: Vladimir **FEINGOLD**

Co-Author(s): Siqi **DAI**

Purpose: To evaluate the safety and efficacy of Flexivue Microlens in treating emmetropic presbyopic patients.

Methods: This was a prospective study of 421 patients who underwent implantation of Flexivue Microlens with a follow-up duration of 3 years. Patient age ranged from 40 to 60 years, and all had an uncorrected near visual acuity (UCNVA) of 20/50 or worse. The microlens power ranged from +1.50 D to +3.00 D. Implantation was performed at a depth of 300 μ m within a stromal pocket created using a femtosecond laser.

Results: After surgery, 93% of patients achieved uncorrected near visual acuity (UCNVA) of 20/40 or better, with a mean improvement of 5 ETDRS lines. Binocular uncorrected distance visual acuity (UCDVA) of 20/40 or better was achieved in 98.4% at 24 months and 99.5% at 36 months. Endothelial cell density remained unchanged, and intraocular pressure was stable throughout the study. Patient satisfaction was very high. The microlens could be safely removed if replacement was required or if patients were unable to adapt to multifocality.

Conclusions: Flexivue Microlens implantation in 421 emmetropic presbyopes demonstrated safety, efficacy, and high patient satisfaction, supporting its role as a viable option for presbyopia correction.

Abstract No.: 204781

LALEX (Laser Assisted Lenticule EXtraction) Provides Wider Horizons for High Myopia

First Author: Sami **ALRABIAH**

Purpose: To study the possibility of correcting higher degrees of myopia by LALEX, that were not possible in regular Femtolasik, yet not to cross the safety limits such as 1) Residual bed thickness; 2) Over-flattening the K value; 3) Reaching the toxic levels of spherical aberration

Methods: At Alrabiah Medical Center, Kuwait, using Z8 Ziemer Femtolasik, 96 myopic patients with myopia varying from -7.00 to -10.00 diopters underwent the LALEX procedure to correct their high myopia, compared to a similar group of patients (age, sex) with myopia from -1.00 to -6.00 diopters underwent the routine Femtolasik procedure to correct their myopia. All patients had investigations such as Retinoscopic refraction, Topography, Tomography, Pachmetry, measuring High order aberrations, corneal biomechanics. On months 2-4-6 post procedures. All patients had repeated all their investigations.

Results: The results of LALEX for higher errors of refractions were very encouraging, with excellent post-operative vision and no compromise of the safety limits.

Conclusions: LALEX has proven itself to be safe and effective in treating high myopia.

Abstract No.: 203335

Long-Term Safety and Efficacy of Personalized Directional EVO ICL V4c Implantation in Patients With Relatively Shallow Anterior Chambers and High Crystalline Lens Rise

First Author: Wenjie **LIU**

Co-Author(s): Lingling **NIU**, Xingtao **ZHOU**

Purpose: To assess long-term safety and efficacy of personalized, UBM-guided directional EVO ICL V4c implantation in eyes with relatively shallow anterior chambers and high crystalline lens rise (CLR).

Methods: Prospective study of 72 patients (143 eyes) with customized ICL sizing/orientation based on WTW, ACD, horizontal/vertical STS, STSL, pupil size, iris configuration, and ciliary sulcus width. Eyes were stratified by ACD: Group A 2.8–3.0 mm, Group B >3.0–3.3 mm, Group C >3.3 mm. Outcomes included UDVA, CDVA, refraction, IOP, ECD, ACA, ACV, lens density, and ICL vault with ≥3-year follow-up.

Results: Safety index ranged 1.21–1.23 and efficacy index 1.10–1.15 across groups. CDVA improved ≥2 lines in 22–26% and by 1 line in 40–49%; no losses occurred. UDVA ≤0 logMAR was achieved in 96–100% of eyes (all ≤0.3). Manifest spherical equivalent was within ±0.50 D in 76–80% and within ±1.00 D in 96–100%. Mean vault differed by ACD (A 325±193 μm, B 457±168 μm, C 490±153 μm; P<0.05). No significant intergroup differences were found for IOP, ECD, or lens density, while ACD, ACV, and ACA differed significantly (P<0.05).

Conclusions: Personalized, UBM-guided directional EVO ICL V4c implantation provided durable visual efficacy and a favorable safety profile over ≥3 years in eyes with shallow anterior chambers and high CLR. Vault increased with deeper ACD, while IOP, ECD, and lens density remained stable, supporting use of this approach in anatomically challenging eyes.

Abstract No.: 201588

Management of Hyperopic Residual Refraction and Presbyopia After Trifocal Intraocular Lens Implantation With Lenticule Transplantation

First Author: Njomza **HIMA-MUSA**

Co-Author(s): Fetih Furkan **ARSLAN**, Ceren Ece **SEMIZ**, Faruk **SEMIZ**

Purpose: To evaluate visual outcomes after myopic lenticule transplantation in pseudophakic patients with hyperopic residual refractive error and presbyopia.

Methods: This retrospective study included 32 patients (64 eyes), aged 41–62 years, with hyperopic residual refraction and presbyopia following trifocal intraocular lens (IOL) implantation. Residual hyperopia ranged from +0.75 to +1.75 D, presbyopia from +1.00 to +2.50 D, and astigmatism from +0.50 to +1.25 D. Donor lenticules, obtained from individuals aged 20–33 years who had undergone SMILE (Small Incision Lenticule Extraction) for myopic refractive error correction, had a mean thickness of 43.52 ± 7.22 μm (range: 30–50 μm) and were sized 0.5 mm larger than the recipient's optic zone to minimize glare. A stromal pocket was created using the SMILE module, and a convex-shaped myopic lenticule—0.5 D greater than the residual error—was implanted based on the lower keratometric value. All patients were followed for 1 year.

Results: At 1 year, UDVA improved from 0.35 ± 0.20 to 0.003 ± 0.01 logMAR, corneal central thickness increased from 500.39 ± 18.88 to 543.66 ± 19.37 μm, spherical error decreased from +1.20 ± 0.28 to -0.33 ± 0.30 D, cylindrical error from 0.92 ± 0.32 to 0.37 ± 0.13 D, K1 from 41.02 ± 1.27 to 43.52 ± 0.79 D, K2 from 41.98 ± 1.28 to 43.88 ± 0.80 D, and Q-value from -0.41 ± 0.03 to -0.59 ± 0.05 (all p < 0.001).

Conclusions: Myopic lenticule transplantation effectively addresses residual hyperopia and presbyopia after trifocal IOL by enhancing corneal asphericity and improving vision at all distances.

Abstract No.: 203481

One-Year Follow-Up of Retinochoroidal Changes After ICL Implantation in High Myopia: Insights From UWF-SS-OCTA and AI-Based 3D Modelling

First Author: Wang **XUZE**

Co-Author(s): Han **WEI**

Purpose: To investigate the long-term changes in retinal and choroidal structure and perfusion in highly myopic eyes following ICL V4c implantation, using ultra-widefield swept-source optical coherence tomography angiography (UWF-SS-OCTA) combined with a three-dimensional modeling algorithm.

Methods: Retinal and choroidal parameters, including retinal thickness (RT), capillary plexus

density, foveal avascular zone (FAZ), retinal curvature, choroidal thickness (CT), and three-dimensional choroidal vascularity index (3D-CVI), were assessed preoperatively and at multiple postoperative time points. Repeated measures mixed-effects models were employed to compare pre- and postoperative measurements and to explore correlations among the parameters.

Results: Significant improvements in refractive outcomes and visual acuity were achieved postoperatively, with a stable safety profile and no major complications. Retinal thickness and perfusion exhibited transient changes within the first month, followed by gradual normalization. Retinal curvature slightly increased postoperatively, without statistical significance. Choroidal parameters, especially CT and 3D-CVI, demonstrated a progressive and sustained increase across most regions, with the most pronounced changes in the foveal and perifoveal zones. Correlation analysis revealed surgical duration and axial length as key factors influencing retinal and choroidal responses, respectively.

Conclusions: ICL V4c implantation in high myopia leads to dynamic yet self-limiting changes in retinal morphology and perfusion, alongside sustained enhancement in choroidal vascular parameters. The use of 3D-CVI offers deeper insights into choroidal remodeling and perfusion recovery, highlighting the long-term ocular safety and structural adaptation following ICL implantation.

Abstract No.: 203594

Phakic Presbyopic Intraocular Lenses: A Systematic Review

First Author: Javier H. **GONZALEZ-LUGO**

Co-Author(s): Jorge L. **ALIÓ**, Jorge **ALIÓ DEL BARRIO**, Marcielle **GHANEM**, Hao **ZHANG**

Purpose: Presbyopia remains one of the greatest unmet needs in refractive surgery. While corneal and lens-exchange procedures are established options, they carry significant trade-offs, including decreased contrast sensitivity, photic phenomena, and increased retinal detachment risk in young myopes. Phakic intraocular lenses (pIOLs) designed for presbyopia correction aim to restore full-range vision while preserving the natural crystalline lens.

Methods: This systematic review was registered in PROSPERO (CRD420251138158) and conducted according to PRISMA guidelines. MEDLINE, EMBASE, Cochrane Library, and trial registries were searched through July 2025. Eligible studies included clinical trials and observational series reporting refractive, visual, safety, and patient-reported outcomes of presbyopia-correcting pIOLs.

Results: Six studies comprising 354 eyes of presbyopic patients aged 38–62 years were included.

Contemporary designs evaluated were the EVO Viva ICL (extended depth of focus), the trifocal Implantable Phakic Contact Lens (IPCL), and the iris-fixated ArtiPlus lens. Across studies, $\geq 75\%$ of eyes achieved refractive outcomes within ± 0.50 D of target, and spectacle independence reached 80–90%. Binocular defocus curves demonstrated functional vision across distance, intermediate, and near. Patient satisfaction was consistently high. Visual disturbances such as glare and halos were common but generally mild. No sight-threatening complications were reported during short-term follow-up.

Conclusions: Presbyopia-correcting pIOLs show promising safety and efficacy, offering a reversible, lens-preserving option with favorable visual outcomes and high patient satisfaction. Nonetheless, current evidence is limited to small, short-term, largely industry-sponsored studies. Independent, long-term trials are needed to confirm safety and establish their role in presbyopia management.

Abstract No.: 202207

Pioneering Presbyopia Correction in Bo'ao Medical Pilot Zone: Early Outcomes With an Intracorneal Microlens

First Author: Wei **CHEN**

Co-Author(s): Siqi **DAI**, Vladimir **FEINGOLD**, Mimi **LIU**, Meng **QI**

Purpose: To evaluate the safety and efficacy of Presbia Flexivue Microlens for presbyopia correction in patients treated in Bo'ao Medical Pilot Zone, Hainan, China.

Methods: This prospective case series included 20 presbyopic patients who underwent implantation of the Flexivue intracorneal microlens beginning in January 2024. All procedures were performed in the Bo'ao Medical Pilot Zone, which offers unique regulations enabling early clinical adoption of internationally approved medical devices. The microlens was implanted in the non-dominant eye using an enhanced monovision mechanism termed "Smart Monovision". Primary assessments included uncorrected and best-corrected near and distance visual acuity (UCNVA, BCNVA, UCDVA, BCDVA), measured both monocularly and binocularly. The maximum follow-up to date was 20 months.

Results: At the latest follow-up, average binocular UCNVA improved by 4–5 lines. Monocular UCDVA in the treated eye decreased by ~ 2 lines, while binocular UCDVA showed a negligible change. No loss was observed in BCDVA or BCNVA. The procedure demonstrated a favourable safety profile with no serious adverse events. Patient satisfaction was very high, with the majority reporting functional improvement in near vision and willingness to recommend the treatment.

Conclusions: The introduction of Flexivue in the Bo'ao Medical Pilot Zone demonstrated promising safety and efficacy for presbyopia correction in Chinese presbyopic patients, with high levels of patient satisfaction and willingness to recommend the treatment.

Abstract No.: 205302

Reprogramming of Human Corneal Stromal Cells From SMILE-Derived Lenticules Into Stem-Like Cells by Conditioned Medium and 3D Spheroid Culture

First Author: Yuexi **CHEN**

Co-Author(s): Jiansu **CHEN**, Zheng **WANG**

Purpose: To create a novel three-dimensional (3D) cell culture system based on a polydimethylsiloxane (PDMS) microwell platform composed of many V-bottom microcavities for generating human corneal stromal cell spheroids and further promoting the plasticity and stemness of human corneal stromal cells (hCSCs).

Methods: In the study, we isolated hCSCs from SMILE-derived lenticules and maintained their physiological phenotype by culturing them in a medium supplemented with human corneal stromal extract (hCSE). Then, we conducted a novel three-dimensional (3D) cell culture system based on a 3D-printed PDMS microwell platform composed of many V-bottom microcavities for generating 3D-CSCs. The 3D-CSCs were cultured in the PDMS microwell platform with induced pluripotent stem cells conditioned medium (iPS-CM) for two weeks. Finally, we evaluated the stemness of cells cultured on this platform.

Results: Using a PDMS microwell platform through 3D printing technology, we successfully generated 3D corneal stromal cell spheroids (3D-CSC) with uniform size and stable structure, achieving a mean diameter of $230.38 \pm 22.12 \mu\text{m}$. These spheroids exhibited significantly increased expression of key pluripotency factors, including OCT4, NESTIN, NANOG, SOX2, KLF4, and PAX6. RNA sequencing and proteomics analyses revealed that 3D-CSCs exhibited superior proliferation, differentiation, cell adhesion, migration, and neurogenesis compared to traditional monolayer cultures, underscoring the role of biophysical cues in promoting hCSCs stemness.

Conclusions: The 3D-printed derived PDMS microwell platform could efficiently fabricate the human corneal stromal cell spheroids and enhance the stemness of cells, providing valuable insights into corneal tissue engineering and regenerative medicine, particularly for treating corneal opacities and diseases.

Abstract No.: 203342

Safety of Implanting Large-Size ICLs in High Myopia Patients With Shallow Anterior Chamber Depth (ACD < 3 mm) and Small Corneal Diameter (WTW ≤ 11.2 mm)

First Author: Wenjie **LIU**

Co-Author(s): Jiewei **LIU**

Purpose: To evaluate the clinical safety of implanting relatively large implantable collamer lenses (ICL 12.6 mm) in high myopia patients with shallow anterior chamber depth (ACD < 3 mm) and small white-to-white corneal diameter (WTW ≤ 11.2 mm).

Methods: This retrospective study included 231 patients meeting the anatomical criteria, divided into two groups: 127 eyes received a 12.1 mm ICL, and 98 eyes received a 12.6 mm ICL. Preoperative anatomical parameters (ACD, WTW, lens thickness), intraoperative sulcus-to-sulcus (STS) distances, and postoperative safety indicators (safety index, efficacy index, intraocular pressure [IOP], corneal endothelial cell density, vault, anterior subcapsular opacity, etc.) were compared between the two groups. Statistical significance was defined as $p < 0.05$.

Results: The safety indices (postoperative CDVA / preoperative CDVA) were 1.19 ± 0.15 and 1.20 ± 0.16 in the 12.1 mm and 12.6 mm groups, respectively. The efficacy indices (postoperative UDVA / preoperative CDVA) were 1.11 ± 0.20 and 1.13 ± 0.19 , respectively. The 12.6 mm group showed significantly greater horizontal STS (11.23 ± 0.35 mm vs. 10.84 ± 0.44 mm) and vertical STS (11.82 ± 0.41 mm vs. 11.42 ± 0.35 mm) than the 12.1 mm group (both $p < 0.01$). The STS-WTW difference was also significantly higher (0.20 ± 0.32 vs. -0.06 ± 0.44 , $p = 0.035$). Vault: The 12.6 mm group had a significantly higher postoperative vault ($340.89 \pm 40.12 \mu\text{m}$ vs. $320.12 \pm 35.65 \mu\text{m}$, $p = 0.012$), and a lower proportion of cases with vault < 250 μm (14.29% vs. 23.62%). Other safety indicators: All patients had normal postoperative IOP (10–21 mmHg), endothelial cell density > 2300 cells/ mm^2 , and anterior chamber angle (TIA > 23°). No cases showed anterior subcapsular opacities, endothelial cell loss > 30%, or elevated IOP.

Conclusions: For high myopia patients with ACD < 3 mm and WTW ≤ 11.2 mm, selection of ICL size based on STS measurements and ciliary sulcus morphology allows safe implantation of both 12.1 mm and 12.6 mm ICLs. Larger ICLs do not increase the risk of elevated IOP, endothelial loss, or lens-related complications, and provide vaults within the safe range.

Abstract No.: 200159

SmartSight Lenticule Extraction for High Myopic Astigmatism (>2.00 D) Utilizing the SCHWIND ATOS Femtosecond Laser

First Author: Thuy DINH THI PHUONG

Purpose: To assess the effects of correcting high astigmatism in SmartSight lenticule extraction procedures for myopic astigmatism with an advanced femtosecond laser platform.

Methods: A total of 120 eyes from 60 patients undergoing consecutive treatment for myopic astigmatism with a preoperative cylinder exceeding 2.00 diopters (D) were assessed at the 6-month postoperative visit. Patients had a mean age of 25.8 ± 5.4 years, with an average spherical equivalent of -6.07 ± 2.32 D and a mean refractive astigmatism of 2.45 ± 0.31 D.

Results: At 6 months, astigmatism was 0.22 ± 0.19 D. Uncorrected distance visual acuities were 0.05 ± 0.13 logMAR. Differences between postoperative UDVA and preoperative CDVA were $+0.39 \pm 0.67$ lines better than preoperatively ($P < 0.005$).

Conclusions: The six-month evaluation confirms that SmartSight is a reliable and efficient approach for managing myopic astigmatism, including cases with high preoperative astigmatism.

Abstract No.: 201799

Systematic Review of Higher-Order Aberrations Following Ray-Tracing-Guided Myopic LASIK Using the InnovEyes Sightmap Platform

First Author: Yuen Tsing Adeline HO

Co-Author(s): Au CHI LIK

Purpose: Ray-tracing systems have gained popularity in refractive surgery due to their ability to personalize corneal ablation profiles. With the launch of InnovEyes Sightmap platform, the additional benefit of it on refractive outcomes remains a topic of great interest among LASIK surgeons.

Methods: A comprehensive search over PubMed, MEDLINE, EMBASE, Scopus, and Web of Science was conducted on 1 April 2025 to identify studies reporting outcomes in patients undergoing myopic LASIK with the InnovEyes Sightmap platform. The keyword "Wavelight plus" was also searched. Studies reporting pre- and post-LASIK Higher-Order Aberrations (HOA) were included. Publications using modified platforms or without post-operative 3-month outcomes were excluded.

Results: A total of 106 papers were yielded from the literature search. After excluding irrelevant publications, 4 studies with 904 eyes from 577 patients were included in the analysis. Pre-operative uncorrected distance visual acuity (DVA) was 0.925

logMAR; spherical equivalent was -3.69 D, with -0.87 D cylinder, which decreased to -0.21 D post-operatively. Average ablation depth was $97.5\mu\text{m}$. At 3 months after LASIK, HOA increased from $0.217\mu\text{m}$ to $0.264\mu\text{m}$, whereas spherical aberration halved from $0.071\mu\text{m}$ to $0.035\mu\text{m}$. All studies reported outcomes on coma, a couple of them reported separately the vertical (mean $-0.033\mu\text{m}$ to post-LASIK $-0.106\mu\text{m}$) and horizontal coma ($-0.006\mu\text{m}$ to $-0.022\mu\text{m}$). Interestingly, post-LASIK corrected DVA 0.059 was worse than uncorrected DVA -0.104 .

Conclusions: The ray-tracing platform reviewed appears reliable with good post-operative outcomes. HOA, spherical aberration, and coma may explain the poorer corrected DVA than uncorrected.

Abstract No.: 206777

The Role of Patient Personality Traits in Laser Refractive Surgery

First Author: Emma PARYANI

Co-Author(s): Kendrick SHIH

Purpose: Guiding a patient to make an informed decision on laser refractive surgery is a rewarding challenge for the ophthalmologist. Apart from the patient's refractive error, dry eye status, cornea parameters and occupation, a better understanding of patients' personality traits may improve consultation experiences. In this study, we aim to investigate the personality traits of patients undergoing refractive surgery and compare them to age-and education-matched individuals who opt against it.

Methods: 175 subjects were asked to provide demographic details and undergo a 44-item Big Five Inventory Questionnaire. In the end, 168 completed questionnaires were analysed (93 refractive surgery patients, 68 controls). A single surgeon at the Hong Kong Sanatorium and Hospital conducted the preoperative consultation to all 100 patients before making the final decision for refractive surgery. Continuous variables were presented as mean $\pm$ SD. Student's T test was used to compare personality trait scores between groups (Refractive Surgery vs No Refractive Surgery, LASIK vs SMILE). Chi Squared test was used to compare demographics.

Results: Differences in personality traits were found between subjects undergoing and those not interested in laser refractive surgery. In aspects of extraversion, agreeableness, conscientiousness and openness, the two groups performed similarly except for neuroticism, which was significantly higher in the refractive surgery group ($p < 0.05$). Comparing between LASIK (78 subjects) and SMILE (15 subjects) groups, neuroticism was higher in the SMILE group ($p 0.08$). Regarding occupation, the group undergoing refractive surgery was significantly more likely to be in service or retail occupations compared to age and occupation matched controls ($p < 0.05$).

Conclusions: Refractive surgeons should consider the higher levels of neuroticism trait in patients when setting expectations preoperatively and managing postoperative outcomes. Further studies investigating the impact of personality traits on patient satisfaction with postoperative outcome and association with postoperative complications like corneal neuropathic pain should be considered.

Abstract No.: 204695

Three-Month Outcomes After SMILE PRO Surgery for High Astigmatism Correction With the Visumax 800

First Author: Lan **HUONG THI TRAN**

Co-Author(s): Hong-son **CUNG**, Thanh **NGOC TRAN**

Purpose: To evaluate outcomes after small incision lenticule extraction (SMILE PRO) surgery using the VISUMAX 800 for correcting high astigmatism.

Methods: This prospective study was conducted on patients with high astigmatism treated with SMILE PRO surgery using the VISUMAX 800 at Hong Son Eye Hospital, Viet Nam, from November 2024 to July 2025 (IRB: HMUIRB1649). Patients with astigmatism from – 2.0 diopters (D) to – 5.0 D, spherical equivalent up to – 12.50 D, a preoperative corrected distance visual acuity (CDVA) of 20/25 or better, and ages ranging from 18 to 40 years old were included in the study. Monocular uncorrected distance visual acuity (UDVA), CDVA, refraction, and vector analysis were evaluated at 3 3-month postoperatively. Intraoperative and postoperative complications were also recorded.

Results: Eighty eyes from 80 patients (53.75% women, mean age of 23.73 ± 5.09 years) were analyzed 3 months after surgery. The mean preoperative spherical equivalent refraction (SEQ) was -7.05 ± 1.89 D. The postop SEQ was within ± 0.50 D in 85% and ± 1.00 D in 100% of eyes. UDVA was 20/25 or better in 97.5 % and was 20/32 or better in 100% of eyes. The astigmatism was within ± 0.50 D in 68.8% and ± 1.00 D in 95% of eyes. One eye lost one line of CDVA. Efficacy index was 0.97, and safety index was 0.99. No eye had suction loss during the operation, and no other complications had been observed during and after the surgery.

Conclusions: The study indicated that SMILE PRO surgery with the VISUMAX 800 was safe and effective for correcting high astigmatism.

Abstract No.: 205842

A Pilot Study of the Mechanism of X-Linked Congenital Retinoschisis on a Retinal Organoid Platform

First Author: Shibo **TANG**

Co-Author(s): Jiansu **CHEN**, Zekai **CUI**, Shengru **MAO**, Xihao **SUN**

Purpose: To define how the disease-causing RS1 R102W mutation alters retinal organoid (RO) development, intercellular signaling, and neuronal function.

Methods: The iPSCs were reprogrammed from urine cells of XLRS patients and controls. Isogenic R102W mutation $\rightarrow$ iso-mutant $\rightarrow$ iPSCs cell line and R102W corrected iPSCs cell line were established by CRISPR/Cas9 system. iPSCs cell lines from above were differentiated into retinal organoids with the 3D differentiation method. Developmental states were profiled by immunostaining and single-cell RNA sequencing (scRNA-seq) at day 50. (MEA) recordings at day 90 (D90). Intercellular signaling and adhesion networks were analyzed across major retinal cell types.

Results: At D50, R102W, and iso-mutant ROs showed reduced CHX10 expression, indicating impaired RPC maintenance. scRNA-seq revealed increased RPCs and photoreceptor precursors (PR-Ps) but reduced RGCs and AC/HCs, with downregulation of CRX and NRL despite higher PR-P abundance, suggesting incomplete photoreceptor differentiation. Intercellular signaling analyses showed weakened neurotrophin and NCAM/JAM-mediated adhesion, reduced expression of adhesion genes (LAMB2, CDH2, JAM2/3, COL9), and loss of COL9-dependent AC/HC–PR-P interactions. Aberrant ECM activity was reflected by FN1 enrichment in RPCs and PR-Ps. At D90, MEA recordings revealed impaired spontaneous activity in R102W ROs, with fewer spikes per burst and lower peak firing rates, while burst duration and interburst intervals were unchanged, indicating reduced burst efficiency.

Conclusions: Our findings demonstrate that the RS1 R102W mutation disturbs retinal cell fate specification and disrupts intercellular communication networks during organoid development, ultimately leading to impaired neuronal activity. These results highlight a critical role of RS1 in coordinating retinal differentiation and synaptic function in XLRS.

Abstract No.: 201759

Acute and Continuous Exposure of PM2.5: Diverse Outer Blood–Retinal Barrier Damages and Disease Susceptibilities

First Author: Yuzhou **GU**

Co-Author(s): Qiuli **FU**, Ke **YAO**

Purpose: The association between air pollution and retinal diseases such as age-related macular degeneration (AMD) has been demonstrated, but the pathogenic correlation is unknown. Damage to the outer blood–retinal barrier (oBRB), which consists of the retinal pigment epithelium (RPE) and choriocapillaris, is crucial in fundus diseases. This study aims to describe the effects of airborne fine particulate matter (PM2.5) on the oBRB and disease susceptibilities.

Methods: A PM2.5-exposed mouse model was established through the administration of eye drops containing PM2.5. OCTA, TEM, and immunofluorescence staining were applied to study the oBRB changes. A co-culture model of ARPE-19 cells with stretching vascular endothelial cells was established to identify the role of choroidal vasodilatation in PM2.5-associated RPE damage.

Results: Acute exposure to PM2.5 resulted in choroidal vasodilatation, RPE tight junctions impairment, and ultimately an increased risk of retinal edema in mice. These manifestations are similar to the pachychoroid disease represented by central serous chorioretinopathy (CSC). After continuous exposure, the damage to the RPE was gradually repaired, but AMD-related early retinal degenerative changes appeared under continuous choroidal inflammation.

Conclusions: This study is the first to identify and describe the effects of air pollution exposure on the oBRB. Choroidal vasodilatation and damage to the RPE occurred after acute PM2.5 exposure, with an increasing risk of retinal edema. After continuous exposure, the RPE was repaired to some extent, but early retinal degenerative changes were observed. These findings further elucidate the association of air pollution with retinal diseases such as CSC and AMD.

Abstract No.: 205019

Aflibercept 8 mg in Treatment-Naïve Macular Edema Secondary to Retinal Vein Occlusion: Primary Endpoint Results From Phase 3 QUASAR Study

First Author: Andrew **CHANG**

Co-Author(s): Timothy Yuk Yau **LAI**

Purpose: To evaluate the efficacy and safety of intravitreal aflibercept 8-mg administered every 8 weeks, after 3 (8q8/3) or 5 initial monthly injections (8q8/5) versus 2-mg every 4 weeks (2q4), in patients with treatment-naïve macular edema secondary

to retinal vein occlusion (RVO) through Week 36 of QUASAR.

Methods: In the on-going 64-week QUASAR (NCT05850520), patients were randomized 1:1:1 to receive 8q8/3, 8q8/5, or 2q4. Dosing intervals could be adjusted by 4 weeks based on predefined criteria (minimum interval: 4 weeks). The primary objective was to determine if 8q8 provides non-inferior best-corrected visual acuity (BCVA) change compared to 2q4 (non-inferiority margin: 4 letters), with BCVA change from baseline at Week 36 as the primary endpoint.

Results: A total of 892 patients (8q8/3: n=293; 8q8/5: n=298; 2q4: n=301) were treated. The primary endpoint was met: aflibercept 8-mg showed non-inferior BCVA gains versus 2-mg. The least squares (LS) mean difference in BCVA versus 2q4 at Week 36 was 8q8/3: -0.1 (-2.0, 1.9) letters; 8q8/5: +0.8 (-1.1, 2.7) letters, (both p<0.0001). Patients receiving 8-mg had fewer injections (8q8/3: 6.0; 8q8/5: 6.7; 2q4: 8.5) over 36 weeks, with majority patients (8q8/3: 88.5%; 8q8/5: 93.4%) maintained 8-week interval. The safety profile of 8-mg was consistent with that of 2-mg.

Conclusions: Aflibercept 8-mg met the primary endpoint in macular edema secondary to RVO, demonstrating non-inferiority in BCVA gains compared with 2-mg, with fewer injections and no new safety signals observed through Week 36.

Abstract No.: 204100

Aflibercept 8mg for the Treatment of Diabetic Macular Edema in the Chinese Population: the PHOTONic Study

First Author: Nicholas **FUNG**

Co-Author(s): Wenbin **WEI**

Purpose: PHOTON was a global pivotal study of aflibercept 8mg for the treatment of diabetic macular edema (DME). The PHOTONic (PHOTON in China) study aims to investigate the efficacy and safety of aflibercept 8mg in a Chinese population with DME. Here we report the study design and objective.

Methods: PHOTONic (NCT06422507) is an ongoing phase 3, multi-center, randomized, double-masked, active-controlled, 60-week study in Chinese patients with center-involving DME. The primary objective is to determine whether aflibercept 8mg at 16-week intervals provides non-inferior best-corrected visual acuity (BCVA) gains compared to aflibercept 2mg dosed every 8 weeks in Chinese patients.

Results: From May 2024 to January 2025, 525 Chinese patients were screened from 51 sites in Mainland China and Hong Kong. At baseline, 333 eligible patients were randomised 1:1 to aflibercept 2mg every 8 weeks (2q8) after 5 initial monthly doses or 8mg every 16 weeks (8q16) after 3 initial monthly doses. From Week 16, patients in the 8q16 arm can have their dosing intervals shortened if they meet visual and anatomical criteria,

indicating worsening DME. The primary endpoint is the change from baseline in BCVA by ETDRS letter score at Week 48. Additional secondary and exploratory functional, anatomic, and safety-related endpoints are assessed.

Conclusions: PHOTONiC will generate valuable data on clinical outcomes with aflibercept 8 mg in Chinese patients with DME. Outcome data are expected in 2026.

Abstract No.: 200681

Alterations of the Vitreoretinal Interface in Retinal Vein Occlusion (RVO) Patients Post-Anti-VEGF Treatment

First Author: Zhengwei **ZHANG**

Purpose: To investigate the characteristics of vitreoretinal interface (VRI) changes and factors influencing therapeutic outcomes in retinal vein occlusion (RVO) patients undergoing anti-vascular endothelial growth factor (VEGF) therapy.

Methods: This study enrolled RVO patients treated with anti-VEGF agents from January 2020 to June 2024. Optical coherence tomography (OCT) evaluated pre- and post-treatment VRI changes, including posterior vitreous detachment (PVD) status, epiretinal membrane (ERM) incidence/location.

Results: The study included 200 RVO patients (106 central RVO, 94 branch RVO), aged 18–86 years, receiving 4–17 anti-VEGF injections over 3–17 months of follow-up. Baseline assessment revealed five eyes (2.5%) exhibited macular epiretinal membrane (ERM) and one eye (0.5%) had ERM. Initial PVD status distribution was: complete PVD in 64 cases (32%), partial PVD in 47 (23.5%), and no PVD in 39 (19.5%). Among 194 eyes without VRI abnormalities, 84 (43%) developed new ERM. Anti-VEGF agents showed differential effects on ERM formation ($P < 0.05$). Treatment significantly promoted PVD progression ($P < 0.01$), with 78% exhibiting PVD progress. Patients with baseline absent/partial PVD demonstrated higher ERM rates (58% and 52%, respectively) versus complete PVD (12%, $P < 0.01$). In BRVO cases, 92/94 (97.9%) showed ERM location correlated with occlusion quadrant ($P = 0.01$). Age ≥ 50 years and female were identified as independent ERM risk factors.

Conclusions: Anti-VEGF therapy modulates VRI via PVD progression, with ERM development linked to injection parameters, drug selection, lesion location, and baseline PVD status, warranting VRI monitoring for treatment optimization.

Abstract No.: 201294

An Analysis of Time-to-Photodynamic Therapy: Subretinal Fluid Duration and Treatment Outcomes in Central Serous Chorioretinopathy

First Author: Ryoh **FUNATSU**

Co-Author(s): Hiroki **IMATSUJI**, Naohisa **MIHARA**, Shoki **MIYAKE**, Koki **OKAMURA**, Taiji **SAKAMOTO**, Takato **SAKONO**, Hideki **SHIHHARA**, Shozo **SONODA**, Hiroto **TERASAKI**

Purpose: To evaluate the effect of prolonged serous retinal detachment (SRD) during the waiting period for photodynamic therapy (PDT) on clinical outcomes in patients with central serous chorioretinopathy (CSC).

Methods: This retrospective case series included consecutive patients with CSC who underwent PDT. We excluded patients whose SRD resolved spontaneously while PDT waiting period. We measured best-corrected visual acuity (BCVA) and retinal layer thickness at baseline and on the day of PDT. We evaluated the relationships between the duration of this period and the outcomes and the differences in these parameters during the waiting period. Primary outcomes were associations of the time-to-PDT with 12-month BCVA, SRD remission at 12 months, and changes in retinal layer thickness during the waiting period.

Results: 94 patients (94 eyes) with CSC were included, with a mean age of 57.6 ± 12.2 years, a mean BCVA of 0.18 ± 0.24 logMAR (Snellen: 20/30), and a mean waiting period of 50.8 ± 50.2 days. The outer nuclear layer (ONL) thinned significantly during the waiting period (mean reduction = $1.9 \pm 4.4 \mu\text{m}$, $P = 3.4 \times 10^{-5}$), and waiting times were positively associated with the amount of thinning (Crude: $\beta = -0.04$, $P = 3.4 \times 10^{-6}$; Adjusted: $\beta = -0.04$, $P = 1.3 \times 10^{-6}$). However, the waiting duration was not significantly associated with 12-month treatment outcomes.

Conclusions: While a one- to two-month waiting period does not appear to compromise the efficacy of PDT for patients with CSC, significant ONL thinning occurs during this time.

Abstract No.: 206474

Aqueous Humor Proteomics Reveals Commonalities and Specificities Between Neovascular AMD and Pathologic Myopia CNV

First Author: Hanqing **ZHAO**

Co-Author(s): Li **DONG**, Wenbin **WEI**

Purpose: Neovascular age-related macular degeneration (nAMD) and pathologic myopia-associated choroidal neovascularization (pmCNV) both present with choroidal neovascularization as a common pathological endpoint, yet differ markedly in pathogenesis, prognosis, and response to anti-VEGF

therapy. Current understanding of their molecular similarities and differences remains limited. This study applied aqueous humor (AH) proteomic profiling to systematically identify shared and unique molecular features in nAMD and pmCNV, thereby clarifying their distinct pathophysiological mechanisms.

Methods: We collected aqueous humor samples from 67 participants who were categorized into four groups: nAMD (n = 20), pmCNV (n = 19), pathologic myopia without CNV (n = 8), and normal controls (n = 20). We performed proteomic analysis using liquid chromatography–tandem mass spectrometry (LC–MS/MS) and analyzed differential protein expression with the limma package, adjusting for age and gender as covariates. We validated key differentially expressed proteins using public datasets.

Results: The global protein expression profiles of nAMD and pmCNV correlated weakly ($r = 0.227$). We prioritized proteins based on rank abundance curves and p-value ranking, and ultimately identified 33 characteristic disease-associated proteins. We validated key proteins, including ENO1, using an independent public dataset.

Conclusions: This study identifies distinct molecular signatures between nAMD and pmCNV, showing that despite similar clinical phenotypes, each disease follows different molecular pathways. These disease-specific proteins offer new insights into their pathology and potential targets for precision diagnosis and therapy.

Abstract No.: 204912

Assessment of Retinal Lesions in Diabetic Retinopathy Using Two Wide-Field Fundus Imaging Systems

First Author: Nivedita MURALI

Co-Author(s): Naresh Babu KANNAN, Kim RAMASAMY

Purpose: To compare the ability of two wide-field fundus imaging systems to detect retinal lesions in diabetic retinopathy (DR).

Methods: This comparative study included 193 eyes with DR. Patients with clear media were included. A single image centered on the fovea was obtained using two imaging systems: Clarus and Eidon with an ultrawidefield (UWF) module. Each image was analysed and graded by two retina fellows blinded to the clinical grade. DR lesions were counted using both cameras and compared.

Results: DR grades using Eidon and Clarus images showed 90.2% and 86.5% similarity to clinical grading, respectively. 25.9% eyes were graded as severe non-proliferative diabetic retinopathy (NPDR) on Eidon but moderate NPDR on Clarus images. This is attributed to more number of intraretinal microvascular abnormalities (IRMA) identified on Eidon images. On assessment of individual DR lesions, more number of

NVD, NVE and IRMA were seen on Eidon images in 5.4%, 19.5% and 20.5% eyes respectively.

Conclusions: We conclude that Eidon's confocal technology provides superior contrast and sharper images compared to Clarus, making it more effective for detecting fine lesions in DR.

Abstract No.: 205568

Association Between Intravitreal Anti-VEGF Injections and Long-Term Dementia Risk: A 10-Year Real-World Study

First Author: Cheng-jui TSAI

Co-Author(s): Cheng-kuo CHENG

Purpose: Vascular endothelial growth factor (VEGF) has dual roles in neuroprotection and neurodegeneration, influencing angiogenesis, neurogenesis, and blood–brain barrier integrity. Most real-world studies on intravitreal anti-VEGF therapy have been limited to short-term follow-up of no more than five years, leaving the long-term cognitive implications uncertain.

Methods: Patients who received intravitreal anti-VEGF injections between January 2005 and December 2015 were identified from the TriNetX network and matched to controls undergoing visual field or optical coherence tomography examinations using propensity scores matching across 65 covariates. Kaplan-Meier analyses were performed to estimate 10-year risks of all-cause and subtype-specific dementia. Dementia risk was further compared between patients with a higher number of injections (>5) and those with a lower number (≤ 5).

Results: After matching, 11,812 patients were included in both the anti-VEGF and control groups. Intravitreal anti-VEGF injection was not associated with increased risk of all-cause dementia (HR: 0.95, $p=0.16$) or any dementia subtypes, and was associated with lower risk of mild cognitive impairment (HR: 0.815, $p=0.001$). No significant differences were observed between patients with a higher and lower number of injections for all-cause dementia or most subtypes, whereas the risk of vascular dementia was significantly lower among those receiving >5 injections (HR: 0.69, $p=0.03$).

Conclusions: Intravitreal anti-VEGF therapy was not associated with an increased long-term risk of dementia. A lower risk of mild cognitive impairment was observed in the treatment group, while a reduced risk of vascular dementia was noted among patients receiving more injections. These associations warrant further investigation to confirm causality and elucidate underlying mechanisms.

Abstract No.: 203175**Association Between Lipid Metabolism 1 Abnormalities and Early Retinal Microvascular Changes in Diabetic Patients***First Author: Li SU*

Purpose: Dyslipidemia is common in diabetic patients and may exacerbate retinal microvascular damage via multiple pathways. This study aimed to explore the associations between lipid metabolism parameters and retinal vascular perfusion density, as well as choroidal morphological indices, in diabetic patients without diabetic retinopathy (DR). It also analyzed how hyperlipidemia impacts retinal microvascular structure and function.

Methods: This cross-sectional study recruited 191 type 2 diabetes patients without DR from the National Metabolic Management Center (May 2021–March 2022) of Shanghai General Hospital. Participants underwent comprehensive eye exams and optical coherence tomography angiography (OCTA). Conventional (total cholesterol, triglycerides, LDL-C, HDL-C) and novel (sdLDL, free fatty acids, apolipoproteins) lipid biomarkers were measured. Partial correlation and propensity score matching evaluated parameter associations, while multivariate linear regression identified independent risk factors.

Results: Analysis showed sdLDL negatively correlated with superficial capillary plexus (SCP) perfusion and vessel length density ($r = -0.260$ to -0.321 , $P < 0.05$), outperforming conventional LDL-C. Apolipoprotein A1 (ApoA1) positively correlated with SCP parameters ($r = 0.233$ – 0.296 , $P < 0.01$), indicating protective effects. Deep capillary plexus changes were milder. Hyperlipidemic patients had lower SCP perfusion and vessel density, especially in the inner-ring ($P < 0.0001$), and reduced macular thickness. Multivariate regression confirmed sdLDL as a risk factor and ApoA1 as protective.

Conclusions: This study first clarified lipid–retinal microvascular 23 correlations in DR-free diabetic patients. sdLDL negatively impacted perfusion, while ApoA1 protected against damage. Hyperlipidemia altered SCP structure and macular thickness, highlighting lipid management's role in preventing diabetic retinal microvascular injury.

Abstract No.: 200643**Association Between Serum Vitamin D Levels and Diabetic Macular Edema: A Cross-Sectional Study***First Author: Drishti KAUSHAL**Co-Author(s): Sakshi JAIN, Vinod KASHYAP, Anerudh MATHUR*

Purpose: To assess the relationship between serum vitamin D levels and diabetic macular edema (DME).

Methods: A clinic-based, cross-sectional study was conducted at the Department of Ophthalmology, Indira Gandhi Medical College (IGMC), Shimla, from May 2023 to May 2024. A total of 100 subjects with Type 2 Diabetes Mellitus were enrolled and stratified into groups with and without diabetic retinopathy (DR). Those with DR were further classified based on the presence and type of diabetic macular edema using optical coherence tomography (OCT). Exclusion criteria included Type 1 diabetes, intake of medications affecting vitamin D metabolism, and systemic conditions that alter vitamin D levels. All participants underwent dilated fundus examination and testing for HbA1c, serum creatinine, and 25-hydroxy-vitamin D (25(OH)D) levels.

Results: There was no significant difference in age, sex, or multivitamin use between the two groups. Patients with DR had significantly lower 25(OH)D levels compared to those without DR (48% with values <20 ng/ml vs. 14%, $p < 0.001$). Among patients with DME, those with advanced OCT features such as vitreomacular traction (VMT) and taut posterior hyaloid membrane (TPHM) were exclusively vitamin D deficient. Fisher's exact test confirmed a significant association between vitamin D deficiency and DME severity.

Conclusions: This study demonstrates a significant association between low serum 25(OH)D levels and the presence and severity of DME, suggesting that vitamin D may play a role in the pathogenesis and progression of diabetic retinal disease.

Abstract No.: 204520**Association of Early Macular Leakage Resolution With Extended Dosing Intervals in Patients With Retinal Vein Occlusion: A Post-Hoc Analysis of the BALATON/COMINO Trials***First Author: Hemal MEHTA**Co-Author(s): Nicholas DAGINCOURT, Carl DANZIG, Christiana DINAH, Liliana Paris PEREIRA, Joern SCHWEITZER*

Purpose: In BALATON/COMINO (NCT04740905/ NCT04740931), a greater proportion of patients with RVO (retinal vein occlusion)-related macular edema achieved absence of ML (macular leakage) with faricimab vs. aflibercept @W24 (Week-24). We examined the association between ML-area @W24 and extended-dosing intervals and BCVA (best-corrected visual acuity) gain @W68.

Methods: Between day1–W20, patients were randomized to faricimab-6.0mg or aflibercept-2.0mg Q4W (every-4-weeks). At W24–W72, all patients received faricimab Q4W–Q16W per a modified treat-and-extend regimen. The association between ML-area subgroups @W24: $\leq 1\text{mm}^2$ (ML-resolution, $n=502/989$) vs. $\geq 10\text{mm}^2$ (high-ML, $n=143/989$) and the percentage

of patients on extended dosing ($\geq$ Q12W) or BCVA change from baseline at W68 was evaluated.

Results: At W68, 59.0% and 37.8% patients with W24 ML-areas $\leq 1\text{mm}^2$ and $\geq 10\text{mm}^2$, respectively, achieved $\geq$ Q12W dosing (nominal $P=0.0001$). In multivariable modelling, patients with W24 ML-area $\leq 1\text{mm}^2$ were >2 -fold more likely to achieve $\geq$ Q12W dosing @W68 compared with W24 ML-area $\geq 10\text{mm}^2$ (odds ratio [95% confidence-interval]: 2.5[1.6–3.9]; nominal $P<0.0001$). Patients in the $\leq 1\text{mm}^2$ subgroup gained an average of 3.8 letters (95% confidence interval: 1.2–6.3) more than those in $\geq 10\text{mm}^2$ subgroup (Least square mean [standard error] BCVA change from baseline @W68: 18.8[0.6] vs. 15.0[1.1] letters; nominal $P=0.0036$).

Conclusions: Early ML resolution may be associated with extended dosing intervals and greater vision gains @W68. As more patients achieved ML absence with faricimab vs. aflibercept @W24, faricimab treatment may achieve extended dosing in RVO by promoting vascular stability beyond vascular endothelial growth factor inhibition.

Abstract No.: 205855

Associations of Microbiota-Friendly Diet With Risk of Diabetic Retinopathy in NHANES: Mediating Role of Oxidative Stress and Inflammation

First Author: Yuan Yue **CUI**

Co-Author(s): Jing **JIN**, Wei **WANG**, Dandan **XIE**

Purpose: Growing evidence implicates gut microbiota dysbiosis in the pathogenesis of diabetic retinopathy (DR). This study aimed to investigate the associations between the dietary index for gut microbiota (DI-GM), a novel metric reflecting gut microbiota composition and diversity, and DR risk, as well as to examine the mediating role of inflammatory and oxidative stress biomarkers.

Methods: This cross-sectional study analyzed 4,003 diabetic individuals (mean age 59 years, 51.21% men) from the 1999-2018 National Health and Nutrition Examination Survey. DI-GM was derived from self-reported 24-hour dietary recalls. Mediation analysis was used to investigate the role of inflammation (neutrophils, lymphocytes, and alkaline phosphatase) and oxidative stress (gamma-glutamyl transferase, uric acid, and total bilirubin) biomarkers in the effects of DI-GM on DR prevalence. Binary logistic regression analysis was adopted to explore the association of DI-GM and DR prevalence.

Results: The prevalence of DR was 19.64%. Multivariate-adjusted odds ratios (95% confidence intervals) for the associations between DI-GM and DR prevalence were 0.73 (0.68-0.79). Restricted cubic spline curves showed a non-linear inverse relationship between DI-GM and DR prevalence. Subgroup analysis indicated that the association between DI-GM and DR

prevalence was more pronounced in participants with a body mass index $> 25 \text{ kg/m}^2$. Alkaline phosphatase and total bilirubin mediated 10.27% and 9.45% of the effects of DI-GM scores on DR prevalence.

Conclusions: Adherence to a microbiota-friendly diet was associated with a lower DR prevalence, especially among individuals with overweight or obesity. Alkaline phosphatase and total bilirubin may be associated with the gut microbiota-retina interactions in DR.

Abstract No.: 204629

Automated Quantification of Retinal Fluid in Patients With Diabetic Macular Edema: Analysis of Faricimab vs Aflibercept in YOSEMITE/RHINE

First Author: Ka Ho **SZETO**

Co-Author(s): Thomas **ALBRECHT**, Kara **GIBSON**, Nancy **HOLEKAMP**, Gavin S. **TAN**, Ming **YANG**

Purpose: This YOSEMITE/RHINE (NCT03622580/ NCT03622593) post-hoc analysis quantifies changes in retinal fluid volume, IRF (intraretinal fluid), and SRF (subretinal fluid) with faricimab using novel ROSA (retinal OCT [optical coherence tomography] segmentation algorithm) in patients with DME (diabetic macular edema).

Methods: Patients (pooled $N=1,891$) were randomized 1:1:1 to faricimab-6.0mg Q8W (every-8-weeks; $n=631$) or via T&E (treat-and-extend)-based regimen (Q4W–Q16W; $n=632$), or aflibercept-2.0mg Q8W ($n=627$). YOSEMITE/RHINE-patients with baseline Spectralis OCT images and fluid volume measurement (faricimab-Q8W: $n=504$; faricimab-T&E: $n=506$; aflibercept-Q8W: $n=492$) are analyzed. Fluid volume (3-mm central-subfield; baseline-W100) was quantified using novel artificial intelligence/machine learning-based ROSA with R2 scores characterizing performance: IRF:0.94; SRF:0.88.

Results: Mean (standard-error) baseline SRF and IRF volumes were 38.8 (5.6), 43.7 (5.9), and 42.7 (5.3), and 249.5 (9.5), 240.4 (9.3), and 261.1 (9.5) nL for faricimab-Q8W, faricimab-T&E, and aflibercept-Q8W, respectively. Adjusted mean (95%CI [confidence interval]) SRF changes from baseline at year-2 were comparable for faricimab-Q8W (-40.4 [-41.9, -38.9] nL), faricimab-T&E (-40.3 [-41.7, -38.8] nL), and aflibercept-Q8W (-38.6 [-40.1, -37.1] nL). Corresponding IRF changes were greater for faricimab-Q8W (-212.0 [-221.6, -202.4] nL) and faricimab-T&E (-212.1 [-221.5, -202.8] nL) vs aflibercept-Q8W (-184.1 [-193.8, -174.3] nL); differences vs aflibercept: -27.9 nL (-41.6, -14.2; $P<0.0001$) for faricimab-Q8W; -28.1 nL (-41.6, -14.5; $P<0.0001$) for faricimab-T&E. At Week-12, adjusted mean(95%CI) IRF changes from baseline were greater for faricimab-Q8W (-158.3 [-168.3, -148.2] nL) and faricimab-T&E (-168.8 [-178.8, -158.8] nL) vs aflibercept-Q8W (-143.6 [-153.8, -133.4] nL). Differences vs aflibercept: -14.7 nL (-29.0, -0.4;

P=0.0446) for faricimab-Q8W; -25.2 nL (-39.5, -10.9; P=0.0006) for faricimab-T&E.

Conclusions: Quantitative OCT assessment demonstrated that IRF volume reductions were greater with faricimab vs aflibercept as early as Week-12 and through year-2 in DME patients, supporting faricimab's potential to improve DME disease control beyond vascular endothelial growth factor-inhibition alone.

Abstract No.: 202955

Avacincaptad Pegol Reduces Progression of Ellipsoid Zone Loss and Degradation in Eyes With the Highest Baseline Ellipsoid Zone Burden

First Author: Seung-young **YU**

Co-Author(s): Katherine **TALCOTT**, Reem **AMINE**, Karen **MATAR**, Asmita **INDURKAR**, Amy **TANG**, Lyndsey **DELLA VECCHIA**, Hasan **CETIN**, John **MAMONE**, Jamie **REESE**, Don **LUO**, Dan **LUO**, Dina **ABULON**, Justis **EHLERS**

Purpose: Ellipsoid zone (EZ) integrity, or photoreceptor health, is a potential biomarker for geographic atrophy (GA) progression rate. The impact of avacincaptad pegol (ACP), a US FDA-approved therapy for GA, was assessed on the progression of EZ integrity over 12 months in eyes with the highest baseline EZ burden (based on the fourth-quartile EZ burden cutoff with sham: >39.3% for total EZ attenuation; >61.6% for partial EZ attenuation).

Methods: GATHER1/GATHER2 evaluated the efficacy and safety of ACP 2mg vs sham in GA. In this pooled post-hoc analysis, SD-OCT was used to assess EZ integrity in the study eye. EZ features were measured as a percentage of the macular area with EZ-to-RPE thickness ≤ 20 μ m (partial EZ attenuation) and 0 μ m (total EZ attenuation). Mean growth rates at months 6 and 12 were assessed for each parameter to determine progression of EZ loss/degradation.

Results: In eyes with the highest baseline total EZ attenuation, the mean total EZ attenuation growth rate with ACP and sham, respectively, was 4.1% vs 5.4% at month 6 and 7.7% vs 9.4% at month 12. In eyes with the highest baseline partial EZ attenuation, the mean partial EZ attenuation growth rate with ACP and sham, respectively, was 0.5% vs 3.6% at month 6 and 2.1% vs 6.3% at month 12.

Conclusions: In eyes with the highest baseline EZ burden, ACP reduced EZ loss/degradation vs sham over 12 months. ACP showed a more pronounced reduction in partial EZ attenuation vs sham, suggesting a more optimal intervention window, particularly in eyes with partially preserved photoreceptor structure.

Abstract No.: 202502

Baseline and Early Treatment Response Variables of Faricimab Durability in Treatment-Naïve Neovascular Age-Related Macular Degeneration

First Author: Ji Hun **SONG**

Co-Author(s): Adrian Hock Chaun **KOH**, Marie Joan **LOY**, Philippe **MARGARON**, Colin **TAN**, Ming **YANG**

Purpose: In TENAYA/LUCERNE (NCT03823287/ NCT03823300), 80% treatment-naïve nAMD (Neovascular Age-related Macular Degeneration) patients achieved $\geq$ Q12W (every-12-weeks) and >60% achieved Q16W faricimab dosing at week-112. This post-hoc analysis evaluated the association of baseline characteristics and early treatment-response variables with always-extended ($\geq$ Q12W) and potential Q20W faricimab dosing.

Methods: Patients received faricimab-6.0mg up to Q16W after four Q4W doses. Following assessments at weeks-20/24, patients received fixed dosing up to Q16W until week-60 and then a T&E (treat-and-extend) dosing. Univariate and multivariable analyses evaluated the association of baseline characteristics and early treatment-response variables with $\geq$ Q12W dosing from weeks-20/24 to week-112 and patient eligibility for potential Q20W extension during T&E phase.

Results: Odds ratio (95% confidence interval) of faricimab-treated patients on $\geq$ Q12W dosing during maintenance period (n=310) increased with lower baseline CST (central subfield thickness) (100- μ m decrease; 1.9 [1.2,2.8]), lower baseline maximum PED (pigment epithelial detachment) thickness (100- μ m decrease; 1.4 [1.2,1.6]), and smaller baseline choroidal neovascularisation lesion-size (5-mm² decrease; 1.3 [1.0,1.6]). Odds also increased for greater change in CST from baseline (additional 100- μ m improvement; 1.7 [1.1,2.7]) and SRF (subretinal fluid) absence at week-12 (2.5 [1.4,4.3]). Odds for potential Q20W extension during T&E-phase (n=591) increased with baseline presence of intraretinal fluid (1.5 [1.1,2.1]), lower baseline maximum PED thickness (100- μ m decrease; 1.3 [1.2,1.5]) and SRF absence at week-12 (2.4 [1.4,4.1]).

Conclusions: These findings suggest favorable baseline characteristics (lower CST, smaller PED, smaller lesion size) and early treatment response (greater CST reduction, SRF absence at week-12) are associated with extended durability of faricimab in treatment-naïve nAMD patients, including potential Q20W extension.

Abstract No.: 202298
Bilateral Serous Retinal Detachment After Cardiopulmonary Resuscitation

First Author: Magdalena **FUTYMA ZIAJA**

Co-Author(s): Grzegorz **BEDNARCZYK**, Piotr **FUTYMA**, Łukasz **ZARĘBSKI**

Purpose: To describe a rare case of bilateral serous retinal detachment following cardiopulmonary resuscitation (CPR).

Methods: An 81-year-old female underwent balloon angioplasty of the right superficial femoral artery. During the procedure, the patient experienced sudden cardiac arrest and required immediate CPR. Following successful resuscitation, she was diagnosed with hypoxic encephalopathy. Three days post-event, the patient reported bilateral visual disturbances. B-scan ultrasound and OCT revealed new-onset bilateral serous retinal detachment, absent in preoperative baseline scans. Central retinal thickness (CRT) increased from 206/216 μm (right/left eye) preoperatively to 1500/1041 μm on day 3. Then, CRT decreased to 233/271 μm on day 8, with almost complete resolution by day 15 (200/261 μm). Visual acuity decreased to 0.1/0.5 on day 3, improved to 0.7/0.9 on day 8, and stabilized at 0.7/1.0 by day 15.

Results: Despite significant visual deterioration in the early phase, the patient showed substantial recovery of visual function without surgical intervention. Treatment consisted of topical dexamethasone and nepafenac.

Conclusions: This is the first documented case of bilateral serous retinal detachment following cardiopulmonary resuscitation. Prompt recognition is essential in patients with post-resuscitation visual symptoms.

Abstract No.: 200876
Bispecific Peptide Binds to VEGFR2 and Integrin $\alpha\text{v}\beta 3$, Forming an Artificial Extracellular Matrix for Anti-Ocular Neoangiogenesis

First Author: Yuhong **YE**

Co-Author(s): Hao **CHEN**, Da **LONG**, Ye **ZHANG**, Pan **ZHAO**

Purpose: This study aimed to develop a bispecific peptide (BsPt) capable of targeting both VEGFR2 and integrin $\alpha\text{v}\beta 3$ for the treatment of retinal and choroidal neovascularization (RNV/CNV).

Methods: Two BsPts with identical targets but different molecular structures were designed and synthesized: palmitic acid-K-FFVLK(KHVDSDH)-ATWLPPR (PF(K)A) and palmitic acid-K(KHVDSDH)-FFVLK-ATWLPPR (P(K)FA). Their binding affinity, fibrillogenesis, and cytotoxicity were evaluated in vitro using rat retinal microvascular endothelial cells (rMECs) and MCF-7 cells. The in vivo efficacy and safety of the selected BsPt, PF(K)A,

were assessed in mouse models of oxygen-induced retinopathy (OIR) and laser-induced CNV. Additionally, the gene expression profile of rMECs treated with PF(K)A was analyzed using RNA sequencing to investigate the underlying mechanisms of its anti-angiogenic and anti-leakage effects.

Results: BsPt binds to both receptors on endothelial cells (ECs) and forms nanofibrous networks on their surfaces, resulting in potent NV inhibition. In vitro, BsPt suppressed retinal EC migration and tube formation. Intravitreal BsPt injection outperformed aflibercept in mouse models of OIR and laser-induced CNV. RNA sequencing revealed that BsPt-induced nanofibers upregulated extracellular matrix (ECM) and cell adhesion genes, which may contribute to anti-angiogenesis and anti-leakage effects.

Conclusions: BsPt targeting VEGFR2 and integrin $\alpha\text{v}\beta 3$, particularly PF(K)A, exhibits enhanced therapeutic potential for treating RNV and CNV. This novel approach holds promise for the development of more effective treatments for ocular neovascular diseases.

Abstract No.: 203350
Brolucizumab Efficacy and Safety Single-Arm Descriptive Trial in Patients With Persistent Diabetic Macular Edema (BEST Study)

First Author: Honghua **YU**

Co-Author(s): Dan **CAO**, Yunyan **HU**, Ziyi **HUANG**, Jing **LI**, Anyi **LIANG**, Chenxiao **SHEN**, Chunwen **ZHENG**

Purpose: To evaluate the efficacy and safety of brolucizumab in patients with pDME (persistent diabetic macular edema) (BEST study, NCT06498050).

Methods: The BEST study is a 28-week, prospective, single-arm, open-label clinical trial involving 52 Chinese subjects with pDME, defined as CST (central subfield thickness) $\geq 320 \mu\text{m}$ despite ≥ 3 anti-vascular endothelial growth factor injections within 20 weeks, and baseline BCVA (best-corrected visual acuity) 23-78 letters. Study eyes receive brolucizumab 6mg injections every 6 weeks (at week 0, 6, 12, 18, and 24) or switch to a 12-week interval (at week 0, 6, 12, and 24) if no disease activity at week 18.

Results: Of the 52 patients enrolled, 50 (96.2%) and 49 (94.2%) completed the 18-week and 28-week visits, respectively. At week 28, 61.2% of eyes achieved CST $< 300 \mu\text{m}$, and 89.8% achieved a ≥ 5 -letter gain in BCVA. Mean baseline CST was $510.9 \pm 18.4 \mu\text{m}$, and BCVA was 58.4 ± 2.0 letters. At week 28, the adjusted mean change from baseline for CST was $-199.5 \mu\text{m}$ (95% CI, -221.9 to -177.2 ; $P < 0.0001$) and $+13.0$ letters for BCVA (95% CI, 10.7 – 15.3 ; $P < 0.0001$). At week 18, 90.0% of subjects had no disease activity and were extended to 12-week dosing intervals. Intraocular inflammation (IOI) occurred in 1 eye (1.9%) and resolved rapidly with topical steroid treatment.

Conclusions: Brolucizumab 6mg administered every 6 weeks achieved clinically significant anatomical and visual improvement in patients with pDME.

Abstract No.: 204470

Carotid Revascularization and Circle of Willis in Ocular Ischemic Syndrome: Association With Neovascular Glaucoma and Visual Prognosis

First Author: Jialin **WANG**

Co-Author(s): Xueru **CHENG**

Purpose: Ocular ischemic syndrome (OIS) and subsequent neovascular glaucoma (NVG) lead to irreversible visual impairment. This study aimed to investigate the association of carotid artery revascularization and the collateral circulation types via the circle of Willis (CoW) with NVG and visual prognosis in patients with OIS.

Methods: This retrospective cohort study included 22 patients with OIS, with a median follow-up of 12 months. The collateral circulation patterns via the CoW were classified into five types. The association of the carotid artery revascularization, collateral circulation types via the CoW, and morphological characteristics of the CoW with the presence of NVG and visual outcomes was assessed.

Results: The median time interval from baseline to visual decline during follow-ups in patients with carotid artery revascularization was longer than that in patients without carotid artery revascularization (13 months vs. 9.5 months, $P=0.041$). Lacking collateral inflow via the CoW to the hemisphere ipsilateral to OIS was associated with NVG (OR, 11.000; $P=0.022$). The diameters of the C6 and C7 segments of the internal carotid artery, the A1 segment of the anterior cerebral artery, and the ophthalmic artery in OIS eyes were smaller than those in the contralateral eyes.

Conclusions: Early carotid artery revascularization should be considered in patients with OIS, with or without NVG, as it may contribute to an improved visual prognosis. Patients without collateral inflow via the CoW to the hemisphere ipsilateral to OIS may have a higher risk of NVG.

Abstract No.: 206303

Causal Effects of Gut Microbiota and Associated Metabolites on Retinal Diseases and Visual Impairment: A Mendelian Randomization Study

First Author: Chuyao **YU**

Co-Author(s): Wen-bin **WEI**

Purpose: Previous observational study findings have indicated a vital association between gut microbiota features and retinal diseases based on the “gut-retina”

axis. However, whether their relationships underlie causal effects remains to be established.

Methods: Based on GWAS data of 211 gut microbiota taxa and 28 gut-related metabolites/pathways as exposures, a two-sample Mendelian randomization analysis was conducted to assess their causal effects on multiple retinal conditions—including diabetic retinopathy, early AMD, retinal detachment/breaks, retinal vascular occlusion, choroid/retinal disorders, and visual impairment. Causal relationships were evaluated using IVW, MR-Egger, weighted median, simple mode, and weighted mode methods.

Results: Through MR analysis of 211 microbes and six clinical phenotypes, 35 gut microbiome taxa and 3 associated metabolites were identified as linked to various outcomes. Cochrane’s Q test showed no significant heterogeneity among instrumental variables, and no horizontal pleiotropy was detected by MR-Egger and MR-PRESSO tests. After Bonferroni correction, Genus id.2041 (OR = 0.874, 95% CI: 0.816–0.936, $p=1.10e-04$, IVW) demonstrated a robust causal association with disorders of the choroid and retina, and was nominally correlated with multiple other retinal diseases. Seven exposure–outcome associations remained significant after adjusting for BMI or alcohol intake frequency in multivariable MR analyses. Reverse MR analysis indicated no significant causal effects of outcomes on gut microbiota, with no heterogeneity or horizontal pleiotropy detected.

Conclusions: We confirmed a potential causal relationship between some gut microbiota features and retinal diseases, thus providing new insights into the gut microbiota-mediated mechanism of retinopathy and indicating vital biomarkers for potential diagnostic, therapeutic and prevention strategies.

Abstract No.: 201785

Central Retinal Thickness as a Biomarker in Parkinson’s Disease: A Meta-Analysis of Spectral-Domain Optical Coherence Tomography Studies in Asian Populations

First Author: Michelle **TYRAYOH**

Co-Author(s): Vivian **ANGELINA HARSONO**, Franciscus **ASSISI TIMMY BUDI YUDHANTARA**, Hendrawan **CHANDRA KUSUMA**, Mia **PURNAMA**

Purpose: Parkinson’s disease (PD) involves retinal changes measurable by spectral-domain optical coherence tomography (SD-OCT). This meta-analysis evaluated whether central retinal thickness (CRT) differs between Asian PD patients and healthy controls, considering rising PD prevalence and potential genetic/anatomical differences.

Methods: Following PRISMA 2020, major databases were searched up to March 2025. Quality was assessed using the Newcastle–Ottawa Scale. Pooled mean differences (MD) with 95% confidence intervals (CI)

were calculated. Subgroup analyses were conducted to differentiate results obtained using Cirrus HD-OCT (Cirrus) and Spectralis SD-OCT (Heidelberg).

Results: Fifteen predominantly good-quality cross-sectional studies involving 1,884 eyes were included. Macular thickness was lower in PD patients (Cirrus MD $-5.0\ \mu\text{m}$, 95% CI -7.4 to -2.7 ; Heidelberg MD $-5.5\ \mu\text{m}$, 95% CI -6.7 to -4.2), particularly in the central macular region. Retinal nerve fiber layer (RNFL) thickness was lower in PD patients (Cirrus MD $-4.1\ \mu\text{m}$, 95% CI -5.5 to -2.7 ; Heidelberg MD $-2.9\ \mu\text{m}$, 95% CI -4.1 to -1.7), especially in the superior and inferior quadrants. Macular volume was significantly lower on Cirrus (MD $-0.2\ \text{mm}^3$, 95% CI -0.3 to -0.1). Ganglion cell–inner plexiform layer (GC-IPL) on Cirrus was borderline significant (MD $-4.1\ \mu\text{m}$, 95% CI -8.2 to 0.0).

Conclusions: In Asian populations, OCT reveals central macular thickness and superior/inferior RNFL thickness differences between PD patients and controls. Macular volume differences were detected with Cirrus. OCT parameters may provide potential non-invasive biomarkers for PD.

Abstract No.: 206231

Characterization of Collateral Circulation After Anti-VEGF Treatment for Retinal Vein Occlusion

First Author: Yuntao **HU**

Co-Author(s): Renyan **WANG**

Purpose: This is a retrospective study on the effects of anti-VEGF therapy and systemic factors on the formation of collateral circulation in patients with retinal vein occlusion (RVO).

Methods: Among 157 patients clinically diagnosed with RVO (157 eyes), 87 had branch retinal vein occlusion (BRVO), and 70 had central retinal vein occlusion (CRVO). 62.07% of BRVO cases developed collateral circulation with an average establishment time of 172 days, while only 18.57% of CRVO cases developed collateral circulation with an average establishment time of 333 days.

Results: Different anti-VEGF therapy regimens did not significantly affect the formation of collateral circulation in BRVO patients ($P=0.90$), whereas a significant difference was observed in CRVO patients ($P<0.0001$), with fewer patients establishing collateral circulation after receiving anti-VEGF therapy. Diabetes and hypertension did not show a statistically significant effect on collateral circulation formation in either BRVO or CRVO patients.

Conclusions: Collateral circulation is an important prognostic factor for RVO. Collateral circulation is usually beneficial to RVO results. In this study, we did not find that anti-VEGF affected the formation of collateral circulation in RVO patients.

Abstract No.: 209326

Choriocapillary Flow Deficit Ratio and Subretinal Drusenoid Deposit Area as Indicators of Atrophy Development in Dry Age-Related Macular Degeneration

First Author: Liang **ZHOU**

Co-Author(s): Steve **BAILEY**, Yukun **GUO**, Yali **JIA**, Jie **WANG**

Purpose: To evaluate the predictive value and temporal dynamics of choriocapillaris (CC) and retinal vascular and structural metrics for the development of complete retinal pigment epithelium and outer retinal atrophy (cRORA) in eyes with intermediate age-related macular degeneration (iAMD).

Methods: Retrospective longitudinal observational study. Twenty-nine eyes with iAMD underwent serial $3 \times 3\ \text{mm}$ spectral-domain OCT angiography (SD-OCTA; Avanti or Solix, Optovue Inc.; 70–120 kHz A-scan rate) centered on the fovea. Quantitative OCTA metrics including CC flow deficit ratio, nonperfusion area (NPA) in the superficial (SVC), intermediate (ICP), and deep (DCP) capillary plexuses were computed using automated algorithms. Automated quantitative OCT metrics included subretinal drusenoid deposit (SDD) area and volume, and drusen volume. Univariable and multivariable Cox regression analyses identified metrics as predictors for cRORA; receiver operating characteristic (ROC) and Kaplan–Meier analyses determined optimal thresholds and cumulative incidence. Intraclass correlation coefficients (ICCs) assessed repeatability.

Results: Among 29 eyes with iAMD, 11 developed cRORA within 24 months, while 18 remained free of atrophy. Of all vascular and structural methods, only greater baseline CC flow deficit ratio and larger SDD area were independently associated with increased risk of cRORA within 24 months (HR = 1.11, 95% CI 1.01–1.23, $p = 0.035$; HR = 1.03, 95% CI 1.01–1.05, $p = 0.001$, respectively). ROC analyses identified optimal thresholds of 0.073 for CC flow deficit ratio (AUC = 0.99) and 0.262 mm^2 for SDD area (AUC = 0.92). Longitudinal analysis showed progressive CC impairment and a gradual SDD decline preceding atrophy onset. The NPA of the DCP increased at the time of cRORA (Figure 1). All OCTA-derived quantitative metrics demonstrated excellent repeatability (intraclass correlation coefficient > 0.89 ; $p < 0.001$). Figure 2 illustrates a representative case that developed cRORA during follow-up.

Conclusions: Baseline CC flow deficits and SDD area are independent risk factors for predicting development of cRORA in eyes with iAMD. CC flow deficits and SDD progressively declined prior to cRORA, while an increase of DCP NPA was associated with cRORA. OCT/OCTA-derived metrics have potential to become important biomarkers for risk stratification and therapeutic evaluation.

Abstract No.: 200839

Clinical Characteristics and Prognostic Factors Affecting Clinical Outcomes in Cytomegalovirus Retinitis Following Allogeneic Hematopoietic Stem Cell Transplantation

First Author: Qiaozhu **ZENG**

Co-Author(s): Jing **HOU**, Heng **MIAO**, Yuou **YAO**

Purpose: This study aimed to evaluate the clinical characteristics and identify the prognostic factors affecting visual outcomes, retinal detachment, and recurrence in cytomegalovirus retinitis (CMVR) patients following allogeneic hematopoietic stem cell transplantation (allo-HSCT).

Methods: A retrospective analysis of 54 CMVR patients (84 eyes) who underwent allo-HSCT between 2015 and 2024 was conducted. Ophthalmologic and systemic evaluations were performed. The visual outcomes were classified as improvement, stabilization, and deterioration. Logistic regression and LASSO regression models were used to identify the prognostic factors.

Results: Improved or stabilized visual outcomes were found in 22 eyes, while 62 eyes suffered from deterioration. Larger lesion areas were independently associated with poorer visual outcomes (OR 0.989, $p = 0.002$). Eight (9.5%) eyes had rhegmatogenous retinal detachment, and thirteen (15.5%) eyes suffered from recurrence. Retinal detachment was significantly predicted by higher baseline aqueous CMV DNA load (OR 5.087, $p = 0.026$). Macula involvement (OR 5.322, $p = 0.032$) and more intravitreal injections (IVs) (OR 1.263, $p = 0.008$) were independent risk factors for recurrence. No systemic factors were found to be associated with the clinical outcome of eyes with CMVR.

Conclusions: Ocular characteristics, rather than systemic factors, were more useful to predict the clinical outcome of eyes with CMVR. Routine ophthalmic screening and early intervention are essential to improving outcomes in this vulnerable population.

Abstract No.: 202000

Clinical Characteristics in Childhood Versus Adult-Onset Unilateral Coats Disease: A Global Collaborative Study

First Author: Chung-ting **WANG**

Co-Author(s): Andrew S.h. **TSAI**, Wei-chi **WU**

Purpose: To compare clinical features and outcomes of childhood- versus adult-onset Coats disease.

Methods: International, multicenter, non-comparative retrospective case series. Clinical data were collected from 19 international ophthalmic centers. Patients diagnosed at ≤ 18 years old were classified as childhood-onset, and those diagnosed after 18 years

old as adult-onset. Demographics, presenting features, clinical characteristics, and visual outcomes were compared.

Results: A total of 687 eyes from 687 patients were analyzed. Early-stage disease (stage 1–2) was significantly more common in adult-onset cases (92.2% vs. 51.8%, $p < 0.001$). Both groups showed male predominance, though the proportion of females was higher in adult-onset disease (22.5% vs. 11.7%, $p = 0.001$). Childhood-onset cases had significantly worse presenting and final visual acuity. Adult-onset patients more frequently presented with decreased vision and floaters, whereas strabismus and leukocoria were more common in childhood-onset disease. Subfoveal nodules were more frequent in childhood-onset cases (40.7% vs. 13.7%, $p < 0.001$). Childhood-onset disease was associated with extensive exudation (52.4% vs. 40.3%, $p = 0.007$), while exudates confined within the arcade were more common in adult-onset eyes (23.9% vs. 17.9%, $p = 0.001$). Among those with extramacular exudation, involvement of a single quadrant was more frequent in adult-onset cases (39.0% vs. 27.8%, $p = 0.011$).

Conclusions: Adult-onset Coats disease tends to present with less aggressive features, fewer subfoveal nodules, and more limited exudation, resulting in better visual outcomes. Despite overall male predominance, a higher proportion of female patients was observed in adult-onset disease.

Abstract No.: 204700

Clinical Characteristics of the Vascular Changes in Pediatric Patients With Congenital Retinoschisis

First Author: Jing **MA**

Co-Author(s): Hai **LU**

Purpose: To investigate the clinical characteristics of abnormal vascular changes in the fundus of pediatric patients with congenital X-linked retinoschisis (XLRS).

Methods: This retrospective case series study included pediatric patients (age ≤ 18 years) diagnosed with XLRS at Beijing Tongren Hospital, Capital Medical University, between December 2017 and November 2024. All eyes underwent wideangle fundus photography, with some patients additionally receiving fundus fluorescein angiography (FFA). The prevalence and patterns of vascular abnormalities were analyzed, along with their correlations with clinical outcomes.

Results: A total of 112 pediatric cases (218 eyes) were included. All patients were male, with a median age of 5.00 years (range: 9 months to 17 years). Abnormal vascular changes were detected in 139 eyes (63.8%) on fundus photography, including vascular sheathing (35.8%), tortuosity (32.6%), bridging vessels (29.4%), exudation (9.2%), and neovascularization (3.2%). Among 85 FFAevaluated eyes (44 patients), 96.5%

exhibited abnormalities, including nonperfusion areas (96.5%, 82/85), extramacular leakage (94.1%, 80/85), and neovascularization (15.3%, 13/85). Vascular anomalies were observed in both schitic and nonschitic peripheral retina in 78.8% (67/85) of eyes, exclusively in schitic areas in 17.6% (15/85), and in nonschitic regions in 1.2% (1/85). One eye with exudative retinal detachment secondary to massive subretinal exudation achieved complete resolution following antiVEGF therapy. Eyes with abnormal vascular changes demonstrated significantly higher rates of peripheral retinoschisis, vitreous hemorrhage, retinal detachment and tractional retinal detachment compared to unaffected eyes (all $P < 0.05$). Worse median visual acuity was observed in eyes with peripheral retinoschisis, vitreous hemorrhage, retinal detachment, abnormal vascular changes, vascular sheathing, tortuous vessels compared to unaffected eyes (all $P < 0.05$).

Conclusions: Pediatric XLRS patients exhibit diverse fundus vascular abnormalities. Eyes with vascular abnormalities demonstrate significantly higher complication rates and worse visual acuity.

Abstract No.: 206862

Clinical Characteristics, Imaging Features, and Outcomes of Retinal Arterial Macroaneurysms: A Retrospective Study at a Tertiary center of Taiwan

First Author: Yu Hsuan **YEN**
Co-Author(s): Kuan Jen **CHEN**

Purpose: Retinal arterial macroaneurysms (RAM) are focal dilatations of retinal arterioles, often near the superior temporal artery bifurcations. They may impair vision through hemorrhage, exudation, or macular edema. However, standardized management guidelines and epidemiologic data, especially in Taiwan, remain limited. This study evaluates the clinical features, imaging, management, and outcomes of RAM in a Taiwanese tertiary center.

Methods: This retrospective study reviewed approximately 120 RAM patients at Linkou Chang Gung Memorial Hospital between 2004 and 2025. Data included demographics, systemic/ocular history, symptoms, imaging (OCT, FA, fundus photos), treatments (observation, laser, anti-VEGF, pneumatic displacement, vitrectomy), and visual/anatomical outcomes. Analyses used descriptive statistics and multivariate regression.

Results: Patients were mostly female, mean age 75, with high hypertension prevalence. RAM commonly occurred at second or third superior temporal branches, often hemorrhagic and macula-involving. Treatment distribution among preliminary cases was: Observation: 50%, Anti-VEGF injections: 15%, Pneumatic displacement: 25% and Pars plana vitrectomy (TPPV): 10%. Anatomical and functional

improvements were noted, especially in cases treated with anti-VEGF or surgery. Representative imaging highlighted ILM detachment and sub-ILM hemorrhages with notable visual recovery in some cases.

Conclusions: This first large-scale Taiwanese RAM study highlights its clinical and imaging spectrum. RAM may indicate systemic vascular disease and is frequently underdiagnosed. Although no standard treatment exists, anti-VEGF use is rising with favorable outcomes in selected cases. Prospective studies are needed for evidence-based protocols.

Abstract No.: 201156

Clinical-Grade Artificial Intelligence for Diabetic Retinopathy Grading and Lesion Detection With UK NHS-Validated Standards for High-Volume Triage in Remote and Virtual Eye Care

First Author: Pradipta **CHOWDHURY**
Co-Author(s): Prakash Kumar **CHOWDHURY**, Anureet **KAUR**

Purpose: To develop a clinical-grade deep learning system that integrates NHS-standard diabetic retinopathy (DR) severity classification with granular lesion-level detection, optimized for high-volume triage and clinician-assistive workflows in remote and virtual ophthalmic care.

Methods: We designed a dual-branch convolutional neural network based on the DenseNet-201. The severity branch was trained on 63,077 fundus photographs labeled by NHS diabetic retinopathy grading standards: R0 (no retinopathy), R1 (mild non-proliferative), R2 (moderate to severe non-proliferative), and R3 (proliferative retinopathy), alongside M0 (no maculopathy) and M1 (presence of maculopathy). The second dataset included 18,533 fundus images with lesion-level annotations for ten diabetic retinopathy pathologies: microaneurysms, retinal hemorrhages, cotton wool spots, hard exudates, intraretinal microvascular abnormalities (IRMA), neovascularization at the disc (NVD), neovascularization elsewhere (NVE), venous beading, vitreous hemorrhage, and tractional retinal detachment (TRD). Severity classification used focal loss with softmax, while lesion detection applied sigmoid outputs with binary cross-entropy. Image augmentation, class weighting, and Grad-CAM validation were incorporated.

Results: The severity model achieved 94.2% accuracy, sensitivity 93.3%, specificity 92.6%, F1-score 92.9%, and macro-AUC 0.976. Detection was strongest for proliferative DR with maculopathy (AUC 96.9%), weakest for R2-M0 (AUC 91.4%). The lesion model achieved a mean AUC of 0.981, the highest for exudates (98.8%) and microaneurysms (98.4%), the lowest for IRMA (93.8%) and TRD (92.2%). Grad-CAM

heatmaps aligned with annotated lesions in 92.5% of cases, confirming model interpretability.

Conclusions: This dual-branch AI enables precise Diabetic Retinopathy grading, lesion detection, scalable screening, clinician support, and smartphone deployment.

Abstract No.: 205024

Comparable Ocular Safety Profiles Shown With Aflibercept 8 mg and 2 mg: A CANDELA, PHOTON, PULSAR, and QUASAR Trial Pooled Safety Analysis

First Author: Voraporn CHAIKITMONGKOL

Purpose: To compare the ocular safety of aflibercept 8 mg and 2 mg across the Phase 2 and 3 trials.

Methods: Patients were randomly assigned to aflibercept 8 mg or 2 mg in the CANDELA and PULSAR nAMD, PHOTON DME, and QUASAR RVO studies. Safety data to Week 96 were pooled for analysis.

Results: Overall, 2665 patients (8 mg: n=1808; 2 mg: n=857) were treated and evaluated. Study eye ocular treatment-emergent adverse events (TEAEs) were reported in 42.7% (8 mg) and 40.6% (2 mg) of patients: most commonly cataract, reduced visual acuity, increased intraocular pressure (IOP), and conjunctival hemorrhage. Similar rates of IOP-related TEAEs in the study eye (such as IOP increase and ocular hypertension) were observed across the studies (8 mg: 4.5%; 2 mg: 3.4%). No clinically relevant difference in pre- to post-injection IOP change was observed between aflibercept 8 mg and 2 mg groups. Rates of intraocular inflammation (8 mg: 1.1%; 2 mg: 1.5%) and endophthalmitis (8 mg: <0.1%; 2 mg: 0.5%) were low and similar, with no occlusive retinal vasculitis cases reported.

Conclusions: The ocular safety profile of aflibercept 8 mg was consistent with that of 2 mg to Week 96 across all indications.

Abstract No.: 202497

Comparative Efficacy of Faricimab for the Treatment of Diabetic Macular Edema at 1 and 2 Years: A Systematic Literature Review and Network Meta-Analysis

First Author: Colin TAN

Co-Author(s): Mark BARAKAT, Christian BUEHRER, Kara GIBSON, Nancy HOLEKAMP, Jakob SIEDLECKI

Purpose: Faricimab, a dual angiopoietin-2/VEGF (vascular endothelial growth factor)-A bispecific antibody, improves disease control and extends treatment durability in DME (diabetic macular edema). This systematic literature review and Bayesian NMA (network meta-analysis) of RCTs (randomized controlled trials) compared the efficacy and safety of faricimab per a personalized T&E (treat-and-extend)

regimen (Q4W [every-4-weeks]–Q16W) with other DME therapies.

Methods: Faricimab-6mg (T&E/Q8W) data from YOSEMITE [NCT03622580] / RHINE [NCT03622593] RCTs were used. Comparators included aflibercept-2mg Q4W/Q8W/PRN (pro-re-nata), aflibercept-8mg Q12W/Q16W, bevacizumab-1.25mg PRN, brolucizumab-6mg Q4W/Q12W, ranibizumab-0.3/0.5mg T&E/PRN/Q4W, dexamethasone-0.7mg PRN, and laser photocoagulation PRN. Outcomes were change in BCVA (best-corrected visual acuity; ETDRS [Early Treatment Diabetic Retinopathy Study] letters) and CST (central subfield thickness) through 12- and 24-months, and ≥15-ETDRS letter gainers and ≥1 ocular AE (adverse event) at 12-months.

Results: The NMA included 24 RCTs. Faricimab-T&E showed comparable/favorable mean BCVA and CST changes through 12 months vs aflibercept-8mg Q12W and Q16W (mean differences [95%CrI, credible interval]: -1.1 [-4.0,1.7], -1.9 [-4.8,1.0] ETDRS letters; and 32.6 [0.8,64.3], 39.7 [7.2,71.6]μm, respectively). Similar results were observed through 24 months. Aflibercept-8mg Q16W had lower (OR [odds ratio] [95%CrI]: 0.35 [0.16,0.75]), while other anti-VEGF treatments had similar ≥15-ETDRS letter gainers at 12-months vs faricimab-T&E. Occurrence of ≥1 ocular AE at 12-months was similar for all treatments vs faricimab-T&E except bevacizumab (OR[95% CrI]: 4.4 [1.6,13.0] and dexamethasone (4.2 [2.3,7.8]).

Conclusions: These data highlight faricimab's (T&E up to Q16W) potential to provide greater and durable DME disease control vs anti-VEGF alone.

Abstract No.: 201305

Comparative Efficacy of Large Language Models (Google Gemini and ChatGPT 4.0) in Screening Patients for Diabetic Retinopathy

First Author: Ahana SEN

Co-Author(s): Bhagyashree, Rohan BASAK, Sarang GOKHALE, Ankeet PANDA, Rupak ROY

Purpose: To study the comparative efficacy of 2 publicly accessible Large Language Models (LLMs), namely Google Gemini & Chat GPT 4.0, in diabetic retinopathy (DR) screening.

Methods: Fundus photos of 151 eyes of patients with a diagnosis of diabetic retinopathy and 50 control eyes with normal fundus findings were uploaded to Gemini and ChatGPT. Specific questions regarding the presence of DR and its referability were asked for each image, and the responses were recorded, analysed, and evaluated against the grading of the same images by a retina fellowship-trained human grader.

Results: A total of 201 images were randomly selected, of which 151(75.1%) had diabetic retinopathy and 50(24.8%) were control eyes with normal fundus findings. The responses were recorded and compared

with the answers of the human grader. Sensitivity and specificity of the LLMs in detecting DR were 84.40% and 95.10% for Chat GPT and 88.70% and 59.30% for Gemini. For referability of the eye, sensitivity and specificity were 86.40% and 82.60% for ChatGPT and 91.60% and 56.30% for Gemini.

Conclusions: This is the first study to explore the utility and efficacy of LLM in DR screening. Use of LLMs can have a huge impact on health care benefits, like screening of diabetic patients in remote areas where trained eye care personnel may not be available.

Abstract No.: 201055

Comparison of Intraocular Inflammation Associated With High-Dose Intravitreal Anti-Vascular Endothelial Growth Factor Agents: A Real-World Disproportionality Analysis

First Author: Du JIANTONG

Purpose: The safety profiles of high-dose intravitreal anti-vascular endothelial growth factor (VEGF) agents remain incompletely characterized. This study aimed to compare ocular adverse events, especially intraocular inflammation associated with brolocizumab, faricimab, and 8 mg aflibercept.

Methods: Adverse event reports for high-dose anti-VEGF agents were extracted from the FDA Adverse Event Reporting System (FAERS) database. After data standardization, quantitative signal detection analyses were performed using multiple pharmacovigilance tools. Clinical characteristics and time-to-onset profiles of adverse events were also assessed.

Results: Among 8,470 reports where high-dose anti-VEGF agents were designated as primary suspects, intraocular inflammation was the primary adverse reaction. The strongest signals were: retinal vasculitis with brolocizumab (retinal perivascular sheathing; reporting odds ratio (ROR)=7,451.51 [95% CI:4,528.22-12,261.99]), vitritis with faricimab (ROR=655.54 [95% CI:548.85-782.95]), and anterior chamber inflammation with 8 mg aflibercept (anterior chamber cells: ROR=1,749.13 [95% CI: 1,149.34-2,661.92]). SMQ analysis confirmed a descending gradient of inflammatory signal strength: brolocizumab exhibited the strongest signals, followed by aflibercept 8 mg, then faricimab.

Conclusions: Intraocular inflammation profiles differ significantly among high-dose anti-VEGF agents. Comprehensive evaluation of individual patients' risk factors is recommended to guide clinical decision-making.

Abstract No.: 205679

Comparison of Three-Dimensional Choroidal Contour in Patients With Neovascular Age-Related Macular Degeneration and Their Fellow Eyes

First Author: Sumit RANDHIR SINGH

Co-Author(s): Jay CHHABLANI, Kiran KUMAR

VUPPARABOINA, Elham SADEGHI, Jose-alain SAHEL

Purpose: To compare the 3-dimensional choroidal contour map of patients with neovascular age-related macular degeneration (nAMD) and their fellow eyes.

Methods: This cross-sectional study included 30 patients with nAMD in one eye and early/intermediate AMD in the fellow eye. Wide-field (12*12mm) swept source optical coherence tomography (SS-OCT) volumetric scans were obtained. Choroidal inner and outer boundaries (CIB, COB) were delineated based on our previously reported deep-learning model. Best-fit spherical radius (R, mm) was calculated for CIB and COB and compared in both groups using paired t-tests. The regional variation of RCIB and RCOB in different sectors (superior, inferior, nasal, temporal, and central) was compared. P values ≤ 0.05 were considered statistically significant.

Results: Mean ($\pm$ SD) RCIB was 32.8 ± 8.6 mm and 32.5 ± 9.4 mm in nAMD group and their fellow eyes, respectively ($p=0.80$). Similarly, mean ($\pm$ SD) RCOB was 31.3 ± 7.0 mm in nAMD group with no statistically significant variation in their fellow eyes (early/intermediate AMD: 31.5 ± 9.0 mm, $p=0.88$). Comparison of RCIB (nAMD: 15.0 ± 9.1 mm; fellow eye: 15.2 ± 10.4 mm; $p=0.91$) and RCOB (nAMD: 13.6 ± 8.1 mm; fellow eye: 12.2 ± 9.0 mm; $p=0.48$) in the central sector where AMD lesions were located was not significant. Intragroup sectoral comparisons of RCIB and RCOB in both groups were statistically significant (all p values < 0.01).

Conclusions: RCIB and RCOB exhibited significant regional variations across different sectors in both eyes, including nAMD and fellow eyes. However, the comparison of RCIB and RCOB between the two groups was not significantly different.

Abstract No.: 200272

Congenital Hypertrophy of the Retinal Pigment Epithelium: Clinical Spectrum and Imaging Characteristics From a Retrospective Fundus Photography Cohort

First Author: Sashwanthi MOHAN

Purpose: To describe the clinical and imaging characteristics of congenital hypertrophy of the retinal pigment epithelium (CHRPE) identified through retrospective analysis of fundus photographs over a 2-year period.

Methods: A retrospective chart review was conducted using electronic medical records of patients diagnosed with retinal and choroidal disorders, identified via relevant ICD-10 codes. Fundus photographs of 65 patients were reviewed, and 21 patients (23 eyes) were found to have lesions consistent with CHRPE. Data collected included demographics, laterality, number and morphology of lesions, and fundus autofluorescence (FAF) imaging findings, where available.

Results: Twenty-three eyes from 21 patients were analyzed. The mean patient age was 32.4 years (range: 6–74), with a slight female predominance. Most lesions were solitary and unilateral. Grouped CHRPEs were counted as single lesions. In total, 25 individual CHRPE lesions were included in the analysis. Over half of the lesions were located in the mid-periphery and were round in shape. FAF imaging, available in 14 eyes, revealed predominantly hypoautofluorescent patterns. One patient had bilateral multifocal CHRPE, fulfilling criteria for referral for systemic screening to rule out familial adenomatous polyposis (FAP).

Conclusions: CHRPE is most commonly seen as a solitary, benign, and unilateral lesion. However, meticulous clinical evaluation and imaging are essential to distinguish it from simulating lesions such as choroidal nevi and to identify atypical presentations. Bilateral multifocal CHRPE warrants further systemic evaluation for syndromic associations, such as Gardner syndrome. This study highlights the utility of fundus photography in the detection and documentation of CHRPE.

Abstract No.: 200463

Crocini in Patients With Central Serous Chorioretinopathy: A Pilot Randomized Clinical Trial

First Author: Mojtaba **HEYDARI**

Co-Author(s): Mohammad Karim **JOHARI**

Purpose: To evaluate the efficacy and safety of crocin in patients with central serous chorioretinopathy in a randomized clinical trial.

Methods: In this pilot randomized, double-blind, placebo-controlled trial, 40 individuals diagnosed with CSCR were randomized to receive either crocin supplementation (n=20) or placebo (n=20) for six months. Evaluations included changes in visual acuity (using ETDRS scores), retinal structure via optical coherence tomography (OCT), and monitoring for any adverse effects. Measurements were taken at baseline and after the intervention period.

Results: Baseline characteristics such as age, weight, BMI, and gender were similar between the two groups ($p > 0.05$). Participants receiving crocin demonstrated significantly greater improvement in mean ETDRS letter score compared to those receiving placebo (4.27 ± 3.63

vs. 0.57 ± 7.23 ; $p = 0.024$). Additionally, improvements of ≥ 10 , ≥ 5 , and ≥ 1 ETDRS letters were observed in 20%, 40%, and 80% of the crocin group, compared to 7%, 21%, and 29% in the placebo group ($p = 0.316$, $p = 0.280$, and $p = 0.005$, respectively). Although reductions in subretinal fluid, central macular thickness, and choroidal thickness were greater in the crocin group, the differences were not statistically significant ($p > 0.05$). No adverse effects were reported in either group during the study.

Conclusions: This preliminary trial suggests that crocin supplementation may enhance visual outcomes in CSCR patients. However, its effect on retinal anatomy remains inconclusive and warrants further investigation in larger trials.

Abstract No.: 202652

Cuticular Drusen in Asian Neovascular Age-Related Macular Degeneration: Clinical Features and Polypoidal Choroidal Vasculopathy Association

First Author: Chenxi **ZHANG**

Co-Author(s): Hiok Hong **CHAN**, Chui Ming Gemmy **CHEUNG**, Beau J **FENNER**, Noa **GILEAD**, Zehua **JIANG**, Anna C S **TAN**, Kelvin Yi Chong **TEO**

Purpose: To characterize the clinical features of cuticular drusen (CD) in Asian patients with neovascular age-related macular degeneration (nAMD), and to evaluate its association with polypoidal choroidal vasculopathy (PCV) and the risk of macular neovascularization (MNV).

Methods: Baseline multimodal images from a prospective Asian nAMD cohort were analyzed. Patients were classified into cuticular drusen (CD), soft drusen (SD), or no drusen (ND) groups based on multimodal imaging. Clinical and imaging features were compared. MNV lesions were subtyped as PCV or typical nAMD. For eyes without MNV at baseline, the 5-year cumulative incidence of MNV was estimated using Kaplan–Meier analysis.

Results: A total of 104 patients (173 eyes) were included: 16 with CD (21 eyes), 43 with SD (62 eyes), and 45 with ND (90 eyes). CD patients had a mean age of 75.5 ± 9.1 years and a balanced gender distribution (50% male), comparable in age to SD (75.6 ± 6.9 years) but older than ND (66.2 ± 7.4 years; $p < 0.001$). CD eyes had shorter axial length than ND ($p = 0.004$) and commonly coexisted with large drusen (66.7%) and subretinal drusenoid deposits (33.3%). MNV was present in 52.3% of CD eyes, with 54.5% classified as PCV, which was intermediate to SD (25.0%) and ND (74.5%). Among CD eyes without baseline MNV, the 5-year incidence was 11.1%, also intermediate to ND (0.0%) and SD (38.2%).

Conclusions: In this Asian nAMD cohort, patients with CD were older with a more balanced gender

distribution. Its notable association with PCV and MNV risk highlights the need for continued monitoring and further investigation.

Abstract No.: 201815

Deep Phenotyping of Eyes Shut Homolog-Associated Retinopathy Based on Visual Impairment Patterns

First Author: Daiki SAKAI

Co-Author(s): Yasuhiko HIRAMI, Yasuo KURIMOTO, Akiko MAEDA, Akishi ONISHI, Masayo TAKAHASHI, Satoshi YOKOTA

Purpose: This study aimed to classify and characterize the phenotypes of eyes shut homolog (EYS)-associated retinopathy based on visual impairment patterns.

Methods: This retrospective, single-center, cross-sectional study was conducted in 154 patients diagnosed with EYS-related retinopathy who underwent genetic testing between December 2017 and July 2023. Phenotyping was performed only in patients who underwent Goldmann perimetry and Humphrey visual field 10-2 testing. Phenotypes were categorized as early, pericentral, typical, and advanced based on peripheral visual field preservation, central visual field impairment, and macular impairment. Genetic and ophthalmological characteristics were compared between the pericentral and typical types.

Results: A total of 39 eyes from 39 patients with EYS-associated retinopathy (average age: 48.2 ± 11.9 years, 21 women) were analyzed. Ten pathogenic variants were identified, with the three major variants (p.G843E, p.S1653fs, and p.Y2935X) accounting for a combined allele frequency of 83.3%. The phenotypes were classified as early (n=3), pericentral (n=18), typical (n=9), and advanced (n=9). No significant differences were observed between the pericentral and typical types in terms of the presence of major variants or biallelic null variants. Age and age at onset also did not differ significantly. However, macular impairment was significantly more frequent in the pericentral type (61.8%) than in the typical type (11.1%) ($P = 0.014$).

Conclusions: The pericentral type is considered a common phenotype of EYS-associated retinopathy, although its correlation with the genotype remains unclear. Despite preserved peripheral vision, careful monitoring is warranted due to the risk of macular impairment.

Abstract No.: 200148

Diabetic Retinopathy (DR) Nomogram Construction Based on Optical Coherence Tomography Angiography Parameters: A Preliminary Exploration of DR Prediction

First Author: Zijong LI

Purpose: To construct a diabetic retinopathy (DR) prediction nomogram based on optical coherence tomography angiography (OCTA) parameters.

Methods: In this retrospective study, patients with type 2 diabetes mellitus who completed DR screening were enrolled and divided into training and validation sets. Fifteen parameters, including OCTA parameters, axial length (AL), age, and sex, were selected via least absolute shrinkage and selection operator (LASSO) in the training set. The chosen parameters were used to construct the model. Model performance was evaluated for both the training and validation sets via receiver operating characteristic (ROC) curves, calibration curves, and decision curve analysis (DCA). A corresponding nomogram was created.

Results: A total of 464 eyes from 464 patients were divided into a training set (324, 69.83%) and a validation set (140, 30.17%). The superficial parafoveal capillary density (CD), deep parafoveal CD, foveal CD in the 300 μm -wide area surrounding the foveal avascular zone (FD-300 area), AL, and patient ages were included in the final model. The area under the curve of the model was 0.825 in the training set and 0.831 in the validation set. The calibration curves showed good alignment between the actual and predicted outcomes in both datasets. DCA demonstrated that the nomogram was clinically useful.

Conclusions: A model with good performance for predicting DR via OCTA parameters was developed. The superficial parafoveal CD, deep parafoveal CD, and FD-300 area were important predictive parameters in this model. The corresponding nomogram may serve as a convenient tool for early DR risk prediction.

Abstract No.: 207635

Distribution Characteristics of Choroidal Thickness in Normal Population

First Author: Xinyuan ZHANG

Purpose: To characterize the distribution characteristics of choroidal thickness in healthy normal subjects and to define the diagnostic cut-off value for pachy choroid.

Methods: This cross-sectional study enrolled 446 eyes of 230 healthy subjects for the choroidal thickness distribution analysis. 149 eyes of 113 patients with CSC, 95 eyes of 81 patients with PCV, 70 eyes of 60 patients with neovascular AMD (nAMD), along with 382 eyes of 199 normal subjects matched for refractive error, age, and gender, were selected for likelihood ratio analysis. Routine eye examinations were performed in all

subjects. Swept-source optical coherence tomography (SS-OCT) of 9 mm×9 mm scanning mode was used to measure the subfoveal choroidal thickness (SFCT).

Results: Age and diopter were strongly correlated with SFCT ($P<0.001$). The diagnostic value range of pachychoroid in the 20-39 years group, 40-59 years group, 60-79 years group, and ≥ 80 years group was 320-330 μm , 330-340 μm , 250-275 μm , and 200-225 μm , respectively. The percentages of eyes with pachychoroid in the 20-39 years group, 40-59 years group, and ≥ 60 years group were 14.71% (10/68), 24.48% (47/192), and 28.89% (55/184), respectively. The proportion of pachychoroid in the ≥ 60 years group was significantly higher than that of the 20-39 years group, showing a statistically significant difference ($P=0.011$).

Conclusions: Age and diopter are the independent influencing factors of SFCT. We established the range of cut-off values for pachy choroid in different age groups when controlling for other factors, including diopters and gender.

Abstract No.: 206710

Drusen and Subretinal Drusenoid Deposits in a Korean Cohort: Five-Year Longitudinal Changes

First Author: Seungyeon **LEE**

Co-Author(s): Jaehwan **CHOI**, Dongkyu **KIM**, Kiyoun **KIM**, Seungyoung **YU**

Purpose: To investigate longitudinal changes in macular drusen and subretinal drusenoid deposits (SDDs) in Korean patients and their association with late age-related macular degeneration (AMD).

Methods: A total of 272 eyes from 172 patients with drusen or SDDs were retrospectively analyzed using en face swept-source OCT. Drusen volume was measured with an automated RPE elevation map. Sixty-four eyes from 40 patients were followed for five years, assessing visual acuity, choroidal thickness, drusen volume, and SDD distribution.

Results: Among 169 eyes with SDDs, groups included SDD-only, SDD with drusen, and large drusen-only. Over 80% of SDD patients were female. SDDs predominantly involved the superior macula, with trizonal distribution in 95%. Over five years, drusen volume increased (0.075 to 0.143 mm^3) but showed an undulating growth with regression in 20%. SDDs were mainly associated with geographic atrophy, while drusen-only eyes more often developed neovascular AMD. Loss of SDD distribution occurred in nearly half of SDD cases and was frequently followed by late AMD progression.

Conclusions: Drusen and SDD changes in Korean patients parallel findings in Caucasians. Drusen generally enlarge but may regress, while SDDs are strongly predisposed to GA. Disappearance of SDDs may signal imminent progression to late AMD.

Dual-Model Translational Framework for Individualized Anti-VEGF Therapy in Diabetic Macular Edema: Bridging Biology and Precision Care

First Author: Aik Kah **TAN**

Purpose: To personalize anti-VEGF therapy in diabetic macular edema (DME), I developed a dual-model framework: a mechanistic model (Model 1) capturing biological treatment response, and an empirical model (Model 2) predicting individualized injection intervals using systemic biomarkers.

Methods: Model 1 employs differential equations to describe VEGF accumulation and anti-VEGF response. Model 2 estimates safe injection intervals (Imodel) from HbA1c, systolic blood pressure (BP), and glycemic variability (GV). Validation used DRCR.net Protocol H data (bevacizumab-treated eyes). Imodel predictions were compared against clinical reinjection thresholds: $>10\%$ increase in central subfield thickness or >5 -letter vision loss. Sensitivity analyses assessed parameter influence.

Results: Among 97 evaluable eyes, Model 2 achieved a safety rate of 63.6%, with a mean deviation of 4.7 ± 13.1 weeks. In a targeted-use subgroup ($n=49$) with poor systemic control (GV suppressed), safety rose to 77.6%, with a tighter deviation (5.0 ± 9.6 weeks). In the post-loading group (2 injections + 1 laser), model predictions closely matched clinical decisions (mean deviation: -0.1 weeks, SD: 5.6). HbA1c exerted $36\times$ more influence on interval prediction than BP. Model 1 supports this by linking poor glycemic control to VEGF rebound and earlier fluid recurrence.

Conclusions: This dual-model framework—linking biological mechanisms to data-driven personalization—offers both scientific transparency and real-world utility. It enables safe interval extension in DME and is designed for future integration with continuous glucose monitoring and explainable AI systems. By bridging theory and application, it advances precision retinal care.

Abstract No.: 200977

Dynamic Frailty Trajectories and Risk of Age-Related Macular Degeneration: A Prospective Cohort Study in UK Biobank

First Author: Yu **PENG**

Co-Author(s): Li Jia **CHEN**, Calvin Cp **PANG**, Jason Cs **YAM**, Yuzhou **ZHANG**

Purpose: To evaluate the longitudinal associations between dynamic frailty trajectories, including aggravation, maintenance, and alleviation, with incident age-related macular degeneration (AMD) risk.

Methods: We included 462,573 UK Biobank participants without baseline AMD and with baseline

frailty phenotype (FP) data for baseline assessment. A subset of 53,059 individuals, AMD-free at final assessment and with ≥ 1 follow-up FP assessment, comprised the trajectory cohort. Participants were categorized as nonfrail, prefrail, or frail based on their FP scores. Annualized frailty progression (Δ FP/year) was estimated via linear regression. Cox models assessed hazard ratios (HRs) and 95% confidence intervals (CIs) for AMD.

Results: Prefrail (HR:1.14; 95% CI:1.10–1.18) and frail (HR:1.36; 95% CI: 1.26–1.47) individuals had significantly higher AMD risks compared to nonfrail participants at baseline assessment. In the frailty trajectory analysis with a median follow-up duration of 3.3 years, 852 incident AMD cases (1.6%) were recorded. Each 1-point FP increase conferred 28% higher AMD risk (HR:1.28; 95%CI:1.18–1.38), while each 0.1-point/year Δ FP increase independently elevated risk by 15% (HR:1.15; 95%CI:1.10–1.21). Compared to stable nonfrail, prefrailty aggravation showed highest AMD risk (HR:2.26; 95%CI:1.51–3.37), followed by frailty alleviation (HR:1.73; 95%CI:0.98–3.04) and frailty maintenance (HR:1.72; 95%CI:0.86–3.41).

Conclusions: Progressive frailty trajectories, independent of baseline status, are associated with increased incident AMD risk. Early interventions targeting frailty progression may mitigate AMD risk in aging populations.

Early Changes of Retinal Inner and Outer Layer Thickness Across Myopia Severity: Implications for Early Detection

First Author: Michael **HARTONO**

Co-Author(s): Muhammad **ALFATIH**, Christina **WUNARDI**, Anggun Rama **YUDANTHA**

Purpose: To evaluate structural alterations of retinal layers across different degrees of myopia.

Methods: Spectral-domain optical coherence tomography (OCT) scans of 104 eyes classified as emmetropia, mild, moderate, or high myopia were segmented to measure central and regional thickness of the retinal nerve fiber layer (RNFL), ganglion cell–inner plexiform layer (GC-IPL), inner retinal (from inner limiting membrane [ILM] to outer plexiform layer [OPL]), and outer retinal layer (from OPL to retinal pigment epithelium [RPE]) using Adobe Photoshop® ruler tool with vertical correction; validation studies confirmed no significant difference compared with the built-in OCT caliper (Zeiss Cirrus™ HD-OCT 5000). Statistical analysis included ANOVA, Kruskal–Wallis and Spearman correlations with spherical equivalent (SE).

Results: Central retinal thickness increased with myopia severity ($p<0.001$), characterized by inner layer thickening ($r=0.375$, $p<0.001$) and outer layer thinning

($r=-0.324$, $p<0.001$). RNFL correlated positively with SE in central and perifoveal regions ($r=0.20-0.36$, $p<0.05$), with changes already noted in mild and moderate myopia. GC-IPL consistently thinned with increasing myopia, most prominent in the outer temporal region ($r=-0.617$, $p<0.001$). The outer layer showed widespread thinning in superior, inferior, nasal, and temporal regions ($r=-0.27$ to -0.45 , all $p<0.01$). Non-significant findings included the inferior and nasal inner layer and inner temporal RNFL.

Conclusions: Myopia is associated with early, region-specific retinal alterations: central inner retinal thickening, perifoveal outer retinal, and GC-IPL thinning. Recognition of these early changes underscores the utility of OCT as a monitoring tool for timely detection, enabling preventive strategies against pathologic progression and long-term visual complications.

Abstract No.: 204501

Early Detection of Retinal Changes in Children With Diabetes Without Retinopathy Using Optical Coherence Tomography and Optical Coherence Tomography Angiography

First Author: Piyaphat **JARUNIPHAKUL**

Co-Author(s): La-ongsri **ATCHANEYASAKUL**, Ornsuda **LERTBANNAPHONG**, Ng Wei **LOON**, Chinnapat **MONTRISUKSIRIKUN**, Pittaya **PHAMONVAECHAVAN**, Nopasak **PHASUKIJWATTANA**, Supalert **PRAKHUNHUNGSIT**, Nuttawut **RODANANT**, Piangporn **SAKSIRIWUTTO**, Jeerunda **SANTIPRABHOB**, Thammanoon **SURACHATKUMTONEKUL**, Somanus **THOONGSUWAN**, Suthipol **UDOMPUNTHURAK**, Sirawadee **WIRIYAUDOMCHART**

Purpose: To detect early retinal structural and microvascular changes in children and adolescents with diabetes mellitus (DM) without diabetic retinopathy (DR) using spectral-domain optical coherence tomography (SD-OCT) and optical coherence tomography angiography (OCTA), and to evaluate associations with glycemic control and disease duration.

Methods: This study is a single-center, cross-sectional observational study conducted at a tertiary referral center. Three hundred participants aged 8–18 years were enrolled, comprising 150 patients with type 1 or type 2 diabetes mellitus and 150 age- and sex-matched healthy controls. All participants underwent comprehensive ophthalmic evaluations, which included ultra-widefield fundus photography, SD-OCT, and OCTA. Laboratory assessments included serum creatinine and serial HbA1c measurements, from which a time-weighted average HbA1c was calculated. The quantitative imaging parameters were recorded and analyzed.

Results: 149 individuals with diabetes and 150 healthy controls were enrolled in the analysis. Within

the diabetic group, 148 patients showed no clinical evidence of diabetic retinopathy. Parafoveal retinal thickness in the superior ($p=0.02$), temporal ($p=0.04$), and nasal ($p=0.02$) quadrants was significantly reduced in the diabetes group. FD-300 was also lower in the diabetic group ($48.60 \pm 3.59\%$ vs $49.76 \pm 3.91\%$, $p=0.01$). Subgroup analysis revealed greater FD-300 reduction ($p<0.01$) in those with diabetes duration exceeding 5 years. Furthermore, longer duration of diabetes was associated with reduced FD-300 values ($r=-0.22$, $p=0.007$).

Conclusions: This study identified retinal alterations in pediatric diabetes patients, including reduced parafoveal thickness and FD-300. The correlation between decreased FD-300 values and longer diabetes duration highlights its utility as a non-invasive biomarker for subclinical retinal involvement that precedes the development of clinical diabetic retinopathy.

Early Versus Delayed Pegcetacoplan Treatment for GA Secondary to AMD: 48 Month Results From OAKS, DERBY, and GALE Open-Label Extension

First Author: Gemmy **CHEUNG**

Co-Author(s): Caroline **BAUMAL**, Dilsher **DHOOT**, Roger **GOLDBERG**, Lawrence **SINGERMAN**, Charles **WYKOFF**

Purpose: To report the efficacy and safety of continuous pegcetacoplan in geographic atrophy (GA) patients, focusing on early versus delayed treatment.

Methods: After completing the 24-month phase 3 OAKS and DERBY studies, patients could enroll in the GALE open-label extension study. Patients in the "Early Treatment" group continued the same pegcetacoplan monthly (PM) or every-other-month (PEOM) regimen in GALE. The "Delayed Treatment" group comprised of the sham patients from OAKS/DERBY that crossed over to receive active pegcetacoplan treatment at the same intervals (PM or PEOM).

Results: In this study, 83% of patients who completed OAKS/DERBY entered GALE. In the first 24 months of GALE, pegcetacoplan reduced GA growth vs projected sham by 36% (PM) and 30% (PEOM) in nonsubfoveal (NSF) GA, and by 28% (PM) and 28% (PEOM) in the overall population (NSF + subfoveal). At Month 48, Early Treatment had better outcomes with 3.16 mm² of retinal tissue preservation compared to 1.11 mm² with Delayed Treatment in NSF GA. The safety profile in the first 24 months of GALE was consistent with OAKS/DERBY, with no study events of retinal vasculitis. Based on real-world and clinical data of an estimated >702,000 injections administered through June 2025, retinal vasculitis appears to be a first-injection phenomenon with an estimated post-marketing rate of ~1/4,000 per first injection in the United States.

Conclusions: Long-term efficacy and safety of pegcetacoplan were demonstrated in GA patients, with results supporting earlier treatment.

Abstract No.: 204124

Effectiveness and Safety of Faricimab in Neovascular Age-Related Macular Degeneration and Diabetic Macular Edema Eyes Beyond Year-1: UK FARWIDE-nAMD and FARWIDE-DME Study Results

First Author: Kenneth **FONG**

Co-Author(s): Parul **DAYAL**, Christine **KIIRE**, Praveen J. **PATEL**, Ian **PEARCE**, Gabriella **DE SALVO**

Purpose: FARWIDE-nAMD and FARWIDE-DME retrospectively evaluate faricimab's durability, safety, and VA (visual-acuity) in nAMD (neovascular age-related macular degeneration) and DME (diabetic macular edema) eyes, respectively, in the United Kingdom. Follow-up data (≥ 18 months) are reported. Updated data will be presented.

Methods: Treatment-naïve eyes had no prior anti-VEGF (vascular endothelial growth factor) treatment. Previously-treated eyes switched from another anti-VEGF treatment to faricimab. Baseline characteristics, VA (ETDRS [Early Treatment Diabetic Retinopathy Study] letters), injection frequency, and safety were analyzed.

Results: Eighteen-month nAMD and DME cohorts included 1,404 (1,667 eyes; treatment-naïve=332, previously-treated=1,335) and 305 (416 eyes; treatment-naïve=122, previously-treated=294) patients, respectively. Previously-treated nAMD (84%) and DME (87%) eyes switched to faricimab from aflibercept-2.0mg. In treatment-naïve nAMD eyes, median (Q1, Q3) VA was 61 (47,70) and 65 (46,76) ETDRS letters at baseline and 18-months, respectively. In treatment-naïve DME eyes, median (Q1,Q3) VA change from baseline to 18-months was +5 (-1,9) letters. In previously-treated nAMD and DME eyes, median VA remained stable. Mean (standard deviation) injections were: 4.8 (0.5), 2.2 (1.0), 1.9 (1.1) in treatment-naïve, and 4.4 (0.9), 3.0 (1.1), 2.8 (1.2) in previously-treated nAMD eyes; 4.4 (1.0), 1.8 (1.2), 1.3 (1.1) in treatment-naïve and 4.3 (1.1), 2.5 (1.3), 2.2 (1.5) in previously-treated DME eyes in months 1–6, 7–12, 13–18, respectively. Overall intraocular inflammation and presumed infectious endophthalmitis rates were consistent with faricimab phase-3 trials.

Conclusions: In both trials, faricimab treatment over 18 months led to improved VA in treatment-naïve eyes, stable VA in previously-treated eyes, greater treatment interval extensions, and consistent safety, supporting faricimab's real-world effectiveness, durability, and safety.

Abstract No.: 201615
Efficacy of Faricimab Secondary to Anti-Vascular Endothelial Growth Factor Agents in Patients With Neovascular Age-Related Macular Degeneration: A Systematic Review and Meta-Analysis

First Author: Adrian **CHAN**

Co-Author(s): Eric **JIN**, George **THOMAS**

Purpose: This study examines the efficacy and safety of faricimab as a secondary treatment for nAMD patients previously treated with anti-VEGF agents.

Methods: A literature search was performed on PubMed, EMBASE, and Cochrane Library up to 24 October 2024. Cohort and observational studies reporting functional and anatomical outcomes in nAMD patients switched to faricimab were included. Meta-analysis with a common and random-effect model was performed using the “metagen” package in R version 3.2.1.

Results: Twenty studies (1,007 eyes) with a baseline central macular thickness (CMT) of 342.07 (± 110.14) μm were included in the final analysis. Switching to faricimab led to significant reductions in CMT at 3 months (Mean difference = -47.08 μm , 95% Confidence Interval (CI) = (-66.01, -28.15), $p=0.009$) and 6 months post-switch (Mean difference = -44.68 μm , 95% CI = (-67.17, -22.20), $p=0.002$). Pigment epithelium detachment (PED) height was also reduced at 3 months (Mean difference = -31.71 μm , 95% CI = (-45.12, -18.30), $p=0.036$) and 6 months post-switch (Mean difference = -34.85 μm , 95% CI = (-50.19, -19.51), $p=0.011$). However, no significant improvements in best corrected visual acuity (BCVA) were observed at 3 months ($p=0.407$), 6 months ($p=0.920$) or ≥ 12 months ($p=0.261$) post-switch. Treatment intervals were significantly extended (Mean difference = 1.87 weeks, 95% CI = (0.41, 33.3), $p=0.019$), with a low incidence of serious adverse events.

Conclusions: In conclusion, faricimab demonstrates favorable structural benefits, stable functional outcomes and extended treatment intervals as a second-line treatment for nAMD in patients with prior anti-VEGF therapy.

Abstract No.: 201252
Efficacy of the Faricimab Loading Regimen in Treatment-Naïve Neovascular Age-Related Macular Degeneration: A Real-World Study From China

First Author: Sheng **LI**

Co-Author(s): Xiaonan **FU**, Dingxi **LIU**, Zijong **ZHANG**

Purpose: To evaluate the 12-week real-world outcomes of three monthly intravitreal faricimab injections in treatment-naïve nAMD

Methods: Prospective single-center cohort (Dalian Third People’s Hospital, Jan–Apr 2025). Inclusion: treatment-naïve nAMD verified by OCT-A or FFA and completion of three consecutive monthly faricimab injections. Evaluations at baseline and every 4 weeks included BCVA (logMAR), CST, SRF/IRF presence, and, when applicable, PED height/area. All adverse events were recorded.

Results: Twenty-three eyes of 23 patients (mean age 71.2 ± 9.1 years) completed follow-up. • BCVA improved from 0.75 ± 0.35 to 0.58 ± 0.37 logMAR ($P < 0.001$). • CST decreased from 568.6 ± 322.2 to 313.9 ± 153.5 μm ($P < 0.001$). • SRF resolved in all 14 affected eyes (100%). • IRF resolved in 6/8 eyes (75%); one eye worsened. • Among 18 eyes with baseline PED, mean height fell from 398 ± 328 to 152 ± 162 μm and area from 0.73 ± 1.03 to 0.30 ± 0.42 mm^2 (both $P < 0.05$); 5 eyes achieved complete flattening. No endophthalmitis, retinal vasculitis, or other serious adverse events occurred.

Conclusions: Three monthly faricimab injections significantly improved vision and reduced exudation in treatment-naïve nAMD eyes with an acceptable short-term safety profile. A longer follow-up is needed.

Abstract No.: 201026
Enhancing RB1 Gene Mutation Detection in Retinoblastoma: A Comprehensive Study Using Long-Read Sequencing and Its Correlation With Clinical Features

First Author: Li **CAO**

Co-Author(s): Jiyun **YANG**

Purpose: This study aims to investigate the characteristics of RB1 gene mutations, evaluate their associations with clinical features, and develop and validate a long-read sequencing methodology to enhance the detection rate of RB1 gene mutations.

Methods: From October 2016 to February 2024, 57 Chinese RB patients and their relatives were recruited for the study. Targeted NGS was performed on blood samples of all 57 probands to identify RB1 gene mutations. A novel long-read sequencing methodology was developed to improve the detection of deep intronic mutations, promoter regions, and regulatory elements. This methodology was applied to 46 samples and compared to conventional NGS to assess its effectiveness in improving mutation detection.

Results: In the analysis of 57 RB patients, 28 (49.1%) had RB1 gene mutations. Mutation frequency was higher in younger patients (75% in 0-12 months vs. 16% in older patients). Bilateral RB patients had higher mutation rates (90%) compared to unilateral patients (27%). Long-read sequencing of 46 samples identified 28 pathogenic variants, including 19 SNVs and 9 CNVs, with 8 CNVs affecting RB1 and 1 affecting TP53. This sequencing method confirmed NGS results and

detected five additional mutations not found by NGS, demonstrating its superiority in identifying complex mutations.

Conclusions: Bilateral RB and patients diagnosed within 12 months had significantly higher RB1 mutation rates than unilateral RB and those diagnosed after 12 months. Long-read sequencing outperformed NGS in detecting rare RB1 mutations and improved the mutation detection rate. This method identified more diverse genotypic variations than NGS, enhancing the genetic diagnosis of RB.

Abstract No.: 201964

Epidermal Growth Factor Receptor Promotes Diabetic Retinal Fibrogenesis Through a YAP-CCN2-Dependent Mechanism

First Author: Zhang Wei **ZHANG**

Purpose: This study investigated whether epidermal growth factor receptor (EGFR) activity in retinal vascular endothelial cells (RVECs) contributes to the activation of retinal Müller cells (rMCs) and the development of retinal fibrosis in DR.

Methods: Diabetic mice were treated with the EGFR kinase inhibitor erlotinib, and the effects on extracellular matrix (ECM) deposition and retinal fibrosis were assessed. The role of conditioned medium from primary cultured RVECs in activating a human Müller cell line (hMCs) was evaluated to explore paracrine signaling. The involvement of the profibrotic factor connective tissue growth factor (CCN2) in EGFR-dependent retinal fibrosis and the activation of Yes-associated protein (YAP) were also examined.

Results: Erlotinib treatment significantly reduced ECM accumulation and diabetic retinal fibrosis. Conditioned medium from diabetic RVECs enhanced hMC activation in vitro, supporting a paracrine mechanism. Specific gene deletion of CCN2 in retinal endothelial cells markedly suppressed rMC activation and ECM deposition in diabetic mice. We demonstrated that YAP regulates CCN2 expression, and both genetic deletion and pharmacological inhibition of YAP attenuated retinal fibrosis and inhibited rMC activation. Further analysis revealed that EGFR modulates YAP activity in diabetic retinas through a RhoA/Rock-dependent pathway.

Conclusions: This study reveals that RVECs promote rMC activation and retinal fibrosis via EGFR-dependent paracrine signaling. The EGFR-YAP-CCN2 axis represents a promising therapeutic target for mitigating diabetic retinal fibrogenesis.

Abstract No.: 201962

Epidermal Growth Factor Receptor Promotes Diabetic Retinal Fibrosis by Regulating YAP Signaling Through Modulation of SAV1 Degradation

First Author: Zhang Wei **ZHANG**

Purpose: The epidermal growth factor receptor (EGFR) and Yes-associated protein (YAP) signaling pathways are key regulators of fibrosis, yet the intracellular mechanisms linking these pathways remain poorly understood. This study aimed to elucidate the role of EGFR and YAP signaling in retinal Müller cell-mediated diabetic retinal fibrosis, both in vivo and in vitro.

Methods: Human retinal Müller cells (MIO-M1) were transfected in vitro with either a Flag-tagged EGFR plasmid or EGFR-targeting siRNA. The involvement of EGFR in the SAV1-Herc4 interaction and subsequent SAV1 degradation was evaluated using Western blotting and co-immunoprecipitation (Co-IP). In vivo, streptozotocin (STZ)-induced diabetic mice were treated with either intraperitoneal Erlotinib (an EGFR inhibitor) or intravitreal anti-EGFR antibody. Retinal fibrosis was assessed through histopathological analysis and evaluation of YAP signaling activity.

Results: EGFR was found to suppress the Hippo pathway by promoting SAV1 degradation via enhancing the interaction between SAV1 and the E3 ubiquitin ligase Herc4. This suppression led to YAP activation, its nuclear translocation, and the subsequent transcription of downstream Hippo target genes, thereby promoting diabetic retinal fibrosis. Pharmacological inhibition of EGFR activated the YAP signaling pathway and significantly reduced fibrotic changes in the retinas of diabetic mice. Furthermore, intravitreal administration of an anti-EGFR antibody effectively attenuated diabetic retinal fibrosis, with early initiation and repeated dosing showing enhanced therapeutic efficacy.

Conclusions: Our findings indicate that EGFR promotes diabetic retinal fibrosis in Müller cells by inhibiting the Hippo pathway through SAV1 degradation.

Abstract No.: 206491

Eye-Brain Connection: Unveiling the Transient Brain Neurochemical and Behavioral Shifts After Retinal Ischemia-Reperfusion Injury

First Author: Lei **DU**

Co-Author(s): Rong **HUANG**, Guojing **LU**, Xuan **XIAO**

Purpose: Retinal ischemia-reperfusion injury (RIRI) is a significant pathological process involved in many blinding eye diseases that has also been linked with mood disorders. Herein, we investigated whether RIRI could induce transient brain neurochemical and behavioral alterations.

Methods: RIRI was induced in C57BL/6J mice and evaluated at one and seven days post-injury. Mood-related behaviors were measured using open-field, elevated plus-maze, and forced swimming tests. Retinal damage and apoptosis were analyzed using H&E and TUNEL staining. Brain metabolites from six regions were quantified using $[1-^{13}\text{C}]$ glucose infusion and ^1H - $[^{13}\text{C}]$ -nuclear magnetic resonance (NMR) spectroscopy.
